**METHODS:** Seventy-five healthy subjects (30 men; 50 ± 10 years) performed two ISWT in a 10-m long corridor. Other measurements included height, weight, body mass index (BMI), forced expiratory volume in 1s (FEV<sub>1</sub>), forced vital capacity (FVC) and reported physical activity (RPA). Blood pressure, heart rate (HR), dyspnea and leg fatigue were assessed at baseline and at the end of the ISWT.

**RESULTS:** The average ISWT was 541 ± 172 m and was greater in male when compared to female subjects (675 ± 182 m vs. 469 ± 128 m;  $p < 0.05$ , respectively). Substantial variability in the ISWT was present in these healthy subjects, with a range of 210-1090 m. Subjects reached 75 ± 13% of their maximal predicted heart rate. Age ( $r = -0.45$ ), height ( $r = 0.56$ ), weight ( $r = 0.28$ ), FEV<sub>1L</sub> ( $r = 0.50$ ), FVC<sub>L</sub> ( $r = 0.64$ ), %HR<sub>max</sub> ( $r = 0.55$ ) and RPA ( $r = 0.34$ ) were significantly correlated with ISWT ( $p < 0.05$ ). The following regression equation showed that age, height, weight and gender were independent contributors to the ISWT in Brazilian healthy subjects explaining 42.6% of the variability:  $ISWT_m = -245.794 - (6.112 \times \text{age}_{\text{years}}) - (3.743 \times \text{weight}_{\text{kg}}) + (8.079 \times \text{height}_{\text{cm}}) + (100.776 \times \text{gender}_{\text{males}=1; \text{females}=0})$ . A modest learning effect was apparent between the first and the second test (493 ± 159 m vs. 541 ± 172 m;  $p = 0.095$ ).

**CONCLUSIONS:** The present study showed considerable variability of the ISWT in Brazilian healthy subjects. However, an important part of the variability was explained adequately by demographic and anthropomorphic attributes as age, weight, height and gender. Moreover, the ISWT represents a submaximal exercise in Brazilian healthy subjects. Other studies are necessary to confirm if one practice walk should be performed.

---

**2169 Board #57 May 28 3:30 PM - 5:00 PM****Relationship Between Streaming Triaxial Accelerometry And VO<sub>2</sub> During Treadmill Locomotion On An Uphill Grade**

James A. Yaggie<sup>1</sup>, Michael A. Busa<sup>2</sup>, Timothy Muth<sup>2</sup>, Erik M. Bollt<sup>3</sup>, Stephen J. McGregor<sup>2</sup>. <sup>1</sup>University of Findlay, Findlay, OH. <sup>2</sup>Eastern Michigan University, Ypsilanti, MI. <sup>3</sup>Clarkson University, Potsdam, NY.

(No relationships reported)

**INTRODUCTION:** High resolution accelerometry (HRA) has been used increasingly for gait analysis, while lower resolution “activity monitors” have been used to estimate energy expenditure. The purpose of this study was to test the reliability of HRA in repeated trials and determine if HRA could be used as a valid proxy for VO<sub>2</sub> during uphill locomotion on a treadmill.

**METHODS:** Procedures were approved by the EMU-HSRC. Ten recreationally active students (27.7±7.4 yr, 62.7±12.7 kg, 43.9±6.4 ml/kg/min) performed two incremental treadmill trials at 10% grade, starting at 2 kph and increasing 2 kph every two minutes until volitional exhaustion. Metabolic gasses were collected using an Oxycon Mobile (Viasys, CA) and averaged over 15 sec intervals. Data was streamed at 625 Hz from wireless, triaxial accelerometers (Microstrain, VT) affixed to the lower back of subjects corresponding to the L4-L5 segment. Raw signal from three axes, vertical (V), medial/lateral (M/P) and anterior/posterior (A/P) was integrated to obtain resultant (RES) acceleration vectors (Matlab; Mathworks, MA). Axial root mean square (RMS) calculations using the last minute of acceleration data, per stage, were also computed (LabView, v 8.6, National Instruments, Austin, TX) and compared to relative VO<sub>2</sub> using Pearson's correlation (SPSS, IL;  $\alpha = 0.05$ ).

**RESULTS:** Axial RMS test-retest correlations were 0.93, 0.96, 0.73 and 0.96 for V, M/L, A/P and RES, respectively ( $p < .001$ ), and Chronbach's Alpha was 0.96 ( $p < .001$ ). Highly significant, strong correlations of individual axes and VO<sub>2</sub> were 0.80, 0.76, 0.60, 0.90 and .97 for V, M/L, A/P, RES and speed, respectively ( $p < .001$ ). Curve fit regressions showed a linear fit was best for RMS of RES vs VO<sub>2</sub>, but a quadratic fit of RES vs speed exhibited an  $r = 0.94$  ( $p < .001$ ).

**CONCLUSIONS:** These data indicate HRA is a reliable tool for the determination of RES, VO<sub>2</sub> and speed, in addition to the typical biomechanical analyses during uphill locomotion. Further study is warranted to compare these relationships in subjects of varied training status, as well as other locomotive conditions.

**D-28 Free Communication/Poster - Fitness Testing**

**2170 Board #58 May 28 2:00 PM - 3:30 PM**  
**Comparison Of Self-selected Paces For Walking And Stair-climbing**

Jeffrey A. McClung, Ashley Crockett, Jessica Proffitt. *Berea College, Berea, KY.*  
Email: mcclung101@yahoo.com  
(No relationships reported)

**PURPOSE:** To describe the differences between self-selected paces during level walking (SSWP) and stair climbing (SSCP).

**METHODS:** Maximal oxygen consumption (MVO<sub>2</sub>) of 45 women and 54 men (32.6±14.3 yrs and 29.6±13.4 yrs, 41.7±10.4 ml/kg/min and 53.2±12.0 ml/kg/min) was determined using a modified Bruce treadmill protocol. VO<sub>2</sub> at ventilatory threshold (VT) (30.9±7.6 ml/kg/min and 38.5±8.8 ml/kg/min) and lactate threshold (LT), VO<sub>2</sub> at 4mmol blood lactate (30.4±9.8 ml/kg/min and 37.0±10.8 ml/kg/min), were calculated from the maximal treadmill test. On a motor-driven treadmill, subjects were instructed to identify a walking pace (SSWP) that they would use typically when walking across campus (3.05±.22 mph and 3.14±.35 mph, p>.05), described as a functional pace. For the stair-climbing test, they were instructed to climb the stairs at a pace (SSCP) that they normally would when they encounter a flight of stairs. VO<sub>2</sub> (using telemetry), RPE, LA, and HR were recorded for SSWP and SSCP. The Student unpaired t-test was used to determine whether there were any significant differences between genders and SSWP and SSCP.

**RESULTS:** While both women and men showed similar VO<sub>2</sub> (p>.05) at SSWP (17.54±3.8 ml/kg/min and 17.6±3.7 ml/kg/min) and SSCP (26.7±6.5 ml/kg/min and 27.3±5.0 ml/kg/min), there were significant differences (p.05) and stepping frequency at SSCP (113.3±22.1 steps/min and 120.7±18.2 steps/min) was also compared. While the men walked and climbed at the same step frequency (p<.05), the women did not (p=.09).

**CONCLUSIONS:** Subjects chose to climb at higher VO<sub>2</sub> during SSCP than SSWP. While SSWP and SSCP were the same for both, this represented a higher intensity for the women.

**2171 Board #59 May 28 2:00 PM - 3:30 PM**  
**Effect Of Moderate Hypoxia On The Power-endurance Relationship**

Jeanne Dekerle, Helen Carter. *University of Brighton, Eastbourne, United Kingdom.* (Sponsor: Tom barstow, FACSM)  
Email: j.dekerle@brighton.ac.uk  
(No relationships reported)

**PURPOSE:** The asymptote of the hyperbolic power-endurance relationship (Critical Power, CP) has been suggested to represent a sustainable power output using renewable aerobic energy. Work rates above CP would result in blood [lactate] rising until peak VO<sub>2</sub> is attained and exhaustion would occur when the curvature of the power-endurance relationship, defined as a fixed Anaerobic Work Capacity (AWC), is totally depleted. Since CP is dependent on aerobic energy supply, we tested the hypothesis that it should be reduced systematically under hypoxia while AWC would remain unaltered.

**METHODS:** Seventeen subjects (8 males; age: 37 ± 3; mass: 71 ± 2 kg) performed a ramp test to determine peak VO<sub>2</sub>, and three to four constant-load tests to exhaustion in order to model the linear P-t<sup>-1</sup> relationship (using a 2-parameter model where CP is the intercept, and AWC the slope). All tests were performed in a random order under moderate hypoxia (FiO<sub>2</sub>=0.15; pre-exercise SaO<sub>2</sub> of 93.5 ± 0.8%) and normoxia (pre-exercise SaO<sub>2</sub> of 98.3 ± 0.3%) on a SRM cycle ergometer with VO<sub>2</sub> measurement using a breath-by-breath analyzer (Ergocard; Medi-Soft). Paired t-tests were performed to identify differences. Relationships were explored using the Spearman correlation coefficient. The significance was set at P<0.05.

**RESULTS:** Peak VO<sub>2</sub> (3.55 ± 0.17 L.min<sup>-1</sup> vs 3.11 ± 0.15 L.min<sup>-1</sup>; P<0.01) and CP (225 ± 10W vs 193 ± 8 W; 2.86 ± 0.13 L.min<sup>-1</sup> vs 2.45 ± 0.12 L.min<sup>-1</sup>; P<0.01) were both significantly reduced by hypoxia. The decrease in CP (-14 ± 2%; range from 1 to -26%) and peak VO<sub>2</sub> (-12 ± 1% decrease; range from -1 to -21%) were significantly correlated (r=0.82; P<0.05). AWC was not significantly different under hypoxia (11.8 ± 1.2 kJ vs 12.2 ± 0.9 kJ; P>0.05) with the changes in AWC (+12 ± 8%; range from +60 to -36%) being highly correlated with the changes in CP (r=-0.80; P<0.05).

**CONCLUSION:** The present study demonstrates the aerobic nature of the intercept of the P-t<sup>-1</sup> relationship. A reduction in the systemic O<sub>2</sub> transport systematically affects CP, with 67% of its change being explained by peak VO<sub>2</sub> changes. The extreme changes in AWC in individuals whose CP were most affected by hypoxia, challenges the current interpretation of this parameter.

**2172 Board #60 May 28 2:00 PM - 3:30 PM**  
**'Reverse Lactate Threshold' - A Novel Approach To High-resolution, Single-session Determination Of The Anaerobic-threshold**

Raffy Dotan. *Brock Unoversity, St Catharines, ON, Canada.* (Sponsor: Dr. David Gariel, FACSM)  
Email: rdotan@brocku.ca  
(No relationships reported)

Existing single-session tests for estimating of the Anaerobic-Threshold (AnT) or Maximal Lactate Steady-State (MLSS) show unsatisfactory validity, reliability, or resolution. The main shortcomings of the accepted 'Gold Standard', the multi-session MLSS test, are prohibitive impracticality and unproven reliability.

**PURPOSE:** To introduce the proposed single-session 'Reverse Lactate Threshold' test (RLT) for AnT/MLSS determination, validate it against the accepted 'Gold Standard' (MLSS test), and test its reliability.

**METHODS:** The RLT consists of 2 contiguous series of continuous 4-min stages. A 3-5-stage series is progressively incremented from a mild work load to 5-20% above the presumed MLSS intensity. It is followed by a 3-6-load reverse series decremented in small steps. Capillary blood is sampled at the end of each stage for lactate concentration ([La]). [La] is then plotted against load and the power output at peak [La] during the reverse series is taken as the RLT-determined AnT. Four athletes of different training levels and disciplines (rowing, cycling, running) served for RLT validation and completed all RLT and MLSS-verification tests. Accepted MLSS-determination criterion was used for verification ([La] rise of ≤1.0mM in the last 20 min of the 30-min MLSS test). One athlete was retested, following a 2.5-month endurance-training period, to gauge RLT's sensitivity to fitness changes. Additional 10 trained and untrained cyclists were tested twice, 2-5 days apart, to evaluate the RLT's test-retest reliability.

**RESULTS:** RLT-MLSS agreement within 1W (<0.5%) or <0.1 mph (~0.5%) was shown in all 4 'validation' subjects. Post-training, both RLT-determined AnT and MLSS increased by 15W and were in complete agreement. The test-retest coefficient in the reliability testing was 0.998.

**CONCLUSIONS:** The RLT precisely predicted MLSS intensity in all subjects. Its single-session attribute makes it highly practical for routine testing of trained and untrained individuals. Based on the present data, the RLT appears to at least match the MLSS test's accuracy and exceed its resolution in estimating true AnT exercise intensity and in reflecting training-induced AnT changes. The observed level of reliability is higher than any reported for any existing test.

**2173 Board #61 May 28 2:00 PM - 3:30 PM**  
**Familiarization, Reliability, And Evaluation Of A Multiple Sprint Running Test Using Self-selected Recovery Periods**

Mark Glaister<sup>1</sup>, Chad Witmer<sup>2</sup>, Dustin W. Clarke<sup>2</sup>, John J. Guers<sup>2</sup>, Justin L. Heller<sup>2</sup>, Gavin Moir<sup>2</sup>. <sup>1</sup>St Mary's University College, Twickenham, United

Kingdom. <sup>2</sup>East Stroudsburg University, East Stroudsburg, PA. (Sponsor: Dr Gregory B Dwyer, FACSM)  
Email: Glaistem@smuc.ac.uk  
(No relationships reported)

**PURPOSE:** The aims of the present study were to investigate the process of self-selected recovery in a multiple sprint test with a view to using self-selected recovery time as a means of reliably quantifying an individual's ability to perform this type of exercise.

**METHODS:** Twenty physically active exercise science students (Means  $\pm$  standard deviation for age, height, body mass, body fat, and  $\text{VO}_{2\text{max}}$  of the subjects were:  $21 \pm 2$  years,  $179.2 \pm 8.6$  cm,  $83.7 \pm 10.8$  kg,  $16.6 \pm 3.9\%$ , and  $52.7 \pm 7.2$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$  respectively) completed four trials of a  $12 \times 30$  m multiple sprint running test under the instruction that they should allow sufficient recovery time between sprints to enable maximal sprint performance to be maintained throughout each trial. Heart rate and ratings of perceived exertion (RPE) were recorded throughout each trial, with sprint and recovery times recorded using twin-beam photocells.

**RESULTS:** Mean recovery times across the four trials were  $73.9 \pm 24.7$  s,  $82.3 \pm 23.8$  s,  $77.6 \pm 19.1$  s, and  $77.5 \pm 13.9$  s respectively; with variability in the first two trials considered evidence of learning effects. Test-retest reliability across trials 3-4 revealed a good level of reliability as evidenced by a coefficient of variation of 11.1% (95% likely range: 8.0 to 18.1%) and an intraclass correlation coefficient of 0.76 (95% likely range: 0.40 to 0.91). Despite no change in sprint performance throughout the trials, RPE increased progressively and significantly ( $p < 0.001$ ) from a value of  $10 \pm 2$  after sprint 3 to  $14 \pm 2$  after sprint 12. Mean heart rate throughout trial 4 was  $152 \pm 18$  b $\cdot$ min $^{-1}$ . The correlation between absolute  $\text{VO}_{2\text{max}}$  and mean recovery time was 0.46 (95% likely range: -0.03 to 0.77).

**CONCLUSIONS:** Although self-selected recovery time is a reliable measure in a multiple sprint test, it only appears to be moderately associated with an individual's  $\text{VO}_{2\text{max}}$ .

**2174 Board #62 May 28 2:00 PM - 3:30 PM**  
**The Effect Of Music Loudness On Anaerobic Performance And Muscular Endurance**

Janet McMordie. *St. Francis Xavier University, Antigonish, NS, Canada.* (Sponsor: Dr. Darren Burke, FACSM)  
Email: jmcmodi@uwo.ca  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effect of music loudness on average anaerobic power, bench press muscular endurance, and leg press muscular endurance in regularly active 20 to 22 year old females.

**METHODS:** At each testing session, participants were randomly assigned to 1 of 4 music loudness levels: zero decibels (Db), 20 Db lower than preferred volume, 20 Db higher than preferred volume, and preferred volume. Leg press repetitions to fatigue, bench press repetitions to fatigue, and average power (watts/kilogram) on a 30-second Wingate test were measured for each participant at every music loudness level.

**RESULTS:** Wingate data revealed that soft music resulted in significantly higher average power than no music ( $p=0.035$ ), preferred music resulted in significantly higher average power than no music ( $p=0.009$ ), and loud music resulted in significantly higher average power than no music ( $p=0.005$ ). Bench press data revealed that preferred music resulted in significantly higher repetitions to fatigue than no music ( $p=0.004$ ), loud music resulted in significantly higher repetitions to fatigue than no music ( $p=0.031$ ), and loud music resulted in significantly higher repetitions to fatigue than then soft music ( $p=0.009$ ). Leg press data revealed that loud music resulted in significantly higher repetitions than no music ( $p=0.011$ ), and loud music resulted in significantly higher repetitions than soft music ( $p=0.041$ ).

**CONCLUSIONS:** Music had a positive effect on performance, as measured in all exercises, with preferred and loud music conditions having the greatest impact.

**Allometric Modeling Of Anaerobic Capacity In College Men And Women**

Jerry Mayhew<sup>1</sup>, Alexander J. Koch<sup>1</sup>, Bryant England<sup>1</sup>, Abbie E. Smith<sup>2</sup>. <sup>1</sup>Truman State University, Kirksville, MO. <sup>2</sup>University of Oklahoma, Norman, OK.  
Email: jmayhew@truman.edu  
(No relationships reported)

The Wingate ergometer test has become the standard for the measurement of anaerobic capacity (AnC). The outcome of the test is typically reported in absolute (W) and relative terms (W/kg). Both of these methods may disproportionately favor the heavier individual. Allometric modeling has been used in place of simple ratio standards in order to normalize distribution of raw variables and eliminate disproportionalities.

**PURPOSE:** To evaluate the use of allometric scaling for assessing the gender difference in AnC from the Wingate ergometer test.

**METHODS:** College-aged participants (200 F, 90 M) performed a 20-sec supramaximal sprint on a standard friction-loaded bicycle ergometer (Monark, model 894) against a load equivalent to 0.075 g/kg of body mass. A computerized program monitored revolutions per minute and determined power output based on load. Following a 5-min warmup, each subject performed several 10-s familiarization sprints in order to set the workload and allow the subject to start from a pre-loaded condition.

**RESULTS:** Men ( $792 \pm 143$  W and  $9.8 \pm 1.3$  W/kg) had significantly greater ( $p<0.001$ ) absolute peak and relative peak AnC than women ( $481 \pm 108$  W and  $7.4 \pm 1.3$  W/kg). Men ( $655 \pm 122$  W and  $8.2 \pm 1.2$  W/kg) also had significantly greater ( $p<0.001$ ) absolute mean and relative mean AnC than women ( $406 \pm 88$  W and  $6.3 \pm 1.1$  W/kg). Linear regression of log-transformed values indicated no significant gender interaction. The common mass exponents were 0.85 for peak power (95% C.I. = 0.79 to 0.96) and 0.81 for mean power (95% C.I. = 0.79 to 0.96). Production of proportionality constants for each gender in each power component indicated that men produce approximately 1.6 times more AnC than women. The Fatigue Index was not significantly different between men ( $63.2 \pm 14.9\%$ ) and women ( $62.8 \pm 13.5\%$ ). The new allometric scaling coefficient for AnC in this sample was significantly greater than the theoretical value of 0.67.

**CONCLUSIONS:** Allometric scaling of AnC may be more appropriate than ratio comparisons in active young men and women when assessing gender difference. The proportional difference in AnC between the genders is comparable to differences noted previously in muscular strength.

---

**The Effect Of Climbing Experience On Metabolic Responses To Graded Exercise Tests Performed On A "Treadwall", Treadmill, And Cycle Ergometer**

Jason Wickwire<sup>1</sup>, John McLester, FACSM<sup>1</sup>, Brenda Harrison<sup>2</sup>. <sup>1</sup>Kennesaw State University, Kennesaw, GA. <sup>2</sup>Southern Connecticut State University, New Haven, CT.  
Email: wickwire@kennesaw.edu  
(No relationships reported)

Evidence suggests that subjects will achieve an ~16% lower  $\text{VO}_2$  during a GXT performed on a cycle ergometer (CE) and a vertical treadmill {treadwall (TW)} as compared to a treadmill (TM). However, there appears to be no data comparing the same parameters between experienced (Ex) and nonexperienced (NEx) climbers.

**PURPOSE:** To compare metabolic data between Ex and NEx subjects that performed GXT's on a TM, CE, and a TW.

**METHODS:** NEx (n=22 (11 males & 11 females);  $24.0 \pm 3.5$  yrs;  $170.8 \pm 12.4$  cm;  $69.7 \pm 14.0$  kg;  $19.1 \pm 7.5\%$  bf) and Ex (n=8 (7 males & 1 female);  $28.0 \pm 8.7$  yrs;  $175.8 \pm 5.4$  cm;  $67.9 \pm 10.3$  kg;  $8.6 \pm 4.6\%$  bf) subjects were tested on the different ergometers on separate days to determine their highest achievable  $\text{VO}_2$  (order counterbalanced).  $\text{VO}_2$ , respiratory exchange ratio (RER), and heart rate (HR) were measured, along with several metabolic parameters.

**RESULTS:** A significant difference ( $p < 0.05$ ) was found between groups (Ex vs. NEx) for  $\text{VO}_2$  on the TM, CE, and TW, but not for RER or HR on any ergometer. With Ex and NEx grouped separately, a significant main effect was found between all ergometers for  $\text{VO}_2$ , RER, and HR. A significant difference was found for  $\text{VO}_2$  between TM (Ex =  $52.1 \pm 6.0$ ; NEx =  $42.9 \pm 4.6$ ) and CE (Ex =  $48.0 \pm 4.4$ ; NEx =  $35.9 \pm 4.9$ ) and between TM and TW (Ex =  $45.3 \pm 6.1$ ; NEx =  $36.2 \pm 4.1$ ) in both the Ex and NEx groups. There was also a significant difference found for RER between TM (Ex =  $1.11 \pm 0.08$ ; NEx =  $1.10 \pm 0.04$ ) and CE (Ex =  $1.19 \pm 0.08$ ; NEx =  $1.19 \pm 0.06$ ), between TM and TW (Ex =  $1.01 \pm 0.05$ ; NEx =  $1.05 \pm 0.06$ ), and between CE and TW in both the Ex and NEx groups. Lastly, a significant difference was found for HR between TM ( $195.1 \pm 7.2$ ) and CE ( $183.3 \pm 10.1$ ) and between TM and TW ( $180.6 \pm 7.7$ ) in the NEx group. However, in the Ex group the only significant difference found for HR was between TM ( $186.6 \pm 15.9$ ) and TW ( $175.8 \pm 17.7$ ).

**CONCLUSION:** There was found to be a 7.9% difference between TM and CE for  $\text{VO}_2$  in Ex. However, the difference in  $\text{VO}_2$  between TM and CE was 16.3% in NEx. The percentage difference for  $\text{VO}_2$  was more similar for the Ex and NEx groups between TM and TW (13.1% and 15.6% respectively), which suggests regardless of climbing experience subjects performing a GXT on a TW will hit a ceiling in  $\text{VO}_2$  at approximately the same point relative to their aerobic fitness.

**Comparison Of Blood Vs. Saliva Lactate Measurements Resulting From Lactate Minimum Vs. Constant Load Tests**

Ruediger Reer<sup>1</sup>, Philipp Semerak<sup>1</sup>, Marc Ziegler<sup>1</sup>, Tobias Schmidt<sup>1</sup>, Detlef Loppow<sup>1</sup>, Serge P. von Duvillard, FACSM<sup>2</sup>, Klaus-Michael Braumann<sup>1</sup>.

<sup>1</sup>University of Hamburg, Hamburg, Germany. <sup>2</sup>University of Salzburg, Salzburg, Austria.

Email: reer@uni-hamburg.de

(No relationships reported)

The determination of saliva lactate concentrations in saliva samples represents a non-invasive and an innovative method for determination of endurance capacity and endurance diagnostics.

**PURPOSE:** To assess the concentration of saliva lactate (SL) in contrast to blood lactate concentration (BL).

**METHODS:** 18 healthy subjects (13 male, 5 female; age:  $27.3 \pm 6.2$  yrs; physical activity:  $6.9 \pm 2.7$  h $\cdot$ wk<sup>-1</sup>) performed four cycle ergometer tests (one lactate minimum test [LMT] and 3 constant load tests at 95%, 100% and 105% of the workload at the maximum lactate steady state [MLSS] determined from the LMT). Blood and saliva samples were collected simultaneously and analyzed for lactate.

**RESULTS:** All tests exhibit a clear delay in SL measurements when compared to BL. SL values were lower than BL values (range: 2-5 times). SL curve leveled off later than BL during the constant load tests. Workload of MLSS from the constant load test [BMLSS<sub>CL</sub>] ( $209.7 \pm 44.8$  W) was significantly lower in comparison to workload measured for maximum lactate steady state during LMT generated from blood [BMLSS] ( $219.7 \pm 45.5$  W;  $n = 18$ ;  $p < 0.05$ ) and saliva [SMLSS] ( $235.9 \pm 58.4$  W;  $n = 16$ ;  $p < 0.05$ ).

**CONCLUSION:** More inertial appearance of SL may be explained by an additional diffusion of lactate in the salivary glands. An approximation of BMLSS<sub>CL</sub> by SMLSS is not possible when using the established protocol with an increment duration of 3 min. due to the delayed appearance of lactate in saliva.

**Cerebral And Skeletal Muscle Oxygen Response To Two Brief High Intensity Exercise Trials**

Reid Nelson, Melissa Crabb, Megan Crowe, Angela Davis, Nicole Kusko, Kathryn Reith, Carly Schneeberg. *Concordia University Wisconsin, Mequon, WI.*

Email: reid.nelson@cuw.edu

(No relationships reported)

The 30 second Wingate Anaerobic Test (WAT) is an accepted assessment of anaerobic power. The use of 30 seconds however, is sometimes associated with adverse symptomatic responses immediately following the supramaximal effort. Previous studies have looked at multiple 15 second WATs that may better represent brief high intensity intervals seen in many anaerobic sporting events and also may reduce adverse responses sometimes seen with the 30 second WAT.

**PURPOSE:** The purpose of this study was to examine the oxygen response in cerebral tissue (CT) and skeletal muscle (SM) during two 15 second WATs (WAT1 and WAT2), separated by a 4 minute recovery period in both anaerobically trained and non-anaerobically trained individuals.

**METHODS:** Seventeen participants (9 soccer players, 8 sedentary; mean age  $20.7 \pm 1.4$  yrs) were recruited for this study. Participants completed one familiarization session and one data analysis session. Two 15 second supramaximal cycling efforts (resistance =  $0.075$  kg/kg body weight) were separated by a 4 minute active recovery. SM and CT O<sub>2</sub> responses for oxy-hemoglobin (O<sub>2</sub>Hb) and deoxyhemoglobin (HHb) were assessed using a four-channel continuous wave near infrared spectrophotometer (NIRS). O<sub>2</sub>Hb and HHb was measured simultaneously at 3 sites on the right side of the body; rectus femoris (RF), vastus lateralis (VL), and the forehead approximately 1 inch above the eyebrow.

**RESULTS:** O<sub>2</sub>Hb demonstrated a significantly greater reduction during the second 15 second period compared to the first 15 second WAT in both RF ( $-9.20 \pm 10.35$  vs  $-11.10 \pm 11.15$   $\mu\text{m}$ ) and in VL ( $-9.81 \pm 8.17$  vs  $-11.01 \pm 8.18$   $\mu\text{m}$ ) in all participants ( $p < 0.05$ ). Cerebral O<sub>2</sub>Hb remained stable or demonstrated a slight increase during both WAT1 ( $2.47 \pm 0.95$   $\mu\text{m}$ ) and WAT2 ( $1.81 \pm 1.24$   $\mu\text{m}$ ). There was no significant difference in power measurements for either peak or mean power when comparing WAT1 ( $677.48 \pm 136.85$  W and  $650.68 \pm 114.20$  W) vs WAT2 ( $678.31 \pm 134.29$  W and  $651.61 \pm 112.11$  W). These results were consistent when comparing anaerobic vs non-anaerobic individuals.

**CONCLUSIONS:** The results of this study suggest that although there is a significant decrease in SM O<sub>2</sub>Hb during the second test, cerebral O<sub>2</sub>Hb remains stable and power is maintained with two 15-second WAT utilizing four minute active recovery between bouts.

**Predicting Maximal Oxygen Uptake Via A Sub-maximal Perceptually Regulated Treadmill Exercise Test.**

Michael Morris, Kevin Lamb, John Hayton, David Cotterrell, John Buckley. *University of Chester, Chester, United Kingdom.*

Email: m.morris@chester.ac.uk

(No relationships reported)

Recent research has provided encouraging results to support the prediction of maximal oxygen uptake ( $\text{VO}_{2\text{max}}$ ) from a perceptually regulated exercise test (PRET). Studies to date have solely investigated its application to cycle ergometry.

**PURPOSE:** To determine if  $\text{VO}_{2\text{max}}$  can be predicted with acceptable accuracy and repeatability from a sub-maximal treadmill PRET.

**METHODS:** Eighteen volunteers ( $21.7 \pm 2.8$  years) completed three treadmill PRETs (each separated by 48hrs) and one maximal graded exercise test. Participants self regulated their exercise at RPE levels 9, 11, 13 and 15 in a continuous and incremental fashion. Oxygen uptake ( $\text{VO}_2$ ) was recorded continuously during each three minute bout.  $\text{VO}_2$  values for the RPE range 9-15 were extrapolated to RPE 20 using regression analysis to predict individual  $\text{VO}_{2\text{max}}$  scores. This same procedure was also adopted to calculate estimated  $\text{VO}_{2\text{max}}$  from treadmill speed and gradient using ACSM metabolic equations. The concordance of the predicted and actual  $\text{VO}_{2\text{max}}$  scores and the trial-to-trial reliability of the predicted scores were analysed using intraclass correlation coefficients (ICC) and the limits of agreement (LoA) technique.

**RESULTS:** The mean  $\text{VO}_2$  following the last stage of the PRET (RPE 15) was  $73 \pm 8\%$  of  $\text{VO}_{2\text{max}}$ . The LoA between actual ( $48.0 \pm 6.2$  ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>) and predicted scores were  $1.9 \pm 13.3$ ,  $1.0 \pm 8.8$  and  $-0.6 \pm 7.1$  ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> for trials 1, 2 and 3, respectively. The corresponding values from the ACSM calculations were  $3.2 \pm 19.8$ ,  $0.2 \pm 11.9$  and  $-0.7 \pm 9.9$  ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>. Reliability analysis for the PRET  $\text{VO}_{2\text{max}}$  predictions yielded ICCs of 0.76 and 0.84 and LoAs of  $0.9 \pm 12.3$  ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> and  $1.7 \pm 8.5$  ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> for trial1 versus trial 2, and trial 2 versus trial 3, respectively.

**CONCLUSIONS:** These findings demonstrate that, given practice, a sub-maximal treadmill PRET can yield predictions of  $\text{VO}_{2\text{max}}$  that are acceptably reliable and more

---

**2180 Board #68 May 28 2:00 PM - 3:30 PM**  
**The Metabolic Cost Of Critical Velocity At Different Treadmill Grades**

Helen Carter, Jeanne Dekerle. *University of Brighton, Eastbourne, United Kingdom.* (Sponsor: Tom Barstow, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to test whether the Critical Velocity (CV) represents a set metabolic rate, regardless of the treadmill grade used.

**METHODS:** Nine volunteers (4 male; mean  $\pm$  SD, age  $31.8 \pm 6$  years; mass  $65.7 \pm 7.3$  kg; height  $170.7 \pm 8.6$  cm) performed a series of tests on two differing treadmill grades: 0% and 10%. The testing series comprised 1) a fast ramp to determine maximum oxygen uptake (treadmill velocity increasing  $0.1 \text{ km}\cdot\text{h}^{-1}$  every 6s); 2) three trials to determine CV, with intensities selected to bring about exhaustion between 3 and 15 minutes; and 3) a trial to exhaustion at the grade specific CV. Oxygen uptake ( $\text{VO}_2$ ), heart rate and blood lactate ([BLA]) data were collected during the exercise tests. Results are expressed mean  $\pm$  SEM, with significance taken at  $P < 0.05$ .

**RESULTS:** There were no differences in the grade specific  $\text{VO}_2\text{max}$  ( $55.7 \pm 4.3$  vs  $56.3 \pm 4.4 \text{ mL}\cdot\text{min}\cdot\text{kg}^{-1}$  in 0% and 10% respectively). However, peak treadmill velocity was significantly higher in 0% ( $17.6 \pm 0.8$  vs  $13.2 \pm 0.6 \text{ km}\cdot\text{h}^{-1}$  in 10%,  $P < 0.001$ ). Although the velocities used to determine CV on both grades differed ( $P < 0.001$ ), the time to exhaustions (TTE), importantly, did not (short:  $215 \pm 13.6$  vs  $201.8 \pm 15.3$  s; middle:  $386 \pm 23.4$  vs  $337 \pm 29$  s; long:  $703.8 \pm 40.2$  vs  $677.5 \pm 43$  s in 0% and 10% respectively). The 0% CV was significantly higher ( $14.1 \pm 0.6 \text{ km}\cdot\text{h}^{-1}$ ) than in 10% ( $9.1 \pm 0.4 \text{ km}\cdot\text{h}^{-1}$ ). When the volunteers ran at each grade specific CV, the metabolic rate ( $\text{VO}_2$  measured at 3 min) did not differ ( $3.24 \pm 0.3$  vs  $3.24 \pm 0.3 \text{ L}\cdot\text{min}^{-1}$ , 0% and 10% respectively, equivalent to 88 and 90%  $\text{VO}_2\text{max}$ ). There was a tendency for  $\text{VO}_2$  at end exercise (EE) to reach a higher percentage of  $\text{VO}_2\text{max}$  in 10% (attaining 95% compared to 89% in 0%). The same pattern was seen with delta [BLA] (EE - 3 min) tending to be higher in 10% ( $\sim 2$  vs  $\sim 1 \text{ mM}$  in 0%). Time to exhaustion at CV, although not statistically different, tended to be longer in 0% ( $1997 \pm 259$  vs  $1752 \pm 205$  s in 10%).

**CONCLUSIONS:** We conclude that CV does indeed represent a set metabolic rate as evidenced by the 'steady state'  $\text{VO}_2$  at minute 3 of exercise at CV. However, the tolerance to exercise at CV in 10% appears to be lower (6 out of 9 subjects having shorter TTE), Supported by a tendency for higher  $\text{VO}_2$  and [BLA] at EE. These differences in fatigue development could be explained by possible differences in muscle fiber recruitment.

**Examination Of Relationship Between Physical Activity And Weight Decrease Rate For Abdominally Obese Japanese Men**

Yoshihiro Matsumura<sup>1</sup>, Kenji Nishino<sup>2</sup>, Tetsutaro Sugiura<sup>1</sup>, Minoru Goto<sup>3</sup>, Tadashi Nakamura<sup>4</sup>, Ichihiro Shimomura<sup>4</sup>. <sup>1</sup>Panasonic Electric Works Co., Ltd., Osaka, Japan. <sup>2</sup>Panasonic Electric Works Creates Co., Ltd., Osaka, Japan. <sup>3</sup>Medical Corporation Kouseikai, Osaka, Japan. <sup>4</sup>Osaka University Graduate School of Medicine, Osaka, Japan.  
Email: y-matsumura@panasonic-denko.co.jp  
(No relationships reported)

Increasing the amount of physical activity is important to prevent metabolic syndrome (MS). To prevent MS, usage of an activity meter (AM) is increasing due to its ability to measure low to moderate physical activity and accuracy in energy estimation.

**PURPOSE:** The aim of this study is to assess the usefulness and the high precision of AM to prevent metabolic syndrome.

**METHODS:** Thirty four male subjects aged 35-55 participated in the study. They were recruited from an electrical appliance company and had abdominal circumferences (AC) larger than 85 cm. None were taking internal medicine (age  $44.0 \pm 6.0$  yr., BMI  $26.9 \pm 2.3 \text{ kg}/\text{m}^2$ , AC  $94.3 \pm 5.4$  cm). Regular physical activity was measured more than a week before intervention by AM with a blinded display. Initial exercise and diet intervention were performed based on the results. AM can display the amount of time of more than 3 METs physical activity and the energy expenditure of physical activity (EE). The data of 12-weeks of exercise and diet intervention were examined. Every morning and evening the subjects weighed themselves, and measured their ACs on a weekly basis. Using AM, they also measured all of their physical activity except sleeping and aqua exercise. The results of these self measurements were reported and sent by e-mail every week. Two telephone and face-to-face coachings were performed during the middle of the intervention. Nutritional surveys by photos were performed three days before and after intervention.

**RESULTS:** The following are the results of three-month interventions. The change of nutritional content was  $-277 \pm 359$  kcal, and the amount of physical activity also significantly increased (EE/weight:  $8.6 \pm 1.5$  to  $10.3 \pm 2.0 \text{ kcal}/\text{kg}/\text{d}$ ;  $p < 0.001$ , gt. 3METs:  $50.7 \pm 13.8$  min to  $67.8 \pm 17.7$  min;  $p < 0.001$ , lt. 3METs  $460.4 \pm 82.4$  min to  $471.3 \pm 81.8$  min;  $p < 0.05$ ). Some MS risk parameters decreased (AC:  $94.5 \pm 5.4$  to  $90.5 \pm 6.0$  cm;  $p < 0.001$ , LDL-C:  $147 \pm 27.6$  to  $133 \pm 25.1 \text{ mg}/\text{dL}$ ;  $p < 0.001$ ). A significant negative correlation was found between the rate of weight change and the physical activity energy expended per unit of weight ( $r = -0.50$ ,  $p < 0.005$ ).

**CONCLUSIONS:** This study suggests that accurate physical activity monitoring is effective for exercise intervention to prevent metabolic syndrome.

**Effect Of Exercise Intensity On The Flow Rate, Viscosity, And Osmolarity Of Human Saliva**

Naoyuki Hayashi<sup>1</sup>, Masumi Kamei<sup>1</sup>, Nami Someya<sup>1</sup>, Yoshiyuki Fukuba, FACSM<sup>2</sup>. <sup>1</sup>Kyushu University, Kasuga, Fukuoka, Japan. <sup>2</sup>Prefectural University of Hiroshima, Hiroshima, Japan.  
(No relationships reported)

The physical nature of saliva during exercise remains as yet un known.

**PURPOSE AND METHODS:** We determined the characteristics of human whole saliva during exercise in 10 males and 5 females, whose ventilatory threshold (VT) was  $120 \pm 17 \text{ W}$  (mean  $\pm$  SD). The subjects performed an incremental cycle ergometer exercise (20 and 30 W every 3 min for males and females, respectively). At each stage, the subjects expectorated once a minute for 2 min. Subjects placed a nylon ball in their oral cavity to promote salivary flow. The flow rate was assessed as the mass of saliva per minute. Using a cone and plate viscometer and vapor pressure osmometer, we measured the viscosity and osmolarity of stimulated saliva. The viscosity was measured at a shear rate of  $22.5$  and  $90.0 \text{ s}^{-1}$ .

**RESULTS:** Compared with the resting baseline, the flow rate gradually decreased, and it showed a significant decrease at intensities of more than VT -  $18 \pm 4 \text{ W}$  ( $p < 0.05$ ). It decreased to half of the baseline value. The osmolarity showed significant increase at intensities of more than VT +  $20 \pm 4 \text{ W}$ . The viscosity revealed a significant increase only at an intensity of VT +  $58 \pm 4 \text{ W}$ .

**CONCLUSION:** These result showed an effect of exercise intensity on the characteristics of saliva. Sympathetic activation increases mucin secretion, which relates to salivary viscosity, whereas parasympathetic activation increases saliva flow. Thus, the results regarding the flow rate and viscosity suggest that a detectable increase in the sympathetic activation of salivary glands occurs at a much higher intensity than the VT, whereas parasympathetic inhibition occurs at a relatively lower intensity.

**Is Anaerobic Power Related To  $\text{Vo}_2$  Max Attainment?**

Ailish C. White<sup>1</sup>, Todd A. Astorino<sup>2</sup>. <sup>1</sup>San Diego State University, San Diego, CA. <sup>2</sup>California State University San Marcos, San Marcos, CA.

(No relationships reported)

**PURPOSE:** To determine if anaerobic power is related to  $\text{VO}_{2\text{max}}$  attainment in recreationally-active men and women.

**METHODS:** Nineteen subjects (10 men and 9 women, mean age, height, mass, and  $\text{VO}_{2\text{max}} = 23.0 \pm 4.1$  yr,  $174.1 \pm 7.3$  cm,  $68.1 \pm 10.7$  kg, and  $42.2 \pm 6.0$  mL/kg/min, respectively) initially completed the Wingate Test. At least 24 h later, subjects completed incremental cycle ergometry followed by 10 min of active recovery, then performed a verification protocol at a supramaximal workload one stage above the last completed stage during the incremental test. During exercise, gas exchange data were obtained every 15 s.  $\text{VO}_{2\text{max}}$  was defined as a change in  $\text{VO}_2$  ( $\text{DVO}_2$ )  $< 2.1$  mL/kg/min. Day-to-day error in  $\text{VO}_{2\text{max}}$  ranged from 3.0 - 3.2 % for the supramaximal and incremental protocol, respectively. A paired t-test was used to examine differences in  $\text{VO}_{2\text{max}}$  and gas exchange data between tests. Linear regression was used to describe the relationship between  $\text{DVO}_2$  at  $\text{VO}_{2\text{max}}$  and peak power, mean power, and fatigue index.

**RESULTS:** Peak power, mean power, and fatigue index were equal to  $9.4 \pm 1.4$  W/kg,  $7.1 \pm 1.0$  W/kg, and  $51.4 \pm 5.6$  %, respectively. Peak power and mean power significantly ( $p < 0.05$ ) predicted  $\text{DVO}_2$ ,  $\text{DVO}_2 = 0.04(\text{MP}) - 0.03(\text{PP}) + 0.79$ ,  $R = 0.56$ ,  $p = 0.05$ . There was no correlation between fatigue index and  $\text{DVO}_2$ ,  $r(19) = -0.29$ ,  $p > 0.05$ . There was no difference ( $p > 0.05$ ) in mean  $\text{VO}_{2\text{max}}$  between the incremental ( $42.2 \pm 6.0$  mL/kg/min) and supramaximal trial ( $42.2 \pm 5.4$  mL/kg/min).  $\text{VCO}_2$  and RER were higher ( $p < 0.05$ ) in response to the incremental ( $3.42 \pm 0.66$  L/min and  $1.20 \pm 0.06$ ) compared to the supramaximal protocol ( $3.13 \pm 0.69$  L/min and  $1.09 \pm 0.07$ ), although maximal HR and  $\text{V}_E$  were similar ( $p > 0.05$ ) between protocols.

**CONCLUSION:** Linear regression revealed that mean and peak power are significant predictors of  $\text{DVO}_2$  yet they explain only 31 % of the variability in  $\text{DVO}_2$ . Despite no difference in mean  $\text{VO}_{2\text{max}}$  between protocols, there were three subjects who had a higher  $\text{VO}_{2\text{max}}$  in the supramaximal trial, and five subjects who had a lower  $\text{VO}_{2\text{max}}$  in the supramaximal trial versus the incremental bout. Additional investigation is needed to further elucidate the  $\text{VO}_{2\text{max}}$  phenomenon, specifically why some subjects do not reveal a 'true'  $\text{VO}_{2\text{max}}$  after completion of a verification protocol.

(No relationships reported)

Sang-Koo Woo, Soo-Hyun Park, Tae-Kyung Han, Hyun-Sik Kang. Andong National University, Andong, Sungkyunkwan University, Suwon, Republic of Korea

Substantial evidence supports the use of CRF and physical activity as powerful predictors of health outcomes, including metabolic syndrome, among western populations. No such studies have been conducted in Asians including Koreans.

**PURPOSE:** To investigate the relationship between cardio/respiratory fitness (CRF) and metabolic syndrome (MS) in young Korean men.

**METHODS:** In a cross-sectional study, we examined 909 young Korean men (mean  $\pm$  SD age,  $24.0 \pm 2$  years) who were healthy and not taking any medications affecting blood pressure, glucose, or lipids concentrations. Body fatness, resting blood pressures, and fasting blood levels of lipids, glucose, and insulin were measured with our standardized laboratory protocols. CRF was quantified as the maximum volume of minute oxygen consumption measured during a graded treadmill test.

**RESULTS:** Group analyses showed significant and inverse dose-response trends between the metabolic risk factors and CRF levels such that men with high and moderate CRF levels had more favorable profiles in body fatness, resting blood pressures, mean values in fasting lipids, glucose, and insulin, and homeostasis model of assessment-insulin resistance than men with low CRF level. After adjusting for several potential confounders such as age, smoking, and body fatness variables, the low and moderate CRF groups had odds of 4.64 (95% CI, 2.00 to 10.79) and 2.57 (95% CI, 1.04 to 6.34) for having MS than the high CRF group.

**CONCLUSION:** These findings suggest that low CRF is significantly associated with elevated risk of MS independent of body fatness in young Korean men.

**Validation Of The Cosmed Fitmate For Predicting Maximal Oxygen Consumption**

Jungmin Lee, David R. Bassett, FACSM, Dixie L. Thompson, FACSM, Eugene C. Fitzhugh. University of Tennessee, Knoxville, TN.

Email: jlee55@utk.edu

(No relationships reported)

**PURPOSE:** The primary purpose of this study was to assess the validity of the Cosmed Fitmate (FM) in predicting maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ), compared to the Douglas bag (DB) method. In addition, this study examined whether measuring submaximal  $\text{VO}_2$ , rather than predicting it, can improve upon the prediction of  $\text{VO}_{2\text{max}}$ .

**METHODS:** Thirty-two males and sixteen females (Mean  $\pm$  SD: age  $30 \pm 9$  yr, body mass  $72.9 \pm 13.0$  kg, height  $1.75 \pm 0.09$  m, BMI  $23.4 \pm 3$  kg·m<sup>-2</sup>) volunteered to participate in the study. Each participant completed a submaximal and a maximal treadmill test using the Bruce protocol on two separate occasions. During the submaximal test,  $\text{VO}_{2\text{max}}$  was predicted using the FM, while during the maximal test  $\text{VO}_{2\text{max}}$  was measured using the DB method. The Cosmed Fitmate predicts  $\text{VO}_{2\text{max}}$  by extrapolating the linear regression relating heart rate and measured  $\text{VO}_2$  to age-predicted maximum heart rate (HR = 220-age). This study also examined the validity of predicting  $\text{VO}_{2\text{max}}$  by using the ACSM metabolic equations to estimate submaximal  $\text{VO}_2$ .  $\text{VO}_{2\text{max}}$  values from the FM, the DB method, and ACSM prediction equations were analyzed using repeated measures ANOVA and linear regression analyses. The level of significance was set at  $P < 0.05$  for all statistical analyses.

**RESULTS:** There was no significant difference between  $\text{VO}_{2\text{max}}$  predicted by the FM ( $45.6$  mL·kg<sup>-1</sup>·min<sup>-1</sup>, SD 8.8) and measured by the DB method ( $46.5$  mL·kg<sup>-1</sup>·min<sup>-1</sup>, SD 8.8) ( $p = 0.152$ ). The results of this study showed that a strong positive correlation ( $r = 0.897$ ) existed between  $\text{VO}_{2\text{max}}$  predicted by the FM and  $\text{VO}_{2\text{max}}$  measured by the DB method, with a standard error of the estimate (SEE) =  $3.97$  mL·kg<sup>-1</sup>·min<sup>-1</sup>. There was a significant difference in  $\text{VO}_{2\text{max}}$  predicted by the ACSM metabolic equations ( $53.6$  mL·kg<sup>-1</sup>·min<sup>-1</sup>, SD 8.0) and  $\text{VO}_{2\text{max}}$  measured by the DB method ( $p = 0.01$ ). The correlation between these variables was  $r = 0.699$  (SEE =  $5.84$  mL·kg<sup>-1</sup>·min<sup>-1</sup>).

**CONCLUSION:** These findings suggest that the Fitmate is a small, portable, and easy-to-use metabolic system that provides reasonably good estimates of  $\text{VO}_{2\text{max}}$ , and that measuring submaximal  $\text{VO}_2$ , rather than predicting it from the ACSM metabolic equations, improves the prediction of  $\text{VO}_{2\text{max}}$ .

**Identification Of A RPE Based Warning Zone To Anticipate Graded Treadmill Test Termination.**

Fredric L. Goss, FACSM, Robert J. Robertson, FACSM, Luke Haile, Maressa P. Krause, Elizabeth F. Nagle, FACSM, Kenneth F. Metz, FACSM. Univ. of Pittsburgh, Pittsburgh, PA.

Email: goss@pitt.edu

(No relationships reported)

Ratings of perceived (RPE) exertion provide a measure of an individual's feelings of effort and fatigue and the relative exercise intensity. Therefore, RPE have the potential to be used to anticipate exercise test termination.

**PURPOSE:** To identify a perceptually-based warning zone for termination of the Bruce treadmill test.

**METHODS:** Clinically normal adult females (n= 116) and males (n=55) participated in this single observation perceptual estimation paradigm. Subjects completed a Bruce treadmill test. Ratings of perceived exertion (i.e. Borg 6-20 scale) for the overall body were estimated during the last 15 s of each min of exercise. Tests were terminated owing to subject fatigue. The time to test termination was determined from the point during the treadmill test that subjects estimated a RPE of 12, 13, 14, 15, 16 & 17. The criterion to establish impending test termination was the duration of a single intensity stage of a progressive protocol, i.e. 180 s. Multiple dependent t-tests were used to examine within gender differences in the time to test termination associated with each RPE. Multiple independent t-tests were used to examine the between gender differences in the time to test termination corresponding to each RPE.

**RESULTS:**

Table 1. Time(s) to test termination						
			RPE			
Male	12	13	14	15	16	17
	300.0	232.0*	190.0*	120.1*	110.3*	60.4*
	+133.0	+102.1	+102.0	+ 80.0	+60.2	+50.3
	(n=36)	(n=43)	(n=36)	(n=35)	(n=20)	(n=29)
Female	12	13	14	15	16	17
	242.7	188.1*	141.9*	99.2*	104.9	53.2*
	+98.9	+100.1	+88.7	+65.0	+111.6	+47.0
	(n=80)	(n=91)	(n=65)	(n=65)	(n=39)	(n=49)

Values are Means + SD \*different from preceding RPE (p<0.003)

**CONCLUSIONS:** It is recommended that when an RPE of 14 is reported by females and a 15 by males during a multistage treadmill protocol, test termination will occur in less than 180 s and procedures to end the test should be initiated. Accurate and timely prediction of test termination using RPE will enhance the safety of exercise testing and facilitate endpoint measures upon which to prescribe exercise intensity.

**Electromyographical Analysis Of The Rectus Abdominis Muscle In Athletes Performing 10 Different Abdominal Exercises**

Adam Hawkey, Sivasubramanian Shunmugam, Ross Cloak, Alan Nevill. *University of Wolverhampton, Walsall, United Kingdom.* (Sponsor: Prof Greg Whyte, FACSM)

Email: A.Hawkey@wlv.ac.uk

(No relationships reported)

There has been debate recently regarding the type of exercise that optimally benefits the development of the rectus abdominis (RA) muscle. Currently, the traditional abdominal crunch is the exercise of choice, although comparative research is limited.

**PURPOSE:** To compare the myoelectric action potential using root mean square (RMS) of the RA musculature during execution of 10 different abdominal exercises (AE) using portable surface electromyography.

**METHODS:** Following informed consent and medical screening of all subjects, surface electrodes were placed symmetrically and bilaterally over the upper, middle and lower parts of the RA musculature on a sample of 15 athletes {(Mean ± SD) age 27.53± 6.8 yrs, height 1.77 ± 0.1 m, and mass 74.93± 8.8 kg} with flat abdominal walls. The skin site was cleansed with alcohol-wipes to reduce the impedance. Subjects performed 10 repetitions of each of the 10 AE. Exercises performed were the traditional abdominal crunch (TAC), bicycle manoeuvre, crossover crunch, reverse crunch (RC), isometric abdominal exercise (IAE), swiss ball, decline bench (DB), abdominal roller, hanging knee-to-waist raise, and hanging knee-to-chest raise (HKCR). All exercises were performed to the pace of a digital metronome at the rate of 2 seconds per repetition, with a rest period of 10 minutes between each exercise. The order of exercises was randomised using Standardised Latin-Square design to reduce the effects of muscular fatigue and the hip and knee angles were standardised throughout testing. Repeated measures One-way ANOVA with post-hoc Least Significant Difference (LSD) correction was used to analyse the data.

**RESULTS:** Myoelectric action potential, measured using RMS, was significantly greater when performing the HKCR exercise (4.04mV, p=0.008), and the DB exercise (3.63mV, p=0.013) in comparison to the TAC (3.13mV). RMS was significantly reduced when performing the IAE (0.73mV, p<0.000) and the RC (1.83mV, p=0.001) compared to the TAC (3.13mV).

**CONCLUSION:** Hanging knee-to-chest raise and DB elicit the highest RMS activity, while IAE and RC elicit the lowest activity in the RA muscle. HKCR and DB are, therefore, suggested to be the best exercises to train the abdominal muscles. Future research should be conducted to analyse the vertebral compression forces during these AE.

**Elliptical Trainer Brands And The Development Of A Metabolic Prediction Equation**

Daniel P. Swearl<sup>1</sup>, Christopher Ray<sup>2</sup>, Mark Ricard<sup>2</sup>, Lance Dalleck<sup>3</sup>, Jennifer Blevins-McNaughton<sup>4</sup>. <sup>1</sup>Northwestern, Orange City, IA. <sup>2</sup>UT Arlington, Arlington, TX. <sup>3</sup>University of Wisconsin Eau-Claire, Eau-Claire, WI. <sup>4</sup>Tarleton State University, Stephenville, TX.

(No relationships reported)

**PURPOSE:** The primary purpose of this study was to determine the effect of elliptical trainer brand on gas exchange data as well as to develop separate brand-specific equations.

**METHODS:** Twenty-three healthy volunteers (22.3 ± 4.6 yrs, 172 ± 8.2 cm, 67.5± 9.3 kg) completed two testing sessions on two different brands of elliptical trainers, the Precor EFX 576i® and the TRUE TS1®, exercising equivalent watt output readings on each elliptical trainer was determined by resistance and cadence. Each subject exercised on each machine for six, 5-min. stages for a total exercise time of 30 minutes per session. Oxygen consumption (VO<sub>2</sub>), heart rate, rating of perceived exertion (RPE), and caloric cost of the exercise were measured during each session. Two (machine) x three (workload) repeated measures ANOVA was used to analyze differences between machines. Stepwise multiple nonlinear regression analysis was used to develop metabolic equations for submaximal elliptical trainer exercise on both the Precor and the TRUE.

**RESULTS:** Significant differences were found between elliptical trainer brands for all exercise variables analyzed (p<0.001), with the TRUE eliciting higher values than the Precor for equivalent watt output readings. Oxygen consumption values at the same watt output reading were 6.85 ± 4.4 ml/kg/min higher on the TRUE for watt levels between 107 and 131 watts. Two separate metabolic equations were developed for submaximal elliptical trainer exercise on the TRUE (R<sup>2</sup> = 0.95, SEE = 2.6), and the Precor (R<sup>2</sup> = 0.92, SEE = 2.4).

**CONCLUSIONS:** Differences exist in physiological responses to submaximal elliptical trainer exercise at equivalent watt output readings. These differences may require the acceptance of a metabolic prediction equation that is specific to a particular brand of elliptical trainer.

**Bruce Protocol Versus Costill-fox Protocol For Vo2 Max In College Male Cross Country Athletes**

Miles Erwin, Coleen Fava, Ludmila Cosio-Lima. *University of West Florida, Pensacola, FL*  
(No relationships reported)

VO2 max is the most reliable method to predict cardiovascular performance. Several protocols have been used; which have mostly been developed in the late 1960's and 1970's. The most commonly used protocol is the Bruce protocol.

**PURPOSE:** To determine if the Bruce protocol, which is a slow speed and high-incline based VO2 max protocol will produce the same results as the Costill-Fox protocol, which has a higher speed yet lower incline.

**METHODS:** Five college male cross country runners age 19.4 yrs +/- 1.14, with a height of 1.77m +/- .06, and a weight of 68.55kg +/- 7.99, were tested for VO2 max using the Bruce protocol and the Costill-Fox protocol. Each subject had 7 to 18 days between testing. The protocols were performed in random order. The subjects were monitored on a metabolic cart to determine VO2 max during the 2 running treadmill tests. VO2 max results were compared using a paired samples T test with a significance level of (0.05).

**RESULTS:** VO2 max for the Bruce protocol resulted in an average of 66.74 ml/kg +/- 6.63 and the Costill-Fox in an average of 69.52 ml/kg +/- 4.90. Average RER recorded for the Bruce protocol was 1.04 +/- .07 while the Costill-Fox average was 1.08 +/- .08. Average heart rate for the Bruce protocol tested as 179.80 +/- 20.12 with the Costill-Fox heart rate average as 190.60 +/- 7.83. A significant ( $p < 0.05$ ) difference in VO2 max was observed between the 2 protocols.

**CONCLUSION:** The protocol used to determine VO2 max will have an effect on the outcome. The athletes were able to achieve a higher exertion on the Costill-Fox protocol without being restricted by running steep inclines. Higher results can be achieved by well trained runners when a protocol is implemented that uses greater speed with a lower incline by allowing the individual to extend themselves more fully.

**2190 Board #78 May 28 2:00 PM - 3:30 PM**  
**Effect Of Different Cycling Protocols On The Anaerobic Capacity**

Ankie Vink<sup>1</sup>, Dionne A. Noordhoff<sup>1</sup>, Florentina J. Hettinga<sup>1</sup>, Jos J. de Koning, FACSM<sup>1</sup>, Carl Foster, FACSM<sup>2</sup>. <sup>1</sup>VU-University, Amsterdam, Netherlands. <sup>2</sup>University of Wisconsin-la Crosse, La Crosse, WI.  
Email: j.dekoning@fbw.vu.nl  
(No relationships reported)

**BACKGROUND:** The anaerobic capacity (AnC) can be determined with the gross efficiency (GE) method. The AnC can be determined during different exercise protocols, but it is expected that the AnC would be the same for different exercise protocols with durations ranging from 2-5 min.

**PURPOSE:** This study evaluated the effect of closed loop (time trial) versus open loop (a ride to failure at a constant PO) exercise protocols on the computed value of the AnC.

**METHODS:** Well trained male cyclists ( $n=15$ ) performed two exercise protocols; a 2500m cycling time trial (TT)(closed loop) and a ride to failure at constant power output (CPO)(open loop), at the mean PO of the TT. With the GE method, the mechanical power attributable to the anaerobic energy system ( $P_{an}$ ) is calculated by summing the difference between the mechanical aerobic power production ( $P_{aer}$ ) and the total mechanical power output ( $PO_{total}$ ) over time. GE was determined from measures of PO and gas exchange preceding each trial.

**RESULTS:** The duration of TT ( $199.9 \pm 6.8$  s) was significantly longer than of CPO ( $167.4 \pm 46.4$  s) ( $p=0.01$ ). The AnC computed during TT ( $246 \text{ J/kg} \pm 74$ ) was not significantly different from that during CPO ( $281 \text{ J/kg} \pm 60$ ) ( $p=0.11$ ). Despite the finding that there is no significant mean difference in AnC between closed loop & open loop exercise protocols, a non significant ( $p=0.24$ ) correlation was found between methods ( $r=0.32$ ). Only 10% of the variance in the computed AnC during the CPO could be explained by the variance in AnC during the TT.

**CONCLUSIONS:** These results indicate that there were no mean differences in AnC between open loop & closed loop exercise protocols, but there were meaningful individual differences.

**Comparison Of Cardiac Diastolic Time In Exercise Among Different Fitness Groups**

Shigeru Obara<sup>1</sup>, Masaki Takahashi<sup>1</sup>, Takuro Matsuda<sup>2</sup>, Peter H. Brubaker, FACSM<sup>3</sup>, Hiroaki Tanaka<sup>2</sup>. <sup>1</sup>The University of Tokushima, Tokushima, Japan. <sup>2</sup>Fukuoka University, Fukuoka, Japan. <sup>3</sup>Wake Forest University, Winston-Salem, NC.  
Email: obara@ias.tokushima-u.ac.jp  
(No relationships reported)

Heart sounds have been used in conjunction with ECG, to determine cardiac cycle parameters including electro-mechanical systole. Cardiac perfusion time significantly correlates with the degree of coronary stenosis and is determined as  $[(RR)-(S1-S2)]\Delta f_{HR}$ , where S1 and S2 represent the first and second heart sounds. The values for diastolic perfusion time at the ischemic threshold ranged from 27 to 33.5 sec. Furthermore, we have reported that cardiac systolic time (ST) and diastolic time (DT) fit well a cubic regression equation in relation to RR interval that converged to the origin of the coordinates. These reports indicated the usefulness of heart sounds during exercise.

**PURPOSE:** The purpose of this study is to compare the percent of DT for RR interval at the same HR, specifically at the same RR interval, during exercise among persons of different age (young vs. old), fitness (low vs. high) and disease history (cardiac vs. none).

**METHODS:** Subjects were 9 elderly low fit persons (LFG), 8 elderly high fit persons (HFG) and 8 young male students (YMG). We obtained the informed consents from all subjects before exercise test. The exercise test was performed on a cycle ergometer with an incremental loading method. ECG and heart sounds were recorded throughout the test, ST was determined by measuring interval between S1 and S2, and DT was calculated by subtracting ST from RR interval. DT was plotted in relation to RR interval, and the cubic regression curve was fit in each subject. DTs at 100 and 110 bpm of HR were calculated from each regression equation, and %DT was calculated as  $DT/RR\Delta f_{100}$ . %DTs at HR 100 and 110 bpm were compared among three groups.

**RESULTS:** At HR 100 bpm, mean ( $\pm$ SD) %DTs were 49.4  $\pm$  2.4 %, 55.6  $\pm$  4.7 %, 57.4  $\pm$  1.5 %. At HR 110 bpm, the mean %DT were 47.2  $\pm$  2.2 %, 54.7  $\pm$  4.9 %, 56.0  $\pm$  1.5 % in three groups of LFG, HFG and YMG, respectively. The %DTs in LFG were significantly lower than that in HFG and YMG. However, there was no significant difference of %DTs between HFG and YMG.

**CONCLUSIONS:** These results indicate that low fitness elderly appear to reach an ischemic threshold at HR 100 bpm. Furthermore these results demonstrate the importance of evaluating the diastolic perfusion time during exercise.

**Bilateral Comparison And Reliability Of Ground Reaction Forces During Single Leg Hop Test**

Michael T. McElveen<sup>1</sup>, Bryan L. Riemann<sup>2</sup>, George J. Davies<sup>2</sup>. <sup>1</sup>Florida Southern College, Lakeland, FL. <sup>2</sup>Armstrong Atlantic State University, Savannah, GA. (Sponsor: T. Jeff Chandler, FACSM)  
Email: mmcelveen@flsouthern.edu  
(No relationships reported)

**PURPOSE:** To compare single leg horizontal hop ground reaction forces (GRF) between the dominant (DOM) and non-dominant (NDOM) limbs and to determine the reliability GRF based variables.

**METHODS:** After a standardized warm-up, 20 (10 men, 10 women) physically active (Tegner score = 6.5  $\pm$  1.7, range 4-9) young adults (21.7  $\pm$  2.1 yrs) performed three DOM and three NDOM single leg horizontal hops in random order during two sessions 72 hours apart. In addition to recording hop distance, GRF were used to calculate 10 variables using the vertical (vGRF) and anterior-posterior (apGRF) GRF: peak, peak to ground off (GO), impulse, average force, and impulse time. Reliability was assessed across session one trials (intrasession) and between sessions one and two (intersession) using intraclass correlation coefficients (ICC) and standard error of measurement. Separate two factor analysis of variance were conducted to assess interactions between limb (DOM, NDOM) and direction (vGRF, apGRF) using the session one three trial average. The relationship between hop distance and GRF variables were established using correlational analyses.

**RESULTS:** No significant hop distance difference was found ( $t_{19} = -.840$ ,  $P = .412$ ) between the NDOM (1.07  $\pm$  .12 % ht, 95% CI: 1.03 - 1.09) and DOM (1.06  $\pm$  .11 % ht, 95% CI: 1.02 - 1.08) limbs. Similarly there were no significant limb differences (interactions or main effects) for any of the GRF variables ( $P > .05$ ). A significant direction main effect was observed for peak (vGRF > aGRF, PaGRF,  $P < .001$ ), average force (vGRF > aGRF, PvGRF,  $P = .75$ ) with the exception of intrasession vGRF peak to GO (both limbs). Four GRF variables significantly related to hop distance: DOM vGRF impulse ( $r = .480$ ,  $P = .032$ ), DOM aGRF peak ( $r = .524$ ,  $P = .018$ ), DOM aGRF impulse ( $r = .677$ ,  $P = .001$ ) and NDOM aGRF impulse ( $r = .765$ ,  $P < .001$ ).

**CONCLUSION:** Equal hop distances and underlying GRF may be expected between DOM and NDOM in healthy individuals. Except vGRF peak to GO, all GRF based variables were reliable. Further research is needed to determine if GRF analyses increases the sensitivity of the single leg hop test in identifying performance deficits, and/or injury predisposition.

**Determining The Anaerobic Capacity With Two Computational Methods**

Dionne A. Noordhof<sup>1</sup>, Ankie Vink<sup>1</sup>, Florentina J. Hettinga<sup>1</sup>, Jos J. de Koning, FACSM<sup>1</sup>, Carl Foster, FACSM<sup>2</sup>. <sup>1</sup>VU-University, Amsterdam, Netherlands. <sup>2</sup>University of Wisconsin-La Crosse, La Crosse, WI.  
Email: j.dekoning@fbw.vu.nl  
(No relationships reported)

**BACKGROUND:** The primary method for estimating the anaerobic capacity (AnC) has been the maximally accumulated oxygen deficit (MAOD). This method requires an individual power output (PO)-oxygen uptake (VO<sub>2</sub>) relationship, based on multiple submaximal steady state exercise bouts, to be extrapolated to predict the VO<sub>2</sub> demand during a supramaximal task. The MAOD is calculated by subtracting the summated measured VO<sub>2</sub> from the accumulated VO<sub>2</sub> demand. An alternative AnC procedure is to determine the anaerobic power production (P<sub>an</sub>) by subtracting the aerobic power production (P<sub>aer</sub>) from the PO<sub>total</sub> and summing this difference over time. P<sub>aer</sub> is calculated from VO<sub>2</sub>, RER, and gross efficiency (GE). This method is referred to as the GE method.

**PURPOSE:** This study compares the AnC based on the MAOD and GE method.

**METHODS:** Well trained male cyclists (n=15) performed a maximal incremental exercise test, 10 x 10 min submaximal bouts to establish the PO-VO<sub>2</sub> relationship and one supramaximal constant PO trial (441  $\pm$  41 W). The MAOD was calculated according to Medbø et al. (1988). The supramaximal trial was preceded by a single work bout to determine GE. Results of both methods were expressed in terms of O<sub>2</sub> equivalents.

**RESULTS:** The difference between the AnC determined with the MAOD (50.7 ml O<sub>2</sub>/kg  $\pm$  19.5) and GE (62.3 ml O<sub>2</sub>/kg  $\pm$  14.7) method was not significantly different ( $p = 0.06$ ). A significant interaction effect was found between the mean VO<sub>2</sub> during min 4 and min 8 of the 10 min submaximal bouts, and the submaximal exercise intensity steps ( $p < 0.001$ ). This indicates that during the highest submaximal exercise bouts a slow component in VO<sub>2</sub> was present. Consequently, the O<sub>2</sub> demand at the higher exercise intensities was overestimated with the MAOD method, if we assume that during the relatively short supramaximal PO trial (167 s  $\pm$  46) no slow component in VO<sub>2</sub> was present. The MAOD calculated with a PO-VO<sub>2</sub> relationship based on the mean VO<sub>2</sub> of min 4 instead of min 8-10 was 33.2 ml O<sub>2</sub>/kg  $\pm$  22.5 and significantly different from the GE method ( $p < 0.001$ ). Therefore, the values for the AnC calculated with the MAOD method as proposed by Medbø et al. (1988) may be an overestimation and meaningful different from the values of the GE method.

**CONCLUSION:** The values for the AnC calculated with the MAOD method and GE method are not directly comparable.

**Using Maximal Isometric Force To Determine The Optimal Load For Measuring Dynamic Muscle Power**

Barry A. Spiering<sup>1</sup>, Stuart M.C. Lee<sup>1</sup>, Ajitkumar P. Mulavara<sup>2</sup>, Jason R. Bentley<sup>1</sup>, Roxanne E. Nash<sup>3</sup>, Joseph Sinka<sup>1</sup>, Jacob J. Bloomberg<sup>4</sup>. <sup>1</sup>Wyle Integrated Science and Engineering Group, Houston, TX. <sup>2</sup>Universities Space Research Association, Houston, TX. <sup>3</sup>University of Houston, Houston, TX. <sup>4</sup>National Aeronautics and Space Administration, Houston, TX. (Sponsor: Lori Ploutz-Snyder, FACSM)  
Email: Barry.Spiering-1@nasa.gov  
(No relationships reported)

Maximal power output typically occurs when subjects perform ballistic exercises using loads of ~30-50% of one-repetition maximum (1-RM). However, performing 1-RM testing prior to power measurement requires considerable time, especially when testing involves multiple exercises. Maximal isometric force (MIF), which requires substantially less time to measure than 1-RM, might be an acceptable alternative for determining the optimal load for power testing.

**PURPOSE:** To determine the optimal load based on MIF for maximizing dynamic power output during leg press and bench press exercises.

**METHODS:** Twenty healthy volunteers (12 men and 8 women; mean  $\pm$  SD age: 31  $\pm$  6 y; body mass: 72  $\pm$  15 kg) performed isometric leg press and bench press movements, during which MIF was measured using force plates. Subsequently, subjects performed ballistic leg press and bench press exercises using loads corresponding to 20%, 30%, 40%, 50%, and 60% of MIF presented in randomized order. Maximal instantaneous power was calculated during the ballistic exercise tests using force plates and position transducers. Repeated-measures ANOVA and Fisher LSD *post hoc* tests were used to determine the load(s) that elicited maximal power output.

**RESULTS:** For the leg press power test, six subjects were unable to be tested at 20% and 30% MIF because these loads were less than the lightest possible load (i.e., the weight of the unloaded leg press sled assembly [31.4 kg]). For the bench press power test, five subjects were unable to be tested at 20% MIF because these loads were less than

the weight of the unloaded aluminum bar (i.e., 11.4 kg). Therefore, these loads were excluded from analysis. A trend ( $p = 0.07$ ) for a main effect of load existed for the leg press exercise, indicating that the 40% MIF load tended to elicit greater power output than the 60% MIF load (effect size = 0.38). A significant ( $p \leq 0.05$ ) main effect of load existed for the bench press exercise; *post hoc* analysis indicated that the effect of load on power output was: 30% > 40% > 50% = 60%.

**CONCLUSIONS:** Loads of 40% and 30% of MIF elicit maximal power output during dynamic leg presses and bench presses, respectively. These findings are similar to those obtained when loading is based on 1-RM.

**Estimating Lactate Threshold Power From The End Power Of A 3-min All-out Cycling Test**

Jay Francis<sup>1</sup>, Timothy J. Quinn, FACSM<sup>1</sup>, Markus Amann<sup>2</sup>, Dain P. LaRoche<sup>1</sup>. <sup>1</sup>University of New Hampshire, Durham, NH. <sup>2</sup>University of Zürich, Institute of Physiology and ETH Zürich, Exercise Physiology, Zürich, Switzerland.

Email: JayFrancis@aol.com

(No relationships reported)

The average power output over the last 30 s of a 3-min all-out cycling test (end power, EP) has been shown to be equivalent to critical power, a power sustainable for approximately 30 min. By comparing EP to the power at established measures of blood lactate concentration ([BLA]), the 3-min all-out cycling test (3MT) could be used in place of a lactate threshold (LT) test in certain applications.

**PURPOSE:** The primary aim of this study was to compare power at LT to EP. A secondary aim was to provide the methodology to perform the 3MT using equipment readily available to cyclists.

**METHODS:** Eight competitive cyclists (7 men, 1 woman, age =  $35 \pm 7$  yrs,  $\dot{V}O_{2peak} = 64 \pm 7$  mL•kg<sup>-1</sup>•min<sup>-1</sup>) completed 3 laboratory visits within a 14 d period, each visit separated by at least 48 h. All tests were performed using the subjects' own bicycles and a laboratory provided rear wheel with a power measuring hub (WHEEL). Visit 1: The subjects performed an incremental load test (100 W initial load increasing stepwise 25 W every 4 min) to volitional termination using an electronically controlled load. Blood samples were taken during minute 3 of each 4 min stage, and immediately analyzed for [BLA].  $\dot{V}O_{2peak}$  was established as the highest 20 s average  $\dot{V}O_2$  observed. [BLA] versus power was fit to a third order polynomial curve and 3 measures of power at LT were mathematically determined: power at an absolute [BLA] of 4 mmol•L<sup>-1</sup> (P-OBLA); power at a [BLA] of 1 mmol•L<sup>-1</sup> over exercise baseline (P-1E); and power at the second of 2 subsequent  $\geq 1$  mmol•L<sup>-1</sup> increases in [BLA] (P-1+1). Visits 2 and 3: Subjects performed the 3MT using a progressive resistance trainer, and were instructed to give maximal effort throughout the test. A familiarization trial for the 3MT was performed on Visit 2. During Visit 3, the EP was recorded as the mean power over the last 30 s of the 3MT.

**RESULTS:** Repeated measures ANOVA showed EP ( $278 \pm 47$  W) was significantly greater ( $P < 0.05$ ) than P-OBLA ( $239 \pm 55$  W), P-1E ( $209 \pm 48$  W), and P-1+1 ( $216 \pm 60$  W). Pearson correlation showed EP was correlated with P-OBLA ( $r = 0.82$ ,  $P = 0.007$ ), P-1E ( $r = 0.79$ ,  $P = 0.010$ ), and P-1+1 ( $r = 0.86$ ,  $P = 0.003$ ). Using linear regression, P-OBLA could be estimated at 86% EP, P-1E at 75% EP, and P-1+1 at 78% EP.

**CONCLUSION:** The EP from the 3MT can be used to estimate power at LT in competitive cyclists, using readily available equipment.

**2196 Board #84 May 28 2:00 PM - 3:30 PM**  
**Relationship Between Two Upper Extremity Functional Performance Tests And Shoulder And Trunk Muscle Strength**

Bryan L. Riemann, George J. Davies. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)

Email: Bryan.Riemann@armstrong.edu

(No relationships reported)

In contrast to the lower extremity, data concerning upper extremity (UE) functional performance tests (FPT) are more limited.

**PURPOSE:** To determine the relationship of two UEFPT with shoulder and trunk flexion peak torque (PT) and anthropometric characteristics.

**METHODS:** In a random order, 26 healthy, physically active men ( $1.80 \pm 0.07$  m,  $80.9 \pm 10.1$  kg  $24.9 \pm 2.7$  yrs) completed two UE FPT and concentric isokinetic assessments for shoulder internal rotation (IR) and trunk flexion during a single session. All testing was performed using the dominant arm. The UE FPT consisted of the Underkoffler Softball Throw for Distance (USTD) and a one-arm seated shot put throw (SPT). Following two submaximal and one maximal effort warm-up trials, the average of three maximum effort trials of each UE FPT were used for data analysis. Shoulder IR PT (60°/s, 180°/s, 300°/s) and trunk flexion PT (60°/s, 120°/s) were calculated across five trials at each speed. Height, mass and body mass index (BMI) were also measured. Correlational analyses were conducted between UE FPT performance, shoulder PT and trunk flexion PT, and anthropometric characteristics.

**RESULTS:** No significant relationships were revealed with the anthropometric characteristics or trunk flexion PT; however shoulder IR PT at all speeds were moderately related to both UE FPT.

	Anthropometrics			Shoulder IR			Trunk Flexion	
	Mass	Height	BMI	60°/s	180°/s	300°/s	60°/s	120°/s
USTD	$r = -.049$ $P = .841$	$r = .288$ $P = .154$	$r = -.293$ $P = .147$	$r = .676$ $P < .001$	$r = .574$ $P = .002$	$r = .566$ $P = .003$	$r = .208$ $P = .309$	$r = .053$ $P = .795$
SPT	$r = .302$ $P = .134$	$r = .349$ $P = .081$	$r = .055$ $P = .790$	$r = .564$ $P = .003$	$r = .484$ $P = .012$	$r = .521$ $P = .006$	$r = .218$ $P = .284$	$r = .383$ $P = .053$

**CONCLUSION:** Normalization to body mass, height and BMI do not appear to be necessary for either UE FPT. The USTD and SPT tests appear to moderately reflect shoulder IR force production capabilities. The lack of significant relationships with trunk flexion PT may be a function of the UE FPT requiring coupled trunk flexion and rotation simultaneously. These data support using the USTD and SPT tests as indicators of shoulder function.

**Physiological Characteristics Of College Age Students Enrolled In Entry Level Fitness Classes**

Sarah Wright, Cortney Whitebay, Tara Plusch, Josh O'Brien, Robert M. Otto, FACSM, John W. Wygand. *Adelphi University, Garden City, NY.*

Email: swright324@gmail.com

(No relationships reported)

Physical fitness characteristics of college students today are purportedly diminished compared to normative data established in the 1960's.

**PURPOSE:** The purpose of this study was to compare a range of physiological characteristics of college students enrolled in entry level physical fitness classes to norms established almost 50 years ago.

**METHODS:** 84 male (ht  $177 \pm 6.6$  cm, body mass  $80.4 \pm 17.4$  kg) and 135 females (ht  $162.8 \pm 6.0$  cm, body mass  $63.5 \pm 13.8$  kg) students, age  $19.9 \pm 1.7$  yr enrolled in personal fitness classes at

a medium size private university were assessed by well-trained laboratory staff prior to initiating cardiovascular, metabolic and resistance stimulus intervention. Blood pressure (BP) was obtained at rest. Three minute curl-up (CU) and hand grip (HG) dynamometer were used to assess muscular endurance and strength, respectively. Flexibility was assessed by the Wells Sit and Reach test (F) and body composition by skinfold technique (%fat). Cardiovascular function was assessed in the mile run (MR) and extrapolated to estimated max  $\text{VO}_2$ .

**RESULTS:** BP  $127/77$  and  $117/72$  mmHg, CU  $54.9 \pm 20.2$  and  $44.3 \pm 21.6$ , sum of HG  $64.1 \pm 15.7$  and  $27.7 \pm 10.2$  kg, F  $39.9 \pm 10.7$  and  $44.9 \pm 10.4$  cm, body fat  $14.6 \pm 7.6$  and  $27.7 \pm 6.9$  % fat, MR  $8.86 \pm 2.6$  and  $11.81 \pm 2.8$  min, and max pred  $\text{VO}_2$   $42.8 \pm 8.2$  and  $34.1 \pm 7.4$  mL/kg·min<sup>1</sup> for males and females, respectively. With the exception of flexibility for both sexes and percent body fat of the females, all characteristics were classified as average or better. Relative to muscular endurance (CU) and max  $\text{VO}_2$ , both males and females were classified as good.

**CONCLUSION:** This 2008 sample of college age students reveals that with the exception of female body composition, there is little difference in physiological characteristics compared to data accrued from college age students almost 5 decades ago.

**2198 Board #86 May 28 2:00 PM - 3:30 PM**  
**Effects Of Stepping Pattern And Speed On Energy Expenditure**

Seungyun Shin<sup>1</sup>, Duck Hyun Nam<sup>1</sup>, Seoung Ki Kang<sup>1</sup>, Seung Hoon Park<sup>2</sup>, Weimo Zhu, FACSM<sup>3</sup>. <sup>1</sup>*Yongin University, Yongin, Republic of Korea.*  
<sup>2</sup>*Kyunghee University, Suwon, Republic of Korea.* <sup>3</sup>*University of Illinois at Urbana-Champaign, Urbana, IL.*  
 Email: seungyuns@gmail.com

(No relationships reported)

Stepping is a common physical movement (e.g., in dance or DDR), but its corresponding energy expenditure (EE) has not been well studied.

**PURPOSE:** To examine effects of stepping pattern and speed on energy expenditure when subjects stepped on a close diamond shape. **METHOD:** 15 male volunteers (20.40±1.24 yrs older; HT = 177.20±5.59 cm and WT = 74.33±7.97kg) were asked to step on three patterns (sideways [SW], back and forth [BF], & random [RD]) at three speeds (30 beats/M, 40 beats/M, & 50 beats/M) within in a 80 x 80 cm diamond shape. Each mode went on for 10 minutes, with a 20-min break between, and testing order was chosen randomly. Each subject was tested 3 modes a day and finished testing in 3 days. EE during the resting and testing was measured by COSMED K4b2 portable pulmonary.

**RESULTS:** The results of two-way repeated measures ANOVA indicate that there were statistically significant differences in EE among stepping speeds (30B/M vs.40B/M vs. 50B/M p<.05). There was a statistically significant difference between BF and RD step patterns. There was no interaction effect between stepping speed and pattern on EE. Similar finding was confirmed in MET values by speed and pattern.

DVs	Energy expenditure (Kcal)			METs		
IVs	SW	BF	RD	SW	BF	RD
30B/M	44.90±	46.14±	36.56±	3.71±	3.94±	2.60±
	12.51	11.16	9.33	0.95	1.02	0.77
40B/M	53.80±	55.69±	39.81±	4.38±	4.82±	3.46±
	11.26	7.77	6.53	1.02	0.62	0.55
50B/M	60.16±	63.53±	49.26±	5.41±	5.64±	4.18±
	5.08	6.26	7.45	0.35	0.70	0.62

**CONCLUSIONS:** Speed is the key determinant in stepping. While there was no difference in EE between sideways and back-and-forth patterns, they both had a higher EE than the random pattern.

**Characterization Of Joba Core Trainer Cardiopulmonary Responses**

Marianna Broccatelli<sup>1</sup>, Antonio Sgadari<sup>2</sup>. <sup>1</sup>*University of Study "Foro Italico", Rome, Italy.* <sup>2</sup>*Catholic University of Sacred Heart, Rome, Italy.* (Sponsor: Prof. Fredric Goss, FACSM)

Email: marianna.broccatelli@iusm.it

(No relationships reported)

The Joba® Core Trainer (JOBA) is an ergometric device which simulates horseback riding. The computer-driven saddle reproduces all components of horse movements, except vertical displacement. Based on the counterbalance principle, it efficiently engages trunk and thigh muscles. Previous research showed that JOBA enhances glycemic control in diabetic patients and reduces pain and disability in subjects with chronic low back pain. However, no data are available about the cardiopulmonary responses elicited by JOBA.

**PURPOSE:** To describe the cardiopulmonary responses induced by using JOBA at different speeds.

**METHODS:** Twenty healthy subjects (11 men, 9 women) were investigated (age 54.8±11.8 yrs). ECG and respiratory gas exchange were measured during a training session with JOBA (3 min warm-up, 5 steps of 7 min of duration each with speed increasing from lowest to highest, 3 min cool down). The following day an incremental, cardiopulmonary stress test was carried out on a cycle ergometer to determine peak aerobic power and ventilatory threshold (VT) by means of the V-slope method.

**RESULTS:** Heart rate (HR) and oxygen consumption ( $\text{VO}_2$ ) did not differ among speeds (from 82.7±13.2 beats/min at speed 1 to 87.0±9.7 at speed 9, n.s., and from 4.2±1.2 mL/kg/min to 4.9±1.5, n.s., respectively). Respiratory Exchange Ratio remained unchanged across different speeds of exercise (from 0.9±0.1 to 1.0±0.2, n.s.). HR and  $\text{VO}_2$  were also expressed as a percentage of their respective VT values: HR increased from 78.7±13.9 % of VT at the lowest exercise intensity to 83.3±15.5 at the highest (n.s.), while  $\text{VO}_2$  raised from 33.6±8.6 to 38.8±11.3 (n.s.). Eventually, at the highest speed, HR reached 65.5±11.4% of peak HR and  $\text{VO}_2$  20.8±5.6% of peak  $\text{VO}_2$  (n.s. vs. lowest speed).

**CONCLUSION:** Training with JOBA at increasing speeds resulted in a slight modification of cardiopulmonary parameters. Even at the highest speed, HR and  $\text{VO}_2$  remained well below the values measured at the VT. Thus, JOBA may be a safe alternative to usual ergometers in the rehabilitation process of subjects with severely reduced exercise tolerance, such as frail elderly, patients with heart failure, cardiac transplant, and severe obstructive pulmonary disease. Further studies are needed to describe the cardiopulmonary responses to JOBA of patients in these clinical subgroups.

**Reliability Of The Reverse Lactate Threshold Test**

Rotem Cohen, Bareket Falk, Raffy Dotan. *Brock University, St Catharines, ON, Canada.* (Sponsor: Dr. David Gabriel, FACSM)

Email: rc07to@brocku.ca

(No relationships reported)

The multi-session Maximal Lactate Steady-State (MLSS) test is the accepted 'Gold Standard' for anaerobic threshold estimation. Existing single-session tests for anaerobic threshold estimation suffer from unsatisfactory validity, reliability and resolution.

**PURPOSE:** To evaluate the test-retest and intra-evaluator reliability of the Reverse Lactate Threshold Test (RLT) - a newly proposed, single-session test, based on a novel

testing concept.

**METHODS:** Eight trained and 2 untrained cyclists (26-51 yrs) were tested twice, 2 to 5 days apart, on an electro-magnetically-braked cycle ergometer. The cycling version of the RLT consists of a series of 4-5 continuous 4-min stages, progressively incremented (by 20-40W) to a load 5-20% above the presumed MLSS, immediately followed by 4-6 loads progressively decremented (by 10W). Fingertip capillary blood was sampled at the end of each stage for blood lactate concentration ([La]). [La] was then plotted against load and the power output at peak [La], during the decremental (reverse) loading was taken as the RLT-determined anaerobic threshold. When all 20 tests were completed, they were plotted, coded and standardised so as to facilitate anonymity of the plot. All plots were then given to the reviewer for 'blind' AnT determinations.

**RESULTS:** There was no significant difference between the 1<sup>st</sup> and 2<sup>nd</sup> test in the mean RLT-determined anaerobic threshold ( $238.5 \pm 69.3$  &  $237.7 \pm 67.0$  W, respectively) and no order effect was found. The test-retest reliability coefficient ( $n=10$ ) was 0.998 ( $R^2=0.996$ ) and the inter-reviewer reliability was ( $r=0.998$ ).

**CONCLUSIONS:** The new RLT was shown to be highly reliable in its estimation of the AnT in cycling. The observed level of reliability is higher than any reported for existing tests. [Funding: Brock University]

**A Comparison Of Physiological And Pain Responses Between Exercise Modalities**

Michael J. Turner, Alison B. Williams, Amy L. Williford, Mitchell L. Cordova, FACSM. *UNC Charlotte, Charlotte, NC.*

Email: miturner@unc.edu

(No relationships reported)

**PURPOSE:** Elliptical cross-trainers (ECT) have become an increasingly popular exercise modality within the fitness industry. Cybex International, Inc. has recently manufactured a new exercise modality, the Cybex® Arc Trainer (ARC), that utilizes a low impact mechanical design. To determine differences in physiological responses and perceived discomfort during maximal and submaximal exercise with two common exercise modalities, the ECT and the ARC which undergoes an excursion of motion utilizing an arc pathway.

**METHODS:** Eighteen subjects (10 male and 8 female; age= $24.7 \pm 2.6$  yrs, ht= $172.2 \pm 10.3$  cm, mass= $69.8 \pm 14.9$  kg, %fat= $22.5 \pm 8.1$ %; mean $\pm$ SD) performed maximal exercise protocols on a treadmill (TML), the ECT, and ARC. Subjects also performed three 10-minute submaximal exercise bouts on the ECT and ARC at 55%, 65%, and 75% of TML VO<sub>2</sub>max where HR, VO<sub>2</sub>, VE, RER, hip, knee and low-back discomfort were monitored using a 1 - 10 scale, 1 indicating no pain and 10 suggesting extreme pain. All ECT and ARC tests were performed in a counterbalanced order.

**RESULTS:** VO<sub>2</sub>max was greater during TML exercise compared to ECT ( $P=0.007$ ), but similar to the ARC. Both ECT and ARC elicited lower HR<sub>max</sub> values compared to maximal TML exercise ( $P=0.0001$ ). No difference was observed between ECT and ARC for VO<sub>2</sub> during the submaximal exercise bouts ( $P>0.05$ ). However, HR was greater during submaximal ECT exercise ( $P>0.05$ ). Perception of discomfort was not different between ECT and ARC for knees ( $P>0.05$ ) and lower back ( $P>0.05$ ), but different for the hips ( $P=0.02$ ).

**CONCLUSIONS:** Similar VO<sub>2</sub>max values were observed with ARC and TML modalities. Greater perceptions of discomfort were observed with ECT compared to ARC at similar submaximal exercise intensities suggesting individuals with, or at risk for, lower extremity joint pathology may benefit from exercise with modalities other than the ECT.

Equipment was provided by Cybex International, Inc.

**Comparison Of Rpe Values From A Maximal Graded Exercise Test Between Firefighters And Non-firefighters**

Marla M. Graves, Matthew J. Comeau, Shana Barker, Thomas M. Adams, III. *Arkansas State University, State University, AR.* (Sponsor: Lee Brown, FACSM)

Email: mgraves@astate.edu

(No relationships reported)

Certain occupations, due to their nature, repeatedly place greater physical and psychological demands on individuals. Individuals exposed to this type of high, work-related physical and psychological stress include firefighters, policemen/women, and military personnel.

**PURPOSE:** The purpose of this investigation was to determine if such individuals (firefighters -FFs) when compared to lay persons (non-firefighters -non-FFs) would report similar rating of perceived exertion (RPE) values when performing a maximum graded exercise treadmill test.

**METHODS:** A total of 94 FF (mean age 36 yrs) and 30 non-FFs (mean age 27 yrs) participated in this study. All subjects completed a standard Bruce Treadmill Protocol. ACSM guidelines for maximum aerobic testing were used to determine if maximum effort was achieved. Those guidelines included 1) a respiratory exchange ratio (RER) value greater than 1.15, 2) reaching 85% of maximum heart rate, 3) an RPE of more than 17 (6-20 scale).

**RESULTS:** Sixty-eight FFs and 24 non-FFs meet both physiological criteria (85% of max HR and 1.15 RER value) indicating a maximal test was achieved. Of these, 46 of the FFs and 9 of the non-FFs did not report a RPE value indicating they were working at a maximal effort (17 or above/very hard). FFs under-reported maximal effort as indicated by RPE by 67% compared to 37% of non-FFs, respectively. An independent t-test showed there was a significant difference in mean RPE values for FFs that meet all three criteria versus those that meet only physiological criteria ( $p=0.00$ ). Those that meet all three criteria had a mean RPE of  $17.6 (\pm 0.85)$  compared to a mean RPE of  $14.3 (\pm 1.99)$  in those that meet only the two physiological criteria. There was also a significant difference ( $p=0.035$ ) between the FFs under-reported mean RPE value ( $14.3 \pm 1.99$ ) and the mean for the non-FFs that under-reported RPE ( $15.8 \pm 0.44$ ).

**CONCLUSION:** According to these findings, due to the strenuous nature of their job, FFs, and other individuals with physically and psychologically demanding jobs, may not perceive physical stress caused by exercise the same way lay individuals do. In addition to affecting verbal responses to perceived stress of exercise testing, it may also carry over into their work environment and lead to an underestimation of perceived physical stress on the job.

**2203 Board #91 May 28 2:00 PM - 3:30 PM**

**Examination Of A Single-stage Submaximal Treadmill Test To Estimate Aerobic Capacity**

Jeff Lynn, Kimberly Smith, Anne Hays, Nicole Zeller, Jeremy Gebhart, Kristen Vogt, Meredith Velez, Andrea Campbell. *Slippery Rock University, Slippery Rock, PA.* (Sponsor: Patricia Pierce, FACSM)

(No relationships reported)

**PURPOSE:** The purpose was to evaluate the reliability and validity of a one-stage submaximal treadmill test (Vehrs, PR *et al.*, 2007) to estimate VO<sub>2</sub>max.

**METHODS:** VO<sub>2</sub>max was measured by expired gas analysis using a maximal treadmill protocol in 34 SRU students (23 women and 11 men, aged  $19 \pm 1$  years) with average to above average fitness (VO<sub>2</sub>max range, 37 to 69 ml/kg/min). The submaximal estimation test (SET) was performed on 2 separate days. Subjects sustained a comfortable jogging pace (4.3-7.5 mph, 0% grade; HR =  $158 \pm 12$  bpm) for 5 minutes on a treadmill while heart rate was measured via heart rate monitor. The steady state heart rate at the end of the test was used in the following equation to estimate VO<sub>2</sub>max:  $58.687 + (7.52 \times \text{sex}, 1=\text{male and } 0=\text{female}) + (4.334 \times \text{speed in mph}) - (0.211 \times \text{weight in kg}) - (0.148 \times \text{HR}) - (0.107 \times \text{age})$ .

**RESULTS:** The SET produced similar results when repeated on 2 separate days ( $46.4 \pm 4.7$  ml/kg/min and  $46.3 \pm 5.1$  ml/kg/min), and there was a strong correlation between the results of the SETs ( $r = .965, p \leq 0.01$ ). The SET underestimated VO<sub>2</sub>max in 30 of 34 subjects, including every subject with a VO<sub>2</sub>max above 50 ml/kg/min. A paired t-test revealed that estimated VO<sub>2</sub>max was significantly lower than measured ( $52.6 \pm 8.0$  ml/kg/min,  $p < 0.01$ ). The correlation between estimated and actual VO<sub>2</sub>max was statistically significant, but not strong ( $r = 0.656, p < 0.01$ ). The standard error of the estimate (SEE) was 3.6 ml/kg/min.

**CONCLUSIONS:** In a small sample of college students, the Vehrs SET for  $\dot{V}O_{2\max}$  had excellent test-retest reliability, but tended to underestimate  $\dot{V}O_{2\max}$ , particularly in subjects whose  $\dot{V}O_{2\max}$  was over 50 ml/kg/min. This submaximal estimation test appears to lack concurrent validity, especially in high fit subjects.

**Ventilatory Threshold And Lactate Threshold Coincide Using The Dmax Method**

Charilaos Papadopoulos, Andrew T. DelPozzi. *Central Washington University, Ellensburg, WA.* (Sponsor: Christopher P. Ingalls, FACSM)  
Email: papadoph@cwu.edu  
(No relationships reported)

The ventilatory threshold has been used as a non-invasive technique to monitor exercise intensity during training. The ventilatory threshold and the lactate threshold have been shown to coincide using visual inspection. The Dmax method has been proposed to provide an accurate estimate of the lactate threshold.

**PURPOSE:** The purpose of this study was to determine the relationship between the ventilatory threshold and the lactate threshold when both being determined by using the Dmax method.

**METHODS:** Twenty-two trained male subjects, 8 cyclists and 14 runners (age:  $31.9 \pm 7.5$  yrs; height:  $178.9 \pm 5.6$  cm; weight:  $71.5 \pm 7.3$  kg; body fat:  $9.7 \pm 4.27\%$ ;  $\dot{V}O_{2\max}$ :  $63.0 \pm 7.04$  ml  $\text{kg}^{-1} \text{min}^{-1}$ ) completed a single continuous incremental maximal exercise test to determine their individual lactate profile. Oxygen consumption, minute ventilation, and blood lactate were measured. Blood samples were collected at the end of each exercise stage and at maximal exercise through a venous catheter placed in an antecubital vein and analyzed using an automated lactate analyzer. The Dmax method was used to identify the lactate and ventilatory thresholds. Pearson's Correlation Coefficient was used to determine the relationship between the two thresholds. A paired *t* test was used to determine differences between the two estimates.

**RESULTS:** The ventilatory threshold and lactate threshold were significantly correlated ( $r=0.91$ ;  $P<0.05$ ). The paired *t* test indicated no difference ( $P=0.42$ ) in the intensity determined by each threshold.

**CONCLUSIONS:** These results indicate that the ventilatory threshold determined by the Dmax method can be used as a non-invasive technique to estimate the lactate threshold.

**Spring-mass Leg Stiffness Is Not Affected By Brief Static Or Dynamic Stretching**

Jon E. Goodwin, Mark Glaister, Richard A. Lockey, Emma Payne. *St Mary's University College, Middlesex, United Kingdom.*  
Email: goodwinj@smuc.ac.uk  
(No relationships reported)

Stretching has had a longstanding use in the development of flexibility, prevention of injury, and preparation for exercise. Recent research has demonstrated a loss of muscle power following an acute bout of prolonged static stretching. However studies using briefer periods of stretch or dynamic stretching have provided equivocal results.

**PURPOSE:** To investigate the effect of brief static and non task-specific dynamic stretching on spring-mass leg stiffness in a vertical bouncing task.

**METHODS:** 37 physically active male volunteers completed the study. Subjects were randomly assigned to one of two groups (natural bouncing [NAT],  $n=20$ ; maximal bouncing [MAX],  $n=17$ ). NAT bounced at their self-selected stiffness and MAX were instructed to bounce as stiffly as possible. Bouncing was controlled at a frequency of 2.2 Hz ( $\pm 5\%$ ). After each of four treatment conditions, subjects completed three  $\times 30$  s bouts (separated by 2 minute rest periods) of vertical bouncing, in a counterbalanced crossover design. Treatment conditions were: no stretch (NO); single 30 s stretch (SS); repeated ( $4 \times$ ) 30 s stretch (RS) and dynamic stretch (DY). Stretches were carried out on the gluteals, hamstrings, quadriceps and calves and did not involve any direct replication or rehearsal of the movements used in the bouncing task. Spring-mass leg stiffness was calculated as the ratio of peak vertical force to vertical displacement during ground contact. Data was collected via a piezoelectric force plate (1000 Hz) and vertical displacement calculated from the second integral of the acceleration curve.

**RESULTS:** Three-factor ANOVA (group  $\times$  treatment  $\times$  bout) with repeated measures indicated that the MAX group were predictably stiffer than the NAT group ( $31162 \pm 10080$  vs  $17324 \pm 4871$  N $\cdot\text{m}^{-1}$ ;  $F=35.8$ ;  $p<0.001$ ), the NAT group scores being similar to those elsewhere in the literature. There were no significant effects of treatment ( $F=0.46$ ;  $p=0.71$ ), bout ( $F=0.05$ ;  $p=0.95$ ), or interactions ( $p>0.05$ ) on leg stiffness scores.

**CONCLUSIONS:** Relative to control (NO), the results of this study showed that brief static stretching or non task-specific dynamic stretching does not affect spring-mass leg stiffness during vertical bouncing.

**2206 Board #94 May 28 2:00 PM - 3:30 PM**  
**The Influence Of Bout Interruptions On Predicted Physical Activity During Treadmill Walking And Running**

Stephanie M. Howe<sup>1</sup>, Daniel P. Heil, FACSM<sup>2</sup>. <sup>1</sup>University of Oregon, Eugene, OR. <sup>2</sup>Montana State University, Bozeman, MT.  
Email: howe2@uoregon.edu  
(No relationships reported)

Activity monitors (AM) are commonly used to assess daily physical activity (PA) behaviors in clinical and research settings. However, the presence of bout interruptions (BI), which are brief pauses ( $\leq 2$  min) in PA, can complicate the interpretation of AM determined PA outcome variables.

**PURPOSE:** This study systematically assessed the effect of 1- and 2-min BIs on PA outcome variables derived from AMs.

**METHODS:** Subjects (6 women, 9 men; Mean $\pm$ SD:  $23 \pm 3$  yrs.,  $68.0 \pm 9.7$  kg,  $176.2 \pm 8.6$  cm) completed a series of walking (53.6 and 107.2 m/min at 0% grade) and running (160.8 m/min, 0% grade) trials on a treadmill while wearing AMs on the right hip (RH) and left wrist (LW) to predict activity energy expenditure (AEE) and Activity Time. Treadmill speeds were selected to elicit light (L), moderate (M), and vigorous (V) PA intensities. Subjects completed three 5-min walking/running bouts separated by successive 1- and 2-min BIs. Predicted AEE and time were evaluated using three BI rules: 1) No allowance for a BI (BI0), 2) Allowance for 1-min BI (BI1), and 3) Allowance for a 2-min BI (BI2). AEE was calculated from raw AM data using previously validated hip and wrist double regression modeling algorithms. Activity Time, defined as the time spent at or above a moderate intensity, was calculated using an AEE cut point of 0.0831 kcal/kg/min = 3 METs. A 2-factor RMANOVA was used to compare each BI definition within each intensity category for both AEE and time variables ( $\alpha=0.05$ ).

**RESULTS:** AEE significantly increased when allowing for BI1 (RH: 0.5, 1.0, 3.0 kcal; LW: 0.5, 0.5, 3.0 kcal) and BI2 (RH: 0.3, 1.0, 3.0 kcal; LW: 0.7, 0.5, 3.0 kcal) at L, M, and V intensities, respectively. Activity Time increased an average of +3 mins when going from BI0 to BI1 and +5 mins when going from BI1 to BI2 for both AMs. When expressed as a percentage, the increase between BI0 & BI1 and between BI1 & BI2 was 0.3-2.7% for AEE and 5.5-11.0% for Activity Time.

**CONCLUSIONS:** This study indicates that allowing for a BI within a PA bout significantly increases predicted AEE and Activity Time from AMs during treadmill locomotion. These results are especially important when interpreting AM data in terms of 8-10 min minimum bout durations as suggested by ACSM. Thus, rules for BIs in AM analyses should be established since BIs will significantly influence PA outcome variables.

**2207 Board #95 May 28 2:00 PM - 3:30 PM**  
**Comparison Of Resting, Walking, And Jogging Energy Expenditure Prediction Equations In Normal And Overweight Females**

Timothy D. Heden<sup>1</sup>, James D. LeCheminant<sup>2</sup>, John D. Smith<sup>3</sup>, Kay Covington<sup>1</sup>. <sup>1</sup>*Southern Illinois University Edwardsville, Edwardsville, IL*. <sup>2</sup>*Brigham Young University, Provo, UT*. <sup>3</sup>*Texas A&M University – Kingsville San Antonio, Kingsville San Antonio, TX*.  
Email: theden@siue.edu  
(No relationships reported)

Knowledge of resting energy expenditure (REE) and energy expenditure (EE) during physical activity is essential for designing dietary and exercise interventions for weight management.

**PURPOSE:** To compare 7 estimated REE prediction equations (Table 1.) and the ACSM walking/jogging EE prediction equations to measured REE and EE.

**METHODS:** 13 normal weight (22.2±2.0 BMI) and 10 overweight (27.2±2.4 BMI) healthy university females between the ages of 18 and 24 were assessed for REE and EE using indirect calorimetry (Parvo Medics' TrueOne® 2400) while walking (79 mmin<sup>-1</sup>) and again while jogging (134 mmin<sup>-1</sup>) for 1.6 km, on separate days.

**RESULTS:** The Bernstein, Owen, and BOD POD estimates of REE were significantly different (p<.05) from the measured in both groups (Table 1.). The measured EE while walking was not significantly different from the ACSM predicted EE in normal weight females (67.4±6.5 and 69.0±7.0 kcal, respectively), but was significantly different in overweight females (81.8±7.5 and 85.9±6.6 kcal, respectively). The measured EE during running was significantly different from the ACSM predicted EE in normal weight (94.3±11.2 and 107.9±11.0 kcal, respectively) and overweight (113.4±14.4 and 134.4±10.3, respectively) females.

	Normal Weight (n=13)	Overweight (n=10)
Measured	1461±161	1643±107
Harris Benedict	1447±66.2	1591±62.2
Bernstein	1158±45.3*	1270±43.6**
Livingston	1364±66.8	1517±55.9
Mifflin	1358±81.7	1518±76.9
Owen	1224±43.7*	1329±41.2**
Quick Estimate	1315±134	1637±126
BODPOD	1180±95.7*	1391±135**

Note: values are kcal/day in means±SD.  
\*Significantly different from measured in normal weight (p<.05).  
\*\* Significantly different from measured in overweight (p<.05).

**CONCLUSIONS:** The results suggest that normal weight females can use the Harris Benedict or Livingston equation and overweight females can use the Harris Benedict or Quick Estimate equation to accurately predict their REE. With only a 4 kcal difference between measured and estimated EE while walking in the overweight group, the ACSM walking equation predicted EE well in both groups; however, the jogging equation has a tendency to overestimate EE in both groups and should therefore be used with caution.

**2208 Board #96 May 28 2:00 PM - 3:30 PM**  
**Actigraphy Assessment Of The Effects Of Circuit Training Exercise On Sleep In Healthy, Morning-type Women**

Kirsten Engelbrecht, Hermann J. Engels, FACSM, Jean E. Davis, Hossein N. Yarandi. *Wayne State University, Detroit, MI*.  
(No relationships reported)

**PURPOSE:** The purpose of this study was (1) to compare wrist actigraphy-derived nocturnal sleep characteristics of healthy, morning-type women between non-exercise days and structured exercise program (circuit training class) days, and (2) to examine whether a change in the regular time-of-day of their established exercise routine from the morning hours to the early evening hours affects sleep.

**METHODS:** Fifteen healthy, morning-type women (age: 47.4±5.5 yrs) were recruited for this study. All subjects were following an established (6 weeks or longer) morning (between 7am-9am) exercise training routine that consisted of a 60 min, personal trainer supervised, moderate-intensity, circuit-training program at a commercial fitness facility. For purpose of this study, sleep/wake patterns were determined from 24-hour wrist actigraphy (AW 64 Actiwatch) recordings over five successive weekdays. During three of these five weekdays, subjects did not participate in any formal exercise training sessions. On the remaining two (always non-consecutive) days, subjects completed their regular circuit training classes on one day during their normal morning hours and on the other day it was changed to the evening hours (between 5pm-7pm). Actigraphy data were scored using the Actiware (version: 5.0) sleep analysis software (Mini Mitter, Bend, OR) for the assessment of total sleep time (TST), sleep onset latency (SOL), wake after sleep onset (WASO), and sleep efficiency (SE).

**RESULTS:** Descriptive means (±SD) for the global score on the Pittsburgh Sleep Quality Index and the Beck Depression Inventory for the study cohort was 4.33 (±2.94) and 3.64 (±3.65), respectively. Repeated measures ANOVA revealed no significant differences between actigraphy-derived nocturnal sleep characteristics for TST, SOL, WASO, and SE between non-exercise and normal morning exercise days (>0.05). Moreover, changing the habitual exercise training routine from the morning hours to the early evening hours failed to have a significant effect on these sleep measures (p>0.05).

**CONCLUSIONS:** Moderately intense circuit training exercise, either performed during a regular accustomed morning training time period or when changed to an unaccustomed early evening time period, does not seem to influence the normal sleep of healthy, morning-type women.

**Comparison Of Muscle Activity During Jumping On The Ground Versus The Pneubounder**

Brandon K. Doan<sup>1</sup>, Andrew J. Amack<sup>1</sup>, Jeffrey L. Nelson<sup>1</sup>, Michael D. Brothers<sup>1</sup>, Raoul F. Reiser, FACSM<sup>2</sup>. <sup>1</sup>*USAF Academy, USAF Academy, CO*. <sup>2</sup>*Colorado State University, Fort Collins, CO*.  
Email: brandon.doan@usafa.edu  
(No relationships reported)

The most safe and efficient training methods to develop functional movement capacity and explosive power have been debated for decades. Explosive power training is often associated with risk of injury, specifically from high impacts associated with landing. A prototype pneumatic exercise machine that allows the user to jump or perform leg presses against a platform Supported by compressed air in a closed-chain exercise while standing in a an upright position has been developed.

**PURPOSE:** To compare peak muscle activity during ground vs. pneumatically dampened jumping.

**METHODS:** Surface EMG of 14 core and lower extremity muscles was recorded during repeated, maximal counter-movement jumping on the ground and on the machine. Data was collected at 1000 Hz, band-pass filtered (10 - 500 Hz), and RMS was calculated (50 ms envelope) on 6 men and 2 women (age = 28.8 ± 9.7 years; mass = 79.4 ± 15.7 Kg; height = 176.7 ± 9.3 cm).

**RESULTS:** Data was analyzed using repeated measures ANOVA. No statistically significant ( $p < 0.05$ ) differences were noted in peak EMG amplitude in any of the muscles between conditions. Peak EMG amplitude for machine and ground jumps respectively were (mean  $\pm$  SE): multifidus ( $632.2 \pm 58.6$  vs.  $701.5 \pm 84.35$   $\mu$ v), longissimus thoracis ( $766 \pm 84.7$  vs.  $793 \pm 176.6$   $\mu$ v), oblique abdominals ( $306.7 \pm 73.76$  vs.  $429 \pm 114.8$   $\mu$ v), lower rectus abdominus ( $835.0 \pm 208.7$  vs.  $739.0 \pm 158.4$   $\mu$ v), iliacus ( $767.3 \pm 104.32$  vs.  $829.5 \pm 121.38$   $\mu$ v), gluteus medius ( $403.3 \pm 78.9$  vs.  $405.8 \pm 77.7$   $\mu$ v), gluteus maximus abductor ( $397.4 \pm 71.1$  vs.  $422.88 \pm 73.77$   $\mu$ v), gluteus maximus extensor ( $769.1 \pm 234.0$  vs.  $758.25 \pm 238$   $\mu$ v), rectus femoris ( $612.0 \pm 64$  vs.  $730.5 \pm 112.7$   $\mu$ v), vastus lateralis ( $736.9 \pm 138.4$  vs.  $725.3 \pm 116.5$   $\mu$ v), vastus medialis ( $817.3 \pm 191.3$  vs.  $743.6 \pm 195.1$   $\mu$ v), VMO ( $1203.6 \pm 219.5$  vs.  $1223.25 \pm 184.3$   $\mu$ v), gastrocnemius ( $376.86 \pm 59.8$  vs.  $490.57 \pm 22.0$   $\mu$ v), and tibialis anterior ( $384.86 \pm 65.1$  vs.  $509.3 \pm 81.6$   $\mu$ v).

**CONCLUSIONS:** Similar peak muscle activity was recorded for ground versus potentially safer and lower impact exercise on the machine. Training on such a device may benefit rehabilitation, performance, and neuromuscular function in athletes and at-risk populations, such as the elderly, with less risk of injury.

**Reliability Of A Dorsiflexion Lunge Test (dflt) And Star Excursion Balance Test (sebt)**

Argia Langarik<sup>1</sup>, Jose F. Aramendi<sup>2</sup>, Julien Castellano<sup>1</sup>, Julio Calleja<sup>1</sup>, Jose I. Emparanza<sup>3</sup>, Jeffrey Mjaanes, FACSM<sup>4</sup>. <sup>1</sup>University of the Basque Country, Vitoria-Gasteiz, Spain. <sup>2</sup>Osasunkiroi-Salud y Deporte, Hondarribia, Spain. <sup>3</sup>Clinica-Hospital Donostia, San Sebastian, Spain. <sup>4</sup>Rush University Medical Center, Chicago, IL.  
(No relationships reported)

Ankle sprains are the most frequent acute injuries in physical activity. A significant amount of research has focused on identification of possible risk factors for sprains and, thus, prevention of these injuries. Understanding the risk factors at play is essential for the development of individualized prevention programmes. Current literature identifies ankle dorsiflexion (DF), posture sway and proprioception as factors that likely play a role in the occurrence of ankle sprains. The Dorsiflexion Lunge Test (DFLT) and the Star Excursion Balance Test (SEBT) are used to assess these three factors and to be used as valid testing tools must be reliable.

**PURPOSE:** To evaluate the reliability of the Dorsiflexion Lunge Test (DFLT) and the Star Excursion Balance Test (SEBT) in female athletes.

**METHODS:** The tests were given to female volleyball players. Twenty-five players ( $14.3$  years  $\pm 1.9$ ) took the DFLT twice. Eleven players ( $15$  years  $\pm 2.1$ ) performed the SEBT with three lines (anterior; A, posterolateral; PL, posteromedial; PM) on five different occasions using two different procedures: three times without centimetre markings on the lines (SBETw/m) and twice with centimetre marks (SBETm). To test the reliability of the tests we performed variance component analyses of different facets using SAS (SAS Institute Inc, 1999), *Generalizability Theory [GT]* (Ysewijn, 1996). Also Bland & Altman (1995) graphic (BAG) was performed. For DFLT, the components analyzed included: *date* (2 levels), *player* (25 levels), *leg* (2 levels), *attempt* (3 levels) and *measurement* (3 levels). In SEBT 3 facets were included: *date* (3 levels), *line* (3 levels) and *player* (11 levels).

**RESULTS:** The generalizability coefficient (CG) is 0.71 for DFLT using three attempts and 0.99 using the average of all attempts. BAG is adequate. The CG is 0.979 in SBETw/m but BAG aren't appropriate. SBETm CG is 0.997 and BAG is better than SBETw/m but it isn't enough.

**CONCLUSIONS:** The DFLT is a reliable method to assess ankle DF in female athletes using the average of three attempts. The SBETm is more reliable than SBETw/m but the reliability of SBET is questionable. Further research with a focus on different subjects (different ages, type of sports...) and including more detailed facets (different lines, more attempts, changes in the warm up...) is necessary.

**Influence Of Difference In Knee Alignment On Site Of Pain After Long-distance Walk**

Akitoshi Sogabe<sup>1</sup>, Kayo Yamamoto<sup>1</sup>, Kenji Ito<sup>1</sup>, Michitaka Kamata<sup>2</sup>. <sup>1</sup>Konan University, Kobe, Japan. <sup>2</sup>Nara University, Nara, Japan. (Sponsor: Andrew C.Fry, FACSM)  
Email: sogabe@konan-u.ac.jp  
(No relationships reported)

**PURPOSE:** Walking exercise has recently been accepted as a safe aerobic exercise. On the other hand, varus or valgus deformity of the knee is associated with a high risk of lower limb pain and may lead to gonarthrosis. This study examined whether the differences in the intercondylar and intermalleolar distances affect the site of pain in the lower limb after a continuous long-distance walk.

**METHODS:** A total of 40 healthy subjects (24 males and 16 females; mean age,  $21.2 \pm 1.3$  years) were instructed to perform continuous walking exercise for 3 days (total walking distance, 85 km), and to record episodes and sites of pain. Subjects were then classified according to the intercondylar and intermalleolar distances by an increment of 2.0 cm to analyze the relationship between the distances and the occurrence of pain.

**RESULTS:** A total of 80 episodes of pain were reported after the 3-day walking exercise. The mean numbers of pain episodes per subject were as follows: 2.4 episodes in subjects with an intermalleolar distance of  $\geq 2.0$  cm (valgus knee), 2.19 episodes in those with an intercondylar distance of  $\geq 2.0$  cm (varus knee), and 1.5 episodes in the other subjects (normal knee). The common sites of pain included the sole of the foot (17 episodes, 21.3%), posterior side of the tibia (11 episodes, 13.8%), anterior side of the thigh (10 episodes, 12.5%) and hip joint (10 episodes, 12.5%). Subjects with varus knee accounted for 53% (9/17) of the subjects complaining of pain in the sole of the foot and 60% (6/10) of those complaining of pain in the hip joint. Subjects with valgus knee accounted for 72.7% (8/11) of those complaining of pain in the posterior side of the tibia.

**CONCLUSIONS:** Subjects with knee deformity tend to experience pain in particular parts of the lower limbs after a long-distance walk. It is thus important to understand the individual characteristics of the knee and consider measures to prevent pain before performing walking exercise.

**Metabolic And Ventilatory Responses During Exercise Using Medgraphics Cpx Ultima And Vo2000**

Jason M. Winkle, Peter J. Dilg, Blanche W. Evans, Sarah J. Galparoli. Indiana State University, Terre Haute, IN.  
(No relationships reported)

The usefulness of a portable metabolic measuring system is dependent upon its ability to produce valid and reliable results when compared to standard laboratory equipment such as non-portable metabolic measuring systems. Results from studies comparing the VO2000 with non-portable systems have been inconsistent.

**PURPOSE:** To compare the metabolic and ventilatory values during exercise using a portable metabolic measuring system (VO2000) with a facemask (FM) and mouthpiece/nose clip (MP) and a standard laboratory metabolic measuring system, CPX-Ultima (CPX/U).

**METHODS:** Eighteen volunteers (age  $25.7 \pm 7.2$  years) completed three 20 min exercise sessions (10 min walking/10 min jogging) using the CPX/U, FM, and MP. A counter-balanced design determined treatment order. Metabolic and ventilatory values were recorded at 20 s intervals and averaged over the last five min of walking and jogging. A one-way ANOVA with repeated measures compared the mean values for each variable for the three conditions during walking and jogging.

**RESULTS:** No significant difference ( $p > .05$ ) in HR or VO<sub>2</sub> was found due to treatment order. The VO2000 produced similar metabolic and ventilatory values whether using the FM or MP ( $p > .05$ ). However, significant differences ( $p < .01$ ) were found for VE, VO<sub>2</sub>, VCO<sub>2</sub>, and RER among the CPX/U, FM and MP during walking and jogging. The VO2000 overestimated the VO<sub>2</sub> values compared to the CPX/U by  $\hat{a} \sim 2$  ml.kg<sup>-1</sup>.min<sup>-1</sup> during walking and by  $\sim 7$  ml.kg<sup>-1</sup>.min<sup>-1</sup> during jogging.

**CONCLUSIONS:** The VO2000 is reliable, but should not be used in the field with confidence until explanations or corrections are provided for the differences between systems reported in this study. Future research should focus on internal as well as external sources of error that account for the differences between the VO2000 and standard

**Development Of Moving Artifacts Simulator For Reliability Evaluation Of Heart Rate Monitors**

Chunho Choi. *Wellness Technology Center, Cheonan-si, Republic of Korea.*

Email: choi.chunho@gmail.com

(No relationships reported)

**PURPOSE:** To develop a signal simulator with dynamic noise originated from the actual walking and running, for evaluation of reliability of HRMs.

**METHODS:** We classified variations of measured HR signal during exercise as three categories: actual physiological changes, effect of respiration and change in the electrode contact (moving artifact). To separate each, respiration and walking/running bounce rate were measured by independent devices: Volunteers wore 1 channel ECG device without any signal filters to their chest to get the composite signal, and used gas analyzer to measure respiration rates and wore accelerometer on their waist to monitor motional bounce. Data from each device are analyzed by frequency response method to investigate the characteristic frequencies of each artifacts and actual physiological signal. With those frequency distribution and corresponding power spectrum, simulated ECG signal contains noises due to walking/running effect were generated with known actual physiological part.

**RESULTS:** Results show that both characteristic frequencies of respiration and moving artifact are linearly increased with respect to walking speed, range from 0.59Hz to 0.88Hz and 2Hz to 2.95Hz, respectively with speed change from 5km/h to 9km/h. When subjects are running, respiration and moving artifact show different but linear increase with respect to running speed, 0.87Hz~1.0Hz and 2.95Hz~3.35Hz, respectively with speed change 7km/h~12km/h. Power spectrum, i.e., noise amplitude, of moving artifact also linearly increased when walking/running speed are increased. With these information, derived physiological signal, respiration signal and moving artifact signal were combined by using a signal generator to get the artificial ECG signal contains moving noise. Generated artificial ECG signal were strongly correlated with original signal ( $R^2 = 0.91$ ), which shows that moving artifact effect with various speed can be artificially simulated by a signal generator.

**CONCLUSIONS:** A simulation method for ECG signal with noise from moving effect was developed. Simulated signal with known signal composition including moving artifact could be used for objective evaluation of reliability of HRMs.

**Validity Of The Salutron Smarthealth Heart Rate Watch And Treadmill Handgrip Sensors**

Clarence M. Lee, Haruki Nii, Mark Gorelick. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)

Email: cmlee@sfsu.edu

(No relationships reported)

One of the more recently developed heart rate monitoring devices is a strapless heart rate watch. Such a device may be more user-friendly than classic heart rate monitors as there is no need to wear a chest strap.

**PURPOSE:** To examine the validity of the Salutron Strapless Smarthealth heart rate watch (SHW) and the Salutron treadmill handgrip contact heart rate sensors (HG) by comparing them to an electrocardiogram (EKG).

**METHODS:** Healthy adults ( $n=25$ ; age:  $27.3 \pm 5$  yrs) engaged in a period of standing rest and graded exercise on a treadmill. Heart rate was monitored and recorded via: 1) an EKG, 2) a SHW, and 3) HG. The protocol consisted of 5-min periods of 1) standing rest, 2) 2.0 mph walking, 3) 3.5 mph walking, 4) 4.5 mph jogging, and 5) 6.0 mph running. During each period, an EKG was printed at 30-sec intervals and served as the criterion measure. Additionally, the SHW readings were recorded at time periods of 0:30, 1:30, 2:30, 3:30, and 4:30, while HG readings were recorded at time periods of 1:00, 2:00, 3:00, 4:00, and 5:00. The EKGs were analyzed to determine heart rate which was reported as a 5-beat average. Heart rate values recorded from the SHW and HG were compared to the EKG at the respective time periods. Correlation coefficients ( $r$ ) and standard error of estimate (SEE) were calculated to determine the validity of SHW and HG.

**RESULTS:** Correlation coefficients ranged from 0.95 to 0.97 between SHW and EKG and from 0.97 to 0.99 between HG and EKG. Furthermore, the SEEs were  $<5$  bpm for SHW and  $<4$  bpm for HG (Table 1).

**CONCLUSION:** Correlation coefficients were high between both devices and the EKG and SEEs were low indicating both are valid and provide accurate measures of heart rate during treadmill exercise.

Table 1.

		0 mph	2 mph	3.5 mph	4.5 mph	6 mph
EKG vs. SHW	$r$	0.96	0.95	0.96	0.98	0.97
	SEE	3.96	4.75	4.46	4.1	4.24
EKG vs. HG	$r$	0.98	0.99	0.99	0.99	0.97
	SEE	3.06	2.34	2.47	2.6	3.38

**Bilateral Differences In Emg Responses During Submaximal Arm Ergometry**

Swapn Mookerjee<sup>1</sup>, James Smoliga<sup>2</sup>. <sup>1</sup>Bloomsburg University, Bloomsburg, PA. <sup>2</sup>Marywood University, Scranton, PA. (Sponsor: Eric Rawson, FACSM)

Email: smookerj@bloomu.edu

(No relationships reported)

**PURPOSE:** To investigate differences in electromyographic responses during submaximal arm ergometry.

**METHODS:** 19 subjects (12 males, 7 females; mean age  $\pm$  SD:  $22.63 \pm 2.01$  yrs) underwent a graded maximal arm ergometry test to determine peak oxygen uptake ( $\text{VO}_{2\text{peak}}$ ). On a separate day subjects completed two, 15-minute submaximal workloads (40% and 60% of maximal workload) administered in a randomized order. During the submaximal session electromyographic activity (EMG) of the left and right biceps brachii (BB), triceps (Tri), latissimus dorsi (LD) were recorded (sampling rate 1000 Hz). Data were divided into thirds to represent the start, middle and last three repetitions of exercise. Integrated EMG (iEMG) was calculated. Differences between conditions were analyzed with multivariate repeated measures ANOVA.

**RESULTS:** The mean  $\pm$  SD  $\text{VO}_{2\text{peak}}$  was  $1.92 \pm 0.44 \text{ L}\cdot\text{min}^{-1}$ . There were significant differences ( $p<0.05$ ) in submaximal  $\text{VO}_2$  between 40% and 60% workloads ( $1.21 \pm 0.30 \text{ L}\cdot\text{min}^{-1}$  and  $1.63 \pm 0.44 \text{ L}\cdot\text{min}^{-1}$ , respectively). Time-dependent bilateral asymmetries were evident in the iEMG data, which are presented in the table below. Pairwise comparisons demonstrated significant changes in iEMG for all muscles between start vs. mid (BB:  $p=0.040$ , Tri:  $p=0.004$ , LD:  $p=0.008$ ), and start vs. end (BB:  $p=0.021$ , Tri:  $p=0.002$ , LD:  $p=0.042$ ), but none for

mid vs. end. Univariate analysis revealed significance for speed in BB ( $p=0.006$ ), Tri ( $p=0.031$ ), and LD ( $p=0.004$ ). Univariate analysis revealed significance for side in the BB ( $p=0.001$ ), Tri ( $p<0.001$ ), and LD ( $p<0.001$ ).

**CONCLUSIONS:** These results suggest a trend toward time-dependent, bilateral differences in muscle activity during submaximal arm ergometry.

	Left BB	Tri	LD	Right BB	Tri	LD
Start 40%	144.6 ± 61.9	188.6 ± 94.4	62.5 ± 37.4	249.1 ± 161.9	436.3 ± 300.7	202.4 ± 141.2
Middle 40%	161.1 ± 57.8	202.8 ± 88.6	70.8 ± 39.6	261.4 ± 159.6	457.5 ± 222.2	213.9 ± 140.0
End 40%	172.8 ± 64.4	214.8 ± 80.0	75.1 ± 42.9	265.4 ± 158.8	454.6 ± 162.4	209.2 ± 120.6

### Acute And Late Effects Of Passive Stretching And “Crochetage” In Hamstring Muscles Flexibility In Young Healthy Women

Karina F. Lagoa<sup>1</sup>, Lilian L. Cardoso<sup>1</sup>, Wagner R. Martins<sup>1</sup>, Luiz Guilherme G. Porto<sup>2</sup>. <sup>1</sup>Brasilia University Center - UniCEUB, Brasilia, Brazil. <sup>2</sup>Brasilia University Center - UniCEUB and University of Brasilia Faculty of Medicine, Brasilia, Brazil.

Email: karinalagoa@hotmail.com

(No relationships reported)

Flexibility is a component of physical fitness and doubts still persist on the efficacy of different training methods. The Crochetage (CRO) is one of the methods based upon muscular womb traction using a specific steel hook, during a 5-7 min period.

**PURPOSE:** To evaluate the acute (AE-after each session) and late effects (LE-after 10 sessions) of the passive stretching (PS) and the CRO, on hamstring muscles in healthy young women.

**METHODS:** Ten women aged 18-30 yrs, BMI of  $22.5 \pm 0.9 \text{ kg/m}^2$  were submitted to 10 consecutive flexibility sessions on week days. They received PS (one 30 sec repetition) on one thigh and CRO in the other. The application of PS or CRO was randomly assigned to each volunteer by a unique researcher. Popliteal angle (PA) was measured before and after each session by another researcher, blinded to the flexibility method. All measurements were made at the point that produced an uncomfortable sensation without pain, during the passive knee extension, in dorsal decubitus, with hip at  $90^\circ$  and the opposite leg extended. The PA was re-evaluated 14 days after the end of the program, to search for flexibility maintenance. The average differences were analyzed before and after each session (AE). Late effects were evaluated comparing the average values of the 10<sup>th</sup> session in relation to the first. The effects of PS and CRO were tested with paired t-test and the comparison between them with unpaired t-test. Differences were considered significant when  $p<0.05$ .

**RESULTS:** Baseline values for PS ( $153.5 \pm 9.7^\circ$ ) were similar to the CRO ( $156.3 \pm 8.8^\circ$ ;  $p=0.50$ ). The average values after each session of PS were higher ( $158.1 \pm 11.1^\circ$ ) than the previous ones ( $153.5 \pm 9.7^\circ$ ;  $p<0.0001$ ). The same occurred with the CRO after ( $160.0 \pm 8.9^\circ$ ), compared with the previous ( $156.3 \pm 8.8^\circ$ ;  $p<0.0001$ ). The average magnitudes of AE in PS ( $+4.7 \pm 1.6^\circ$ ) and in CRO ( $+3.7 \pm 0.8^\circ$ ) were similar ( $p=0.12$ ). The increase of flexibility (LE) with PS ( $+7.9 \pm 7.7^\circ$ ;  $p<0.01$ ) was similar ( $p=0.93$ ) to that with CRO ( $+8.8 \pm 5.7^\circ$ ;  $p=0.001$ ). After 14 days, flexibility values were similar to those observed in the last training session, in both thighs ( $p>0.05$ ).

**CONCLUSION:** Training with both PS and CRO provided similar acute and late increase in the hamstring muscles flexibility. The improvement persisted after 14 days without training and was similar to both methods.

## 2217 Board #105 May 28 2:00 PM - 3:30 PM

### Non-exercise Prediction Of Anaerobic Power

Jennifer J. Wages, Ronald K. Hetzler, FACSM, Michelle A. Cleary, Melissa Lentz, Christopher D. Stickley, Iris F. Kimura. University of Hawaii at Manoa, Honolulu, HI.

(No relationships reported)

Previous studies have documented that reasonable estimates of maximal oxygen uptake can be obtained through the combination of selected anthropometric data and a paper and pencil test.

**PURPOSE:** This study examined the possibility of predicting anaerobic power as measured by the Wingate Anaerobic Cycle Test using anthropometric data and a questionnaire.

**METHODS:** Ninety-seven (54 males and 43 females) subjects volunteered to participant in this study. Peak power (PP) and mean power (MP) were determined using a standard Wingate protocol at a resistance of 0.075 and 0.10  $\text{kg} \cdot \text{kgbw}^{-1}$  for females and males, respectively. A series of eight questions were generated corresponding to variables associated with anaerobic power, using a Likert-type scale to quantify the response. Additionally, previously published scales from papers investigating non-exercise aerobic power estimates were also included in the analysis (Jackson et al, 1995 and George et al, 1997). Descriptive statistics were generated and multiple regression were performed on SAS v9.0 with an alpha level of  $p<0.05$ .

**RESULTS:** Mean ( $\pm$  SD) age, ht, wt, BMI, resting heart rate (RHR), PP, and MP, for males and females were:  $21.9 \pm 2.5$  yrs,  $175.0 \pm 7.8$  cm,  $79.2 \pm 12.4$  kg,  $25.8 \pm 3.3$ ,  $67.3 \pm 12.1$  BPM,  $1055.7 \pm 192.2$  W and  $800.7 \pm 125.7$  W; and  $22.4 \pm 3.3$  yrs,  $163.7 \pm 7.6$  cm,  $61.0 \pm 11.2$  kg,  $22.7 \pm 3.8$ ,  $69.7 \pm 10.3$  BPM,  $607.9 \pm 121.6$  W and  $481.7 \pm 71.0$  W; respectively. The mean estimated jump height (EJHt) Likert-scale values were  $5.7 \pm 1.5$  and  $4.7 \pm 1.3$  (on a 1-9 scale) for the males and females respectively. The mean activity code (AC) (Jackson et al. 1995) was  $4.9 \pm 1.6$  and  $5.1 \pm 1.5$  for males and females respectively. Multiple regression revealed the most parsimonious models to predict PP and MP were: PP =  $195.97 + 257.05(\text{gender}) + 8.48(\text{wtkg}) + 2.81(\text{EJHt})^2 - 2.48(\text{RHR})$ ,  $R^2 = 0.80$ , SEE = 122.9 W; MP =  $214.83 + 180.93(\text{gender}) + 0.06(\text{wtkg})^2 - 0.16(\text{BMI})^2 + 66.31(\text{AC}) - 5.97(\text{AC})^2 + 14.8(\text{EJHt}) - 1.54(\text{RHR})$ ,  $R^2 = 0.91$ , SEE = 60.0 W.

**CONCLUSION:** It was concluded that reasonable estimates for Peak and Mean power could be estimated from a combination of anthropometric data and a questionnaire without performing the Wingate anaerobic cycle test.

**2218 Board #106 May 28 3:30 PM - 5:00 PM****Heart Rate and Estimate Energy Expenditure During Three Different Salsa Dancing Conditions**

Gian Pietro Emerenziani, Laura Guidetti, Maria Chiara Gallotta, Emanuele Franciosi, Cosme Franklim Buzzachera, Carlo Baldari. *Università degli Studi di Roma "Foro Italico", Rome, Italy*. (Sponsor: Alan C. Utter, FACSM)  
Email: gianpietro.emerenziani@iusm.it

*(No relationships reported)*

**PURPOSE:** Many people practice Caribbean dances to improve their physical and psychological conditions. Moreover, despite a large practice of this dance, there is paucity information on its intensity request. The aim of this study was to estimate energy expenditure by heart rate of three different salsa dancing conditions: typical salsa lesson (TSL), *rueda de casino* lesson (RCL), and salsa dancing at night club (SDN) in eleven non-professional dancer adult pairs (age: 36±7 yrs).

**METHODS:** Subjects performed a pre-testing session and three testing sessions. During the pre-testing session height, weight and  $\dot{V}O_{2max}$  were assessed. Subjects'  $\dot{V}O_{2max}$  was determined by means of a continuous graded exercise step-test. In the following testing sessions, all subjects performed three different kinds of salsa dance (TSL, RCL and SDN). Heart rate (HR) was assessed during each dance condition and related to direct measures of oxygen uptake and to heart rate obtained during the preliminary incremental step-test. Linear regression analysis was employed to estimate gross and net energy expenditures of the dance conditions. A 2×3 analysis of variance (ANOVA) (gender, salsa condition) with repeated measures on one factor (salsa condition) was performed to assess differences in the physiological variables.

**RESULTS:** Significant differences were observed in ( $p<0.05$ ): % of maximum HR between TSL and SDN ( $58\pm5$  vs  $64\pm8\%$ , respectively) in males, and between RCL and SDN ( $62\pm6$  vs  $75\pm7\%$ , respectively) in females; predicted net % $\dot{V}O_{2max}$  value between TSL and the two other conditions ( $41.5\pm8$  vs  $50.6\pm6$ ; and vs  $50.1\pm11\%$  for TSL, RCL and SDN, respectively) in males, and between TSL and RCL ( $46.7\pm9$  vs  $55.8\pm10\%$ , respectively) in females; predicted net energy expenditure value between TSL and the two other conditions ( $237\pm114$  vs  $353\pm81$ ; and vs  $338\pm88$  kcal/h for TSL, RCL and SDN, respectively) in males, and between TSL and RCL ( $181\pm44$  vs  $234\pm67$  kcal/h, respectively) in females. No significant difference between males and females was observed for all variables.

**CONCLUSION:** Our results are in agreement with recommendations of the American College of Sport Medicine (ACSM) for health and fitness improvement. Therefore TSL, RCL and SDN could be useful to improve health and fitness conditions of amateur adult dancers.

---

**2219 Board #107 May 28 3:30 PM - 5:00 PM****Training Volume, Supplemental Conditioning Practices And Injuries Of Competitive Irish Dancers**

Christian Bruhn, Vince Nethery, Leo D'Acquisto, Harry Papadopoulos. *Central Washington Univ., Ellensburg, WA*. (Sponsor: Peter A Harmer, FACSM)

Email: netheryv@cwu.edu

*(No relationships reported)*

Although Irish dance competitions have existed for over two centuries, little is known about either the training-conditioning practices of or the injuries sustained by competitors.

**PURPOSE:** This study determined the relationships among competition levels, specific dance training volume, supplemental training, and types of injuries of Irish dance competitors.

**METHODS:** Data on the aforementioned variables were obtained through an online survey sent to Irish dance academies around the globe. An ANOVA assessed significance of differences among dance competition category responses.

**RESULTS:** Respondents ( $n=351$ ) included male ( $n=23$ ) and female ( $n=328$ ) dance competitors with 75% of respondents in the two highest categories: Open Champion ( $n=168$ ) and Preliminary Champion ( $n=93$ ). Open and Preliminary Champions spent 10.3 and 7.7 hours on specific dance training per week ( $P<0.05$ ) while Prize Winner and Novice categories trained for 5.8 and 3.9 hours respectively (All comparisons  $P<0.05$  except Novice versus Prize Winner  $P=0.09$ ). Supplemental training was incorporated by 65% of Open champions compared to 55% for Preliminary, 45% for Prize Winner, and 44% for Novice participants ( $P<0.05$  except Novice versus Prize Winner). All categories had greater prevalence of injury for the ankle compared to the knee and hip ( $P<0.05$ ) with the Open Champion category having a higher overall prevalence of all injuries than the other three groups ( $P<0.05$ ).

**CONCLUSIONS:** Competition category was directly associated with higher specific dance and supplemental training volumes, and also with a greater prevalence of injury. Trauma to the ankle dominated the injury spectrum regardless of dancer category and this is likely related to the rigid nature of Irish dance movements and the forces imposed upon the distal lower extremity upon landing.

---

**2220 Board #108 May 28 3:30 PM - 5:00 PM****Effects Of 16-wk Jajun Dance Program And Circuit Exercise Training In Improving Physical Fitness, Risk Factors Of Cardiovascular Diseases In Menopausal Women**

Jung-Ja Kwak, Won Il Park, Hyewon Shin, Hyun Min Choi, Hosung Nho. *KyungHee University, Yong In, Republic of Korea*.

Email: milidokjj@hanmail.net

*(No relationships reported)*

Previous studies have demonstrated that circuit exercise training (CET) could improve the risk factors of cardiovascular diseases in menopausal women. Jajun dance program (JDP) (Korean traditional dance) is enjoyable and designed to improve long-term adherence to training. However, little is still known whether JDP could improve health-related physical fitness and the risk factors of cardiovascular diseases.

**PURPOSE:** To investigate the physiological effects of Jajun dance program compared to CET in menopausal women.

**METHODS:** All subjects were divided into two groups: JDP group performed Jajun dance and CET group performed dumbbell, theraband, gymball exercise. Both groups participated in 16-week, 3days/wk supervised program consisting of 10 min warm up, 40 min exercise (exercise intensity corresponding to 50-60% HRmax, RPE 13-15), and 10 min cool down. Blood glucose levels (BG), systolic blood pressure (SBP), diastolic blood pressure (DBP), grip strength, balance, trunk extension, side step were measured.

**RESULTS:** with CET and JDP, FBG, SBP, and DBP were significantly decreased in both groups. Balance, strength, agility, flexibility were significantly improved in both groups after 16 weeks program.

**CONCLUSION:** This study suggests that Jajun dance is an effective exercise program as a mean to improve health-related physical fitness and the risk factors of cardiovascular diseases.

Variable	JDP (n = 13)		CET (n =12)	
	Pre	Post	Pre	Post

SBP (mmHg)	138.8 ± 6.8	130.1 ± 4.6*	127.8 ± 10.7	125.3 ± 13.2
DBP (mmHg)	90.5 ± 3.7	84.5 ± 4.6*	82.9 ± 9.3	79.9 ± 4.1
HRrest (b/min)	72.2 ± 9.6	74.3 ± 11.2	66.5 ± 22.4	63.0 ± 20.4
BG (mg/dl)	127.9 ± 20.8	113.5 ± 19.1	89.7 ± 27.6	88.9 ± 27.3
Grip strength (kg)	19.5 ± 3.9	23.9 ± 4.3*	25.0 ± 3.1	24.7 ± 3.4
Balance (s)	12.2 ± 10.4	18.5 ± 15.0*	10.1 ± 11.8	12.3 ± 7.6
Trunk extension (cm)	14.7 ± 3.6	19.6 ± 3.4*	16.7 ± 7.3	19.5 ± 8.6*
Side step (num/20 sec)	5.5 ± 0.7	8.5 ± 1.8*	25.4 ± 9.7	24.2 ± 8.0

Data were expressed as mean value ± standard deviation. \*significantly different from prevalue (P<0.05).

## 2221 Board #109 May 28 3:30 PM - 5:00 PM Physical Activity Assessment Using Different Accelerometer Epoch Lengths During A Low-intensity Ballroom Dance Class

Duncan Radley, Stephen P. Cobley, Nick Wattie, Peter K. Mackreth, Jim McKenna. *Leeds Metropolitan University, Leeds, United Kingdom.*

Email: d.radley@leedsmet.ac.uk

(No relationships reported)

Until recently accelerometry data has been commonly collected using 1-minute sampling intervals (epochs). However, 1-minute epochs may misclassify bouts of (in)activity when compared to more intermittent assessment (e.g. 2-second epochs).

**PURPOSE:** To evaluate variability in physical activity intensity levels using different epoch lengths during a low intensity community dance programme. **METHOD:** Subjects were 66, mostly senior, adults with a self-assessed status of being physically inactive, who participated in a 2-hour beginners ballroom dance class. During class, physical activity was measured using an Actigraph GT1M accelerometer, set at 2-second epochs. Later, activity counts were transformed into 4, 6, 10, 20, 30 and 60-second epochs. Time spent in sedentary, light and moderate-to-vigorous (MTV) activity was calculated, using adjusted intensity thresholds for each epoch based on counts per minute values of <200, 200-1952 and >1952, respectively.

**RESULTS:** Using 2-second epochs, participants spent 142 ± 9 mins, 32 ± 7 mins and 6 ± 3 mins of class time in sedentary, light and MTV physical activity, respectively. However, sedentary activity based on 4, 6, 10, 20, 30 and 60-second epochs underestimated totals by 5, 7, 10, 14, 17 and 20 mins, respectively. In contrast, time spent in light activity was overestimated by 5, 7, 10, 14, 18 and 22 mins when applying the same epoch periods. Considering MTV, time spent was underestimated by <1 min using 4, 6 and 10-second epochs, and by 1-2 mins using 20, 30 and 60-second epochs. All differences were statistically significant (p<0.01).

**CONCLUSION:** In this case, where a large proportion of time was spent in sedentary and low intensity activity, it is unlikely that the differences obtained for time spent in MTV activity using varying epoch lengths are of biological significance. However, during low intensity activity evaluation, more sensitive (short duration) epochs may provide more accurate estimations. Further research is required to investigate the effect of different epoch lengths when assessing activity changes over time.

## 2222 Board #110 May 28 3:30 PM - 5:00 PM Prevalence Of Musculoskeletal Disorders In Step Instructors

Maria Machado<sup>1</sup>, Rita Santos-Rocha<sup>2</sup>, Filomena Carmide<sup>1</sup>, Rui Marreiros<sup>2</sup>. <sup>1</sup>Faculty of Human Kinetics, Technical University of Lisbon, Cruz Quebrada, Portugal. <sup>2</sup>Sport Sciences School of Rio Maior, Polytechnic Institute of Santarém, Rio Maior, Portugal.

(No relationships reported)

It is widely believed that Step Exercise Programs are a powerful form of workout that elicits a number of favorable responses contributing to a healthy life. Basically, the participants follow the instructor in a routine which involves stepping up and down on platforms of varying heights, at varying cadences, in order to achieve a sound workout. Although it appears relatively safe for participants, with respect to the magnitude of loading, Step instructors are exposed to a huge amount of work that could affect their professional lives.

**PURPOSE:** to assess the prevalence and the body areas affected by musculoskeletal disorders (MSDs) in Portuguese step instructors.

**METHODS:** An adapted version of the Nordic Questioners was applied to 200 Step instructors (mean age of 26 ± 8 years), randomly select from the two most important Portuguese Fitness Convention. Statistic analyses were conducted using SPSS.

**RESULTS:** 75% of the Step instructors are concerned about the impact of MSDs in their professional lives. Independently the gender, age and professional experience, the prevalence of MSDs was high (41%). The knee (44%), ankle (42%) and foot (31%) are the most affected body areas. In the last year, 28% Step instructors interrupted their professional activities, 44 % required medical care, and 40 % were inhibited to realize their own daily activities. 44% of the professionals also reported the need of changing some routines to avoid MSDs which was confirmed by the positive correlation between MSDs, medical care, injury severity and working incapacity.

**CONCLUSIONS:** The results showed a high prevalence of MSDs in Step instructors, with negative repercussions on their professional activity. Further research is needed to identify the real impact of the MSDs in fitness instructors, and to establish the optimal amount and combinations of exercise to reduce them.

## D-30 Free Communication/Poster - Immunology

MAY 28, 2009 1:00 PM - 6:00 PM

## 2223 Board #111 May 28 3:30 PM - 5:00 PM Melanocortin 3 Receptor: A Novel Mediator Of Exercise-induced Inflammation

Tara M. Henagan<sup>1</sup>, Melody D. Phillips<sup>2</sup>, Dennis Cheek<sup>2</sup>, K. Michele Kirk<sup>3</sup>, James Joseph Barbee<sup>3</sup>, Laura K. Stewart<sup>1</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>Texas Christian University, Fort Worth, TX. <sup>3</sup>John Peter Smith Hospital, Fort Worth, TX.

Email: thenag1@lsu.edu

(No relationships reported)

Chronic exercise training significantly decreases inflammatory cytokines in individuals at rest and after an acute bout of exercise; however the mechanism by which resistance

training (RT) mediates reductions in inflammation has yet to be elucidated.

**PURPOSE:** Determine the effects of chronic RT on melanocortin 3 receptor (MC3R) mRNA expression in whole blood samples at rest and after an acute bout of resistance exercise (RE). Determine if MC3R mRNA expression correlates with increased sensitivity to inflammatory stimuli, assessed by tumor necrosis factor alpha (TNF $\alpha$ ).

**METHODS:** Obese (BMI  $32.7 \pm 3.7$ ), post-menopausal women aged  $65.6 \pm 2.8$  yrs were randomized to either a control (CN) or exercise (EX) group. EX performed progressive RT 3 days/week for 12 weeks at 80% of the subjects' estimated 1RM and included 3 sets of 10 exercises. Blood samples used for mRNA analysis were collected from CN and EX, before (PR) and after the intervention period (PO), and immediately following RE. Lipopolysaccharide (LPS)-stimulated TNF $\alpha$  from whole blood cultures was measured by ELISA and expressed per monocyte.

**RESULTS:** No change in body weight (BW) or fat percentage (FP) was found in either group. MC3R mRNA was upregulated 11-fold ( $p > 0.05$ ) in response to RT in obese women. RT MC3R mRNA increased in EX to a higher degree (13-fold increase,  $p > 0.05$ ) in comparison to CN (10-fold increase,  $p > 0.05$ ). LPS-stimulated TNF $\alpha$  concentrations did not change in response to RT in EX ( $29 \pm 3$  vs.  $43 \pm 7$  fg/monocyte,  $p > 0.05$ ) nor CN ( $32 \pm 6$  vs.  $39 \pm 3$  fg/monocyte,  $p > 0.05$ ). RE elicited no change in LPS-stimulated TNF $\alpha$  ( $43 \pm 7$  vs.  $40 \pm 7$  fg/monocyte,  $p > 0.05$ ) whereas CN exhibited a slight increase ( $39 \pm 3$  vs.  $48 \pm 6$  fg/monocyte,  $p > 0.05$ ).

**CONCLUSIONS:** Chronic RT increases MC3R in whole blood and may improve sensitivity of immune cells to inflammatory stimuli independent of changes in BW or FP.

**Exercise Training Does Not Influence Cd8+ Phenotype Or Mitogen-activated Tnf- $\alpha$  Production In Previously Inactive Elderly.**

Kyle L. Timmerman<sup>1</sup>, Michael G. Flynn, FACSM<sup>2</sup>, Paul M. Coen<sup>3</sup>, Melissa M. Markofski<sup>2</sup>, Brandt D. Pence<sup>4</sup>. <sup>1</sup>University of Texas Medical Branch, Galveston, TX. <sup>2</sup>Purdue University, West Lafayette, IN. <sup>3</sup>University of Pittsburgh, Pittsburgh, PA. <sup>4</sup>University of Illinois, Champaign, IL.  
Email: kytimmer@utmb.edu

(No relationships reported)

Aging is characterized by a gradual decline in circulating naïve (CD28+CD8+) T-cells and an increase in effector/cytotoxic (CD28-CD8+) T-cells. A consequence of this shift is increased inflammation. CD28-CD8+ T-cells promote an inflammatory environment, as evidenced by their increased production of inflammatory cytokines (i.e. TNF- $\alpha$ ) compared to naïve CD+ T-cells. While exercise has been shown to exert anti-inflammatory properties, little is known about the influence of exercise training on CD8+ T-cells.

**PURPOSE:** To examine the influence of 12 weeks of combined endurance and resistance exercise training on CD8+T-cell phenotype and function in elderly adults.

**METHODS:** On the basis of their physical activity pattern, male and female subjects, 65-80 yrs. old, were assigned to either a physically active (PA, N=15) or inactive (PI, N=15) group. The PI group performed 12 weeks (3d/wk) of endurance (20 min. @ 70-80% heart rate reserve) and resistance exercise training (8 exercises, 2 sets @ 70-80% of 1 repetition maximum). Subjects in the PA group maintained their habitual activity level. Flow cytometry was used to determine CD8+ subsets and mitogen-stimulated TNF- $\alpha$  production.

**RESULTS:** There was no effect of training on any of the variables measured. However, there were significant group effects with PA subjects showing a significantly lower percentage of CD8+ T-cells expressing TNF- $\alpha$  and lower TNF- $\alpha$  mean fluorescence intensity on memory and cytotoxic CD8+ T-cells than PI subjects.

**CONCLUSION:** Twelve weeks of exercise training had no influence on CD8+ T-cell phenotype or TNF- $\alpha$  production in PI subjects. However, PA subjects had lower TNF- $\alpha$  expression on CD28-CD8+ T-cells, providing limited evidence that a history of physical activity may attenuate inflammation in CD8+ T-cells from healthy, elderly adults.

Supported by an AARP Research Scholars Award.

**2225 Board #113 May 28 3:30 PM - 5:00 PM**  
**An Examination of Immunoendocrine and Oxidative Responses Utilizing a Dual Stress Model**

Chun-Jung Huang<sup>1</sup>, Heather E. Webb<sup>2</sup>, Ronald K. Evans<sup>1</sup>, Kelly A. McCleod<sup>3</sup>, Supatchara E. Tangsilat<sup>3</sup>, Gary H. Kamimori<sup>4</sup>, Edmund O. Acevedo, FACSM<sup>1</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, VA. <sup>2</sup>Mississippi State University, Starkville, MS. <sup>3</sup>University of New South Wales, Sydney, Australia. <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD.  
Email: huangcj@vcu.edu

(No relationships reported)

Oxidative stress has been implicated as a critical contributor to the pathogenesis of cardiovascular disease. Additionally, catecholamine increases and inflammation are related to increases in oxidative stress. Although, physical and psychological stress elicit elevations in catecholamine release and inflammation, there are no studies examining the combined impact of physical and mental challenge on catecholamine, inflammation, and oxidative stress.

**PURPOSE:** The purpose of this study was to examine the catecholamine (epinephrine [EPI] and norepinephrine [NE]), interleukin-2 (IL-2) and 8-isoprostane responses to a dual stress model (combined physical and mental challenge). To elucidate possible mechanisms, relationships among EPI, NE, IL-2, and 8-isoprostane were also examined.

**METHODS:** Seven participants ( $\text{VO}_{2\text{max}} = 45.13 \pm 7.70$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) completed two experimental conditions. The exercise-alone condition (EAC) consisted of cycling at 60%  $\text{VO}_{2\text{max}}$  for 37 minutes, while the dual-stress condition (DSC) included 20 minutes of a mental challenge while cycling.

**RESULTS:** DSC showed greater EPI and 8-isoprostane levels (significant condition by time interaction). In addition, NE and IL-2 revealed significant increases over time in both conditions. EPI area-under-the-curve (AUC) was positively correlated with NE AUC and IL-2 AUC ( $r = 0.805$  and  $r = 0.674$ ,  $p < 0.01$ , respectively). Additionally, NE AUC was positively correlated with IL-2 AUC and peak 8-isoprostane ( $r = 0.575$  and  $r = 0.554$ ,  $p < 0.05$ , respectively). Finally, peak IL-2 was positively correlated with peak 8-isoprostane ( $r = 0.577$ ,  $p < 0.05$ ).

**CONCLUSION:** These results suggest that elevations in catecholamines, IL-2 and oxidative stress in response to physical and mental challenge, may contribute to the pathogenesis of cardiovascular disease. Furthermore, the elevations in NE and IL-2 may explain the elevated oxidative stress during dual stress. Cautious interpretation and further investigation are warranted to understand these results in the context of cardiovascular disease and stress.

**The Influence Of Prolonged Cycling On Monocyte Toll-like Receptor 2 And 4 Expression In Healthy Men**

Marta Oliveira, Chris Toms, Stephen Barrett, Michael Gleeson. Loughborough University, Loughborough, United Kingdom.  
Email: M.Oliveira@lboro.ac.uk

(No relationships reported)

Several studies have reported that some immune cell functions including monocyte Toll-like receptor (TLR) expression and antigen presentation are temporarily impaired following acute bouts of strenuous exercise, which could represent an 'open window' to upper respiratory tract infection (URTI). However, reduced levels of TLR expression over the long term may be beneficial to health due to associated reductions in chronic inflammation, and consequently reducing the risk of developing chronic diseases. To date, there has been little research on the effects of acute and chronic exercise on human monocyte TLR expression.

**PURPOSE:** The purpose of this study was to examine the effects of 1.5 h cycling at 75%  $\text{VO}_{2\text{peak}}$  on human monocyte TLR2 and TLR4 expression.

**METHODS:** Nine healthy endurance trained males (age  $25 \pm 5$  years; body mass  $76.8 \pm 8.1$  kg;  $\text{VO}_{2\text{peak}} = 58.5 \pm 5.6$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, mean  $\pm$  s) had PRE (rest), POST, 1H POST, 4H POST and 24H POST exercise blood samples collected and analysed using four colour flow cytometry. Friedman's ANOVA was used to analyse data that were not normally

distributed and ANOVA with repeated measures was used for other data.

**RESULTS:** Although there was an increase in the total monocyte cell count at POST, 1H POST and 4H POST ( $P < 0.01$ ), exercise reduced monocyte TLR4 expression (geometric mean fluorescence intensity, corrected for non-specific binding using an appropriate isotype control) by 30% at POST and 31% at 1H POST exercise compared with PRE values ( $X^2(4) = 9.511$ ,  $P < 0.05$ ). Values had returned to normal at 4H POST exercise. There were no statistically significant changes in TLR2 expression after exercise ( $X^2(4) = 4.178$ ,  $P = 0.402$ ).

**CONCLUSIONS:** This study showed that prolonged cycling at 75%  $\text{VO}_{2\text{peak}}$  reduces TLR4 expression, which may in part be responsible for post-exercise immunodepression but also for the anti-inflammatory effect of exercise.

**Is The Inflammatory Responses During And After 7-day Marathon A Good Model For Sepsis Mechanism?**

Wen Yu Chan<sup>1</sup>, Jin Jong Chen<sup>1</sup>, Tzai Li Li<sup>2</sup>, Wei Fong Kao<sup>1</sup>. <sup>1</sup>National Yang-ming University, Taipei, Taiwan. <sup>2</sup>National Dong-Hwa University, Hualien, Taiwan.

Email: aac1025@yahoo.com.tw

(No relationships reported)

Purposes: To evaluate changes of the immune system in athletes during and after 7- day marathon and to correlate these changes with mechanism of clinical sepsis.

**METHODS:** The subjects were nine healthy athletes (5 males and 4 females, age 52.4±2.5 yr; means±SEM) in 7-day race of the 2008 Athens ultra-marathon festival. Blood samples were collected before, during and after the competition. The concentrations of plasma cortisol, neutrophil degranulation (total elastase release), and total white blood cell (WBC) and differential WBC counts including lymphocytes, neutrophils and monocytes were measured.

**RESULTS:** (1) Comparing to pre-race, total WBC counts, lymphocyte counts and monocyte counts of subjects significantly decreased (-6.7%~-33.6%, -61.7%~-72.7%, -3.1%~-63% respectively,  $P < 0.05$ ) during the race. Contrarily, neutrophil counts, total elastase release and the concentration of plasma cortisol significantly increased (-3.1%~-43.5%, 21.7%~-119.8%, 288.3%~-387.3% respectively,  $P < 0.05$ ) (2) Total WBC counts, neutrophil counts and total elastase release during the race were less than post-race ( $P < 0.05$ ) while lymphocyte counts slightly recovered after the race. (3) Total WBC counts, neutrophil counts, lymphocyte counts and monocyte counts during post-race were less than pre-race ( $P < 0.05$ ) while the concentration of plasma cortisol was still higher than pre-race concentration ( $P < 0.05$ ).

**CONCLUSIONS:** The main findings of this study were (1) acute inflammatory response in runners occurred in the first day of 7-day race, including increased neutrophil counts and total elastase release, which may be due to heavy stress of ultra-marathon; (2) immunosuppression induced by prolong exercise and presented as the decrement of total and differential white blood cell counts, may not fully recover during 2 days post-race; (3) the inflammatory responses pattern of the immune system in the 7-day marathon runners is similar to the developing of sepsis.

**Effects Of Prolonged And Brisk Exercise On Apoptosis**

Anna Gavrieli<sup>1</sup>, Maria Tsironi<sup>2</sup>, Stavros A. Kavouras, FACSM<sup>1</sup>, Ioannis Papassotiropoulos<sup>3</sup>, George Chrousos<sup>4</sup>, Katerina P. Skenderi<sup>1</sup>. <sup>1</sup>Harokopio University, Athens, Greece. <sup>2</sup>University of Peloponnese, Sparta, Greece. <sup>3</sup>"Aghia Sophia" Children's Hospital, Athens, Greece. <sup>4</sup>Athens University Medical School, Athens, Greece.

Email: a.gavrieli@gmail.com

(No relationships reported)

Exercise is a well-known stress factor and is able to induce an inflammatory-like status and also activates immune system. Apoptosis or programmed cell death is an important mechanism for the regulation of the immune system. Apoptosis is the immune system's major mechanism to maintain immune's system homeostasis.

**PURPOSE:** We sought investigate the effects of prolonged and brisk exercise on circulating proinflammatory cytokines and the soluble apoptosis mediators Fas (sFas) and Fas ligand (sFasL) in ultramarathon runners.

**METHODS:** In 20 male athletes participating in the ultradistance foot race of the 246 Km "Spartathlon" (continuous, prolonged, brisk exercise for up to 36 hours), we measured circulating concentrations of IL-6 using a validated Elisa kit (Quantikine; R&D Systems, Minneapolis, MN) and we determined sFas and sFasL using the multiplex assay kit Linco Human Sepsis/Apoptosis. Free plasma DNA was measured by quantitative real-time PCR using the LightCycle (Roche diagnostics, Mannheim, Germany). All the measurements were performed in samples collected before the race, at the end of the race and 48h post-race.

**RESULTS:** The mean values for IL-6 before the race (phase I) were  $0.9 \pm 0.5$  pg/ml, immediately after the race (phase II) were  $7781.0 \pm 8317.3$  pg/ml, and 48h after the race (phase III) were returned at pre-exercise levels ( $0.7 \pm 0.5$  pg/ml). DNA damage was significantly increased at phase I from  $14.8 \pm 13.9$  genome equivalents/ml to  $146.2 \pm 161.5$  genome equivalents/ml at phase II and was significantly decreased to  $51.5 \pm 73.2$  genome equivalents/ml at phase III. Lastly, apoptosis was observed to remain steady as sFas and sFas ligand were  $2.16 \pm 0.61$  ng/ml and  $0.13 \pm 0.02$  ng/ml, respectively at phase I,  $1.96 \pm 0.53$  ng/ml and  $0.12 \pm 0.02$  ng/ml, respectively at phase II and  $2.32 \pm 57$  ng/ml and  $0.13 \pm 0.02$  ng/ml, respectively at phase III.

**CONCLUSION:** Prolonged and strenuous exercise seems to induce a significant inflammatory response, which in turn induces DNA damage in cells, probably via oxidative stress's increase. However, it is observed that in well trained athletes apoptosis is not being altered because of the development of counterbalancing mechanisms.

**Exercise Increases Regulatory T Cell Suppression And Surface Expression In A Mouse Model Of Asthma**

Thomas Lowder. Univ. of Alabama at Birmingham, Birmingham, AL (Sponsor: Lisa Schwiebert, FACSM)

Email: tlowder@uab.edu

(No relationships reported)

In a mouse model of induced asthma, our lab has previously demonstrated that moderate exercise significantly reduces airway hypersensitivity (AHR) and inflammation, thereby reducing asthma severity. We hypothesized that at least some of these changes may be due in part to regulatory T cells (Tregs), a small population of T cells that have been shown to suppress inflammation and AHR in a number of disease states.

**PURPOSE:** To determine if Tregs from exercise-trained mice differ in suppression and surface expression from Tregs in sedentary mouse in an asthmatic state.

**METHODS:** Female Balb/c mice were induced into an asthmatic state (two intraperitoneal injections with ovalbumin (OVA) at days 0 and 14, followed by 5d of nebulization with OVA). OVA nebulization (10min) was administered 1h prior to exercise training (45min, 3d/wk, at 60-70% of  $\text{VO}_{2\text{max}}$  for a total of 10 bouts). Mice were sacrificed 24hr after the last exercise bout. Tissues (spleen, mediastinal lymph node (MLN), and lung) were stained for CD4+CD25+ surface expression as well as Foxp3, a marker for Tregs and analyzed via flow cytometry. Tregs were isolated from splenocytes using magnetic separation and cultured in order to measure proliferation and suppression.

**RESULTS:** Tregs from exercised mice were found to suppress effector cells at a significantly higher rate when compared with Tregs from sedentary mice ( $p < 0.05$ ). Surface expression, as assessed by CD4+CD25+ as well as Foxp3, the best-known marker for Tregs, was higher in exercised asthmatic mice when compared with sedentary asthmatic mice.

**CONCLUSION:** Exercise increases Treg surface expression on primary and secondary lymphoid organs, and Tregs from exercised mice are able to suppress significantly better than Tregs from sedentary mice.

(No relationships reported)

Delayed-type hypersensitivity (DTH) tests the ability of an individual to mount a memory T cell-dependent response against an antigen to which that individual has been previously exposed. DTH response is elicited by intradermal injection of an antigen or vaccine, and the size of the response indicates the ability of the individual's immune system to respond to the specific challenge.

**PURPOSE:** To examine the effect of a 10 mo cardiovascular exercise intervention (CARDIO) on DTH response to tetanus and candida. We hypothesized that CARDIO would increase both the number of positive responders and strength of DTH response when compared to flexibility (FLEX) controls.

**METHODS:** 137 sedentary older adults (age  $70 \pm 0.45$  yr) were randomized to CARDIO (n=69) or FLEX (n=68) groups. There were no significant group differences in fitness or body composition pre-intervention. CARDIO underwent supervised exercise 3x/wk at 65-70%  $\text{VO}_{2\text{max}}$ . FLEX underwent non-cardiovascular exercise 2x/wk. Candida DTH response for all subjects was assessed at baseline and post-intervention. Tetanus DTH response was assessed in 91 subjects (45 CARDIO, 46 FLEX) at baseline and post-intervention. Induration >5mm was considered positive response.

**RESULTS:** A 10 month CARDIO intervention improved fitness compared to FLEX. There were no between-group differences in either the percentage of responders (32 CARDIO vs. 28 FLEX,  $\chi^2=.376$ ,  $P=.540$ ) or strength of response ( $9.68 \pm 0.71$  vs.  $10.54 \pm 0.82$  mm,  $P=.430$ ) for candida DTH after intervention. There were no between-group differences in either the percentage of responders (8 CARDIO vs. 6 FLEX,  $\chi^2=.392$ ,  $P=.531$ ) or strength of response ( $7.88 \pm 0.88$  vs.  $8.83 \pm 1.49$  mm,  $P=.569$ ) for tetanus DTH after intervention. DTH responses were not different at baseline and did not correlate at either time point with any fitness measures.

**CONCLUSION:** Long-term aerobic exercise does not improve memory T cell-dependent DTH responses to common skin test antigens in older men and women when compared to non-exercising controls.

**Voluntary Wheel Running Does Not Attenuate Lps Induced Sickness Behavior In Cd-1 Mice.**

Stephen A. Martin, Sara A. Dumich, Jason C. O'Connor, Brandt D. Pence, Keith W. Kelley, Robert Dantzer, Jeffrey A. Woods, FACSM. *University of Illinois, Urbana-Champaign, Urbana, IL.*

Email: martin67@uiuc.edu

(No relationships reported)

**INTRODUCTION:** Peripheral inflammation induces acute sickness behavior and depressive-like behavior in mice via centrally mediated proinflammatory cytokine induction. Studies have demonstrated that moderate intensity exercise decreases inflammation and improves mood status.

**PURPOSE:** To examine the effect of voluntary wheel running on inflammation induced sickness behavior. We hypothesized that mice with access to running wheels would have an attenuated sickness response to peripheral inflammation compared to mice in an enriched cage setting and mice in a standard cage.

**METHODS:** 48 mice were randomized into three different housing situations: wheel access (WHL n=16), locked wheel (LWHL n=16), and standard shoebox cages (CON n=16). The study duration was 21 days, and all mice were provided standard chow and water *ad libitum*. Wheel running activity was monitored using VitalView Acquisition Software. At day 21, mice were injected with .083 mg/kg LPS or Saline. 24hr post LPS injection, acute sickness behavior and depressive like behavior were quantified via locomotor activity, forced swim test, and tail suspension test.

**RESULTS:** There was no interaction between housing conditions (WHL, LWHL, CON) and treatment (LPS/Saline) for acute sickness behavior as measured by locomotor activity. There was a main effect for treatment ( $p=.000$ ), as the LPS treated mice displayed increased acute sickness behavior (decreased locomotor activity) 24 hour post-injection. Results were similar for the forced swim test and tail suspension test, two measures of depressive-like behavior. There was no interaction between housing condition and treatment, but a main effect for treatment ( $p=.008$  and  $p=.002$ ; FST and TST), with LPS treated mice displaying higher levels of depressive like behavior.

**CONCLUSIONS:** Three weeks of voluntary wheel running or cage enrichment does not attenuate LPS induced sickness and depressive like behavior in CD-1 mice. Further studies are underway utilizing more sensitive measures to elucidate an interaction between housing condition and LPS induced sickness recovery kinetics.

**Effects Of Eccentric Exercise On The Antibody Response To A Highly Immunogenic Influenza Vaccine**

John P. Campbell, Kate M. Edwards, Victoria E. Burns, Joanna E. Long, Mark T. Drayson, Christopher Ring. *University of Birmingham, Birmingham, United Kingdom.*

Email: JPC632@bham.ac.uk

(No relationships reported)

It has been demonstrated that an acute bout of exercise prior to vaccination can improve the subsequent immune response. However, the mechanisms underpinning this adjuvant effect remain unknown, and further investigation to determine the optimal exercise protocol is warranted.

**PURPOSE:** To determine whether the timing of eccentric arm exercise prior to vaccination influences the magnitude of the adjuvant effect on the antibody response to influenza vaccine.

**METHODS:** 155 healthy participants (75 males, 80 females) were randomly assigned to a control group or one of three groups exercising immediately, 6 hours or 48 hours prior to influenza vaccination. The exercise groups performed eccentric arm exercise of the deltoid and biceps brachii muscles for approximately 20 minutes, at an intensity eliciting 85% of each participants' one repetition maximum. Serum antibody titres were measured at baseline and at 28 days post-vaccination. Plasma creatine kinase (CK) and interleukin-6 (IL-6) were measured at baseline and at the time of vaccination.

**RESULTS:** Analyses of variance indicated that the exercise groups exhibited significant increases in bicep ( $p < .001$ ) and forearm ( $p < .001$ ) circumference, self-reported arm pain ( $p < .001$ ), and plasma markers of muscle damage (CK;  $p < .05$ ) and inflammation (IL-6;  $p < .05$ ). However, there were no significant differences between groups in the antibody responses to the A/Wisconsin, A/Solomon or B/Malaysia viral strains of influenza (all  $p > .05$ ). Comparatively, all strains induced larger antibody responses than those exhibited by antigens in previous exercise and vaccination studies.

**CONCLUSION:** Eccentric arm exercise did not improve the antibody response to influenza vaccination. It is possible that the relative magnitude of the antibody response produced by each strain superseded any potential effect of exercise. This explanation is consistent with previous research which indicates that exercise may have a beneficial effect when the antigen has a lower immunogenic response. Future research should investigate the effect of exercise on the immune response to vaccines with lower immunogenicity.

**Aerobic Exercise Training May Not Offset The Pro-Inflammatory Effects Of High Fat Feeding In Mice**

Lisa M. Esposito, Richard J. Simpson, Kelley A. Strohacker, Katie C. Carpenter, Ygnacio Lopez, III, Brian K. McFarlin. *University of Houston, Houston, TX.*

Email: lmespo@gmail.com

(No relationships reported)

Increased adiposity is associated with an increase in systemic inflammation, which is involved in the pathophysiology of various disease states. A current hypothesis in our laboratory suggests that the toll-like receptor 4 (TLR4) pathway may link physical activity and systemic inflammation.

**PURPOSE:** The primary purpose was to determine if 6-weeks of aerobic exercise training (5 days per week, 1 hour per day. 21-22m/min) would limit the increase in systemic inflammation resulting from high-fat (60% of calories from fat) feeding. A secondary purpose was to determine if changes in cell-surface TLR4 expression would account for observed differences in inflammatory status between mice which exercise and those that remain sedentary.

**METHODS:** 36 CD-1 male mice were randomly assigned to one of three groups (N=12/group): HF (remained sedentary and consumed a high-fat chow (60% fat)), HF-EX (consumed the high-fat chow and underwent an aerobic exercise intervention (running 4.56±0.08 h/week for 6 weeks, or LF (sedentary and consumed a low-fat chow (10% fat)). Key outcome measurements were made on weekly saphenous vein blood samples (~40 uL) using 3-color flow cytometry. Blood glucose and cholesterol concentration were analyzed by an enzymatic assay.

**RESULTS:** Absolute and percent body weight gain over 6-weeks was similar between HF and HF-EX, but significantly greater than LF (P<0.001). HF and HF-EX had 66% more leukocytes than LF at weeks 3-5 (P<0.0001). HF and HF-EX had 145% greater CD11b+/14+/TLR4+ cells than LF (P=0.001). There was no difference in the concentration of CD11b+ cells expressing IL-6 or TNF-alpha following LPS-stimulation between HF and HF-EX. No significant difference was found for blood glucose and cholesterol concentrations between groups.

**CONCLUSIONS:** Exercise training did not prevent weight gain during 6-weeks of high fat feeding. Since HF and HF+EX gained a similar amount of weight, they did not differ with regarding to blood monocytes expressing TLR4. Both HF and HF+EX were elevated above LF. More research is needed to determine how changes in the blood relate to changes in peripheral tissue compartments.

**A Greater Vo2max Is Associated With A Reduced Frequency Of Senescent Blood T-cells In Middle-aged But Not Younger Men**

Guillaume Spielmann<sup>1</sup>, Brian K. McFarlin<sup>1</sup>, Cormac Cosgrove<sup>2</sup>, Keith Guy<sup>2</sup>, Paula JW Smith<sup>2</sup>, Richard J. Simpson<sup>1</sup>. <sup>1</sup>*University of Houston, Houston, TX.* <sup>2</sup>*Napier University, Edinburgh, United Kingdom.*

Email: g.spielmann@napier.ac.uk

(No relationships reported)

The clonal expansion of T-lymphocytes in response to an antigenic stimulus is an essential process of adaptive immunity. Chromosome telomeres become progressively eroded with each round of cell division, eventually leading to replicative senescence. T-lymphocytes with a senescent phenotype are known to accumulate with age, increasing infection risk in middle-aged and elderly individuals. A sedentary lifestyle is associated with shortened telomeres in peripheral blood leukocytes, but the influence of regular exercise on the frequency of T-cells with a senescent phenotype in young and older adults is not known.

**PURPOSE:** To examine the impact of estimated VO2max on the frequency of senescent blood T-cells in young and middle-aged men.

**METHODS:** Twenty young (Y; age: 23.4 ± 3; BMI: 24.6 ± 3) and 20 middle-aged (O; age: 54 ± 3.6; BMI: 26.4 ± 3.4) healthy males provided a fasted resting blood sample, completed an assessment of percentage body fat and a physical activity status questionnaire designed to estimate VO2max. Y and O subjects were then divided into Hi and Lo VO2max groups (VO2max; Y: 51.2 ± 4.4 vs 42.6 ± 2.2 ml·kg<sup>-1</sup>·min<sup>-1</sup>; O: 38.7 ± 3.3 vs 29.5 ± 1.3 ml·kg<sup>-1</sup>·min<sup>-1</sup>) with n=10 in each group. Isolated lymphocytes were assessed for cell surface expression of senescence (KLRG1+, CD28-, CD57+), naïve (CD45RA+) and memory (CD45RO+) T-cell markers on CD3+ T-cells, CD4+ T-cells and CD8+ T-cells using four-colour flow cytometry. Differences in T-cell phenotype among the 4-groups was analysed by one-way ANOVA.

**RESULTS:** O had a greater proportion of KLRG1+, CD57+, CD28, KLRG1+/CD57+ and CD45RA-/CD45RO+ CD8+ T-cells than Y, regardless of estimated VO2max. No differences in senescent phenotypes were found between the Hi and Lo VO2max groups in Y. In contrast, the Hi VO2max group in O had a significantly lower frequency of CD4+ and CD8+ T-cells expressing KLRG1+ (CD4: 58%; CD8: 23% less), CD57+ (CD4: 71%; CD8: 20% less), CD28- (CD4: 91%; CD8: 24% less), KLRG1+/CD57+ (CD4: 89%; CD8: 26% less) and CD45RA-/CD45RO+ (CD4: 20% less), in comparison to the Lo VO2max group in O.

**CONCLUSION:** A higher estimated VO2max is associated with a lowered frequency of senescent and memory CD4+ and CD8+ T-cells in middle-aged but not younger men. These findings highlight the beneficial effects of regular physical activity on cellular immunity during ageing.

**Exercise-induced T-cell Activation In Human Subjects Is Affected By The Mobilization Of Klrp1+ T-lymphocytes Into The Peripheral Blood**

David B. Bartlett<sup>1</sup>, Brian K. McFarlin<sup>1</sup>, Cormac Cosgrove<sup>2</sup>, Guillaume Spielmann<sup>1</sup>, Keith Guy<sup>2</sup>, Richard J. Simpson<sup>1</sup>. <sup>1</sup>*University of Houston, Houston, TX.* <sup>2</sup>*Napier University, Edinburgh, United Kingdom.*

Email: dbartlett@mail.coe.uh.edu

(No relationships reported)

**PURPOSE:** Acute exercise alters the activation status of blood T-cells, evident by changes in the cell surface expression of the early T-cell activation marker CD69. The killer cell lectin-like receptor G1 (KLRG1) is expressed on antigen-experienced T-cells which are unable to clonally expand in response to an antigenic stimulus but are capable of immediate effector functions such as recognizing and killing virally infected cells. T-cells expressing KLRG1 are preferentially mobilized into the peripheral blood in response to acute exercise, which could affect the overall activation status of blood T-cells.

**METHODS:** Ten trained males (age: 24.6 ± 4.8; height: 183.1 ± 6.7cm; mass: 72.8 ± 7.9kg; VO2max; 61.3 ± 5.9 ml·kg<sup>-1</sup>·min<sup>-1</sup>) ran at 80% VO2max until exhaustion (time: 36.1 ± 5.8 minutes). Using monoclonal antibodies and 4-colour flow cytometry, blood lymphocytes isolated before (PRE), immediately after (POST) and 1 hour after (1H) exercise were analyzed for KLRG1 and CD69 co-expression on CD3+/CD4+ and CD3+/CD8+ T-lymphocytes in response to the exercise challenge and after 4h stimulation in culture at 37°C with and without the mitogen PMA.

**RESULTS:** The proportions of KLRG1+ cells among total CD4+ and CD8+ T-cells increased by 17% and 25.2% respectively at POST, with CD8+ T-cells falling below PRE values at 1H. CD69 expression on CD4+ and CD8+ T-cells was unaffected by cell culture or the exercise challenge. When stimulated with PMA, the expression of CD69 at POST increased by 16.7% on CD4+, but decreased by 6.9% on CD8+ T-cells. KLRG1+ cells expressed higher levels of CD69 than KLRG1- cells in both CD4+ and CD8+ T-cells for all stimulated samples. CD69 expression was unaltered by coe on either KLRG1+ or KLRG1-/CD4+ T-cells. In contrast, CD69 expression fell by 11.7% on KLRG1+/CD8+ T-cells POST. No changes in CD69 expression were found on CD4+ or CD8+ T-cells at 1H.

**CONCLUSION:** The increased activation of CD4+ T-cells after exercise might be due to a greater proportion of KLRG1+ cells in blood with a heightened state of activation. In contrast, exercise appears to inhibit the ability of KLRG1+ but not KLRG1- CD8+ T-cells to become activated. As KLRG1+ T-cells are incapable of proliferation, the possibility

that exercise impacts on their effector capabilities remains to be determined.

**The Effects Of A Natural Anti-inflammatory Product On Systemic Markers Of Inflammation Following Downhill Running**

Edith M. Peters<sup>1</sup>, Megan Smith<sup>1</sup>, Aadil Docrat<sup>1</sup>, Anand Nadar<sup>1</sup>, Kovin Chetty<sup>1</sup>, Jo -Ann S. Passmore<sup>2</sup>. <sup>1</sup>University of KwaZulu-Natal, Durban, South Africa. <sup>2</sup>University of Cape Town, Cape Town, South Africa.

Email: futree@ukzn.ac.za

( E.M. PETERS, Financial Support For Expenses Was Provided By Heel Pty South Africa. The Investigational Medicinal Products (Including Placebo) Were Provide By Heel GmbH Germany Without Charge., Ownership Interest.)

Traumeel, a natural anti-inflammatory preparation, is commonly used by athletes to reduce inflammatory response to exercise-induced muscle cell damage.

**PURPOSE:** To establish whether Traumeel, taken during five days before and three days following participation, attenuates exercise-induced systemic markers of the inflammatory response.

**METHODS:** After baseline laboratory and field testing, 24 healthy athletes (14 men and 10 women) were matched according to gender, BMI, training age and status, peak performance and foot strike patterns and randomised into Traumeel (TRS) and control (PLAC) groups in a placebo-controlled, double-blind design. One TRS or PLAC tablet was ingested 3 x per day for five days prior to and three days following a 90-minute exercise trial on a downhill (-6% gradient) at 75% VO<sub>2</sub> max. Blood samples were collected prior to the 90-minute trial, immediately after the trial and 24 hours (24 PE), 48 hours and 72 hours following the trial. They were analysed for full blood count (FBC), serum creatine kinase (CK), lactate dehydrogenase (LDH), cortisol, C- reactive protein (CRP) and myeloperoxidase (MPO) and plasma interleukin (IL) -6, -8, -10 and -12p70 concentrations. Daily records of training and symptoms of delayed onset muscle soreness (DOMS) were kept during the trial period.

**RESULTS:** The 90-minute downhill running protocol resulted in significant elevations in mean circulating leukocyte, neutrophil, CK, LDH, cortisol, CPR, MPO, IL-6, IL-8 and IL-10 concentrations following both laboratory trials ( $p < 0.001$ ). When comparing the TRS and PLAC groups, mean  $\pm$  SD total and differential leukocyte count, CK, LDH, cortisol, CPR, MPO, cytokine concentrations did not differ ( $p > 0.05$ ) over the five time points. At 24 PE, MPO concentrations were significantly higher ( $p = 0.04$ ) in the TRS group ( $227.3 \pm 130.7$  ng/ml) than in the PLAC group ( $137.2 \pm 71.9$  ng/ml), while the severity of DOMS was lower in the TRS group throughout the three-day post-trial period.

**CONCLUSIONS:** The elevated MPO concentration at 24 PE provide preliminary novel evidence of enhanced activation of neutrophil oxidative burst activity following exercise-induced muscle damage which is hypothesized to accelerate the recovery process.

**The Effectiveness Of Iron Supplementation In Endurance Trained Females During The Week Of Menses**

Christianne M. Eason, Judith A. Flohr, Tammy L. Wagner, Christopher J. Womack, FACSM. James Madison University, Harrisonburg, VA.

Email: flohrja@jmu.edu

(No relationships reported)

Decreased work capacity due to iron deficiency anemia has been well documented. Athletes (particularly endurance trained) who train six or more hours per week are at a greater risk of developing an iron deficiency. Menstruating women carry an increased risk for iron deficiency regardless of training status due to monthly blood loss.

**PURPOSE:** The purpose of this study was to examine the effect of one week of iron supplementation during the week of menses on serum ferritin (SF) and serum soluble transferrin receptor (sTfR) values, heart rate recovery (HRR), blood lactate (BLAC) values, predicted VO<sub>2</sub>max (VO<sub>2</sub>max), and exercise time to reach 85% of predicated max heart rate (EXTIME).

**METHODS:** Fifteen pre-menopausal endurance trained females were randomly assigned to either an iron (FE) or placebo (PL) group. The FE group took a ferrous sulfate supplement (65mg of elemental iron) once a day for seven days during menses. Each group completed two testing sessions (baseline and menses) on a cycle ergometer to reach 85% of predicted max heart rate. Blood was taken at baseline and menses testing sessions and analyzed for BLAC, SF, and sTfR. The maximum workload achieved, time to end of trial, and HRR (within 10BPM of pre-exercise heart rate) was recorded for each participant during both trials.

**RESULTS:** There were no significant differences in sTfR and SF values between FE and PL groups for baseline, menses, or supplementation. HRR was significantly ( $p = 0.033$ ) faster in the FE group during menses testing sessions than the PL group ( $4.5 \pm 2$ ,  $8.6 \pm 6.5$  mins respectively). There was no significant difference among participants' predicted VO<sub>2</sub>max at baseline or during menses testing sessions. EXTIME was not statistically different between the iron and placebo group for baseline, menses, or supplementation effect, respectively ( $P > 0.05$ ). Pre and post exercise BLAC levels were not significantly different between iron and placebo groups for baseline, menses, or supplementation effect.

**CONCLUSION:** The significant supplementation effect on heart rate recovery in conjunction with trends observed in VO<sub>2</sub>, EXTIME, and BLAC levels are compelling. Findings illustrate one week of iron supplementation during the week of menses enhanced HRR in this sample of participants.

**Iron Supplementation Is Associated With Aerobic Performance In Iron-deficient Female Soldiers**

J. Philip Karl<sup>1</sup>, Harris B. Lieberman<sup>1</sup>, Sonya J. Cable<sup>2</sup>, Kelly W. Williams<sup>2</sup>, Andrew J. Young, FACSM<sup>1</sup>, James P. McClung<sup>1</sup>. <sup>1</sup>US Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>Directorate of Basic Combat Training, Ft Jackson, SC.

Email: james.p.karl@us.army.mil

(No relationships reported)

Iron deficiency is associated with reduced aerobic performance, and may impair the adaptive response to aerobic training. Furthermore, diminished iron status observed during basic combat training (BCT) is associated with reduced aerobic performance in female Soldiers. The effect of iron supplementation on aerobic performance during BCT is unknown.

**PURPOSE:** To determine the impact of iron supplementation during BCT on aerobic performance in female Soldiers.

**METHODS:** Utilizing a randomized, double-blind, placebo-controlled design, female Soldiers ( $n = 153$ ) were provided with pills containing either 100 mg ferrous sulfate (IRON) or placebo (PLACEBO) daily during a 9-week BCT course. Iron status indicators including red cell distribution width (RDW), serum ferritin (SF), and transferrin saturation (TS) were measured immediately prior to and following BCT. Iron deficiency was defined as presentation with two or more of the following: RDW  $> 15.0\%$ , TS  $< 16.0\%$ , SF  $< 12.0$  ng mL<sup>-1</sup>. Two-mile run time (RT) was assessed following BCT. Student's t-tests were used to compare RT between groups.

**RESULTS:** Fifty-seven (37%) Soldiers began BCT iron deficient. Within this cohort, IRON-treated Soldiers demonstrated faster RT following training than those receiving

PLACEBO (mean  $\pm$  SD); 1068  $\pm$  100 sec vs. 1154  $\pm$  100 sec,  $p < 0.01$ ). No between groups differences for RT were observed in Soldiers beginning BCT with normal iron status (1086  $\pm$  87 sec vs. 1057  $\pm$  72 sec,  $p > 0.05$ ) or overall (1080  $\pm$  92 sec vs. 1095  $\pm$  98 sec,  $p > 0.05$ ).

**CONCLUSIONS:** These data suggest that daily iron supplementation (16 mg·day<sup>-1</sup> elemental iron) may benefit aerobic performance in iron-deficient Soldiers. Future studies should focus on optimizing diet for preventing and treating iron deficiency in female Soldiers during military training. Research funded by MRMCM.

**2239 Board #127 May 28 3:30 PM - 5:00 PM**

### Effect Of Calcium Supplementation On Body Composition And Total Energy Expenditure During Sub Maximal Exercise.

Rehana Jawadwala, Stephen Atkins, Nicola Lowe. *University of Central Lancashire, Preston, United Kingdom.*

Email: rjawadwala@uclan.ac.uk

(No relationships reported)

Epidemiological data suggest a positive relationship between increased calcium intake and decreased fat and total body mass in healthy people.

**PURPOSE:** The objective of the current research was to investigate the effect of 4 weeks of calcium supplementation on Total Energy Expenditure (TEE) during submaximal exercise and to measure changes in body composition.

**METHODS:** Nine moderately trained people (n = 5 males, 4 females; age 40.56  $\pm$  9.51 yrs; stature 171.8  $\pm$  7.50 cm; mass 71.33  $\pm$  10.81kg) were tested using a randomised, double blind, placebo controlled crossover design. Subjects were assigned to a placebo (P) or 1000 mg/d of elemental calcium (citrate) (Ca) group for 4 weeks with a subsequent crossover following a 4 week wash out period. Subjects undertook a 1 hour bicycle ergometer test at 50%VO<sub>2max</sub> at the baseline and end of each intervention. Gas exchange was measured by an online Spirometer (Metalyzer II; Cortex, Leipzig, Germany). TEE was calculated using ACSM guidelines. Body composition was measured using the Harpenden skinfold callipers.

**RESULTS:** Following Ca supplementation, TEE during the 60 min exercise trial increased significantly as compared to the placebo trial ( $p < 0.05$ ) with a commensurate trend towards a decrease in total body mass ( $p = 0.20$ ) and fatness ( $p = 0.29$ ).

	After (P) (difference $\pm$ SD)	After (Ca) (difference $\pm$ SD)
TEE (kJ)	2444 $\pm$ 887	2666 $\pm$ 1063*
Body Mass(kg)	- 0.05 $\pm$ 0.54	- 0.89 $\pm$ 0.73
Fat Mass (%)	0.19 $\pm$ 0.55	- 0.59 $\pm$ 0.09
Lean Mass (%)	- 0.36 $\pm$ 1.18	0.28 $\pm$ 1.07

Table 1: Difference in TEE and body composition at the end of each intervention.

**CONCLUSIONS:** These findings indicate that Ca supplementation for 4 weeks increases TEE during submaximal exercise. This is associated with a concurrent reduction in fat mass and increase in lean mass. These results support previous research that demonstrates an inverse relationship between Ca intake and adiposity, which may be achieved by a shift towards increased fat oxidation.

**2240 Board #128 May 28 3:30 PM - 5:00 PM**

### Bone Mineral Content In Black And White Adolescents Is Related To Dairy Intake And Vigorous Physical Activity

Bernard Gutin, FACSM, Anh Le, Maribeth Johnson, Inger Stallmann-Jorgensen, Paule Barbeau, Mark Hamrick, Yanbin Dong. *Medical College of Georgia, Augusta, GA.*

Email: bernardgutin@yahoo.com

(No relationships reported)

**PURPOSE:** To determine the relations of diet and physical activity (PA) to bone mineral content (BMC) in adolescents.

**METHODS:** The subjects were black and white boys and girls 14-18 years of age (n=660). Total body BMC was measured with dual-energy X-ray absorptiometry. Diet and PA were measured with 4-7 individual, non-consecutive, 24-h recalls; 52% had recalls for all 7 days. For our analyses, we examined total energy intake and percentage of energy from carbohydrates (%CHO), protein (%PRO), and fat (%FAT). The main dietary variables were daily dairy servings, vitamin D (micrograms) and calcium intake (milligrams). The main PA variables were time spent in moderate PA (3-6 METs) and vigorous PA (>6 METs).

**RESULTS:** A base regression model containing age, sex and race was used to assess the effects of the demographic variables on BMC. There was an age by sex interaction, such that the boys increased more than the girls with increasing age ( $p < 0.01$ ). BMC was greater in the blacks than in the whites ( $p < 0.01$ ). When the diet and PA variables were added to the base model one at a time significant proportions of the variance in BMC were explained

by dairy servings, calcium, vitamin D, and vigorous (but not moderate) PA (all  $p$ 's<0.01). Because the 3 diet variables were intercorrelated, results were similar regardless of which one was included in the multivariate analysis. The figure illustrates the results for calcium and vigorous PA. Both calcium intake and vigorous PA ( $p$ 's<0.01) explained independent proportions of the variance in BMC.

**CONCLUSION:** These results are consistent with the hypothesis that youths should eat sufficient amounts of dairy foods and engage in high-intensity exercise in order to develop high levels of bone mass.

**Effects Of Vitamin C Supplementation On Substrate Utilization And Perception Of Fatigue In Overweight Men**

Corey J. Huck<sup>1</sup>, Pamela Swan, FACSM<sup>2</sup>, Carol Johnston<sup>2</sup>. <sup>1</sup>University of Wisconsin, Stevens Point, Stevens Point, WI. <sup>2</sup>Arizona State University, Mesa, AZ.

*(No relationships reported)*

Previous research suggests that vitamin C depletion modifies respiratory exchange ratio (RER) and, in particular, fat oxidation. Impaired fat oxidation has been implicated in the development of obesity and failed weight loss attempts.

**PURPOSE:** The purpose of this study was to assess the effect of vitamin C supplementation on fat oxidation and fatigue (Ratings of Perceived Exertion, RPE) during a 50-minute walk at 40% of estimated maximal oxygen consumption (VO<sub>2</sub>max) using a randomized, double-blinded, placebo-controlled, 4-week intervention trial in vitamin C-depleted overweight men.

**METHODS:** Relatively sedentary, overweight (BMI > 25 kg/m<sup>2</sup>) men (age 30.7 ± 5.9 years) unaware of their vitamin C status volunteered to participate (n = 15). Subjects were instructed to follow a vitamin C poor (~ 40 mg/day) diet for a three-week depletion period and were randomly assigned to either placebo (PL: n = 8) or vitamin C (VC: 1 g/d, n = 7). Independent t-tests and repeated measures ANOVA were used in statistical analyses, significance  $p$  < 0.05.

**RESULTS:** After the 4-week intervention, plasma vitamin C concentrations increased from baseline in VC (0.40 ± 0.20 and 1.17 ± 0.55 mg/dL, respectively) but did not change in PL (0.44 ± 0.21 and 0.56 ± 0.23) ( $p$  = 0.019 for time x group effect). There were no significant differences in measures of body weight, fat mass, BMI, physical activity, or VO<sub>2</sub>max. Exercise RER decreased in both groups (PL: -0.041 ± 0.052; VC: -0.009 ± 0.048) and nearly reached significance in PL ( $p$ -value = 0.079), however, after adjusting for the effects of change in body weight (placebo: -0.83 ± 1.27; vitamin C: 0.27 ± 1.33 kg) and physical activity (placebo: 4.38 ± 14.22; vitamin C: 2.29 ± 4.54 MET-hrs/wk), this trend was no longer observed ( $p$ -value = 0.429). No significant differences between groups were noted during the 50-minute walk in any of the exercise indices.

**CONCLUSIONS:** In summary, vitamin C did not appear to stimulate fat oxidation or lower RPE in free-living, vitamin C-depleted, overweight men during submaximal exercise. Modest acute changes in body weight and physical activity may have a greater role in eliciting beneficial alterations of substrate utilization.

**A Randomized, Placebo-controlled Trial Of Vitamin C Supplementation And Upper Respiratory Infections In Swimmers**

Naama W. Constantini, FACSM<sup>1</sup>, Elliot M. Berry<sup>1</sup>, Eyal Ben-Basat<sup>1</sup>, Avner H. Cohen<sup>2</sup>, Gal Dubnov-Raz<sup>1</sup>. <sup>1</sup>Hadassah-Hebrew University Medical Center, Jerusalem, Israel. <sup>2</sup>Clalit Health Services, Petah Tikva, Israel.

Email: naamacons@gmail.com

*(No relationships reported)*

In a recent Cochrane review, a promising potential role for vitamin C supplementation in decreasing the rate of common colds in runners was identified. We are unaware of such studies in swimmers, a population at high risk of upper respiratory illnesses.

**PURPOSE:** To determine the effect of vitamin C supplementation on the rate, length and severity of upper respiratory tract infections in adolescent swimmers.

**METHODS:** 39 healthy competitive adolescent swimmers (mean age 13.5±1.5 years; 22 males, 17 females; mean training volume 15 hrs/wk) were randomized to receive either vitamin C supplementation (1 g/day) or placebo, given in a double-blinded fashion, for 3 winter months. Incidence, length and severity of upper respiratory infections were documented daily by diaries. Plasma vitamin C levels were obtained on the 8<sup>th</sup> week of study.

**RESULTS:** Swimmers in the vitamin C group had a mean of 3.1±1.9 common cold events during the study period; swimmers in the placebo group had a mean of 3.1±2.3 events, ( $p$ =0.93). The mean duration of cold episodes was 6.6 days in the intervention group and 8.2 in controls ( $p$ =0.3). The total number of sick days during the 3-month study period was high, averaging 23 days in the intervention group and 27 days in controls ( $p$ =0.57). There was no difference in the self-assessed severity of cold events. Plasma vitamin C levels did not differ between groups (1706±700ng/ml vs. 1440±560ng/ml,  $p$ =0.27), and did not correlate with rate, length or severity of cold events.

**CONCLUSIONS:** In this randomized, double-blinded, placebo controlled study of vitamin C supplementation in adolescent swimmers, at a dose of 1gr/day for 3 winter months, no decrease in the rate, length or severity of upper respiratory infections was found. Altogether, swimmers had an average of one cold event per month, lasting more than a week, so that over 25% of the time, these high-level competitive swimmers were sick. Yet based on our findings, vitamin C supplementation should not be considered as a method to decrease the highly prevalent common colds in swimmers.

**Low Vitamin D Levels In Young Qatari Females**

Justin Grantham, Chi Kei Li, Olivier Girard, Ivana Matic, Bruce Hamilton, Sebastien Racinais. ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar.

Email: justin.grantham@aspetar.com

*(No relationships reported)*

Vitamin-D is synthesized in the skin under stimulation of UV light and is available in lesser quantities in some foods. Despite the Middle East experiencing high sunlight levels, women have been shown to have low Vitamin-D levels. This has been attributed to cultural requirements of wearing body covering clothing, and could have significant implications for bone density.

**PURPOSE:** To assess Vitamin-D status in adolescent Qatari girls with concomitant measures of bone health and physical fitness.

**METHODS:** Fifty-four girls (11.7 ± 1.5 yrs) were studied. A step-test was performed to exhaustion to measure aerobic fitness and a fasting blood sample was taken. Anthropometric measures of height and weight were recorded and Dual Energy X-ray Absorptiometry (DEXA) scanning was used to assess hip and spine bone mineral density (BMD).

**RESULTS:** Only one of the 54 girls had a serum 25-hydroxyvitamin D (25-OHD) above 20 ng/ml, 16 girls were between 10-20 ng/ml and the remainder all had levels below 10 ng/ml. Twenty seven girls recorded a 25-OHD less than 7 ng/ml. BMI ranged from 13.5 to 32.4 kg/m<sup>2</sup> with a mean of 19.5 kg/m<sup>2</sup> and the aerobic fitness ranged from 15 to 46 ml/kg/min<sup>-1</sup> with a mean of 27.2 ml/kg/min<sup>-1</sup>. When comparing the 20 % "worst" and 20 % "best" significant differences in L2-L4 (0.52 v 0.95 g/cm<sup>2</sup>), hip neck (0.47 v 0.68 g/cm<sup>2</sup>), and total hip (0.57 v 0.89 g/cm<sup>2</sup>) BMD existed between those with the lowest and highest BMI ( $P$ <0.05). The 20 % highest BMI had a significantly ( $P$ >0.005) lower VO<sub>2</sub>max (19.2 ml/kg/min<sup>-1</sup>) than those with the 20 % lowest BMI (31.3 ml/kg/min<sup>-1</sup>). Similarly, the girls with the lowest 25-OHD had a significantly lower ( $P$ <0.05) VO<sub>2</sub>max (23.5 ml/kg/min<sup>-1</sup>) than those with the highest 25-OHD (30.6 ml/kg/min<sup>-1</sup>).

**CONCLUSIONS:** Vitamin-D deficiency was highly prevalent in this cohort of adolescent Qatari girls. These data suggest that at this early age that a higher body mass is

protective to the skeleton, compensating for Vitamin-D deficiency and low levels of physical activity. Longitudinal studies are needed to track the long term effect of these factors upon metabolic deterioration and bone health.

**2244 Board #132 May 28 3:30 PM - 5:00 PM**  
**Vitamin D Deficiency In Middle Eastern Sportsmen**

Bruce Hamilton, Claude Tremblay, Cristiano Eirale, Sebastien Racinais, Justin Grantham. *ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar.*  
Email: bruce.hamilton@aspetar.com  
(No relationships reported)

Vitamin-D deficiency is well recognized in Middle Eastern Women and is increasingly associated with chronic health conditions such as low bone density, diabetes and cancer. Vitamin-D is synthesized in the skin under stimulation of UV light and is available in lesser quantities in some foods. The Vitamin-D status of Middle Eastern Men is not well described in the literature.

**PURPOSE:** To assess the Vitamin-D Status of professional and semi-professional sportsmen in the Middle East.

**METHODS:** As part of their routine medical screening 93 Middle Eastern male athletes (age  $21.3 \pm 6.9$  years; BMI  $22.6 \pm 4.1$  kg/m<sup>2</sup>) completed a questionnaire and had blood taken for Vitamin-D and bone health markers.

**RESULTS:** Mean Vitamin-D (25-OH) levels observed were 12.4 ng/ml (range 7-28). Fifty-eight percent had Vitamin-D 25-OH levels less than 10 ng/ml, and 33% had levels less than 20 ng/ml. The remainder all had levels less than 30 ng/ml. None of the athletes reported a history of bone stress injuries or routinely supplemented with Vitamin-D. Eighty percent of athletes reported completing 100% of their training outdoors. Individuals with low Vitamin-D levels were significantly more likely to be dark skinned compared to fair or olive skin colouring ( $p < 0.05$ ). Vitamin-D levels did not vary significantly depending on reported sunlight exposure, skin covering or sunscreen use.

**CONCLUSIONS:** Severe Vitamin-D deficiency was highly prevalent in this cohort of Middle Eastern Sportsmen and skin colour was the only variable to correlate with Vitamin-D deficiency. Training outdoors was not protective against Vitamin-D deficiency, reflecting the tendency to train early or late in the day. Given the potential long term health impact of Vitamin-D deficiency, recognition and correction of this deficient state is vital in this group.

**2245 Board #133 May 28 3:30 PM - 5:00 PM**  
**Repeated Bouts Of Exercise And Vitamin E Supplementation: Effect On Inflammatory Markers In Men**

Masashi Miyashita, Kiyoji Tanaka, FACSM. *University of Tsukuba, Tsukuba, Japan.*  
(No relationships reported)

Some, but not all, previous studies have shown that vitamin E supplementation is effective in attenuating C-reactive protein (CRP) and interleukin-6 (IL-6) concentrations following a single bout of strenuous exercise. However, little is known about the influence of vitamin E supplementation on inflammatory markers after repeated bouts of strenuous exercise.

**PURPOSE:** To examine whether vitamin E supplementation can attenuate CRP and IL-6 concentrations after prolonged repeated bouts of strenuous cycling in healthy young men.

**METHODS:** Eight young males (aged 21-30 y) received a vitamin E supplement (300 mg/day) or a placebo (control) for 14 days separated by an interval of at least 1 month in a randomised, counterbalanced design. On day 12 of both trials, the subjects cycled at 80% of maximal heart rate in two, 90-min bouts (150 min rest between each). In each trial, venous blood samples were collected on days 1 (baseline), 12 (pre- and post-exercise 1 and pre- and post-exercise 2), 13, 14, and 15.

**RESULTS:** After 14 days of supplementation, serum  $\alpha$ -tocopherol concentrations increased in the vitamin E trial (mean  $\pm$  SEM, Day 1,  $19.7 \pm 0.9$   $\mu$ mol/L; Day 15,  $40.9 \pm 2.1$   $\mu$ mol/L,  $P < 0.0005$ ) but not the placebo trial (Day 1,  $21.5 \pm 1.2$   $\mu$ mol/L; Day 15,  $19.7 \pm 0.7$   $\mu$ mol/L). In both trials, serum CRP concentrations did not differ between trials and over time (vitamin E,  $0.2 \pm 0.1$  mg/L; placebo,  $0.2 \pm 0.1$  mg/L, mean of 8 measurements). Peak serum IL-6 concentrations observed at the end of the second bouts of exercise did not differ between trials (vitamin E,  $4.2 \pm 0.7$  pg/mL; placebo,  $4.3 \pm 1.0$  pg/mL) and serum IL-6 concentrations did not differ at any time points during the remainder of both trials.

**CONCLUSION:** The study demonstrates that short-term vitamin E supplementation appears to have no effect on attenuating serum CRP and IL-6 concentrations in response to repeated bouts of prolonged cycling in healthy young men.

**Relationship Between Gross Motor Skill And Social Behavior In Children With Autism**

Chien-Yu Pan<sup>1</sup>, Chia-Hua Chu<sup>1</sup>, Hyun-Kyoung Oh<sup>2</sup>. <sup>1</sup>National Kaohsiung Normal University, Kaohsiung, Taiwan. <sup>2</sup>California State University, San Bernardino, CA.  
Email: chpan@nknuc.nknu.edu.tw  
(No relationships reported)

Significant deficits in social behaviors have been reported among children with autism spectrum disorders (ASD), and there is growing recognition that individuals with ASD experience motor difficulties (Berkely et al., 2001; Miyahara et al., 1997). Children with ASD experience early challenges in motor skills, which further correlate with social engagement skill deficits (Trevarthen & Daniel, 2005). However, ASD children with motor deficits were not more likely to receive service than those without the motor deficits, and research investigating the relationship between gross motor skill and social behavior of children with ASD has been limited.

**PURPOSE:** To measure the relationship between gross motor skill and social behavior in children with ASD.

**METHODS:** Sixteen (Asperger, n=8; high-functioning autism, n=8) boys with ASD aged 6-10 ( $7.23 \pm 1.05$  yrs) participated. The Test of Gross Motor Development (TGMD-2; Ulrich, 1985) was used to assess six locomotor skills (run, gallop, hop, leap, horizontal jump, and slide) and six object control skills (striking a stationary ball, stationary dribble, catch, kick, overhand throw, and underhand roll). The School Social Behavior Scales (SSBS-2; Merrell, 2002) was rated by the child's school classroom teacher to assess social competence (peer relations, self-management/compliance, academic behavior) and antisocial behavior (hostile/irritable, antisocial/aggressive, defiant/disruptive). Data are reported as standard score and T-score. Pearson product-moment correlation coefficients were calculated to evaluate the relationship between gross motor skill and social behavior. Significance was set at  $p < 0.05$ .

**RESULTS:** Findings indicate that (a) object control skills were positively correlated with peer relations ( $r_{16} = 0.65$ ,  $p < 0.01$ ), self-management ( $r_{16} = 0.58$ ,  $p < 0.05$ ), and social competence ( $r_{16} = 0.66$ ,  $p < 0.01$ ), (b) gross motor quotient was positively correlated with peer relations ( $r_{16} = 0.64$ ,  $p < 0.01$ ), self-management ( $r_{16} = 0.58$ ,  $p < 0.05$ ),

and social competence ( $r_{16} = 0.61, p < 0.05$ ), and (c) locomotor skills were not correlated with any social behavior variable.

**CONCLUSION:** The better motor skill the child with ASD performed, the more likely the child was to be socially competent.

**2247 Board #135 May 28 2:00 PM - 3:30 PM**  
**Force Variability Due To Strength Differences In Discrete And Continuous Force Control Tasks**

Edward Ofori, Jacob J. Sosnoff, Les G. Carlton. *University of Illinois, Urbana, IL*

*(No relationships reported)*

**PURPOSE:** To examine the relation between muscular strength and force variability in discrete and continuous force control tasks.

**METHODS:** Twenty-four healthy young adults produced discrete and continuous isometric force production via elbow flexors to 7 absolute force levels (30, 45, 60, 75, 90, 105, & 120 N). Maximal voluntary contraction (MVC), the relative (coefficient of variation), and absolute (standard deviation) magnitude of force variability were determined.

**RESULTS:** As expected there were strength differences between the discrete and continuous force control tasks [ $F(1,23) = 27.82; p < .05$ ]. In the discrete force control task, MVC was positively correlated ( $r = .15$  to  $.49$ ) with CV as force level increased. However in the continuous force control tasks, the correlation between MVC and CV decreased as force level increased ( $r = .38$  to  $-.48$ ).

**CONCLUSIONS:** In discrete tasks, force variability increases as strength increases, suggesting that stronger individuals are more variable at discrete force control tasks. In continuous tasks, force variability decreases as strength increases, suggesting that stronger individuals are less variable in continuous force control tasks. This suggests that the mechanisms regulating discrete and continuous force variability are partly related to muscular strength and the effect of muscular strength on force variability are task dependent.

**2248 Board #136 May 28 2:00 PM - 3:30 PM**  
**Post-activation Potentiation following Conditioning Contractions of Maximal And Sub-maximal Intensity**

Joni A. Mettler, Lisa Griffin. *The University of Texas at Austin, Austin, TX.*

Email: jmettler@mail.utexas.edu

*(No relationships reported)*

Post-activation potentiation (PAP) is an increase in muscular force following voluntary contractile activity. It is well known that PAP occurs following maximal voluntary contraction (MVC); however, little is known regarding sub-maximal contractions or the contraction duration needed to elicit maximal PAP.

**PURPOSE:** To compare maximal PAP following voluntary conditioning contractions (CC) of maximal and sub-maximal intensity and to compare the contraction duration needed to achieve maximal PAP at each intensity.

**METHODS:** First five unpotentiated single twitches were evoked with surface electrical stimulation of the ulnar nerve at the wrist. The nine participants ( $24.2 \pm 4.2$  yrs) then performed the following intermittent, isometric thumb adduction CC protocols in random order: 25%, 50% and 100% MVC. Each CC was held 5s followed by a 2s rest interval in which a single twitch was elicited. This pattern was repeated until the twitch force was maximally potentiated. A 20s 25% MVC CC protocol and a 10s 50% MVC CC protocol matched for force-time integral to the 5s 100% MVC CC were also included in the random order. Maximal twitch force potentiation was calculated as the percent increase in twitch force following the CCs compared to the unpotentiated twitch force. Repeated measures ANOVA was used to compare: 1) unpotentiated vs. potentiated twitch force within and between protocols, 2) PAP between force-time integral matched protocols and 3) contraction duration needed to produce maximal PAP between protocols.

**RESULTS:** Twitch force increased following the 50% (mean,  $\pm$  SE:  $23.1 \pm 5.2\%$ ,  $p = .003$ ) and 100% ( $45.2 \pm 10.0\%$ ,  $p < .001$ ) CC protocols, but did not increase following the 25% ( $7.6 \pm 2.3$ ,  $p > 0.05$ ) CC protocol. Maximal PAP was greater for the 100% vs. the 50% and 25% CCs ( $p < .001$ ) and 50% was greater than the 25% CC ( $p = .017$ ). PAP was not different between force-time integral matched protocols ( $p > 0.05$ ). The contraction duration that produced maximal PAP was not different between the 50% and 100% CC protocols ( $29.4 \pm 2.8$  and  $21.1 \pm 2.2$ ,  $p > 0.05$ ).

**CONCLUSIONS:** Although PAP is greater following maximal compared to sub-maximal voluntary contraction, PAP does occur following sub-maximal contraction. Also, the duration of contraction necessary to produce maximal PAP may be dependent on the intensity of muscle contraction.

**The Effects Of Motor Imagery On Performance Of A Motor Task**

Brendon S. Hale<sup>1</sup>, Jack S. Raglin, FACSM<sup>2</sup>, David M. Kocaja<sup>2</sup>. <sup>1</sup>Mississippi State University, Mississippi State, MS. <sup>2</sup>Indiana University, Bloomington, IN.

*(No relationships reported)*

Mental imagery of a motor task has been hypothesized to improve performance in physical activities. It has been suggested mental imagery engages the motor system and activates the cortex during motor imagery positively influencing performance.

**PURPOSE:** To investigate the effects of mental imagery practice on the performance of a motor task.

**METHODS:** 25 adult participants ( $M=22.8$  years,  $SD=5.4$ ; 15 females, 10 males) were examined. Participants mentally imagined a plantar flexion movement of the right foot at two intensities: 20 and 60% of maximum voluntary contraction upon completion of a series of practice trials at these intensities. Five control subjects completed the entire testing protocol but did not perform mental imagery. The subject data was analyzed by calculating the absolute, variable, and constant error scores after conversion into FtLbs.

**RESULTS:** Absolute error (AE) scores for the experimental group in practice were 0.98 FtLbs in the 20% and 1.43 FtLbs in the 60% condition. AE scores for the control group were 1.35 FtLbs in the 20% and 1.88 FtLbs in the 60% condition. Post-imagery performance AE scores were 2.29 FtLbs in the 20% and 1.39 FtLbs in the 60% condition. Control group post scores were 2.78 FtLbs in the 20% and 1.88 FtLbs in the 60% condition. Variable error (VE) scores for the experimental group in practice were 4.61 FtLbs in the 20% and 12.75 FtLbs in the 60% condition. VE scores for the control group were 6.19 FtLbs in the 20% and 15.71 FtLbs in the 60% condition. Post-imagery VE scores were 5.74 FtLbs in the 20% and 13.05 FtLbs in the 60% condition. The control group post scores were 8.1 FtLbs in the 20% and 16.5 FtLbs in the 60% condition. Constant error (CE) scores for the experimental group in practice were 0.9 FtLbs in the 20% and -1.31 FtLbs in the 60% condition. CE scores for the control group were 1.35 FtLbs in the 20% and -1.65 FtLbs in the 60% condition. Post-imagery CE scores were 2.21 FtLbs in the 20% and 0.34 FtLbs in the 60% condition. The control group post scores were 2.78 FtLbs in the 20% and -0.6 FtLbs in the 60% condition.

**CONCLUSION:** Imagery practice in the current study did not influence the accuracy of sub-maximal contractions at either the 20% or 60% MVC conditions, nor was there a reduction in the measures of error following imagery practice.

**Musculoskeletal Profile Of Elite Adolescent Female Athletes In Weight-loaded And Weight-supported Sports**

David A. Greene, Geraldine A. Naughton, Elizabeth Bradshaw, Mark Moresi. *Australian Catholic University, Sydney, Australia.* (Sponsor: Dr Mike Climstein, FACSM)

Email: david.greene@acu.edu.au

(No relationships reported)

In highly-active adolescent athletes, knowledge of skeletal responses to prolonged physical demands is largely derived from two-dimensional technology using dual x-ray absorptiometry. A more advanced understanding of skeletal responses in adolescent athletes is possible using Peripheral Quantitative Computerized Tomography (pQCT). Data acquired from pQCT include bone geometry and micro-architecture which are expected to be more positively influenced by high-impact sports, including gymnastics and athletics, than weight-supported sports such as water polo.

**PURPOSE:** (i) to profile the musculoskeletal health of adolescent female athletes competing at the aspiring elite level in gymnastics, track and field, water polo and less active, age- and sex- matched peers.

**METHODS:** Musculoskeletal parameters of the distal tibia and distal radius was assessed using pQCT in four groups of adolescent females (mean age 14.9 years) comprised of gymnasts (n = 25), track and field (n = 34), water polo (n = 30), and controls (n = 28). Trabecular area and density, cortical area and density, and bone strength was calculated.

**RESULTS:** After covarying for tibial length, gymnasts displayed greater trabecular density, trabecular area, and bone strength ( $p < 0.001$ ) at the 4% distal tibial site compared with water polo athletes and controls. Track and field athletes displayed greater cortical bone area at 14%, 38% and 66% distal tibial sites ( $p < 0.001$ ). Bone strength was greater in weight-loaded sports at 38% distal tibial site compared with water polo athletes and controls ( $p < 0.001$ ). At the 4% distal radius, gymnasts had greater trabecular density, trabecular area, and bone strength compared with track and field, water polo and controls ( $p < 0.001$ ). Compared with water polo and controls, weight-loaded sports showed greater cortical bone area at the 66% distal radial site ( $p < 0.001$ ).

**CONCLUSIONS:** Microarchitectural bone at the distal tibia and radius may be positively influenced by multi-axial, high impact loads associated with gymnastics. Axial compressive loads commonly experienced by track and field athletes may also contribute to greater cortical bone area at the distal tibia and mid-shaft regions. Results support the osteogenic benefits of weight-loaded activities compared to weight-supported sports and non-active controls.

**Effect Of Resistance Training On Carnosine Concentration In Human Skeletal Muscle**

Yasuhiro Suzuki<sup>1</sup>, Kazushige Goto<sup>2</sup>, Hideyuki Takahashi<sup>1</sup>, Kaoru Takamatsu<sup>3</sup>. <sup>1</sup>*Japan Institute of Sports Sciences, Kita-ku Tokyo, Japan.* <sup>2</sup>*Waseda University, Tokorozawa Saitama, Japan.* <sup>3</sup>*Ryutsu Keizai University, Ryugasaki Ibaraki, Japan.* (Sponsor: Robert Kraemer, FACSM)

Email: suzuki.yasuhiro@jiss.naash.go.jp

(No relationships reported)

Carnosine ( $\beta$ -alanyl-L-histidine) is a dipeptide containing histidine and is present in vertebrate skeletal muscles. It has been reported that carnosine contributes to physico-chemical buffering to maintain acid-base balance during high-intensity exercise. Moreover, it has been shown that the repeated accumulation of hydrogen ion with high-intensity exercise training is necessary to increase in carnosine concentration. However, the effects of most type of the training on skeletal muscle carnosine concentration are unclear.

**PURPOSE:** The purpose of the present study was to determine the effects of resistance training on skeletal muscle carnosine concentration.

**METHODS:** Fifteen active but not well-trained healthy males were assigned to either a "Strength-type" (S-type; n= 7) or a "Hypertrophy type" (H-type; n = 8) group and performed leg press exercise twice a week for 8 weeks. The S-type regimen consisted of 5 sets at 90% of 1 repetition maximum (RM) with 3-min rest periods between sets, whereas the H-type regimen consisted of 5 sets at 70% of 1RM with 1-min rest periods between sets. Muscle volume was measured using a magnetic resonance imaging (MRI). Muscle biopsy samples were taken from the vastus lateralis at rest before and after training. The carnosine concentration was determined using an amino acid autoanalyzer.

**RESULTS:** After the 8 weeks of resistance training, muscle volume of thigh and 1RM of leg press were significantly ( $p < 0.05$ ) increased in both groups. In addition, percentage change in muscle volume was larger in the H-type group than that in the S-type group. However, carnosine concentration was not significantly increased in either group.

**CONCLUSIONS:** These results suggest that resistance training does not improve skeletal muscle carnosine concentration regardless of the type of regimen.

**2252 Board #140 May 28 3:30 PM - 5:00 PM**

**Effect Of Reduced Training Frequency In Walk Exercise With Blood Flow Restriction Among Older Subjects**

Satoshi Fujita, Mikako Sakamaki, Masato Sugaya, Hayao Ozaki, Yoshiaki Sato, Takashi Abe. *University of Tokyo, Chiba, Japan.* (Sponsor: Michael G. bembien, FACSM)

(No relationships reported)

Low-intensity resistance exercise combined with blood flow restriction (BFR) has been shown to increase muscle size and strength comparable to those observed after high-intensity training. As such, we have recently demonstrated that the slow walk training combined with blood flow restriction of active limbs (W-BFR) increased muscle mass and strength in young subjects. However, impact of W-BFR on muscle size and function among older individuals has not been explored.

**PURPOSE:** To determine the physiological response of W-BFR with different exercise frequency on muscle mass and strength as well as bone turnover in older individuals.

**METHODS:** Sixteen older women and men (60-78 yrs) were randomized into either W-BFR (n=11) or non-exercise control (CON; n=5) group. W-BFR group walked on the treadmill for 20min at 4.0 km/min. Initially W-BFR group exercised 5 times/wk for 6 weeks, followed by 2 times/wk for 12 weeks. Muscle size and strength as well as blood concentration of anabolic hormones and bone-specific alkaline phosphatase (BAP) were assessed before (pre), at 6<sup>th</sup> week (post-1), and 18<sup>th</sup> week (post-2; W-BFR only).

**RESULTS:** After the initial 6 weeks of training, ultrasound estimated thigh muscle mass increased by 11% (pre:5.3±0.6 kg, post:5.9±0.5 kg,  $P < 0.05$ ) while no change was observed in CON (pre:5.1±0.7, post:4.9±0.7kg,  $P > 0.1$ ). Isokinetic knee extension and flexion strength and isometric knee extension strength all increased in K-WALK (8 to 14%,  $P < 0.05$ ) while no significant increase was seen in CON group ( $P > 0.1$ ). After 12 additional weeks of reduced frequency of training, muscular strength and muscle size were well maintained in K-WALK group without any notable change in muscle mass or strength ( $P > 0.10$ ). While no change in hormonal concentrations were observed in resting condition throughout the training period, blood concentration of BAP increased significantly (pre: 23.7±9.4 U/l, post-2; 31.2±13.8 U/l,  $P < 0.05$ ) at 18<sup>th</sup> week in K-WALK group.

**CONCLUSION:** Walk training combined with blood flow restriction increased muscle size and strength when performed 5times/wk in the elderly. Furthermore, additional 2 times/wk training regimen can maintain the training response and increase bone turnover over 12 week period.

**Effects Of Intensive Interval And Resistance Training On Muscle Size And Function During Unloading**

Hiroshi Akima<sup>1</sup>, Kohei Watanabe<sup>2</sup>, Keisho Katayama<sup>1</sup>, Koji Ishida<sup>1</sup>, Teruhiko Koike<sup>1</sup>. <sup>1</sup>Research Center of Health, Physical Fitness & Sports, Nagoya University, Nagoya, Aichi, Japan. <sup>2</sup>Graduate School of Education and Human Development, Nagoya University, Nagoya, Aichi, Japan. (Sponsor: Katsumi ASANO, FACSM)  
Email: akima@nagoya-u.jp  
(No relationships reported)

We reported that intensive interval training during 20 days of unloading prevented atrophy of the quadriceps femoris (QF) muscles. However, this training was not effective to attenuate a decrease of maximum muscle strength.

**PURPOSE:** The purpose of this study was to clarify the effects of intensive interval and resistance training on size and function of human skeletal muscle during 20 days of unilateral lower limb unloading.

**METHODS:** Twelve healthy men participated in this study and were divided into two groups: unloading with training (Tr group, n = 6) and unloading only (UL group, n = 6). Both groups underwent lower limb unloading of the left leg for 20 days. Exercise training consisted of an interval exercise protocol of 2- to 3-min intervals alternating between 40% and 80% of peak oxygen uptake and a dynamic leg press protocol of 4 sets of 10 repetitions with 70% one-repetition maximum (1RM) with the unloaded leg on every other days during the experimental period. Maximum voluntary contraction (MVC) during isometric knee extension and 1RM during dynamic leg press was measured. Anatomical magnetic resonance imaging (MRI) of the thighs was taken to calculate volume of the QF muscles. Muscle functional MRI (spin-echo, TR/TE 2000/30, 60 msec) of the QF muscles was obtained during submaximal dynamic knee extension exercise (5 sets of 10 repetitions) at a load of 33%MVC.

**RESULTS:** MVC in the Tr ( $532 \pm 178$  N to  $453 \pm 132$  N; -14%,  $P < 0.05$ ) and UL ( $495 \pm 167$  N to  $394 \pm 114$  N; -19%,  $P < 0.05$ ) groups significantly decreased after unloading. 1 RM during leg press for the Tr group significantly increased ( $138 \pm 33$  kg to  $152 \pm 39$  kg; 10%,  $P < 0.05$ ); while in the UL group significant decreased ( $141 \pm 38$  kg to  $115 \pm 32$  kg; -18%,  $P < 0.05$ ). The volume of the QF muscles in the unloading leg in the Tr group did not change after unloading ( $2472 \pm 279$  cm<sup>3</sup> to  $2470 \pm 253$  cm<sup>3</sup>, 0%, N.S.); while, that in the UL group significantly decreased ( $2252 \pm 450$  cm<sup>3</sup> to  $2111 \pm 452$  cm<sup>3</sup>, -6%,  $P < 0.05$ ). There was no significant difference in muscle functional MRI between Tr group and UL groups.

**CONCLUSIONS:** These results suggest that intensive interval and resistance training during 20 days of unloading was effective for prevention of muscle strength and atrophy.

**Changes In Muscle Volume And Strength Following 16 Weeks Of Training Using The Advanced Resistive Exercise Device (ARED) And Free Weights**

Roxanne E. Nash<sup>1</sup>, James A. Loehr<sup>2</sup>, Stuart MC Lee<sup>2</sup>, Kirk L. English<sup>3</sup>, Harlan Evans<sup>2</sup>, Scott A. Smith<sup>2</sup>, R Donald Hagan<sup>4</sup>. <sup>1</sup>University of Houston, Houston, TX. <sup>2</sup>Wyle Integrated Science and Engineering, Houston, TX. <sup>3</sup>JES Tech, Houston, TX. <sup>4</sup>Johnson Space Center, Houston, TX.  
Email: roxanne.e.nash@nasa.gov  
(No relationships reported)

Spaceflight-induced muscle atrophy and loss of muscle strength, particularly in the postural and locomotory muscles, might impair task performance during long-duration space missions and planetary exploration. High-intensity free weight (FW) resistive exercise training attenuates muscle atrophy and strength loss during bed rest, a space flight analog. NASA developed the Advanced Resistive Exercise Device (ARED) to simulate the characteristics of FW exercise (i.e. constant resistance, inertial forces) and to be used as a countermeasure during International Space Station (ISS) missions.

**PURPOSE:** To compare the efficacy of ARED and FW training for inducing muscle hypertrophy and strength gains in ambulatory subjects prior to deploying ARED on the ISS.

**METHODS:** Twenty untrained subjects were assigned to either the ARED (8 males, 3 females) or FW (6 males, 3 females) training group and participated in a periodized training protocol consisting of squat (SQ), heel raise (HR), and deadlift (DL) exercises 3 d-wk<sup>-1</sup> for 16 wks. SQ, HR, and DL muscle strength (1RM) was measured before, after 8 wks, and after 16 wks of training. Muscle volume of the vasti group (V), hamstring group (H), hip adductor group (ADD), medial gastrocnemius (MG), lateral gastrocnemius (LG), and deep posterior muscles including soleus (DP) was measured using MRI at pre- and post-training. Consecutive cross-sectional images (10mm slices) were analyzed and summed. Anatomical references insured that the same muscle sections were analyzed pre- and post-training. Two-way repeated measures ANOVAs ( $p < 0.05$ ) were used to test for differences in muscle strength and volume between training devices.

**RESULTS:** SQ, HR, and DL 1RM increased in both FW (mean $\pm$ SE; SQ:  $49 \pm 6\%$ , HR:  $12 \pm 2\%$ , DL:  $23 \pm 4\%$ ) and ARED (SQ:  $31 \pm 4\%$ , HR:  $18 \pm 2\%$ , DL:  $23 \pm 3\%$ ) groups. Both groups increased muscle volume in the V (FW:  $13 \pm 2\%$ , ARED:  $10 \pm 2\%$ ), H (FW:  $3 \pm 1\%$ , ARED:  $3 \pm 1\%$ ), ADD (FW:  $15 \pm 2\%$ , ARED:  $10 \pm 1\%$ ), LG (FW:  $7 \pm 2\%$ , ARED:  $4 \pm 1\%$ ), MG (FW:  $7 \pm 2\%$ , ARED:  $5 \pm 2\%$ ), and DP (FW:  $2 \pm 1\%$ , ARED:  $2 \pm 1\%$ ) after training. There were no between-group differences in muscle strength or volume.

**CONCLUSIONS:** The increase in muscle volume and strength following ARED training is not different than FW training. These findings indicate that ARED will likely protect against spaceflight-induced muscle atrophy and strength loss.

**Influence Of Physical Activity On Muscle And Fat Depots Assessed By pQCT**

Katrina L. Butner, Kyle W. Creamer, William G. Herbert, FACSM. Virginia Tech, Blacksburg, VA.  
Email: kbutner@vt.edu  
(No relationships reported)

The location and mass of adipose tissue affects disease risk, especially when located centrally. Although physical activity (PA) can attenuate fat accumulation over the total body and trunk, effects on fat depots in the limbs is limited. Analysis of the soft tissues of the limbs, including adipose depots, is possible with magnetic resonance imaging (MRI) and peripheral quantitative computed tomography (pQCT). Specifically, intermuscular adipose tissue (IMAT), the adipose tissue within the fascia surrounding muscle, has been explored (Miljkovic-Gacic et al. *Am J Clin Nut* 2008). MRI analysis has shown associations between higher concentrations of IMAT and insulin resistance, type II diabetes, and reduced muscular strength. However the relationship of PA with IMAT has not been fully explored.

**PURPOSE:** To evaluate the influence of PA on IMAT, subcutaneous fat, and muscle area of the non-dominant foreleg in comparison with total and central body fat.

**METHODS:** 70 pre-menopausal women (Mean age  $\pm$  SD  $38.4 \pm 4.7$  yr) underwent dual energy X-ray absorptiometry (DXA) scans to assess total and central fat and pQCT measurements at a point 66 percent from the tibial distal end to quantify muscle and fat cross-sectional areas. Four day self-reported PA and pedometer step count was translated into MET level x time and then averaged. Subjects were divided into PA tertiles; low active (n=23;  $249.4 \pm 82.1$  MET-min/day; BMI= $28.1 \pm 6.1$  kg/m<sup>2</sup>) and high active were compared (n=23;  $786.7 \pm 150.5$  MET-min/day; BMI= $22.2 \pm 2.1$  kg/m<sup>2</sup>). Independent t-tests were performed between scores for highest and lowest PA tertiles; PA, fat, and muscle scores were correlated, after normalization for BMI.

**RESULTS:** Low active subjects had greater BMI\*, subcutaneous fat/BMI\*, total\* and central body fat\*. High active subjects had greater muscle area/BMI\* and IMAT/BMI\*. IMAT was positively correlated with MET-min/day ( $r=0.46^*$ ) and muscle area/BMI ( $r=0.35^*$ ), but was negatively correlated with total ( $r=-0.46^*$ ) and central body fat ( $r=-0.42^*$ ). \_\_\_\_\_ \* $p < 0.05$

**CONCLUSIONS:** When data was adjusted for body size, IMAT is greater in high active subjects as with muscle area and may suggest a physiological adaptation to increased habitual PA. IMAT may be a useful index for evaluating localized training effects on metabolic adaptations in skeletal muscle.

**Skeletal Muscle Gene Expression After A Follicular Based And A Luteal Based Training In A Female Athlete**

Petra Platen, FACSM, Ahreum Han, Eunsook Sung, Timo Hinrichs. *Ruhr-University Bochum, Bochum, Germany.*  
Email: petra.platen@rub.de  
(No relationships reported)

**PURPOSE:** Each phase of the menstrual cycle is characterized by a certain profile of different hormones. Menstrual cycle specific regulation of many hormones is not clear so far. This is especially true for the interaction between estradiol, human growth hormone (hGH), and IGF-1, all of them possible anabolic hormones on the level of the muscular cell and therefore important supporting factors during strength training. We, therefore, decided to conduct a pilot study in order to investigate possible different effects of follicular phase-based (FT) versus luteal phase-based (LT) strength training on the gene expression profile of skeletal muscle.

**METHODS:** One healthy eumenorrheic woman completed a strength training program for 3 menstrual cycles (approx. 12 weeks). The subject performed FT with muscle groups of the right side of the body and LT with muscle groups of the left side of the body. FT was organized 4 times a week in the follicular phase and once a week in the luteal phase, and LT was organized 4 times a week in the luteal phase and once a week in the follicular phase. Gene expression profile was determined in skeletal muscle biopsy samples (m. vastus lateralis, both legs prior to and after 3 months of either FT or LT, respectively) via microarray encompassing 1.14 million exon probes (Exon Chip) and subsequent Gene Ontology Analysis.

**RESULTS:** Microarray analysis revealed an increase (at least 1.5 fold) in 414 genes and a decrease in 87 genes after FT. LT only induced an increase in 82 genes and a decrease in 75 genes. Most up-regulated genes belonged to processes like cellular metabolism, oxidoreductase activities, generation of precursor metabolites and energy, electron transport, translation, cellular biosynthetic processes, transmembrane receptor activities, electron carrier activity, NADH dehydrogenase (ubiquinone) activity, and mitochondrial electron transport.

**CONCLUSIONS:** The much higher number of activated genes after FT is in accordance with recently published findings of higher maximal strength gains and gains in muscle mass after FT as compared to LT. This is probably due to the specific hormonal milieu during each phase of the cycle. More subjects have to be included in order to further analyze menstrual cycle specific training effects.

(No relationships reported)

**PURPOSE:** Myofibrillar damage that is incurred as a result of resistance exercise is hypothesized to be a precursor to skeletal muscle hypertrophy. Serum creatine kinase activity (CK) responds to acute exercise in proportion to the extent and severity of muscle injury. In a subset of subjects from the FAMuSS study, we tested the hypothesis that the increase in CK measured upon the initiation of training is correlated with the upper arm muscle hypertrophic response observed after 12 weeks.

**METHODS:** 51 men and 51 women ages 18-39 who were previously untrained underwent 12 weeks of resistance training exercise in the nondominant arm. Serum CK was measured at baseline prior to bout 1; 48 h following bout 1 and before bout 2; and 96 h following bout 1, which was also 48 h after bout 2. Upper arm muscle size was measured using magnetic resonance imaging (MRI) at baseline and week 12.

**RESULTS:** Women and men significantly increased upper arm muscle cross sectional area and total volume. Men demonstrated a wider range of peak CK response (11 to 6040 units) compared to women (26 to 915). CK increases were log transformed for correlational analyses. Data are mean  $\pm$  sd.

Group	Whole Muscle CSA, pre (mm <sup>2</sup> )	D Whole Muscle CSA, (mm <sup>2</sup> )	Whole Muscle Volume pre (mm <sup>3</sup> )	D Whole Muscle Volume (mm <sup>3</sup> )	CK, peak (units)	Highest Correlation, CK vs. D Mass
Women	5314 $\pm$ 1590	385 $\pm$ 330	494306 $\pm$ 145903	36171 $\pm$ 31043	142 $\pm$ 180	0.14 (PeakCK 2 vs. D WM Vol)
Men	6245 $\pm$ 1544	751 $\pm$ 506*	575998 $\pm$ 135659	66386 $\pm$ 44689 *	378 $\pm$ 852 *	0.35† (Log [PkCK] vs. D WM Vol)

\* p<0.05 women vs. men; † p=0.012

**CONCLUSIONS:** The CK response to the initiation of training predicted the muscle hypertrophy response at 12 weeks in men. The data support the hypothesis that muscle injury is a precursor to the increase in muscle size in men but not women, at least in previously untrained subjects undertaking 2x per week resistance training according to standard guidelines.

**Is Artificial Gravity An Effective Countermeasure To Microgravity**

Vincent Caiozzo, FACSM, Jason Blank, Mike Baker, Art Kreitenberg, Anqi Qin, Fadia Haddad, Greg Adams, Kenneth M. Baldwin, FACSM.  
*University of California, Irvine, CA.*  
(No relationships reported)

**PURPOSE:** It is well known that microgravity can produce substantial losses in muscle mass and strength, bone mass, and orthostatic tolerance. It has been hypothesized that artificial gravity might represent an important countermeasure for preventing such changes. In this context, the primary goal of this study was to test the hypothesis that hypergravity resistance training (HRT) can produce training adaptations similar to those found using a 1 G<sub>x</sub> 10 repetition maximum resistance training program.

**METHODS:** Subjects were healthy male subjects who exercised no more than 2-3 times per month prior to the study (N=18, aged  $22.7 \pm 0.4$  yrs, height  $176 \pm 2$  cm, mass  $80 \pm 3$  kg, means  $\pm$  S.E.M.). Subjects completed a two-week resistance training program (9 sessions) using either HRT [Space Cycle (SC), n=9] or free weights (FW, n=9). Each workout entailed 3 sets of 10 squats at 70, 80, and 90 % of pre-training 10 repetition maximum for the 1st, 2nd, and 3rd sets, respectively. Torque-velocity relationships were determined before and after the completion of the two-week resistance training program. Muscle biopsies were taken from the right vastus lateralis shortly before, 4 and 24 hrs after the first and last workouts.

**RESULTS:** The improvements in torque-velocity relationships were similar (~7-8%) between the two training groups. The muscle biopsy data were used to assess cellular/molecular markers of growth. Analyses demonstrated that there were significant increases ( $P<0.01$ ) in total RNA for both groups. Both groups also produced acute changes in myogenin mRNA levels, however, comparisons of pre and post training data were not significant.

**CONCLUSION:** This study represents an initial step in testing the HRT hypothesis. Importantly, we found similar adaptations between the HRT and free weight groups, and this offers encouraging evidence for pursuing the potential role of artificial gravity as a countermeasure to microgravity.

**2259 Board #147 May 28 3:30 PM - 5:00 PM**  
**Effect Of Satellite Cell Events Adaptation To Moderate Endurance Training In White Gastrocnemius of Rats**

Zong-Yan Cai<sup>1</sup>, Cheng-Chen Hsu<sup>2</sup>, Mei-Chich Hsu<sup>1</sup>, Mao-Shung Huang<sup>3</sup>, Chao-Pin Yang<sup>4</sup>, Borcherhg Su<sup>5</sup>. <sup>1</sup>National Taiwan Sports University, Taipei, Taiwan. <sup>2</sup>Taipei Medical University, Taipei, Taiwan. <sup>3</sup>Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan. <sup>4</sup>Changhua Christian Hospital, Taipei, Taiwan. <sup>5</sup>Fu Jen Catholic University, Taipei, Taiwan.

*(No relationships reported)*

Moderate endurance training is widely regarded as a natural pharmacology to improve physical health. However, few studies have investigated the satellite cell adaptation to it.

**PURPOSE:** To investigate the adaptive changes of satellite cells and myogenic events to moderate endurance training. Given previous evidence of their predominant role in endurance training induce oxygen availability and cytoprotection respectively, vascular endothelial growth factor (VEGF) and heat shock proteins 70(HSP70) content will also be examined.

**METHODS:** Twenty-eight male Sprague-Dawley (SD) rats were randomly assigned to 4 weeks of exercise trained group (4T), 4 weeks of control group (4C), 8 weeks of exercise trained group (8T), and 8 weeks of control group (8C) (n=7, respectively). The training protocol consisted of treadmill running at 20 m/min for 30 min on a 0% grade, for 3 days/wk. At the end of each training period, exercise-trained rats were sacrificed together with their control counterparts. Immunohistochemistry stain and stereological equations were used to analyze in the white gastrocnemius muscle.

**RESULTS:** Mean density in HSP70, VEGF, c-met positive satellite cells, and Myf-5 myogenic response were greater in 4T than those in the 4C ( $9.69 \pm 2.77$  vs.  $4.61 \pm 2.13$ ;  $1.26 \pm 0.08$  vs.  $1.21 \pm 0.08$ ;  $11.47 \pm 2.77$  vs.  $7.16 \pm 2.49$ ;  $1.51 \pm 0.19$  vs.  $1.33 \pm 0.2$ , respectively,  $p<0.05$ ). VEGF, c-met, and Myf-5 in the 8T were less than those in the 4T ( $1.22 \pm 0.07$  vs.  $1.26 \pm 0.08$ ;  $9.46 \pm 2.69$  vs.  $11.47 \pm 2.77$ ;  $6.6 \pm 2.4$  vs.  $9.69 \pm 2.77$ ,  $p<0.05$ ), but more than those in the 8C ( $1.22 \pm 0.07$  vs.  $1.16 \pm 0.08$ ;  $9.46 \pm 2.69$  vs.  $7.22 \pm 2.23$ ,  $p<0.05$ ) except Myf-5 ( $6.6 \pm 2.4$  vs.  $6.73 \pm 2.95$ ,  $p>0.05$ ). In addition, HSP70 in the 8T group was greater than that in the 4T ( $1.63 \pm 0.19$  vs.  $1.4 \pm 0.18$ ,  $p<0.05$ ). Muscle fiber area in the 8T was greater than that in the 8C ( $3478.41 \pm 719.63$  vs.  $3079.63 \pm 695.00 \mu m^2$ ,  $p<0.05$ ).

**CONCLUSIONS:** Moderate endurance training could stimulate satellite cell activation and promote myogenic response at the initial training stage, and it suggests that these activated satellite cells and myogenic events following training is prepared for subsequent muscle hypertrophy. The training-increased response was attenuated when training adaptation occurs, which might partly mediated by upregulation of HSP70 that enhance cytoprotection.

**2260 Board #148 May 28 3:30 PM - 5:00 PM**  
**Improvements In Plantarflexor Size And Function Following Rehabilitation After Lower Leg Injury**

Robyn Hinds, Jessica Blank, Sunita Mathur, Chris M. Gregory, Trevor Lentz, Susan M. Tillman, Glenn A. Walter, Krista Vandeborne. *University of Florida, Gainesville, FL*  
Email: therobyn@ufl.edu

*(No relationships reported)*

Rehabilitation following injury and immobilization has a positive impact on muscle recovery. However, muscle atrophy and weakness and recover at different rates following immobilization.

**PURPOSE:** To determine changes in plantarflexor (PF) muscle size and strength in subjects with lower extremity fractures, who underwent immobilization followed by a structured rehabilitation program.

**METHODS:** Subjects included 10 males and 7 females [(20-46 yrs, BMI  $24.8 \pm 4.0$  (mean  $\pm$  std)] who sustained lower leg fractures and were immobilized for at least 4 weeks. Subjects participated in a 6-week rehabilitation program that began immediately following immobilization. The program consisted of progressive resistance training of the ankle PFs and progressive treadmill walking. Measurements were taken immediately prior to and following rehabilitation. T1-weighted, axial images of the lower leg were obtained from MRI (1.5T or 3T) and were used to determine the maximal cross-sectional area (CSA) of the PFs. Maximal voluntary isometric torque of the ankle PFs was measured on a Biodex dynamometer. Peak torque and Time to Peak Torque were analyzed using Acknowledge software.

**RESULTS:** Subjects experienced 23% improvement in PF CSA values after rehabilitation in the injured limb compared to a 4% increase in the noninjured limb. Muscle strength measures also showed an improvement, with a 30% increase in peak torque in the injured limb and 14% in the noninjured limb. Time to Peak Torque showed similar results with a 20% improvement in the involved limb and 15% improvement in the uninvolved limb.

**CONCLUSIONS:** Following a period of immobilization and rehabilitation, muscle size tends to recover to a lesser extent than muscle strength. Improvements in muscle size are observed in the injured limb, whereas substantial muscle strength gains are seen in both the injured and uninjured limbs, which may indicate an improvement in neuromuscular recruitment of the PFs following rehabilitation.

**2261 Board #149 May 28 3:30 PM - 5:00 PM**  
**Effect Of Slow-speed Vs. Traditional Resistance Training Regimens On Myonuclear Domain And Satellite Cell Content**

Jennifer R. Herman<sup>1</sup>, Roger M. Gilders<sup>2</sup>, Frederick C. Hagerman, FACSM<sup>2</sup>, Robert S. Hikida<sup>2</sup>, Sharon R. Perry-Rana<sup>2</sup>, Kerry E. Ragg<sup>2</sup>, Robert S. Staron<sup>2</sup>. <sup>1</sup>Colorado College, Colorado Springs, CO. <sup>2</sup>Ohio University, Athens, OH.  
Email: jennifer.herman@coloradocollege.edu

*(No relationships reported)*

**PURPOSE:** The purpose of this study was to investigate muscle fiber adaptations in myonuclear domain and satellite cell content in conjunction with varying degrees of fiber hypertrophy following slow-speed vs. "normal-speed" resistance training protocols.

**METHODS:** Thirty-four healthy adult females ( $21.1 \pm 2.7$  yr.) were randomly divided into four groups: slow-speed (SS), traditional strength (TS), traditional muscular endurance (TE), and non-exercising control (C). Workouts, consisting of 3 sets each of 3 exercises (leg press, squat, and knee extension), were performed 2d/wk for the first week and 3d/wk for the remaining 5 weeks. For each training session, the SS group performed 6-10RM (6-10 repetitions maximum) for each set with 10s con and 4s ecc contractions for each repetition. TS and TE performed 6-10RM and 20-30RM, respectively, at "normal" speed (1-2s/con and ecc contraction). Both TE and SS trained at the

same relative intensity (40-60% 1RM), whereas TS trained at 80-85% 1RM. Pre- and post-training vastus lateralis muscle biopsies were analyzed for fiber cross-sectional area (CSA), myonuclear domain and number, NCAM+ (anti-neural cell adhesion molecule) satellite cells, and fiber type.

**RESULTS:** 1) As previously reported, the CSA of all major fiber types (I, IIA, and IIX) increased post-training for TS, whereas only the fast fiber types increased in size for SS. No significant change in fiber size was found for either the TE or C groups. 2) Myonuclear domain was significantly larger post-training in TS for all major fiber types, whereas only Type IIA domain increased in SS. There were no changes in myonuclear domain for TE or C. 3) Myonuclear number did not differ significantly from pre- to post-training in any group. 4) Satellite cell content increased post-training for TS in all major fiber types, while only NCAM+ nuclei associated with Type IIX and Type IIA fibers increased in SS. No changes in the satellite cell population were observed for TE or C.

**CONCLUSIONS:** Slow-speed resistance training resulted in a larger degree of fiber hypertrophy, increased myonuclear domain, and stimulus to muscle stem cells compared to training with a similar resistance at a normal speed. However, training at a higher intensity (80-85% 1RM) at normal speed resulted in the greatest overall fiber response for each of these variables.

**High Intensity Interval Training Rapidly Increases Skeletal Muscle Oxidative Capacity In Previously Sedentary Middle-aged Adults**

Melanie S. Gardner, Mark A. Tamopolsky, Frank Myslik, Jonathan P. Little, Martin J. Gibala. *McMaster University, Hamilton, ON, Canada.* (Sponsor: Lawrence L. Spriet, FACSM)  
(No relationships reported)

There is growing appreciation of the potential for high intensity interval training (HIT) to rapidly stimulate metabolic adaptations that resemble traditional endurance training, despite a low total exercise volume (*Exerc Sports Sci Rev* 36:58-63, 2008). However, much of this work has been conducted on young active individuals ( $\leq 30$  yr) and the results may not be generalized to older, less active populations. In addition, many studies have employed "all out", variable-load exercise interventions (e.g., repeated Wingate Tests) that may not be safe, practical or well tolerated by certain individuals.

**PURPOSE:** To determine the effect of a short program of low-volume, submaximal, constant-load HIT on skeletal muscle metabolic adaptations in sedentary middle-aged individuals who may be at higher risk for inactivity-related disorders.

**METHODS:** Inactive but otherwise healthy men ( $n=3$ ) and women ( $n=4$ ) with a mean ( $\pm$ SE) age, body mass index and peak oxygen uptake ( $\text{VO}_{2\text{peak}}$ ) of  $45 \pm 2$  yr,  $27 \pm 2$  kg·m<sup>-2</sup> and  $30 \pm 1$  ml·kg<sup>-1</sup>·min<sup>-1</sup> took part in the study. Subjects performed 6 training sessions over 2 wk. Each session consisted of 10 x 1 min cycling at 60% of peak power elicited during a ramp  $\text{VO}_{2\text{peak}}$  test ( $\sim 90\%$  of maximal heart rate) with 1 min recovery between intervals. Needle muscle biopsy samples (v. lateralis) were obtained before training and  $\sim 72$  h after the final training session.

**RESULTS:** Muscle oxidative capacity, as reflected by the maximal activity of citrate synthase, increased by 22% after training ( $12.9 \pm 0.7$  vs.  $10.6 \pm 0.6$  mmol·kg protein<sup>-1</sup>·h<sup>-1</sup>), which is comparable to changes previously reported after 2 wk of Wingate-based HIT in young active subjects.

**CONCLUSIONS:** A short program of low-volume, constant-load HIT is a time-efficient strategy to rapidly increase skeletal muscle oxidative capacity in previously sedentary middle-aged men and women.

Supported by CIHR.

**Lean And Fat Mass Effects On Bone Mineral Density In Female Athletes And Non Athletes**

Meghan L. Ruebel, Megan M. Costello, Scott A. Unruh, Kate A. Heelan. *University of Nebraska at Kearney, Kearney, NE.*  
Email: ruebelml@unk.edu  
(No relationships reported)

There are many factors that effect bone mineral density (BMD) including physical activity, lean body mass, and fat mass. However, controversial evidence has been found regarding contribution of lean mass and fat mass on BMD in young, premenopausal women.

**PURPOSE:** To investigate the impact of fat mass and lean mass on BMD in college female athletes (ATH) and non athletes (NONATH).

**METHODS:** 111 college females (60 ATH:  $19.3 \pm 1.09$ y; 51 NONATH:  $20.1 \pm 1.40$ y) were assessed for lean body mass (LBM), fat mass (FM), body fat percentage (BF) and BMD by whole body dual-energy X-ray absorptiometry (DXA). A stepwise multiple regression analysis was conducted to determine the impact of body weight (BW), Age, LBM, FM, and BF on BMD for ATH and NONATH.

**RESULTS:** Although BW ( $67.96 \pm 12.49$  kg vs.  $65.32 \pm 9.88$  kg,  $p>0.05$ ) and FM ( $18,976 \pm 9,238$  g vs.  $25,460 \pm 27,890$  g,  $p>0.05$ ) did not differ between ATH and NONATH, ATH had significantly lower BF ( $28.1 \pm 8.7\%$  vs.  $33.9 \pm 8.15\%$ ,  $p<0.05$ ), higher LBM ( $45,750.5 \pm 4,904.10$  g vs.  $40,427.2 \pm 4,709.40$  g,  $p<0.05$ ) and BMD ( $1.24 \pm 0.08$  g/cm<sup>2</sup> vs.  $1.18 \pm 0.08$  g/cm<sup>2</sup>,  $p<0.05$ ) compared with NONATH. For ATH, 48% of the variance in BMD was accounted from LBM ( $R^2=0.33$ ,  $p<0.05$ ), BW ( $R^2=0.06$ ,  $p<0.05$ ) and FM ( $R^2=0.08$ ,  $p<0.05$ ). For NONATH 45% of the variance in BMD was accounted for from BW ( $R^2=0.45$ ,  $p<0.05$ ).

**CONCLUSION:** Although body mass is highly associated with increased BMD in college-aged females, our data suggests increased LBM is a more significant contributor in female athletes. Young women should focus on maintaining healthy body mass and body fat levels while increasing LBM in order to enhance peak bone mass. A higher peak bone mass at this age may prevent BMD losses as women age.

**Sport Specificity And Training Influence Bone And Body Composition In Women Collegiate Athletes**

Jennifer Markos, Tara E. Fernandez, Amy F. Bragg, John S. Green, FACSM, Stephen F. Crouse, FACSM, Aaron F. Carbuhrn. *Texas A&M University, College Station, TX.*  
Email: acarbuhrn@hkn.tamu.edu  
(No relationships reported)

This is a novel descriptive study to characterize off-season, pre-season, and post-season bone and body composition measures in women collegiate athletes.

**PURPOSE:** To quantify changes in women collegiate athletes' bone mineral content, bone mineral density (BMD), arm BMD, leg BMD, pelvis BMD, spine BMD, and body composition (i.e., total body mass, lean mass, fat mass, and percent body fat) within each sport through the seasonal periods, and among the sports at each seasonal period.

**METHODS:** 67 women collegiate athletes from softball ( $n=17$ ), basketball ( $n=10$ ), volleyball ( $n=7$ ), swimming ( $n=16$ ), and track jumpers and sprinters ( $n=17$ ) were scanned using dual energy x-ray absorptiometry (DXA) at three seasonal periods: 1) before pre-season training defined as off-season (OFF), 2) at end of preseason training (PRE), and 3) after the competitive season (POST).

summary of **RESULTS:** Repeated measures ANOVA within-sport seasonal changes in table; PRE/POST = highest value measured at PRE or POST.  $\alpha < 0.05$  for all tests of significance.

	Seasonal Period	%Body fat	BMD (g/cm2)	Pelvis BMD (g/cm2)	Spine BMD (g/cm2)
--	-----------------	-----------	-------------	--------------------	-------------------

Softball	OFF	27.1±5.0*	1.254±0.081*	1.385±0.127	1.216±0.149
	PRE/POST	25.7±5.0	1.261±0.082	1.405±0.141	1.268±0.154
Basketball	OFF	25.5±5.5*	1.333±0.064*	1.469±0.123*	1.356±0.178
	PRE/POST	22.7±5.6	1.349±0.055	1.494±0.119	1.391±0.146
Volleyball	OFF	27.7±4.1	1.284±0.065*	1.366±0.139	1.254±0.102*
	PRE/POST	27.1±5.1	1.310±0.071	1.371±0.149	1.360±0.121
Swimming	OFF	22.0±4.3	1.112±0.067	1.110±0.104*	1.063±0.127*
	PRE/POST	21.9±4.1	1.121±0.067	1.124±0.105	1.105±0.126
Track Jumpers and Sprinters	OFF	15.4±4.6*	1.292±0.075*	1.432±0.124*	1.280±0.135*
	PRE/POST	14.3±3.9	1.307±0.080	1.470±0.128	1.337±0.140

Values are means ± standard deviations. \*Significant difference between off-season and pre or post-season

ANOVA for differences by sports at the PRE/POST period showed results for both pelvis BMD and spine BMD as follows: softball = basketball = volleyball = track > swimmers.

**CONCLUSION:** These data serve as sport-specific benchmarks for comparisons at in-season and off-season training periods among women collegiate athletes in various sports. They also serve to document changes in body composition and bone density with training, and may serve to guide coaches in the development of sport specific nutritional and strength and conditioning programs to optimize athletic performance.

**Bone Mineral Density And Body Composition Of Collegiate Modern Dancers**

Karl J. Friesen<sup>1</sup>, Ralph Rozenek<sup>2</sup>, Karen Clippinger<sup>2</sup>, Albert C. Russo<sup>2</sup>, Susan E. Sklar<sup>3</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>California State University, Long Beach, Long Beach, CA. <sup>3</sup>Sklar Center for Women's Wellness, Los Alamitos, CA.  
Email: friesenk@onid.orst.edu  
(No relationships reported)

Weight bearing physical activity is known to increase bone mineral density (BMD) in young women. However women involved in dance often engage in behaviors such as disordered eating that contribute to menstrual dysfunction and decreased BMD. The interrelationships among bone demineralization, menstrual dysfunction, and disordered eating have been studied in ballet dancers but not modern dancers. In question is the degree to which modern dancers exhibit components of the triad as well as if modern dance offers enough impact to increase bone accrual.

**PURPOSE:** To investigate body composition (BC) and BMD in collegiate modern dancers.

**METHODS:** 31 female collegiate dancers (D), 18-25 years of age, and 30 age-matched controls (C) participated in the study. BC and BMD were measured using dual energy x-ray absorptiometry (DXA); upper and lower body strength was assessed by chest and leg press 1-repetition maximum tests. Subjects completed 3-day food records; diet was analyzed using nutritional software. Menstrual dysfunction (MD) and history of eating disorders (ED) was collected via questionnaires. BC and BMD variables were analyzed using MANCOVA & frequency of ED and MD by Chi-Square analysis.

**RESULTS:** Hip and spine BMD were greater in D than C ( $p < 0.05$ ). Total body fat % was lower in D than C ( $25.9 \pm 4.2\%$  vs.  $32.0 \pm 5.9\%$ ;  $p < 0.05$ ), and % of fat distributed in the android region was also lower in D than C ( $28.0 \pm 6.2\%$  vs.  $37.6 \pm 8.6\%$ ;  $p < 0.05$ ). With regard to diet composition only % fat intake was lower in D than C ( $27.54 \pm 6.8\%$  vs.  $31.5 \pm 7.4\%$ ,  $p < 0.05$ ). A greater incidence of ED was reported by D than C ( $12.9\%$  vs.  $0\%$ ;  $p < 0.05$ ), as well as a greater incidence of secondary amenorrhea ( $41.9\%$  vs  $13.3\%$ ;  $p < 0.05$ ). No differences existed for incidence of primary amenorrhea, oligomenorrhea or use of birth control. Correcting for body mass, strength was greater in D than C for both chest press ( $30.1 \pm 0.9$  kg vs.  $28.4 \pm 1.0$  kg;  $p < 0.05$ ), and leg press ( $170.7 \pm 4.2$  kg vs.  $163.1 \pm 3.9$  kg;  $p < 0.05$ ).

**CONCLUSION:** This study indicates that college-aged modern dancers, on average, possess a healthy body weight, yet a higher incidence of ED and MD than found in non-dancing college-aged women. Despite this elevation of two triad components, these dancers possess a high BMD that may be attributed to the imposed impact as well as the strength gains associated with practicing modern dance.

**Musculoskeletal Health Of Male And Female Apprentice Jockeys**

Paul Wyner, Dr David A. Greene, Professor Geraldine A. Naughton, Mr Bob Finlay. Australian Catholic University, Sydney, Australia. (Sponsor: Dr Dan Benardot, FACSM)  
Email: paul@healthworx.com.au  
(No relationships reported)

The typical jockey is small in stature and light in weight. In order to remain within specific weight limits, jockeys often engage in unhealthy weight-loss behaviours that rely on rapid, short-term weight loss and have an increased propensity to engage in disordered eating. Engaging in activities and behaviours that restrict the attainment of peak bone mass during growth produces deleterious musculoskeletal effects in later life. Musculoskeletal responses to prolonged demands of elite physical performance in young adults who regularly experience energy drain from physical activity and disordered eating are relatively unknown. Delayed growth, coupled with intensive training, may predispose apprentice jockeys to repetitive microtraumatic injury to the musculoskeletal system.

**PURPOSE:** (i) to profile the musculoskeletal health of male and female apprentice jockeys and less active, age- and sex- matched peers (control group).

**METHODS:** Two groups of 25 young adults ( $n = 50$ ) (age range 15 - 38 years) comprised of male and female apprentice jockeys, and male and female controls. Peripheral Quantitative Computed Tomography (pQCT) was used to assess musculoskeletal health of the distal tibia and distal radius. Trabecular area and density, cortical area and density, and stress strain index was calculated.

**RESULTS:** After covarying for limb length and weight, apprentice jockeys displayed lesser tibial cortical area and stress strain index at 14%, 38% and 66% sites measured distally ( $p=0.001$ ). No differences between groups were found in cortical density, trabecular area, and trabecular density at the tibia. Apprentice jockeys displayed greater trabecular density at the ultra-distal radial site ( $p=0.001$ ) and greater stress strain index at 66% site measured distally ( $p= 0.01$ ). Control participants showed greater cortical area at 66% radial site ( $p=0.03$ ) and greater stress strain index at the ultra-distal radius ( $p=0.006$ ).

**CONCLUSIONS:** Apprentice jockeys displayed compromised musculoskeletal health at the distal tibia and radius compared to control participants. Only trabecular density at the ultra-distal radius and stress strain index at radial mid-shaft was greater in apprentice jockeys.

**Dose-dependent Effects And Feasibility Of A Home-based Jumping Program For Bone Health In Women**

Kara A. Witzke. *California State University, San Marcos, San Marcos, CA.*  
Email: kwitzke@csusm.edu  
(No relationships reported)

**PURPOSE:** While several studies have shown jumping exercises to benefit the skeleton and may reduce osteoporosis risk later in life, an exercise prescription for improving bone has not been established. Simple, well-tolerated, cost-effective solutions for improving bone mass prior to menopause may potentially improve public health. In preparation for a much larger dose-response study, this pilot study sought to evaluate the feasibility and effectiveness of a home-based jumping program in premenopausal women.

**METHODS:** A total of 31 premenopausal women (aged  $38.5 \pm 9.4$  y) were randomly assigned across 4 jumping groups (8" or 12" step; 10 or 50 jump repetitions), or control for the 15-week study. Women assigned to a jumping group were instructed to step up onto and jump down from their step (two-foot landing) with bare feet on a hard surface, three days per week. Controls maintained their regular physical activity. Women were excluded for medications/conditions known to affect bone, irregular menses, smoking, BMI > 30 kg/m<sup>2</sup>, and regular high-impact activity participation in the past 12 months.

**RESULTS:** Twenty six (84%) women completed the study. Five dropped out due to injuries NOT associated with the program but that prevented their continuation (two from the 12" x 50 group, one from the 8" x 10 group, two from the 8" x 50 group). Overall compliance averaged  $88.4 \pm 11.9\%$  (range 60-100%) and was similar across groups. Subjects tolerated the program well (only one expressed minor joint discomfort). Subjects stated the program was "easy" and only took 30 sec-2 min to complete. Not surprisingly, there were no group differences at baseline and no group effect was observed for measures of femoral neck, greater trochanter, or total hip bone mineral density after the study ( $p > 0.05$ ). Collapsing all jump groups still produced no differences compared to controls.

**CONCLUSIONS:** This pilot study demonstrates that a simple at-home jumping program provides a feasible means to implement safe and controlled impact exercise into the weekly routine of most premenopausal women. The effectiveness of such a program on improving bone mass cannot be established based on this pilot study due to its short duration (15 weeks), but is being investigated in a much larger cohort of premenopausal women over a 9-month period.

**Influence Of Femoral Anteversion On Hip And Knee Motions During Landing**

Anh-Dung Nguyen, Randy J. Schmitz, Sandra J. Shultz, FACS. *University of North Carolina at Greensboro, Greensboro, NC.*  
Email: a\_nguyen@uncg.edu  
(No relationships reported)

Dynamic malalignment of the hip and knee has been suggested to be predictive of knee injury. While increased femoral anteversion (FA) results in an inward torsion of the femur, it is unknown whether increased FA contributes to dynamic lower extremity malalignments during activity.

**PURPOSE:** To compare hip and knee motions during the entire landing phase of a drop jump in those with above (FA<sub>HIGH</sub>) and below (FA<sub>LOW</sub>) average FA.

**METHODS:** FA was measured on the dominant limb of 52 recreationally active females ( $21.7 \pm 2.7$  yrs,  $163.4 \pm 6.4$  cm,  $59.7 \pm 7.8$  kg). Three-dimensional hip and knee kinematics were measured during 5 bilateral drop-jump landing trials from a height of 45cm. The initial landing phase (initial contact to peak knee flexion) of each trial was normalized to 101 data points, then averaged across the 5 trials for analysis. Subjects were classified as FA<sub>HIGH</sub> or FA<sub>LOW</sub> based on the average FA in the overall sample (12.8°). Separate group (FA<sub>HIGH</sub>, FA<sub>LOW</sub>) by time (% landing phase) repeated measures ANOVA compared FA groups on frontal and transverse plane hip and knee motions across the entire landing phase. For significant group by time interactions, post hoc comparisons for each 10% increment determined where in the landing phase groups differed.

**RESULTS:** No main effect for group was identified across the entire landing phase for any joint motion (all  $P$  values > 0.10). Group by time effects were observed for both frontal and transverse plane knee motions ( $P < 0.001$ ). FA<sub>LOW</sub> knees moved into slight knee varus (~2°) whereas FA<sub>HIGH</sub> remained near neutral from 0-20% of the landing. FA<sub>HIGH</sub> then moved into (21-50%) and remained in (51-70%) greater knee valgus, resulting in ~5° greater valgus than FA<sub>LOW</sub> at mid landing. For knee rotation, both groups internally rotated similar amounts (~6°) from 0-30%, then FA<sub>HIGH</sub> knees externally rotated (~4°) while FA<sub>LOW</sub> knees remained near neutral rotation from 41-100% of the landing phase.

**CONCLUSIONS:** Greater structural FA may influence tibiofemoral orientation resulting in more knee valgus and external rotation motion during landing. This work is limited to a single alignment measure and ongoing work is examining a more complete lower extremity postural profile on dynamic malalignments that are known to be predictive of lower extremity injury.

**Possibility For Assessing Low-force Muscle Activation With Real-time Magnetic Resonance Imaging Combined With Vascular Occlusion**

Ryuta Kinugasa<sup>1</sup>, Minoru Shinohara, FACS<sup>2</sup>. <sup>1</sup>Waseda University, Tokorozawa, Japan. <sup>2</sup>Georgia Institute of Technology, Atlanta, GA.  
Email: rkinugasa@aoni.waseda.jp  
(No relationships reported)

Magnetic resonance imaging (MRI) offers a great potential for understanding neuromuscular characteristics and activation of human skeletal muscle. The assessment of muscle activation has been made with non real-time MRI, but was possible only for muscle contractions with moderate to high-force production. We hypothesized that an application of real-time MRI combined with vascular occlusion may overcome this limitation.

**PURPOSE:** The purpose of this preliminary study was to explore the possibility for using real-time MRI combined with vascular occlusion for assessing muscle activation during low-force contractions (< 20% of maximum voluntary contraction, MVC).

**METHODS:** Healthy young adults performed isometric plantar flexion in a 1.5-Tesla MR magnet, using a custom-built MRI-compatible foot-pedal device. The isometric plantar flexion was at low intensities (5, 10, and 20% of MVC) for 1 min with and without vascular occlusion at the proximal end of the thigh by means of a pressure tourniquet (100 mmHg). The knee joint was fully extended and the ankle joint was in the neutral position. Axial mid-calf echo-planar images (repetition time/echo time, 6,000/15.4 ms, 1 cm slice thickness, 40 x 40 cm field-of-view, 64 x 128 imaging matrix) were acquired for 1 min (6 s x 10 phases) before and during the low-intensity plantar flexion. Mean signal intensity (SI) was calculated from the central portion of the medial gastrocnemius muscle at rest and during contractions at each force level with and without vascular

occlusion.

**RESULTS:** With an increase in force level, SI remained low or increased only slightly (4.8~6.2%) without the vascular occlusion in the two tested subjects. With vascular occlusion, SI showed a remarkable elevation (7.0~8.2%) with an increase in force during each contraction in both subjects.

**CONCLUSION:** The preliminary results demonstrated a possibility that real-time MRI may be utilized for assessing muscle activation even during low-force contractions based on enhanced increases in signal intensity if it is combined with vascular occlusion.

**Prolonged Alterations In Hindlimb Emg Following Acl Transection In An Experimental Model Of Osteoarthritis**

Maureen K. Dwyer<sup>1</sup>, Timothy R. Leonard<sup>2</sup>, Walter Herzog<sup>2</sup>, Timothy A. Butterfield<sup>1</sup>. <sup>1</sup>University of Kentucky, Lexington, KY. <sup>2</sup>University of Calgary, Calgary, AB, Canada. (Sponsor: Robert Shapiro, FACSM)

Email: maureen.dwyer@uky.edu

*(No relationships reported)*

Alterations in knee joint loading and hind limb kinematics following anterior cruciate ligament transection (ACLT) have been associated with the onset of osteoarthritis (OA) through a reduction in joint loads. Knee joint loads have been directly measured nine days following ACLT, and subsequent changes in joint kinematics have been documented over the span of one year. However, the magnitude and duration of muscle activation adaptations in the hindlimb remain unknown following ACLT.

**PURPOSE:** To quantify long-term changes in cat hindlimb muscle activation patterns following ACLT.

**METHODS:** In this pilot study, indwelling bipolar electromyographic (EMG) electrodes were surgically implanted in four synergist muscle pairs on the cat hindlimb: rectus femoris (RF) and vastus lateralis (VL); semitendinosus (ST) and semimembranosus (SM); extensor digitorum longus (EDL) and tibialis anterior (TA); and medial gastrocnemius (MG) and soleus (SOL). EMG and high speed video data were recorded during level treadmill walking before ACLT and at 1, 2, 3, 4, and 6 weeks, and at 2, 6, 8, and 9 months following ACLT.

**RESULTS:** Following ACLT, there was a reduction in mean EMG activation of the VL during stance, with an immediate increase in mean EMG amplitude in the RF during swing phase only. Both the SM and ST increased activity during stance phase for nine months after ACLT. Following ACLT, the EDL exhibited an extra burst of activity just prior to, or at paw strike in addition to the increased activity at paw off. Activity in the MG also increased during stance up to nine months, and the onset of muscle activation occurred earlier following ACLT for the SOL and MG.

**CONCLUSION:** Following ACLT the knee flexor and extensor muscles demonstrate compensatory activation patterns that may stiffen the hindlimb, and predispose the knee joint to increased loads. The two-joint EDL muscle is recruited at paw strike following ACLT, suggesting that this muscle may function to assist in stabilizing the ACL deficient joint as a knee extensor in co-contraction with the hamstring muscles. Furthermore, long term increases in activation of the dorsiflexor and plantarflexor muscles during stance may further contribute to increasing joint loads leading to OA.

**Effect Of Tendon Stiffness And Leg Stiffness On Running Economy In Well-trained Middle Distance Runners**

David R. Coleman<sup>1</sup>, Dale Cannavan<sup>2</sup>, Sara Home<sup>2</sup>, Charles Pedlar<sup>1</sup>, Anthony J. Blazeovich<sup>3</sup>. <sup>1</sup>English Institute of Sport, London, United Kingdom. <sup>2</sup>Brunel University, London, United Kingdom. <sup>3</sup>Edith Cowan University, Perth, Australia. (Sponsor: Dr Richard Godfrey, FACSM)

Email: david.coleman@eis2win.co.uk

*(No relationships reported)*

**PURPOSE:** Previous research suggests that a stiff 'leg spring' during running can provide significant energy savings from the elastic properties in the leg's soft tissues. Knowing that the absorption and recovery of elastic energy in muscle-tendon units is important in determining the energy cost of running, researchers have used the leg stiffness measured during the ground contact phase in running as a surrogate for muscle-tendon stiffness. However, no research has examined both the leg spring stiffness and the stiffness of the major tendons simultaneously. The aim of the present study was to examine how leg stiffness and the mechanical properties of the primary ankle and knee tendons influence running economy.

**METHODS:** Eleven well-trained male middle distance runners volunteered for the study. Medial gastrocnemius (MG) and vastus lateralis (VL) tendon force-elongation properties were measured during an isometric maximal voluntary contraction. Tendon forces were determined from joint moments measured by isokinetic dynamometry, corrected for agonist-antagonist co-contraction and joint rotation. Tendon elongation was measured using B-mode 2-D ultrasonography. Eccentric leg stiffness was measured during over-ground running using a previously published kinetic model. Total leg stiffness of the entire ground contact phase was derived from kinetic and kinematic measures. Running economy was measured using a standardised incremental treadmill protocol.

**RESULTS:** Analysis revealed no correlation with MG or VL tendon stiffness and either eccentric ( $r = -0.03$  and  $r = -0.07$ , respectively) or total leg stiffness ( $r = -0.06$  and  $r = 0.16$ , respectively). Leg stiffness was not correlated with running economy; however, MG tendon stiffness and peak ankle joint moment were significantly correlated with economy ( $r = -0.66$  and  $r = -0.68$ , respectively).

**CONCLUSIONS:** Leg stiffness does not appear to be a surrogate for tendon stiffness and is not predictive of running economy in well-trained runners. Leg stiffness might be influenced by changes in leg mechanics or muscular co-contraction. Interestingly, Achilles tendon stiffness tends to be greater in more economical runners. Faster tendon recoil, indicative of stiffer tendons, could benefit power generation at the ankle joint during high speed running.

**Effects Of Different Landing Conditions On Vertical Impact Forces**

Michele LeBlanc, Erin Schroeder, Brandy Newton, Jessica Schroeder, Joy Cyprian, Steven Hawkins, FACSM. California Lutheran University, Thousand Oaks, CA.

Email: mleblanc@callutheran.edu

*(No relationships reported)*

Impact loading has been shown to be an effective means to stimulate bone adaptation. Both the size of the forces and the rate of the forces are important for bone changes.

**PURPOSE:** To determine how vertical impact forces are affected by different landing strategies.

**METHODS:** Sixteen subjects aged 18-25 years with no previous landing training were recruited. Three different landing strategies were randomly assigned on three different days: natural (N), hard (H), and soft (S) landing. Subjects stepped off of boxes at 26cm (Low) and 56cm high (High) with and without shoes in each of the three conditions onto two Kistler force plates set at 600 Hz. Shoes, instructions, and defined "good landings" were standardized. Five good trials were collected for each condition. Peak vertical ground reaction force (maxFz) and rate of maximum force development (RFD) were normalized for body weight (BW) and are given for a single leg. All results were analyzed for the stepping side leg using a repeated measures factorial design with  $p < 0.05$ .

**RESULTS:** Most measures were influenced by strategy and height, but not shoes. MaxFz differed by strategy (3.2±0.2, 4.0±0.2 and 1.9±0.1 BW for N, H, and S, respectively) by shoes (2.9±0.1 and 3.1±0.1 BW for shoes and no shoes, respectively) and by height (2.6±0.1 and 3.4±0.1 BW for Low and High, respectively) ( $p < 0.05$ ). The time to the maximum Fz differed by strategy (0.05±0.002, 0.04±0.004 and 0.06±0.004 s for N, H, and S, respectively), by height (0.06±0.002 and 0.04±0.002 s for Low and High,

respectively), and illustrated an interaction between the two ( $p < 0.05$ ). The downward phase time showed differences based on strategy and on height ( $p < 0.05$ ). There was also an interaction between strategy and height ( $p < 0.05$ ). RFD showed differences based on strategy and height ( $p < 0.05$ ).

**CONCLUSIONS:** The various landing conditions clearly illustrated an effective manner in which large magnitude forces can be applied to the lower extremity. Additionally, the rate of this force development is quite large and thus, training involving these landings could be a useful tool for bone adaptation.

**Eccentric Exercise Alters The Kinematic Structure Of Pointing Movements**

Kurt W. Komatz, Yu-Kai Chang, Chad J. Dickerson. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Allan H. Goldfarb, FACSM)

Email: kurt\_komatz@uncg.edu

(No relationships reported)

It is known that the performance of eccentric muscle contractions often leads to delayed muscle soreness accompanied by declines in strength and isometric force steadiness. However, the effect of eccentric exercise on the performance of a dynamic motor task is not clear.

**PURPOSE:** To examine the effects of a bout of eccentric exercise on kinematic measures related to accuracy (i.e. submovements) during spatially-constrained pointing movements.

**METHODS:** 17 untrained subjects (10 M, 7 F;  $26 \pm 3$  yrs.) performed 20 rapid discrete elbow-extension pointing movements with their right arm before, immediately after (fatigue and muscle damage), and 24-hours after (muscle damage only) fatiguing eccentric exercise on a isokinetic dynamometer. Endpoint (fingertip) movement kinematics were obtained for each pointing trial and examined for secondary submovements identified by zero crossings in the tangential velocity and acceleration profiles.

**RESULTS:** MVC force declined by 44% immediately after eccentric exercise and remained depressed (22%) 24-hrs after the exercise indicating the existence of muscle damage. Movement times were slower and peak velocity decreased immediately after, and only partially recovered 24-hrs after the exercise compared with before ( $222 \pm 40$ ,  $248 \pm 37$  and  $238 \pm 42$  ms,  $P < 0.05$ ;  $3.4 \pm 0.6$ ,  $3.1 \pm 0.6$  and  $3.3 \pm 0.7$  m/s,  $P < 0.01$ ). Only 8% of the trials exhibited submovements before the eccentric exercise, however that number grew to 87% of trials immediately afterward and 29% of trials 24 hrs after. In those trials requiring submovements, subjects traveled  $85 \pm 8$ ,  $64 \pm 6$  and  $72 \pm 11\%$  ( $P < 0.001$ ) of the total movement time before using a secondary submovement.

**CONCLUSIONS:** These results demonstrate that kinematic measures associated with movement accuracy are altered from eccentric exercise and only partially restored after 24 hrs.

**Effects Of Drop Landing Height On Lower Extremity Joint Contact Forces**

Danielle D. Barkema, W. Brent Edwards, Timothy R. Derrick. *Iowa State University, Ames, IA.* (Sponsor: Philip E. Martin, FACSM)

Email: dbarkema@iastate.edu

(No relationships reported)

The impact phase of loading has long been associated with osteogenesis and lower extremity skeletal injuries. Although reaction forces increase with drop landing height, they comprise only a small portion of the joint loading environment. The true loading experienced by the joints can only be realized when muscle forces are taken into consideration.

**PURPOSE:** To determine the effects of drop landing height on lower extremity joint contact forces

**METHODS:** Nine subjects completed ten landings from three heights in a random order (26, 39, and 52 cm). Electromyographical, force platform and kinematic data were collected concurrently. Musculoskeletal modeling and computer optimization techniques were used to determine muscle forces of the lower extremity. Electromyographical data were used to validate muscle optimizations, and joint contact forces at the hip, knee, and ankle were calculated by summing the reaction and muscle forces at each joint. Peak instantaneous joint contact forces during the impact phase (200 ms) were determined. Differences in joint contact forces were compared between conditions using a repeated measures ANOVA with Tukey's post-hoc tests.

**RESULTS:** The knee and hip contact forces significantly increased with drop height. The ankle contact force during the 52 cm drop height was significantly larger than the 26 cm drop height. Respectively, joint compressive contact forces for the 26, 39, and 52 cm drop heights were as follows: ankle 6.8, 7.7, and 8.7 body weight (BW), knee 9.5, 10.5, 12.1 BW, hip 8.6, 9.9, 11.8 BW. Ground reaction forces contributed 20 to 28% of joint contact forces during drop landings.

**CONCLUSION:** The results show an evident increase in ground reaction forces and joint contact forces with an increase in drop landing height. However, ground reaction forces account for only a small portion of joint loading during drop landings. Muscle forces substantially contribute to the joint loading environment. The results suggest that conventional methods using external forces and ground reaction forces may drastically underestimate force experienced by the joint.

**Evidence Of Central And Peripheral Fatigue After A Functional Fatigue Protocol**

Melanie L. McGrath, Darin A. Padua, Michael D. Lewek. *University of North Carolina, Chapel Hill, NC.* (Sponsor: Kevin M. Guskiewicz, FACSM)

(No relationships reported)

Muscle fatigue often occurs during athletic participation, and may lead to injury. The mechanisms that produce muscular fatigue during intermittent, multi-directional exercise (e.g., soccer or basketball) remain unknown. We propose that central activation failure (CAF) will account for a major portion of the decrease in muscle force production that occurs during a functional fatigue protocol (FFP) designed to simulate high-level activities.

**PURPOSE:** To determine the extent of central and peripheral fatigue during a FFP in unimpaired individuals.

**METHODS:** Fourteen (7 M, 7 F) recreationally-active participants volunteered for this study (age:  $21 \pm 2$  years, height:  $175 \pm 9$  cm, mass:  $68 \pm 8$  kg). The FFP consisted of a maximum-effort timed 90m agility course and 5 standing broad jumps for maximum distance. The FFP was repeated (with a 5-sec rest between each repetition) until the time to complete the agility course exceeded 150% of the initial repetition. Voluntary (MVC) and electrically-elicited (EEC) peak isometric quadriceps torque, and maximum vertical jump height (VJ), were measured pre- and post-FFP. Central fatigue was assessed by using the twitch superimposition technique to measure CAF in the quadriceps. A 130V, 10 pulse train of electrical impulses (lasting 100ms) were delivered via two electrodes placed over the quadriceps during a 3s MVC. Peak torque was calculated 100ms prior to, and immediately after the initiation of the electrical pulses. CAF was calculated as the change in peak torque (EEC-MVC) divided by the EEC torque. Peripheral fatigue was assessed by examining the change in EEC torque. Paired t-tests and bivariate correlations were performed to analyze the results between conditions.

**RESULTS:** CAF increased post-fatigue (pre:  $3.5 \pm 2.8\%$ ; post:  $10.2 \pm 6.2\%$ ,  $p = 0.004$ ). Both MVC ( $166.4 \pm 40.1$  Nm to  $139.1 \pm 42.3$  Nm,  $p = 0.010$ ) and EEC ( $172.7 \pm 41.8$  Nm to  $153.7 \pm 40.7$  Nm,  $p = 0.018$ ) decreased post-fatigue. The change in CAF was highly correlated to the loss of MVC torque ( $r = 0.797$ ), explaining 59.4% of the variance ( $p = 0.002$ ). VJ also decreased post-fatigue ( $48.5 \pm 8.3$  cm to  $45.4 \pm 11.8$  cm,  $p = 0.034$ ).

**CONCLUSION:** This FFP produces significant levels of central and peripheral fatigue and decreases isometric quadriceps force and VJ height. The loss of voluntary muscle force is significantly related to the change in CAF.

## Contribution Of The Deltoid To The Early Stages Of Shoulder Abduction

Dennis Landin, Melissa Thompson. *Louisiana State University, Baton Rouge, LA.* (Sponsor: Scott K. Powers, FACSM)

Email: dlandin@lsu.edu

(No relationships reported)

The deltoid is the largest muscle on the lateral portion of the pectoral girdle and it is considered an agonist in many shoulder movements. There is some question, however, about the extent to which it contributes to the early stages of various shoulder movements.

**PURPOSE:** To investigate the joint moment produced by the deltoid in the first 90 degrees of shoulder abduction.

**METHODS:** The shoulder abduction moment of 31 subjects (16 males mean + SD age: 19.0 + 1 y; height: 1.7 + 0.2 m; body mass: 70 + kg, and 15 females mean + SD age: 20.0 + .75 y; height: 1.52 + 0.1 m; body mass: 54 + 10 kg) was tested with selective deltoid stimulation using a monophasic surface electrical generator. The shoulder abduction moment in the frontal plane was measured at shoulder joint angles of 5, 30, 60, and 90 degrees. The peak torque (Nm) of each trial was recorded by an isokinetic dynamometer.

**RESULTS:** The mean torque was highest (14.03 + 7.23 Nm) when the shoulder joint angle was 5 degrees and decreased in a linear fashion as the shoulder moved to 90 degrees, where the mean torque was 3.13 + 2.21 (Nm). There were no differences by gender.

**CONCLUSION:** The deltoid appears to contribute substantially to shoulder abduction in the early stages of the movement. The initial phases of shoulder abduction apparently create a favorable length for the moment arm of the deltoid, which facilitates its work in the early stages of abduction.

### Simulated Reduction in Hip Abductor Muscle Forces Increase Femoral Neck Stress During Running

Elizabeth R. Hageman, W Brent Edwards, Tim R. Derrick. *Iowa State University, Ames, IA.* (Sponsor: Phil Martin, FACSM)

Email: ehageman@iastate.edu

(No relationships reported)

**PURPOSE:** Koch's model of the hip indicates that during the single support phase of gait the hip abductor muscles must counter the varus torque created by the weights and inertial forces of the head, arms and torso. If these muscles become fatigued (especially gluteus medius) they may fail to counter the large varus bending moment in the neck of the femur and thus increase the stress on the superior neck. The purpose of this study was to quantify the increased stress in the superior femoral neck as a result of reduced gluteus medius tension during running.

**METHODS:** Ten experienced male runners (age 22.2 ± 3.2 yrs, height 1.8 ± 0.1 m, mass 69.8 ± 6.5 kg) ran ten trials at their preferred running velocity (4.4 ± 0.5 m/s). Motion-capture (120 Hz) and force platform data (1200 Hz) were collected and three dimensional moments were calculated at the hip, knee, and ankle joints using inverse dynamics. Kinematics were imported into a scaled SIMM model to estimate maximal forces, muscle orientations, and muscle moment arms for 44 lower extremity muscles. Estimations of actual muscle forces using a static optimization procedure found the set of forces that minimized the sum of the muscle stresses squared. Femoral neck geometry was assumed to be an effective hollow cylinder with radii that were chosen such that a scaled FEM model produced stresses that were matched to those calculated from beam theory (radius=1.7 cm). Gluteus medius forces were then reduced in the beam model from about 2 body weights (BW) to 0 BW in 10% increments. Peak superior femoral neck normal stresses were noted.

**RESULTS:** Femoral neck stresses increased from 25.6 MPa with no reduction of the abductors to 43.3 MPa when the abductors were completely removed. This was a 1.8% increase in stress for every 10% reduction in abductor force.

**CONCLUSIONS:** Even though the hip contact forces were reduced from 14 to 12 BW's as gluteus medius forces were reduced, stress on the superior femoral neck was substantially increased. The gluteus medius produced a valgus bending moment at the neck that countered the varus moment caused by the upper body. A fatigued gluteus medius may have decreased force production and therefore femoral neck stress fracture potential may be increased.

## 2278 Board #166 May 28 2:00 PM - 3:30 PM

### Vastus Lateralis Fascicle, Muscle-tendon Complex, And Tendon Length During Three Resistance Training Exercises

Gary S. Chleboun, Elizabeth J. McGhee, Katherine A. Miles, Kelly M. Siefker. *Ohio University, Athens, OH.*

Email: chleboun@ohio.edu

(No relationships reported)

Closed kinetic chain resistance exercises are thought to be more beneficial than open chain because they are more functional. This benefit could be attributed to differences of muscle-tendon complex (MTC), fascicle (FAS) and tendon (TEN) length changes during closed and open chain exercises.

**PURPOSE:** To compare the vastus lateralis (VL) MTC, FAS, and TEN length changes between the eccentric and concentric components of squat, leg press, and leg extension exercises.

**METHODS:** Eleven female subjects (21-25yrs) performed 4 repetitions of each exercise with an 8 RM load at a self-selected speed. While performing each exercise, FAS length and pennation angle of the VL were measured using ultrasonography. Knee angle was monitored with an electrical goniometer and VL EMG with surface electrodes. The MTC was calculated from knee angle and femur length. TEN was calculated as the difference of MTC length and the cosine function of FAS length. The length changes were compared over a knee flexion range of motion of 20-90° in each exercise.

**RESULTS:** MTC, FAS, and TEN length changes were not different between concentric and eccentric contractions in any of the exercises nor were there differences among exercises, but, in general, length changed as expected during the motion. MTC length changed significantly between 20-90° (26.2±1.7 vs. 31.7±1.3, p<0.05) with a greater change from 20-55° than 55-90°. FAS length changed significantly between 20-90° (6.6±1.0 vs. 10.2±0.9, p<0.05) with a greater change from 20-55° than 55-90° in the leg extension and squat but not leg press. TEN length changed significantly only between 20-55° (20.0±1.9 vs. 21.7±1.4, p<0.05). Angular velocity was greatest during squat (squat 76±26°/s, leg press 58±24°/s, leg extension 52±13°/s, p<0.05) and concentric muscle action (71±24°/s vs. 53±15°/s eccentric). The rate of fascicle shortening and lengthening was greatest during the squat (squat 4.9±2.7cm/s, leg press 3.5±1.8cm/s, leg extension 2.1±0.8cm/s, p<0.05), but there was no difference in absolute rate between concentric and eccentric actions.

**CONCLUSIONS:** Despite the inherent differences in weight bearing and differences in angular and fascicle velocity in the 3 exercises, there were no differences in VL MTC, FAS, and TEN length between exercises or between concentric and eccentric muscle actions.

## 2279 Board #167 May 28 2:00 PM - 3:30 PM

### Neurological Insufficiency: The Biceps Brachii Potential In Pronated Elbow Flexion

Torie M. Guidry<sup>1</sup>, Brian J. Campbell<sup>1</sup>, Justin F. Shroyer<sup>2</sup>, Adam C. Knight<sup>2</sup>, Wendi H. Weimar<sup>2</sup>. <sup>1</sup>*University of Louisiana at Lafayette, Lafayette, LA.*

<sup>2</sup>*Auburn University, Auburn, AL.*

Email: torie@louisiana.edu

(No relationships reported)

Studies have shown that elbow flexors, such as the biceps brachii (BB), have varying roles of contribution based on radio-ulnar positioning. Specifically, the BB is suggested to be least active during elbow flexion in a fully-pronated position. The mechanism of this decrease in the BB's contribution is unclear, but may be attributed to a selective de-recruitment, resulting from possible insufficiency at the radio-ulnar joint. Given the established relationship between muscle activity and internal and external counter-moments,

it is logical to suggest that by increasing the external pronation moment, the BB will in turn increase its contribution to elbow flexion.

**PURPOSE:** To determine the recruitment potential of the BB during a fixed external elbow moment using variable external pronation moments.

**METHODS:** Eight healthy males (Age= 25.5 ± 8.38 years) served as participants, and gripped a weighted bar (2.49kg & 77cm) with the dominant elbow flexed at 90° and the radio-ulnar joint in a fully pronated position. The bar was held statically in 3 positions for 2 seconds each: Position 1) the bar's center of mass (COM) - No Pronation Moment (NPM), Position 2) 18.5 cm from the bar's COM - Pronation Moment 1 (PM1), and Position 3) 37.5cm from COM - Pronation Moment 2 (PM2). Participants' percent maximal volitional isometric contraction (%MVIC) electromyography (EMG) data were collected. A repeated measures ANOVA was conducted to determine if there was a difference in the magnitude of pronation moment and activity of the BB.

**RESULTS:** A significant difference in BB activity was noted amongst the three conditions, ( $F_{1,7} = 42.40$ ,  $p < .001$ ,  $h^2 = .867$ ). Post hoc testing demonstrated a significant difference between PM1 and NPM ( $p < .05$ ), a significant difference between PM1 and PM2 ( $p < .01$ ), and a significant difference between PM2 and NPM ( $p < .001$ ).

**CONCLUSIONS:** The results indicate the relationship between external pronation moments and the increase in the BB's muscle activity for the same elbow resistance. Future research will investigate pronator muscle strengthening programs which could result in a neurological increase in the BB's contribution as an elbow flexor in a pronated position, applicable to various physical activities and occupations.

**The Effect Of Isolated Gastrocnemius Contracture And Surgical Gastrocnemius Recession On Strength And Function**

Nicole J. Chimera<sup>1</sup>, Michael Castro<sup>2</sup>, Kurt Manal<sup>1</sup>. <sup>1</sup>University of Delaware, Newark, DE. <sup>2</sup>CORE Institute, Phoenix, AZ.

Email: chimera@udel.edu

(No relationships reported)

Isolated gastrocnemius contracture (IGC), characterized as reduced ankle dorsiflexion with full knee extension, has been linked to foot injuries limiting function and activities of daily living. Patients with IGC may be unable to produce normal plantarflexion force. Gastrocnemius recession surgery has been shown to increase function and dorsiflexion range of motion, but the impact on force production is unknown.

**PURPOSE:** To determine the effect of gastrocnemius recession surgery on function and force production.

**METHODS:** 7 legs with IGC (51 years, 83.78 kg, 1.69 m) and 23 control legs (48 years, 74.19 kg, 1.72 m) performed isometric plantarflexion at maximum ankle dorsiflexion with full knee extension. Subjects with IGC were tested pre- and 3 months post-surgery at their maximum ankle dorsiflexion angle. The Foot and Ankle Ability Measures (FAAM) questionnaire was used to evaluate function. Passive ankle dorsiflexion range of motion (PROM) was measured with the knee in full extension using a bi-plane goniometer.

**RESULTS:** Post-surgery, subjects with IGC had significantly ( $p < 0.01$ ) increased self reported function (91% vs. 59%) and global rating (86% vs. 48%) scores, but these were slightly lower than scores reported by control subjects. PROM significantly ( $p < 0.001$ ) increased post-surgery from 0° to 13°, and was not different from control subjects (14°). There was a 10% increase in isometric plantarflexion strength post-surgery, however significant ( $p < 0.05$ ) weakness persisted compared to control subjects (~ 35 %).

**CONCLUSION:** Gastrocnemius recession surgery is a beneficial treatment option for patients with IGC. Increased function, dorsiflexion range of motion, and plantarflexion strength were observed post-surgery. Although improvements were noted following gastrocnemius recession, subjects were still weaker than controls and therefore may benefit from organized post-surgical rehabilitation. Supported in part by Synthes, Inc. and NIHR01AR040408.

**2281 Board #169 May 28 2:00 PM - 3:30 PM**

**Effect Of Knee Joint Angle On Quadriceps Muscle Force Steadiness**

Glenn N. Williams, Chandramouli Krishnan, Eric J. Allen. University of Iowa, Iowa City, IA.

Email: glenn-williams@uiowa.edu

(No relationships reported)

Force control is often assessed by evaluating the steadiness of force/torque curves during submaximal isometric contractions. The effect of knee angle (muscle length) on quadriceps force steadiness is unclear; however, evidence suggests that the CNS compensates for changes in contractile properties associated with changes in muscle length by modulating motor unit recruitment and discharge properties. Researchers have suggested that these same motor unit properties are primary determinants of muscle force steadiness.

**PURPOSE:** To assess the effect of knee angle on quadriceps force steadiness and muscle activation strategies.

**METHODS:** Twenty people (26.5 ± 4.4 years) with no significant knee injuries underwent quadriceps muscle force steadiness testing at 30° & 90°. The subjects' objective was to precisely match linear torque targets of 2%, 10%, 20%, 30%, and 50% maximum that were presented independently in random order. Force steadiness was quantified using the coefficient of variation (COV) and percent error of the subjects torque curves. The muscle activation strategies of five thigh muscles used during testing were evaluated in both time and frequency domains using surface electromyography.

**RESULTS:** The COVs and percent errors for the subjects' torque curves at 90° of knee flexion were significantly greater ( $P < 0.05$ ) than those for their torque curves recorded at 30° of flexion. The magnitudes of quadriceps (agonist) and hamstrings (antagonist) muscle activity were also significantly higher at 90° of knee flexion ( $P < 0.05$ ). Although there were significant differences in antagonist activity at submaximal force-levels, antagonist muscle activity did not differ between 30° & 90° of knee flexion during MVIC trials ( $P = 0.4$ ). The median frequency of the quadriceps muscle activity recorded at 30° of knee flexion was significantly higher than that recorded at 90° of flexion ( $P < 0.05$ ).

**CONCLUSIONS:** Knee angle has a significant effect on quadriceps force steadiness and muscle activation during isometric knee extension. The reduced force steadiness and increased muscle activation at 90° of knee flexion may be related to increased motor unit synchronization at longer muscle lengths and/or the use of different neuromuscular control strategies at the two angles.

**Aerobic Fitness And Cognitive Variability In Children**

Jean M. Samson<sup>1</sup>, Jacob J. Sosnoff<sup>1</sup>, Sarah M. Buck<sup>2</sup>, Charles H. Hillman<sup>1</sup>. <sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>Chicago State University, Chicago, IL.

(No relationships reported)

It has been suggested that aerobic fitness mediates the executive control of attention in preadolescent children. Recently, it has been found that cognitive variability is

uniquely predictive of cognitive function in adult populations. However, it is not clear if aerobic fitness provides similar mediation to cognitive variability in children.

**PURPOSE:** To examine the influence of aerobic fitness on cognitive variability in preadolescent children during performance of a task requiring activation of the three attentional networks.

**METHODS:** 46 children were separated into a higher fit (n= 24; age 9.8 years) or a lower fit (n=22; age 9.9 years) group based on VO<sub>2</sub> max testing results using a modified Balke protocol. To assess cognitive function participants completed the Attention Network Test (ANT), which combines the cued reaction time paradigm and the Eriksen flanker task. Mean response time (RT) and standard deviation (SD) were calculated along with the coefficient of variation (CV) to control for group differences in response time.

**RESULTS:** Examination of mean RT revealed no significant group differences. Examination of RT variability revealed that the higher fit participants had lower relative variability compared to the lower fit participants in the neutral condition (0.217 vs. 0.245), but not the congruent (0.222 vs. 0.234) or the incongruent conditions (0.206 vs. 0.199) of the flanker task.

**CONCLUSIONS:** Aerobic fitness appears to selectively mediate cognitive variability in children during task components requiring simple stimulus discrimination, but not during task components requiring activation of the executive attention network.

**Physical Activity And Cognitive Processing In Older Men And Women**

Andrew C. Venezia<sup>1</sup>, Jacklyn S. Wierzbicki<sup>1</sup>, Darryl Reitmeyer<sup>1</sup>, Ashley Shick<sup>1</sup>, Christopher D. Still<sup>2</sup>, Eric S. Rawson, FACSM<sup>1</sup>. <sup>1</sup>Bloomsburg University, Bloomsburg, PA. <sup>2</sup>Geisinger Medical Center, Danville, PA.

Email: acvenez2@bloomu.edu

(No relationships reported)

Survey data indicate that physical activity is associated with higher cognitive processing in older individuals, but this has not been assessed using accelerometry.

**PURPOSE:** To determine if physical activity assessed with accelerometry is associated with cognitive processing in older men and women.

**METHODS:** Twenty two subjects performed a battery of neurocognitive tests that included: simple reaction time, code substitution, code substitution delayed, logical reasoning, mathematical processing, running memory, and Sternberg memory recall. The outcome variables for the specific tests, with the exception of simple reaction time, were response speed (RES), number of correct responses (COR), and throughput (THR) (correct responses/minute). Subjects wore an accelerometer (ActiGraph) for 7 days to measure moderate and vigorous lifestyle and walking/running physical activity. Accelerometer data were processed using the Crouter 2 Regression model.

**RESULTS:** Subjects were (mean  $\pm$  SD) 72  $\pm$  6 years and had a Mini Mental State Exam (MMSE) score of 28  $\pm$  2. Minutes of vigorous intensity lifestyle (2  $\pm$  3 min/day), moderate intensity (4  $\pm$  6 min/day), and vigorous intensity (0 min/day) walking/running physical activity were excluded from the analysis due to low volume. We found no relationship between moderate lifestyle physical activity and simple reaction time (RES: r = -0.30, p = 0.17; THR: r = 0.33, p = 0.13), code substitution (RES: r = 0.02, p = 0.94; COR: r = 0.06, p = 0.80; THR: r = 0.10, p = 0.66), code substitution delayed (RES: r = -0.03, p = 0.90; COR: r = -0.25, p = 0.27; THR: r = -0.09, p = 0.69), logical reasoning (RES: r = -0.07, p = 0.77; COR: r = -0.38, p = 0.08; THR: r = -0.01, p = 0.95), mathematical processing (RES: r = -0.08, p = 0.74; COR: r = -0.29, p = 0.21; THR: r = -0.19, p = 0.40), running memory (RES: r = -0.32, p = 0.15, COR: r = -0.24, p = 0.30; THR: r = 0.01, p = 0.98), and Sternberg memory recall (RES: r = 0.03, p = 0.88; COR: r = -0.25, p = 0.26; THR: r = -0.02, p = 0.92).

**CONCLUSION:** We found no relationship between moderate physical activity and cognitive processing. Potentially, our findings resulted from the high levels of cognitive function and/or low levels of vigorous physical activity in this sample.

**The Effects Of Acute Exercise And Nutrition On Cognition In Healthy Older Adults**

Jill M. Slade, Natalie J. Stein, Joseph J. Carlson. Michigan State University, East Lansing, MI. (Sponsor: Lori Ploutz-Snyder, FACSM)

Email: sladeji@radiology.msu.edu

(No relationships reported)

Normal aging is associated with declines in cognition (e.g. executive function, attention). Long-term exercise has been shown to enhance cognitive function in older adults and acute exercise has been shown to improve cognitive function in young adults. Selected nutrients and dietary patterns have also been related to improved cognitive function.

**PURPOSE:** To compare cognition after a moderate exercise bout (EX) and a nutrient dense meal (ND) to cognition after a low nutrient dense meal (LND) in older adults.

**METHODS:** Nineteen adults (70  $\pm$  5 yrs old; 5 males) each completed three randomized visits. A cognitive function battery was done 3 hours after meal consumption and/or 10 minutes after exercise. The computerized battery of 9 tests included both executive function and attention tasks; accuracy and speed were measured. The visits were (1) EXND (EX= 30 mins of exercise at 50-60% heart rate reserve after a high nutrient density meal (ND= plant-based foods rich in unsaturated fats including N-3 fatty acids, fiber, folate, K+, antioxidants, and low saturated fat, (2) consumption of ND meal and (3) consumption of a low nutrient dense meal (LND= animal based food including high saturated fat, methionine, and low unsaturated fats, fiber, K+, folate, and antioxidants).

**RESULTS:** EXND and ND did not result in better cognitive scores compared to LND (see table). Executive function during a card prediction task was more accurate in ND compared to EXND (p=0.02).

**CONCLUSIONS:** A single bout of exercise did not improve cognitive function in older adults. Furthermore a single ND meal did not improve cognitive function as compared to a single LND meal but it does not rule out that chronic exercise or ND meal pattern may improve cognitive function in older adults.

	VISIT TYPE

**Effects Of Square-stepping Exercise On Behavioral Speed In Older Adults**

Ryosuke Shigematsu<sup>1</sup>, Tomohiro Okura<sup>2</sup>, Masaki Nakagaichi<sup>3</sup>, Tomoaki Sakai<sup>4</sup>, Yoshio Nakata<sup>2</sup>, Yoichi Nakamura<sup>5</sup>, Rei Nakanishi<sup>1</sup>, Kiyoji Tanaka, FACSM<sup>2</sup>. <sup>1</sup>Mie Univ., Tsu, Japan. <sup>2</sup>Univ. Tsukuba, Tsukuba, Japan. <sup>3</sup>Nagasaki Univ., Nagasaki, Japan. <sup>4</sup>Doshisha Univ., Kyotanabe, Japan. <sup>5</sup>Ryutu Keizai Univ., Ryugasaki, Japan.

Email: rshige@edu.mie-u.ac.jp

(No relationships reported)

Square-stepping exercise (SSE), which was recently developed as a challenging exercise form, could improve the functional fitness of the lower extremities in older adults. We found that this form of exercise lowered the risk of falling. One reason for the decrease in falls could be improvements in the factors influencing behavioral speed, such as visual search time and accuracy of short movements.

**PURPOSE:** The effects of SSE on behavioral speed have not been examined; we therefore investigated this issue based on the assumption that deterioration in the speed increases the risk of falling.

**METHODS:** Fifty adults, aged 65 to 74 years, were randomly assigned to SSE and control groups. The SSE group participated in a 70-min SSE program twice a week for a period of 3 months. The control group was given a supervised walking instruction to be performed once a week for 70 min for a period of 3 months. The participants in this group were also encouraged to increase their daily walking steps. Behavioral speed was assessed by a modified Trail Making Test, in which the time required for pushing 25 buttons was measured. The buttons were numbered from 1 to 25 and randomly presented on a computer screen. The test consisted of two parts (Parts A and B). Buttons were stationary in Part A, while in Part B, they were randomly relocated after a correct button was pushed. Therefore, Part A required behavioral speed and short-term memory, and Part B, only speed.

**RESULTS:** Data were expressed as the average time (in seconds) required for pushing a correct button. In the SSE group, the time decreased from  $1.79 \pm 0.47$  s to  $1.69 \pm 0.36$  s in Part A, while in the control group, it changed from  $1.83 \pm 0.40$  s to  $1.85 \pm 0.37$  s. Two-way ANOVA revealed that the time (intervention) effect and interaction were not significant. In the SSE group, the time decreased from  $2.93 \pm 0.36$  s to  $2.75 \pm 0.41$  s in Part B, while in the control group, it changed from  $3.08 \pm 0.49$  s to  $3.02 \pm 0.39$  s. The time (intervention) effect was significant.

**CONCLUSIONS:** Along with the benefits derived from walking, SSE contributes to improve behavioral speed by reducing visual search time and increasing accuracy of movements.

**A Matched-pair Prospective Study On The Effect Of A Defined In-hospital Sports Program On Cognitive Functions In Patients Suffering From Cancer**

Fiona Streckmann, Roland Mertelsmann, Martina Kleber, Hartmut Bertz, Jens A. Leifert. *University Medical Center, Freiburg, Germany.*

Email: fiona.streckmann@uniklinik-freiburg.de

(No relationships reported)

**PURPOSE:** The diagnosis and treatment of cancer is, for most people, the greatest challenge by which they are confronted in their lives. It is associated with physical and psychological changes such as anxiety, depression, reduced physical performance or fatigue. The combination of a life-threatening illness and a physically and emotionally exhausting therapy may also have negative effects on cognitive function during the course of the disease. Physical exercise has many positive effects on alterations resulting from the disease or therapy. Therefore we were interested in the effect of a defined sports program on the cognitive functions of cancer patients

**METHODS:** 16 patients were included in the study. The training group (TG, n=8) participated in the program 2-3 times a week for 60-90 min over 3 months. The control group (CG, n=8) was not involved in any form of physical activity. Body composition as a marker for the physical training effect was measured in both groups by BodPod analysis at the start and after completion of the study. A questionnaire (QLQ-C30) was used to evaluate changes in quality of life affected by the program as well as psychological and social effects of the training.

Cognitive capabilities were evaluated by FEDA questionnaire at the start of the study and when training was completed.

**RESULTS:** Evaluation after 3 months showed a significant improvement in the physical performance in the TG compared to the CG. BodPod analysis revealed a significant change in body composition with an increase in muscle of an average of 5.2 % compared to a reduction of 1.6 % in the CG.

Evaluation of quality of life showed a significant improvement in fatigue, physical function, emotional and social function, dyspnea and loss of appetite compared to the CG where no changes in any of the tested items could be detected.

The FEDA questionnaire showed a significant improvement of the cognitive abilities within the TG on all 3 scales:

1. Distraction and slowing down of mental processes
2. Tiredness and sluggishness in practical tasks
3. Lack of motivation and apathy

In contrast, the non-active CG showed even worse results in scale 1 and 2 after 3 months but no significant changes on scale 3

**CONCLUSIONS:** A defined moderate physical activity for cancer patients may prevent cognitive impairment during the course of cancer disease and treatment.

**The Influence Of Exercise On Neurotrophines, Neurotransmission And Cognitive Functioning**

Britta Lorey<sup>1</sup>, Juergen Hennig<sup>2</sup>, Gebhard Sammer<sup>2</sup>, Karen Zentgraf<sup>3</sup>, Joern Munzert<sup>3</sup>. <sup>1</sup>Dept. of Sports Science and Bender Institute of Neuroimaging, Giessen, Germany. <sup>2</sup>Department of Psychology, University of Giessen, Giessen, Germany. <sup>3</sup>Dept. of Sports Science, Giessen, Germany.

Email: britta.lorey@sport.uni-giessen.de

(No relationships reported)

A great body of literature demonstrates that physical active individuals show improved cognitive functions. Nevertheless, the mediating factors are still in discussion. Possible candidates are neurotrophines, like the brain derived neurotrophic factor (BDNF), or neurotransmitters, like dopamine or serotonin. In animal studies, they are up-regulated by physical exercise and therefore are considered to influence synaptogenesis and signal transduction processes.

**PURPOSE:** To investigate the influence of a 4-week endurance exercise training on serotonergic and dopaminergic neurotransmission, on the peripheral BDNF level, and on several cognitive functions, like working memory test and information processing.

**METHODS:** 21 healthy and untrained males were assigned to either an exercise or a control group. Subjects who participated in the exercise group performed a 4-week indoor cycling training (3 times per week). Prior and after the exercise training, participants were scanned in a 1.5 Tesla fMRI scanner and participated in a serotonergic challenge test (Es-Citalopram). Furthermore, peripheral BDNF and Prolactine levels were assessed. For assessing cognitive functioning, participants performed a n-back working memory paradigm and a vigilance test.

**RESULTS:** We found that the 4-week indoor cycling training lead to a significant decrease of peripheral BDNF levels, an increased cortisol response in the serotonergic challenge test, an increase of neuronal activation in the thalamus and a significant reduced performance in the conducted vigilance test. The described parameters remained unaffected in the control group.

**CONCLUSION:** These findings demonstrate that a 4-week endurance exercise training affects neurochemical parameters, like neurotrophines, neurotransmitters and neuronal activation, as well as information processing. Nevertheless, the present data show that the underlying mechanisms are subject to a complex interplay. Therefore, future studies will need to address the issue of the interaction between neurotransmitters, neurotrophines, exercise and cognitive functioning.

**Short-Duration Quercetin Supplementation Does Not Alter Cognitive Function Following Submaximal Exercise In Untrained Men**

Kate Lambourne. *University of Georgia, Athens, GA.*

Email: katel@uga.edu

(No relationships reported)

**PURPOSE:** To investigate the effects of short-duration quercetin supplementation on post-exercise cognitive performance.

**METHODS:** Using a double-blind, pretest-posttest, control-group design, 30 recreationally-active, but not endurance-trained, men were randomly assigned to Quercetin and Placebo groups. Cognition was measured before and after 9-16 d of supplementation with 1 g/d of quercetin in a fruit-punch beverage or a placebo beverage. Three cognitive tests were administered prior to and following 60-min cycling at 50% VO<sub>2</sub>max and a 10-min simulated time trial.

**RESULTS:** Acute exercise facilitated men's performance on tests of executive function ( $F(1,28)=11.25$ ,  $p=0.002$ ), choice-reaction time ( $F(1,27)=10.09$ ,  $p=0.004$ ), and perceptual discrimination ( $F(1,28)=3.99$ ,  $p=0.055$ ). No effects of quercetin on cognitive function were observed.

**CONCLUSION:** Dietary quercetin supplementation with 1 g/d for 9-16 d does not alter young men's cognitive performance following a 70-min acute bout of submaximal cycling.

*Supported by the Beverages Institute for Health and Wellness, The Coca-Cola Company.*

**2289      Board #177    May 28            3:30 PM - 5:00 PM**  
**The Effect Of Using An Active Workstation On Cognitive Function And Simple Motor Skill**

Christina M. Ohlinger, Ronald H. Cox, Thelma S. Horn. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)

Email: ohlingcm@muohio.edu

(No relationships reported)

**PURPOSE:** To assess the ability of subjects to perform tasks requiring selective and divided attention, short term memory, and simple motor skills while using an active workstation.

**METHODS:** Each participant ( $n=50$ ) completed three tests to assess divided attention, short term auditory verbal memory, selective attention, and simple motor skill while the subjects were sitting, standing and walking while using an active workstation at a speed of 1 mph. The Auditory Consonant Trigram test (ACTT) was used to assess divided attention and short term auditory verbal memory; the Stroop Color Word Test (SCWT) was used to measure selective attention; and the Digital Finger Tapping test (FTT) was used to measure motor skill and motor control.

**RESULTS:** A 6 x 3 Mixed Model MANOVA (test order by experimental condition) w/repeated measures on the second factor found no effects associated with test order or order of postural condition. A series of one-way ANOVAs with repeated measures found no significant differences in the sitting, standing, and walking scores for the ACTT ( $52.70 \pm 5.58$ ,  $53.32 \pm 5.39$ ,  $53.04 \pm 5.16$ , mean  $\pm$  SD respectively) or the SCWT ( $55.02 \pm 11.90$ ,  $54.76 \pm 10.72$ ,  $55.38 \pm 10.83$ , mean  $\pm$  SD respectively). A significant difference ( $p<.05$ ) was found between the sitting, standing, and walking scores for the FTT ( $57.15 \pm 8.36$ ,  $56.95 \pm 8.02$ ,  $55.80 \pm 8.04$ , mean  $\pm$  SD respectively). Post-hoc means testing found significant differences ( $p<.05$ ) between sitting and walking and standing and walking. No significant difference was found between sitting and standing. The difference between sitting and walking represents approximately a 2% decrement in simple motor skill.

**CONCLUSION:** There is a decrement in simple motor skill but not divided attention, short term auditory verbal memory, or selective attention when subjects are using an active workstation at a speed of 1 mph. Given that many people find time to be a barrier to engaging in physical activity, alteration of the work environment to increase activity may be effective in producing behavior change. This study supports the feasibility of using active workstations to promote physical activity in the work environment.

**2290      Board #178    May 28            3:30 PM - 5:00 PM**  
**The Association Between Study Time, Grade Point Average And Physical Activity Participation In College Students**

Jennifer I. Flynn, Anna K. Piazza, Joshua J. Ode. *Saginaw Valley State University, University Center, MI.* (Sponsor: James M. Pivarnik, FACSM)

Email: jiflynn@svsu.edu

(No relationships reported)

Previous studies have assessed physical activity in college students, but few investigators have examined the relationship between academic behaviors/performance and physical activity participation.

**PURPOSE:** The purpose of this study was to assess the association between study time, grade point average (GPA) and meeting current recommendations for vigorous and moderate physical activity in college students.

**METHODS:** 141 undergraduate students completed an online survey at the beginning of the Fall 2007 semester. Physical activity was defined as vigorous ( $\geq 20$  minutes of activity that made you sweat and breath hard on  $\geq 3$  days per week) or moderate ( $\geq 30$  minutes of activity that did not make you sweat and breathe hard on  $\geq 5$  days per week). Academic behavior was assessed as the amount of time spent studying per day (study time:  $\leq 1$  hour, 2 hours,  $\geq 3$  hours). Academic performance was assessed as cumulative GPA (GPA: no GPA,  $<3.0$ ,  $3.0-3.5$ ,  $\geq 3.5$ ). Adjusted odds ratios and 95% CIs were calculated to assess the relationship between study time/GPA and vigorous/moderate physical activity while controlling for gender, race, class standing, major, and varsity sport participation.

**RESULTS:** Results suggest that when compared to students who studied  $\leq 1$  hour per day, those who studied  $\geq 3$  hours per day were an estimated 3.5 (95%CI: 1.1-11.2) times more likely to participate in vigorous physical activity and 2.6 (0.9-7.5) times more likely to participate in moderate physical activity. When compared to students with a GPA  $<3.0$ , those with a GPA  $\geq 3.5$  were an estimated 3.2 (0.9-11.8) times more likely to participate in vigorous physical activity.

**CONCLUSIONS:** These results suggest a potential association between academic behaviors/performance and physical activity in college students. Specifically, students who spend more time studying or have a higher GPA are more likely to participate in physical activity. However, due to limited research, additional information is needed to explore this relationship in more detail.

**2291      Board #179    May 28            3:30 PM - 5:00 PM**  
**Promoting Physical Activity By Integrating Exercise Into Academic Lesson Plans In Urban Middle-Schools**

Rohit Majumdar, Scott E. Crouter, Amy Teixeira, Natasha Denis, Kathy Palmer, Kristen McGovern, Kyle J. McInnis, FACSM. *University of*

Massachusetts, Boston, Boston, MA.  
Email: rmajumdar330@gmail.com  
(No relationships reported)

Due to a decrease in physical education and recess, it is imperative to identify innovative ways to get children active while at school. ExerLearning (ExL) is the integration of physical activity (PA) into standard cross-curricular lesson plans that aims to simultaneously increase PA while promoting enhanced academic performance.

**PURPOSE:** The purpose of this study was to examine differences in PA level during traditional academic tutoring (tutoring) and integrated ExL.

**METHODS:** Forty-two racially-ethnically diverse middle-school boys and girls (age  $13 \pm 0.9$  yrs; BMI,  $23.2 \pm 6.5$  kg m<sup>-2</sup>) were randomly assigned to receive tutoring and ExL two times per week for six weeks, at GoKids youth fitness research and training center at UMass Boston, in either a) math (n=23) or b) language arts (LA) (n=19). At each session, kids in each group received 30 minutes of tutoring and 30 minutes of ExL. PA at each visit was measured using an ActiGraph GT1M (AG) accelerometer that was worn on the right hip. AG data were converted to time spent in sedentary behaviors (SB), light PA (LPA), and moderate to vigorous PA (MVPA) using the Trueth equation. At the end of each session participants rated the ExL activities in math or LA (1 to 5 scale) for reinforcement of academic skill development, if the directions were easy to understand and follow, and enjoyment of learning academic skills.

**RESULTS:** On average, participants spent significantly less time in SB during ExL ( $14.0 \pm 4.2$  min) vs. tutoring ( $25.8 \pm 4.4$  min) ( $P < 0.001$ ) and significantly more time in LPA and MVPA during ExL (LPA,  $19.8 \pm 3.6$  min; MVPA  $3.6 \pm 2.2$  min) versus tutoring (LPA,  $9.1 \pm 3.4$  min; MVPA,  $0.7 \pm 0.9$  min) ( $P = 0.001$ ). Males on average, obtained 2.6 more minutes of MVPA than females during ExL ( $P = 0.001$ ). Those in the Math group, compared to the LA group, rated the lessons to help more with their academic skills (3.8 vs. 3.1;  $P = 0.014$ ) and felt the directions were easier to understand (4.3 vs. 3.9;  $P = 0.038$ ). Both groups enjoyed the activities and rated them as 3.8 (Math) and 3.5 (LA) out of 5 ( $P > 0.05$ ).

**CONCLUSION:** ExL has potential to be an effective school-based strategy to decrease SB and increase LPA and MVPA in middle school children, in a time efficient manner, while also teaching the needed core curriculum. Future work needs to examine the effect on academic outcomes and its' relation to improved PA with ExL.

### 2292 Board #180 May 28 2:00 PM - 3:30 PM The Effects Of 12-weeks Cross Training On Fatigue And Mood In Recent Breast Cancer Survivors

Melanie Poudevigne<sup>1</sup>, Janet Wojcik<sup>2</sup>, Betty Lane<sup>1</sup>, Marty Polovich<sup>3</sup>, Suzana Simonishvili<sup>4</sup>. <sup>1</sup>Clayton State University, Morrow, GA. <sup>2</sup>Winthrop University, Rock Hill, SC. <sup>3</sup>Duke Oncology Network, Durham, NC. <sup>4</sup>Emory University, Atlanta, GA. (Sponsor: Dr. Allen Jackson, FACSM)  
Email: mpoudevigne@yahoo.com  
(No relationships reported)

Survivors tend to decrease their physical activity (PA) levels after their diagnosis of cancer, and most continue lower levels of PA through treatment and beyond, rarely returning to their prediagnosis levels of PA. Regular PA decreases feelings of fatigue and mood disturbances and can improve quality of life (QOL).

**PURPOSE:** Examine the adherence to a combined cardiorespiratory and resistance training at moderate intensity and to determine whether breast cancer survivors (BCS) would experience improved energy levels and QOL.

**METHODS:** Twenty sedentary BCS between 2-24 months post-treatment and the ages of 18 and 60 were recruited at three sites. The cancer treatments ranged from lumpectomies (23%), mastectomies (29%), radiations (32%) and chemotherapies (16%). The training consisted of a 12-week exercise program of 3 weekly sessions of 60 min duration, supervised by a certified personal trainer and divided into resistance (30 minutes) and aerobic training (5 minutes warm-up, 20 minutes training, 5 minutes cool-down). The aerobic intensity was set at 60%HRR and reevaluated every three weeks. Blood pressures were taken at baseline and every ten minutes during each cardiovascular exercise. The dependent variables were measured every 3 weeks and included: fatigue and mood disturbances measured by the subscale of the Profile of Mood States, QOL measured by SF-36 and work absenteeism.

**RESULTS:** The mean ( $\pm$ SD) attendance rate was 92 ( $\pm 8.0$ ) %. No musculoskeletal injuries and problematic symptoms occurred during the cross-training. Repeated measures ANOVA showed a large increase in QOL (22%) and significant decrease in fatigue (43%) across 12 weeks (eta squared range: .491 to .708; all p values < .05). No differences were found in work absenteeism. Blood pressure was unchanged after training.

**CONCLUSIONS:** This is the first pilot study- controlled study of the impact of cross training on recent sedentary breast cancer survivors' levels of energy. Combined moderate cardiorespiratory and resistance training during a brief duration is safe and improves QOL and energy levels in recent women BCS.

---

### 2293 Board #181 May 28 2:00 PM - 3:30 PM Acute Effects Of Cycling On Mood And Eeg In Sedentary Young Adults With Persistent Fatigue

Nathaniel Thom, Brett Clementz, Timothy Puetz, Patrick O'Connor, FACS, Rod Dishman, FACS. University of Georgia, Athens, GA.  
Email: natethom@gmail.com  
(No relationships reported)

**PURPOSE:** We previously reported that 6-weeks of exercise training increased feelings of vigor among inactive college students who reported persistent fatigue. The purpose of this study was to examine whether acute effects of exercise during the training period would be similar to those chronic effects. Further, we hypothesized that mood changes after exercise would be related to brain activity measured by electroencephalography (EEG).

**METHODS:** 36 males and females were randomly assigned to 20-min of moderate or low intensity (75% or 40% VO<sub>2</sub> peak) cycling or seated-rest. Measures were taken before and 10 min after 3 acute sessions, each separated by 2 weeks. Mood was measured using the POMS-SF. Four minutes of EEG data were sampled at 500 Hz with an analog filter of 0.1-200 Hz, and inspected offline for bad channels which were replaced by spherical spline interpolation. Data were digitized and filtered from 0.5 to 58 Hz and transformed to a Laplacian montage to improve spatial resolution. Artifacts were removed using independent component analysis. The data were Fast-Fourier transformed to absolute power ( $\mu V^2$ ) averaged over all 4 min, and expressed as  $\log_{10}(\mu V^2)$  in 4 bands: theta (4-7Hz), alpha (8-13Hz), low beta (13-20Hz), high beta (20-30Hz). Top-meridian plots consistently revealed active channels in clusters of anterior and posterior sites. Hypotheses were tested by a 3 group (low- or high-intensity EX or control) x 2 session (pre- vs. post-test) x 3 week (1, 3, 6) RM-ANCOVA, controlling for pre-test mood. EEG power was added as a time-varying covariate in each model to test relations with mood changes.

**RESULTS:** There were group effects for vigor ( $p = 0.001$ ), depression ( $p = 0.04$ ), and EEG activity in posterior regions in all frequency bands ( $p < 0.05$ , mean  $h^2 = 0.31$ ). Posterior theta activity accounted for changes in vigor, and posterior activity in all frequency bands accounted for changes in depression.

**CONCLUSION:** Transient increases in feelings of vigor after acute exercise paralleled the chronic effects. Changes in EEG oscillatory activity partially accounted for increased vigor and decreased depression after 3 acute bouts of moderate intensity exercise. Studies that otherwise manipulate mood and/or EEG activity during exercise are needed to determine whether EEG changes after exercise are causally linked with mood.

---

**2294 Board #182 May 28 2:00 PM - 3:30 PM****Cortisol Contributes To Symptomatic Fatigue And Heart Rate Variability In Persons With Multiple Sclerosis**

Benjamin A. Ingraham<sup>1</sup>, Douglas Woo<sup>2</sup>, Ellen Heyer<sup>1</sup>, April Harkins<sup>1</sup>, Jennifer Dixon<sup>1</sup>, Alexander V. Ng, FACSM<sup>1</sup>. <sup>1</sup>Marquette University, Milwaukee, WI. <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.

Email: benjamin.ingraham@marquette.edu

(No relationships reported)

Symptomatic fatigue is one of the most common complaints in persons with multiple sclerosis (MS). Stress hormones have been hypothesized to be mechanisms that may lead to this symptom of fatigue. Chronically elevated cortisol could lead to hyperactivity of the sympathetic nervous system (SNS) through bi-directional effects of the hypothalamic-pituitary-adrenal (HPA) axis on the SNS.

**PURPOSE:** To test the hypothesis that cortisol is associated with symptomatic fatigue and HRV in persons with MS.

**METHODS:** We tested 7 persons with MS (5 Female, 2 Male) and 11 control (C) subjects (10 Female, 1 Male). The following questionnaire and clinical measures were obtained from all subjects: Symptomatic Fatigue (Fatigue Impact Scale), Depression (Beck Depression Inventory) and Multiple Sclerosis Functional Composite Measure (MSFC). Night-time salivary cortisol (11:00 pm) was measured using EIA. A 10 minute EKG was taken and heart rate variability (HRV), an indication of cardiac autonomic balance, was subsequently analyzed (low/high freq. ratio). Analysis was by unpaired t-test and Pearson correlations. Data are mean (SE). Significance was  $p \leq 0.05$ .

**RESULTS:** MS subjects compared to C reported greater fatigue ( $MS = 51(13)$ ,  $C = 5(2)$ ,  $p < 0.001$ ), and depression ( $MS = 7(3)$ ,  $C = 3(0.5)$ ,  $p = 0.001$ ), and had lower MSFC ( $MS = 2.2$ ,  $C = 2.8$ ). There were no differences between groups in cortisol or HRV. Within the control group, there were no significant correlations between cortisol, HRV, or fatigue. Within the MS group, cortisol was correlated with symptomatic fatigue ( $r = 0.75$ ,  $p = 0.05$ ) and HRV ( $r = 0.82$ ,  $p = 0.02$ ). In turn, fatigue was also correlated with HRV ( $r = 0.75$ ,  $p = 0.05$ ). The relationships observed with HRV are consistent with increased cardiac sympathetic activity influencing fatigue.

**CONCLUSIONS:** While the mechanisms underlying these correlations are unknown, these results implicate cortisol as an important mediator of fatigue in MS subjects. This could be a direct effect or via SNS.

**2295 Board #183 May 28 2:00 PM - 3:30 PM****Evaluation Of Three Distinct Models Of Exercise Performance Following Immune Mediated Fatigue In Mice**

Traci L. Barrilleaux, J. Mark Davis, FACSM, Julia E. Gambone, E. Angela Murphy, Jamie L. McClellan, Crystal Livingston, Martin D. Carmichael. South Carolina University, Columbia, SC.

(No relationships reported)

Various models of exercise have been used to evaluate fatigue in animals; however it is not uncommon for studies to utilize a single model in their investigations of this complex subject. Forced treadmill running (measure of maximal endurance capacity), voluntary wheel running (measures motivation/willingness to be active) and rotorod performance (measure of neuromuscular coordination) are commonly used exercise models of fatigue. However, the stimuli are very different and all are influenced disproportionately by peripheral and central factors.

**PURPOSE:** The purpose of this study was to evaluate the efficacy of three distinct models of exercise behavior following immune-mediated fatigue in mice.

**METHODS:** Fatigue was induced by a single lipopolysaccharide (LPS) (100ug i.p.) injection. In the treadmill experiment mice were assigned to either placebo or LPS treatment. Mice were run on a treadmill (40m/min and 5% grade) on days 1, 3, 5, and 7 following treatment and time to fatigue was recorded. In the voluntary wheel running and rotorod experiments baseline data was collected for each mouse prior to LPS administration. Voluntary activity was measured for 10 consecutive days and rotorod performance was measured on days 1, 3, 5, and 7 following LPS treatment.

**RESULTS:** LPS decreased performance across all three exercise models. Voluntary wheel running activity was affected to the largest extent and for the longest duration (~95% ( $P < 0.05$ ) which returned to baseline by 6-8 days). LPS administration reduced treadmill run time to fatigue by ~50% ( $P < 0.05$ ) which returned to baseline by day 5. Time spent on the rotorod was reduced by ~15% ( $P < 0.05$ ) following LPS injection and returned to baseline by day 7.

**CONCLUSION:** The data suggest that motivation or willingness to run is more affected by immune mediated fatigue than maximal endurance capacity or measures of neuromuscular coordination. Also, there are indications that voluntary wheel running is an effective model and the most sensitive measure to immune-mediated behavioral changes followed by forced treadmill running and rotorod performance. The data reinforce the importance of utilizing multiple models when investigating exercise behavior.

---

**2296 Board #184 May 28 2:00 PM - 3:30 PM****Effects Of Carbohydrate Ingestion On Central Fatigue**

Nicholas Gant, Cathy M. Stinear, Winston D. Byblow. The University of Auckland, Auckland, New Zealand.

Email: n.gant@auckland.ac.nz

(No relationships reported)

Carbohydrate availability is important for maintaining voluntary drive during fatiguing exercise, but little is known about the time course over which central fatigue is offset following feeding.

**PURPOSE:** This study examines the immediate and delayed influences of carbohydrate ingestion on voluntary drive and force production during fatiguing exercise.

**METHODS:** Right-handed males performed two separate bouts of continuous isometric elbow flexion exercise at an intensity equivalent to 15% of maximal voluntary contraction force (15%MVC) for 30 min. Participants performed maximal voluntary contractions (MVC) every 2 min during 15%MVC. At 60 s intervals throughout 15%MVC, and during each MVC, transcranial magnetic stimulation was used to stimulate the contralateral hemisphere to elicit a motor evoked potential and silent period (SP) in the exercising biceps brachii (BB). Force production and surface EMG of BB were monitored continuously, venous blood samples, heart rate and perceptual rating scales were collected every 4 min. After 11 min of exercise a carbohydrate solution (0.4 g·kg body mass<sup>-1</sup>; CHO) or an energy-free placebo solution (PLA) were administered in a randomized crossover, double-blind fashion. Participants mouth-rinsed each solution for 15 s before swallowing.

**RESULTS:** Fatigue was confirmed by decreased force production at 15%MVC and MVC ( $P = 0.01$ ), increased superimposed twitch force ( $P < 0.01$ ), and increased SP duration ( $P < 0.01$ ) in both trials. Comparisons between solutions were made in the period before feeding, following feeding (but prior changes in plasma glucose), and alongside systemic glucose appearance. Immediately after CHO ingestion, MVC tended to be larger and SP duration was shorter ( $P < 0.01$ ), suggesting an acute increase in voluntary drive. There were similar trends with subsequent plasma glucose inflection.

**CONCLUSIONS:** Carbohydrate ingestion improves maximal force production and the ability to generate voluntary drive during fatiguing exercise. These enhancements may occur before ingested carbohydrate is systemically available. Our findings provide insight into signaling mechanisms that regulate central drive according to substrate availability, both prior to, and after glucose appearance in blood.

---

**2297 Board #185 May 28 2:00 PM - 3:30 PM****The Influence Of Scheduling And Fatigue On Injury Rates At The 2008 USA Cup**

Nathan Waibel<sup>1</sup>, William O. Roberts, MD, MS, FACS<sup>1</sup>, Scott Lunos, MS<sup>2</sup>. <sup>1</sup>The University of Minnesota Medical School, Minneapolis, MN.  
<sup>2</sup>University of Minnesota Academic Health Center, Minneapolis, MN.  
(No relationships reported)

The USA Cup Soccer Tournament, divided into the USA Cup Weekend and the USA Cup, is a large annual youth tournament that often requires a team to play more than one game a day. The game durations are shortened from regulation time for each age group. Little is known about the rate of injury as the tournament progresses with respect to the effect of playing more than one game a day or several games in a short time span. Hence, there is a need for research into the affect of tournament scheduling on injury rates in the younger athletes.

**PURPOSE:** To investigate the influence of multiple games on multiple days on tournament athlete injury rates.

**METHODS:** All athletes seeking medical attention for an acute or chronic game related tournament injury were surveyed by questionnaire immediately after registering for care at the on site medical facility. The survey questions were directed at the circumstances of each injury related to the timing of the injury with respect to the amount of soccer played by the injured participant.

**RESULTS:** In the USA Cup Weekend, there were 4.06, 5.14, and 3.92 injuries /1000 PH on July 11<sup>th</sup>, 12<sup>th</sup>, and 13<sup>th</sup> respectively. There was no significant difference in the incidence of injuries for the games on the 2<sup>nd</sup> or 3<sup>rd</sup> day compared to the 1<sup>st</sup> day. The injury rates of first games compared to second games of the day showed no difference (p=0.1259). In the Schwan's USA Cup, the injury rates were 5.65, 8.95, 7.83, 6.94, and 4.62 /1000 PH on July 15<sup>th</sup>, 16<sup>th</sup>, 17<sup>th</sup>, 18<sup>th</sup>, and 19<sup>th</sup> respectively. There were statistically significant differences in the incidence of injuries seen when comparing the 17<sup>th</sup> to the 15<sup>th</sup> (p=0.02; incidence ratio=1.38, 95% confidence interval=1.05-1.82) and the 16<sup>th</sup> to the 15<sup>th</sup> (p=0.0009; incidence ratio=1.58, 95% confidence interval=1.21-2.06). There was no significant difference on other days compared to the 15<sup>th</sup>. A linear test for trend from the 15<sup>th</sup> to the 19<sup>th</sup> was not significant (p=0.0922). The injury rates of first games compared to second games of the day showed no difference (p=0.38).

**CONCLUSION:** The USA Cup format limiting teams to two games per day and decreasing the length of games in each game of the tournament outside of the finals provides adequate protection to participants from injury as a result of fatigue and overuse in the environment conditions that prevailed during the tournaments.

**Associations Between Pain, Fatigue, and Injury in Collegiate Baseball Pitchers**

Johna K. Register-Mihalik, Stephen W. Marshall, Frederick O. Mueller, FACS<sup>1</sup>. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*  
Email: johnakay@email.unc.edu  
(No relationships reported)

Injury from pitching is common among collegiate aged baseball pitchers. Injury at a young age may lead to future complications and may decrease the current quality of life in these pitchers. The literature to date has mainly focused on biomechanical factors postulated to be associated with injury, and has paid scant attention to pitching volume as a injury risk factor.

**PURPOSE:** The primary purpose of this study was to examine the associations between pitching with pain, arm tiredness, and injury in collegiate baseball pitchers.

**METHODS:** A cross-sectional self-administered survey was used (N=628). College baseball pitchers (age=20.09±1.58) self-reported their pitching injuries to the arm, elbow, and shoulder that resulted in 7 or more days lost to pitching, and their experiences pitching with elbow or shoulder pain and/or arm tiredness in the past 12 months. Chi-square tests and odds ratios were used to examine the associations between pain, fatigue, and injury.

**RESULTS:** Significant associations were observed between pitching with pain and upper extremity injury (Chi-Square(1)=15.34; p<0.001), with individuals reporting pitching with pain being more likely to report an injury resulting in 7 or more days time-loss (OR=2.24; 95% CI: 1.487, 3.374). Pitching when the arm was tired was also significantly associated with injury (Chi-Square (1)=15.194; p<0.001); individuals who reported pitching when the arm was tired were more likely to report an injury resulting in 7 or more days time-loss (OR=2.74; 95% CI: 1.627, 4.629). Overall, 89% reported pitching when the arm was tired over the past year and 80% reported pitching with pain over the past year. Prevalence of elbow injury was 43%, shoulder injury was 32%, and arm injury was 12%.

**CONCLUSIONS:** Measures of pitching volume are high among college baseball pitchers. Our data yielded strong associations between measures of pitching volume and injury, consistent with the idea that regulating pitching volume and monitoring signs of over-pitching among baseball pitchers may lead to decreased injury risk among these pitchers.

**Self-management Behaviors (physical Activity) Among Primary Care Patients With Pain And Depression**

Teresa M. Damush, Ph.D.<sup>1</sup>, Jingwei Wu, MS<sup>1</sup>, Matthew Bair, MD, MS<sup>1</sup>, Wanzhu Tu, Ph.D.<sup>1</sup>, Ellen Poleshuck, Ph.D.<sup>2</sup>, Kurt Kroenke, MD<sup>1</sup>. <sup>1</sup>Indiana University, Indianapolis, IN. <sup>2</sup>University of Rochester, Rochester, NY.  
Email: tdamush@iupui.edu  
(No relationships reported)

**PURPOSE:** To determine the long term effects of a combined pharmacological and behavioral intervention on self-management behaviors in primary care patients with musculoskeletal pain and depression.

**METHODS:** We conducted a randomized controlled trial and recruited 250 primary care patients from University affiliated and VA primary care clinics. At baseline, all patients met inclusion criteria of having chronic pain in low back, knee or hip, and half met criteria for clinical depression. Participants were randomized to either usual care or a stepped intervention that consisted up 12 weeks of optimized antidepressant therapy followed by a pain self-management (PSM) program delivered biweekly over 6 sessions during the following 12 weeks, and continuation of the antidepressant therapy over the remaining 6 months with 2 self-management booster sessions at 8 and 10 months. We assessed engagement in self-management behaviors (e.g., physical activity) using validated surveys both at baseline and 12 months later. We compared between group differences between intervention and usual care using intention to treat analyses. We analyzed the data using t-tests to compare group means.

**RESULTS:** Participants were 52% men; 62% White; 33% African-American and had a mean age of 59 years. Compared to usual care, participants in the intervention group significantly increased the time spent on performing self-management behaviors in the following areas: strength exercises (p<.03); stretching exercises (p<.00); progressive muscle relaxation (p<.00); visualizing (p<.02); and mental stress relaxation (p<.00). In addition, intervention participants reported more time spent in walking and engaging in positive thinking than those in usual care, but the differences were not significant.

**CONCLUSIONS:** A combined pharmacological and behavioral intervention may effectively increase the patient self-management behaviors in particular, physical activity, among urban, primary care patients with chronic musculoskeletal pain and depression.

**Pain Coping Styles Of Nontraditional Female Athletes**

Michael C. Meyers, FACS<sup>1</sup>, C. Matthew Laurent III<sup>2</sup>, Arnold D. LeUnes<sup>3</sup>, Anthony E. Bourgeois<sup>3</sup>. <sup>1</sup>West Texas A&M University, Canyon, TX.  
<sup>2</sup>University of Alabama, Tuscaloosa, AL. <sup>3</sup>Texas A&M University, College Station, TX.  
Email: mmeyers@mail.wtamu.edu  
(No relationships reported)

Efforts to address psychological indices of female performance have increased in the last decade due to an observed increase in athleticism and a concomitant rise in the number of

severe injuries. There is, however, a paucity of studies directed toward nontraditional athletes involved in outdoor or extreme sports with a high potential for trauma.

**PURPOSE:** To quantify if differences in pain coping styles exist in athletes across type of individual sport (traditional, nontraditional).

**METHODS:** Following written informed consent, the Sports Inventory for Pain (SIP; direct coping, cognitive, catastrophizing, avoidance, body awareness, total coping response) was completed by 126 athletes involved in either nontraditional, non-NCAA individual sports (n=64; downhill skiing; rock climbing, skydiving, telemark skiing, rodeo, taekwondo; mean age=27.9±6.0 yrs) or traditional NCAA individual sports (n=62; swimming/diving, tennis, equestrian, track, golf; mean age=25.1±9.1 yrs). Multivariate analysis (MANOVA) using Wilks' Lambda criterion indicated no significant sport athlete effect ( $F_{3,123}=1.685$ ;  $p=0.314$ ;  $n-b=0.431$ ) across age ( $p=0.142$ ), number of injuries ( $p=0.131$ ), or number of seasons of sport experience ( $p=0.577$ ).

**RESULTS:** MANOVA indicated a significant main effect across type of athlete (Wilks' Lambda  $F_{6,120}=4.559$ ,  $p=0.0001$ ;  $n-b=0.984$ ). Post hoc procedures indicated that nontraditional sport athletes scored significantly lower on direct coping ( $p=0.0001$ ), cognitive ( $p=0.01$ ), catastrophizing ( $p=0.001$ ), and total coping response ( $p=0.025$ ) than traditional athletes, with no differences observed in avoidance or body awareness indices.

**CONCLUSION:** In conclusion, females participating in nontraditional individual, non-NCAA, less coach-structured sport activity where individualism, self-determination, and autonomy is prevalent, reveal lower pain coping styles than females participating in more traditionally, coach-structured individual NCAA sports. Sport science and medical personnel should consider the type of sport athlete prior to prescribing training, treatment, and rehabilitation for optimal performance and return to play.

**2301 Board #189 May 28 2:00 PM - 3:30 PM**  
**Exercise Intensity As A Determinant Of Exercise Induced Hypoalgesia**

Karen Y. Wonders<sup>1</sup>, Daniel G. Drury, FACSM<sup>2</sup>. <sup>1</sup>Wright State University, Dayton, OH. <sup>2</sup>Gettysburg College, Gettysburg, PA.

Email: karen.wonders@wright.edu

(No relationships reported)

A number of investigations have observed a significant reduction in one's sensitivity to painful stimuli both during and after exercise. This phenomenon is referred to as Exercise-Induced Hypoalgesia (EIH). While EIH is well documented in the literature, a cadre of psycho-physiological variables have been identified as part of this complex phenomenon. Although several investigators have found the onset of EIH to be at or above 70% of one's V<sub>O2</sub>, the underlying physiological justification of this intensity has not been thoroughly described.

**PURPOSE:** The purpose of this investigation was to examine variations in pain perception during and following two bouts of exercise; one performed at an intensity equivalent to 10% above and 10% below the onset of blood lactic acid (A-OBLA and B-OBLA, respectively).

**METHODS:** A total of 27 trained males served as subjects in this investigation. Data was collected over the course of four laboratory visits. On day one, each subject completed a Bruce peak treadmill exercise test where OBLA was determined. On day two, subjects were familiarized with the cold pressor test. On days three and four, subjects completed 30 min of treadmill exercise at a workload that was either 10% A-OBLA or 10% B-OBLA. Time to pain threshold (PT) was determined using the cold pressor test, administered at baseline and 15 and 30 min during each exercise (Ex) bout, and at 15 and 30 min into recovery (Rec). A two-factor repeated measures ANOVA was used to determine differences due to the main effects, and their interaction. A significance level of  $P < 0.05$  was used for all statistical analyses.

**RESULTS:** A-OBLA PT scores were not significantly different than B-OBLA scores at any time point. Both conditions produced a significant increase in PT at 30 min Ex (A-OBLA-  $p=0.018$ ; B-OBLA-  $p=0.022$ ) and 15 Rec (A-OBLA-  $p=0.034$ ; B-OBLA-  $p=0.04$ ) as compared to baseline scores. No difference PT scores were observed at 15 min Ex and 30 min Rec as compared to baseline.

**CONCLUSIONS:** Based upon these data the effects of exercise on pain perception appear to be similar at exercise intensities both above and below OBLA. Because a hypoalgesic effect was not observed in either condition until 30 min of exercise had been completed, total exercise time appears to be an important factor in the augmentation of pain perception under these conditions.

**2302 Board #190 May 28 2:00 PM - 3:30 PM**  
**Impact Of Protease Supplementation On Pain Perception And Exercise Affect During Cycle Ergometry With DOMS**

Paul C. Miller, Eric E. Hall, FACSM, Matthew S. Scoggin, Tara K. Mulcahy, Walter R. Bixby, FACSM, Stephen P. Bailey, FACSM. *Elon University, Elon, NC.*

Email: millerp@elon.edu

(No relationships reported)

Delayed onset muscle soreness (DOMS) is a common occurrence following intense exercise. It has been suggested that protease supplementation may diminish the effects of DOMS. Additionally, feelings of soreness may adversely impact exercise affect.

**PURPOSE:** To examine the effects of protease supplementation on the perception of pain (PP) and exercise affect following the onset of DOMS.

**METHODS:** This study used a matched-pairs design. Twenty-four participants (12 males; Mean BMI =  $24.7 \pm 2.1$ ; 12 females; Mean BMI =  $20.8 \pm 2.3$ ) participated in this investigation. DOMS was induced by performing 6 sets of 10 reps of isokinetic eccentric exercise (EE) at -1.05 rad/sec. Each participant took either 2 protease tablets (PRO) or a placebo (PLAC) 4 times a day for 4 days (from 24 H pre-EE to 48 H post-EE). Supplementation was blinded and randomized. Each participant performed 2 identical, 35 min exercise sessions on a cycle ergometer, one pre-EE and one 2 days post-EE. Intensity for the exercise sessions was set during the initial session by asking each participant to exercise at a "13" on the Borg RPE scale. The ergometer resistance was recorded and used during the post-EE exercise session. Every 5 minutes during the exercise sessions, PP was assessed using Borg's CR-10 scale and affect was measured using the feeling scale (FS) and the felt-arousal scale (FAS). Results were analyzed using a repeated-measures GLM.

**RESULTS:** No differences were seen between the groups for PP, FS, or FAS during the pre-EE exercise session. Differences were seen for PP at the 5, 25, 30, and 35 minute mark of the post-EE exercise session with the PRO reporting less discomfort than the PLAC ( $p<0.05$ ). A significant difference was seen for FS with the PRO reporting greater feelings of pleasantness than the PLAC at the 20, 25, 30 and 35 minute mark of the post-EE exercise session ( $p<0.05$ ). A trend was seen for PP at the 20 minute mark ( $p=0.07$ ). No differences were seen between the groups for FAS.

**CONCLUSION:** Protease supplementation may positively influence an individual's responses to exercise following DOMS. This finding may be important in planning exercise programs, especially when considering return to activity following an intense exercise session.

**Relationships Between Exercise Behavior, Expected And Actual Muscle Pain, Kinesiophobia, And Self-care For Muscle Pain**

Erin A. Dannecker. *University of Missouri-Columbia, Columbia, MO.* (Sponsor: Marybeth Brown, PhD, PT, FACSM)

Email: danneckere@health.missouri.edu

(No relationships reported)

Several studies have shown negative relationships between adherence to therapeutic exercise regimes and pain in clinical samples. However, it is unknown if leisure-time exercise behavior is related to activity-related pain in healthy adults.

**PURPOSE:** This investigation examined associations between leisure-time exercise behavior, expected and actual exercise-induced muscle pain, kinesiophobia (fear of

movement), and use of exercise and rest as self-care treatments for delayed-onset muscle pain.

**METHODS:** Participants (N = 33, 23 yrs old (SD = 2.82), 42.5% women) completed the Leisure-Time Exercise Questionnaire (LTEQ) and ratings of highest expected delayed-onset muscle pain before isokinetic eccentric contractions were completed with the nondominant elbow flexors to induce muscle damage. Post-exercise measures of arm muscle pain, kinesiophobia for the painful arm, and appraisals of self-care for the induced muscle pain were collected across four days.

**RESULTS:** LTEQ mild, moderate, strenuous, and total scores were not significantly correlated to highest expected or actual arm muscle pain ( $r_s = -.03$  -  $(-.27)$ ,  $p > .05$ ). However, LTEQ total and mild scores were negatively associated with the highest fear of moving the nondominant arm ( $r_s = -.43$  -  $(-.49)$ ,  $p < .05$ ). Also, LTEQ total and moderate scores were positively related with the largest perceived benefit to exercising the arm to reduce muscle pain ( $r_s = .42$  -  $.51$ ,  $p < .05$ ). In addition, LTEQ mild scores were negatively correlated to the largest perceived benefit of resting the arm to reduce muscle pain ( $r = -.35$ ,  $p < .05$ ).

**CONCLUSIONS:** These results suggest that leisure-time exercise behavior is negatively associated with participants' fear of moving a painful arm and positively related to participants' cognitive appraisals of the benefits for continuing movement despite pain. Additional studies of these relationships for other modes of exercise in both laboratory and natural settings are needed to examine the role of activity-related pain as a barrier to regular exercise participation in non-clinical samples.

**Obesity Is Associated With Lumbar Pain Related Fear Of Movement And Self Reported Mobility Impairment**

Heather K. Vincent, Morrow R. Omli, Timothy I. Day, Michael Macheck, Kevin R. Vincent, Randy W. Braith, FACSM, Steven Z. George. *University of Florida, Gainesville, FL*

Email: vincehk@ortho.ufl.edu

*(No relationships reported)*

Chronic low back pain (LBP) induces mobility impairment and disability. Obesity is a risk factor for LBP and disability. Pain evokes fear avoidance beliefs and behaviors, thereby worsening LBP. It is unknown whether obesity is associated with fear of movement.

**PURPOSE:** The purposes of this study were: 1) to compare the levels of fear of movement between obese and non-obese individuals seeking therapy for chronic LBP, and 2) to examine whether fear of movement predicted self-reported mobility impairment.

**METHODS:** This was a retrospective, exploratory study of individuals with chronic LBP (N=192; 48.2±18.8 yrs). Participants were stratified into obese (Body mass index [BMI] 36.9±7.1 kg/m<sup>2</sup>) or non-obese groups (BMI 24.5±3.4 kg/m<sup>2</sup>). The Tampa scale of Kinesiophobia (TSK; fear of movement), Short-Form 8 (SF8) and Oswestry Disability survey results were main outcome measures. Self-reported medication use and participation in exercise therapy sessions for LBP were collected. Outcome comparisons were made using univariate analyses of variance. Hierarchical regression modeling was used to determine the contribution of TSK scores to the variance of self-reported disability with walking.

**RESULTS:** TSK scores in obese patients were higher than in non-obese patients (26.2±7.5 vs 23.9±6.8 points;  $p=0.032$ ). The SF8 physical and mental subscores were 6-10% lower in the obese than non-obese patients. Total Oswestry survey scores were 28% higher in the obese patients prior to the exercise therapy program ( $p=0.0001$ ). Hierarchical regression modeling showed that fear of exercise was a significant contributor to self-reported disability with walking ( $p<0.0001$ ). Narcotic use was higher (32.4 vs 17.2%) and non-steroidal anti-inflammatory medication use was lower (18.6 vs 34.9%) in the obese than non-obese group ( $p<0.05$ ). Obese patients cancelled therapy sessions twice as frequently than non-obese patients ( $p=0.012$ ).

**CONCLUSIONS:** Obesity-related fear of movement is an important predictor of disability and participation in exercise therapy for chronic LBP. In addition to traditional exercise therapy protocols to combat LBP in obesity, adjunctive psychosocial strategies should be a serious consideration.

**The Effect Of Exercise Cessation In Well Trained Athletes On Non Articular Tenderness Masseurs.**

Lior Zeller, Dahlia Weitzman, Dan Buskila, Mahmoud Abu-Shakra. *soroka medical center, beer-sheva, Israel.*

Email: zellerl@bgu.ac.il

*(No relationships reported)*

The effect of exercise cessation in well trained athletes on non articular tenderness masseurs and quality of life.

The term chronic multisymptom illness (CMI) includes fibromyalgia (FM), chronic fatigue syndrome (CFS), and a wide spectrum of pain disorders. It is characterized by unexplained chronic pain, fatigue, and cognitive and mood complaints.

**PURPOSE:** The goal of the study was to examine the hypothesis that exercise cessation will be associated with symptoms similar to CMI in a well trained amateur athletes.

**METHODS:** The study population comprised of 26 asymptomatic healthy athletes who regularly exercise  $6.75 \pm 3.65$  hrs per week. All athletes were instructed to refrain from physical activity for 7 days. All participants underwent a complete physical exam, rheumatologic assessment including non articular tenderness threshold (using dolorimeter) and tender points. In addition they completed the SF-36 quality of life questionnaire. Assessments were conducted before exercise cessation and after 7 days.

**RESULTS:** Seven days after sports deprivation all subjects were significantly tender by all tender measures ( $p<0.001$ ) (dolorimeter thresholds and tender point count). As well, there was a significant reduction in the scores for physical role function ( $p<0.001$ ), emotional role function ( $p<0.001$ ) and summary sub-scales of the SF-36 questionnaire after exercise cessation.

**CONCLUSION:** Exercise deprivation is associated with change in non articular tenderness threshold and reduction in quality of life scores. This may be associated with the development CMI.

**2306 Board #194 May 28 2:00 PM - 3:30 PM**

**Effect Of Caffeine Ingestion On Leg Pain During Maximal Knee Extension Exercise**

Michael N. Terzi, Timothy R. Burnett, Miriam Caraveo, Todd A. Astorino. *California State University--San Marcos, San Marcos, CA.*

Email: terzi003@csusm.edu

*(No relationships reported)*

A number of recent studies have tested the effect of caffeine (CAF) on perceived muscle pain during exercise, yet few have assessed its hypoalgesic properties under simulated performance conditions.

**PURPOSE:** The goal of this study was to examine the effect of ingested CAF on leg muscle pain during short-term, high-intensity exercise.

**METHODS:** Subjects consisted of seven active, young men (mean  $\pm$  SD age, body mass, and physical activity =  $27.7 \pm 4.2$  yr, body mass  $77.3 \pm 7.4$  kg, and  $5.1 \pm 1.3$  hr/wk). They ingested one of two CAF solutions or placebo over three separate trials that were conducted a week apart. CAF solutions (2 mg/kg and 5 mg/kg) were ingested in a randomized, single-blind, crossover design. Subjects refrained from intense exercise, CAF ingestion, and alcohol consumption 48 hours pre-trial. Initially, they completed a familiarization trial. On a separate day, they completed two all-out bouts of 40 repetitions of knee extension and flexion on an isokinetic dynamometer at 180 deg/sec. There was a three minute recovery between bouts. Perceived pain intensity was assessed utilizing a category-ratio scale from 0 - 10 with verbal anchors. Rating of perceived exertion (RPE) was also recorded using a standard 0 - 10 scale. During exercise, pain perception was assessed at 15 and 35 repetitions and 2.5 min into recovery, and RPE was recorded after 25 repetitions. Two-way ANOVA with repeated measures was used to assess differences in pain and RPE across time and treatment.

**RESULTS:** From 15 to 35 repetitions, pain sensation (mean  $\pm$  SD) was increased in the 5 mg/kg ( $3.3 \pm 2.2$  to  $5.7 \pm 2.1$ ), 2 mg/kg ( $2.6 \pm 1.3$  to  $5.6 \pm 1.6$ ), and placebo condition ( $3.1 \pm 1.7$  to  $5.7 \pm 2.3$ ). RPE was also enhanced ( $p < 0.05$ ) from bout 1 ( $5.6 \pm 1.7$ ,  $5.0 \pm 1.4$ , and  $5.1 \pm 1.8$ ) to bout 2 ( $6.7 \pm 1.4$ ,  $6.4 \pm 1.1$ , and  $6.3 \pm 2.0$ ) in the 5 mg/kg, 2 mg/kg, and placebo condition. No effect of treatment ( $p > 0.05$ ) on RPE or pain was observed.

**CONCLUSIONS:** These preliminary data show no effect of CAF ingestion on pain or RPE during maximal knee extension and flexion in young, active men who are regular caffeine consumers. Yet, both RPE and pain sensation were significantly augmented with completion of maximal knee extension and flexion. Further study is merited to elucidate analgesic effects of caffeine during short-term exercise dependent upon nonoxidative metabolism.

Email: ckim4@kent.edu

(No relationships reported)

A number of studies have demonstrated that caffeine may alter an individual's perception of effort and strain during exercise. Stay Alert™ chewing gum (100mg caffeine/piece) has been used by military personnel during sustained operations to enhance performance.

**PURPOSE:** The purpose of the current investigation was to determine if low dose (200mg) caffeine administered via chewing gum at different time points would decrease ratings of perceived exertion (RPE) and leg pain (LP-RPE) during cycling to exhaustion.

**METHODS:** Eight apparently healthy, college aged ( $25.5 \pm 4$  yr), physically active ( $45.5 \pm 5.7$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) males volunteered to participate in the present investigation. Participants reported to the exercise science laboratory on five separate occasions, and all trials were separated by a one week washout period. On the first visit, subjects underwent a graded exercise test (Excalibur 1300Wcycle ergometer) to determine maximal oxygen consumption. For the next four visits participants at 85% VO<sub>2max</sub> until exhaustion. Ratings of perceived exertion (RPE) and leg pain (LP-RPE) measures were obtained prior to and every ten minutes during cycling. Two pieces of chewing gum, placebo (PLA) vs. Stay Alert™ (CAFF) was administered in a randomized, counterbalanced, double blind manner at 3 time points (35 min pre-exercise, 5 min pre-exercise, and 10 min following starting of exercise). For the fourth visit PLA gum was administered at all three time points.

**RESULTS:** Dose schedule (PLA, CAFF; at -35, -5, 15min of exercise) by time (Pre-, 10, 20, and 30 min-post initiation of exercise) repeated measures ANOVAs revealed no significant main or interaction effects for dose schedule for RPE and LP-RPE ( $p \geq 0.89$ ).

**CONCLUSION:** These data suggest that low dose caffeine administered via Stay Alert™ does not alter an individual's perception of effort or pain during exhaustive cycling.

**2308 Board #196 May 28 2:00 PM - 3:30 PM**

**Effects Of Water-based Exercise Program Among Frail Elderly Women With Lower Limb Pain**

Ai Shibata, Koichiro Oka, Yoshio Nakamura, Isao Muraoka. *Waseda University, Tokorozawa, Saitama, Japan.* (Sponsor: Mitsuru Higuchi, FACSM)

Email: aishibata@aoni.waseda.jp

(No relationships reported)

Knee osteoarthritis and lumbar spinal stenosis are common musculoskeletal disorders in the elderly. Pain and impairment on those parts frequently leads to moderate to severe limitations of participation in daily life and decreased quality of life (QOL). Water-based exercise (WE) provides several water-specific benefits to reduce pain and improve functional decline.

**PURPOSE:** To examine the effect of WE program on functional fitness and health-related QOL (HRQOL) among frail elderly women with lower limb pain on the community-based setting.

**METHODS:** Participants were 51 elderly women (age=72.1 $\pm$ 4.6years) with confirmed knee and/or low back pain, which were randomly assigned to either WE group (WEG; n=26) or wait-list control group (CG; n=25). WEG first participated in a 12-week WE program. CG was provided the same program immediately after the intervention as a cross-over design. Timed up and go test (TUG), 5-meter walk test (5WT), one-legged standing with eyes open (OLS-O), 5-time sit and stand test (SS5), and grip test, and the Japanese version of SF-8 were assessed at baseline and post-intervention. Both groups completed the same assessment at 3 months after their own WE programs. Mixed factorial and repeated measures ANOVA were utilized for analyses. Effect sizes were calculated.

**RESULTS:** No significant differences at baseline were found between WEG and CG in all variables. TUG (pre=6.6 $\pm$ 0.8s; post=6.2 $\pm$ 0.09), SS5 (10.4 $\pm$ 2.4s; post=9.1 $\pm$ 1.6s), OLS-O, BP (pre=41.9 $\pm$ 6.6; post=47.7 $\pm$ 6.6), and PCS (pre=42.1 $\pm$ 6.2; post=45.9 $\pm$ 6.8) for WEG significantly improved from pre- to post-intervention ( $p < 0.05$ ) whereas did not change in CG ( $p > 0.05$ ). WEG significantly increased in GH following intervention (pre=46.5 $\pm$ 5.9; post=50.0 $\pm$ 6.9;  $p = 0.04$ ) whereas the CG significantly decreased from pre- to post-intervention (pre=48.8 $\pm$ 5.5; post=54.1 $\pm$ 5.9  $p = 0.02$ ). Improvement of TUG, SS5, 5WT, OLS-O, BP, GH, and PCS significantly maintained for 3 months after WE programs ( $p < 0.05$ ). Effect sizes of each measure for the effectiveness of WE and its sustainability were small to moderate and moderate to large, respectively.

**CONCLUSIONS:** WE can not only improve functional mobility and lower muscular strength, but also enhance general health perception and reduce bodily pain perception on HRQOL among elderly women with lower limb pain.

---

**Relationship Between Animal Protein Intake And Muscle Mass Index Independently Of Physical Activity Levels.**

Mylène Aubertin-Leheudre, Herman Adlercreutz. *Folkhälsan Research Center, Helsinki, Finland.*

Email: mylene.aubertin-leheudre@helsinki.fi

(No relationships reported)

The amount, the quality and the type of protein intake could play a role in regard to the level of skeletal muscle mass.

**PURPOSE:** To examine the relationship between the type of protein intake and the level of muscle mass in healthy omnivore and vegetarian Caucasian women.

**METHODS:** Observational and cross-sectional study. Twenty-two omnivores and 20 vegetarians were recruited. Muscle mass index (urinary creatinine), dietary intake (5-day dietary records), and biochemical analyses (urinary estrogen metabolites; plasma sex hormone, phytoestrogen and lipid profiles) were obtained in four seasons. The groups were compared with non-parametric Mann-Whitney test and using a GLM multivariate with SHBG and vegetal protein intake serving as covariables. Correlations were performed between muscle mass index and significant variables. A stepwise regression model was used to determine the predictor of muscle mass.

**RESULTS:** We found differences between groups for muscle mass ( $p = 0.010$ ), muscle mass index ( $p = 0.002$ ), animal protein intake in g/d ( $p = 0.001$ ) and in g/kgBW/d ( $p = 0.003$ ), vegetal protein intake in g/d ( $p = 0.015$ ) and in g/kgBW/d ( $p = 0.007$ ), the animal/vegetal protein intake ratio ( $p = 0.001$ ) and SHBG ( $p = 0.001$ ). Muscle mass index still correlated with animal protein intake in g/d ( $p = 0.001$ ) and in g/kgBW/d ( $p = 0.008$ ), and the animal/vegetal protein intake ratio ( $p = 0.007$ ) even after controlling for SHBG and vegetal protein intake. Finally, animal protein intake (g/d) was the independent predictor of muscle mass index (adjusted  $r^2 = 0.42$ ). These differences are likely independent of physical activity levels.

**CONCLUSION:** A vegetarian diet is associated with a lower muscle mass index than is an omnivore diet at the same protein intake. The best predictor of the muscle mass index is the animal protein intake. These results are important because the loss of muscle mass is associated with functional limitations, falls and fractures.

**Effect Of Protein Supplement Timing On Strength, Power And Body Compositional Changes In Resistance-trained Men**

Jay R. Hoffman, FACSM, Nicholas A. Ratamess, Christopher P. Tranchina, Stefanie L. Rashti, Jie Kang, FACSM, Avery D. Faigenbaum, FACSM.  
*The College of New Jersey, Ewing, NJ.*  
Email: hoffmanj@tcnj.edu  
(No relationships reported)

**PURPOSE:** The effect of 10-weeks of protein supplement timing on strength, power and body composition was examined in 33 resistance-trained men.

**METHODS:** Subjects were randomly assigned to either a protein supplement provided in the morning and evening (AM/PM;  $n = 13$ ), or provided immediately prior to and immediately post workouts (PRE/POST;  $n = 13$ ). In addition, seven subjects agreed to serve as a control (CTR) group and did not use any protein or other nutritional supplement. During each testing session subjects were assessed for strength (one repetition maximum [1-RM] bench press and squat), power (assessed by analyzing power performance of 5 repetitions performed at 80% of 1RM in both the bench press and squat exercise) and body composition (DEXA).

**RESULTS:** A significant main effect for all three groups in strength improvement was seen in 1RM bench press ( $120.6 \pm 20.5$  kg vs.  $125.4 \pm 16.7$  at week 0 and week 10 testing, respectively) and 1RM squat ( $154.5 \pm 28.4$  kg vs.  $169.0 \pm 25.5$  at week 0 and week 10 testing, respectively). However, no significant between group interactions were seen. Significant main effects were also seen in both upper and lower body peak and mean power, but no significant differences were seen between groups. No changes in body mass or body fat % were seen in any of the groups.

**CONCLUSIONS:** Results indicate that the time of protein supplement ingestion in resistance-trained athletes during a 10-week training program does not provide any added benefit to strength, power or body compositional changes.

**2311 Board #199 May 28 2:00 PM - 3:30 PM**  
**Influence Of Spirulina Intake On Muscle Protein Of Rats Recovering From Protein Malnutrition**

Fabricio A. Voltarelli, Michel B. Araújo, Leandro P. Moura, Carla Ribeiro, Clécia S. Mota, Maria Alice R. Mello. *Universidade Estadual Paulista (UNESP), Rio Claro-SP, Brazil.*  
Email: faunesp8@yahoo.com.br  
(No relationships reported)

**PURPOSE:** The present study aimed to evaluate the effects of the blue green alga *spirulina* as the sole dietary source of protein on muscle protein of rats recovering from malnutrition.

**METHODS:** Young (30 days) Wistar rats were separated into 5 groups: I- Casein 17% (C17) from 30 to 150 days of age (d/a); II- *Spirulina* 17% (S17) from 30 to 150 d/a; III- Casein 6% (C6) from 30 to 150 d/a; IV- Casein 6% from 30 to 90 days and *Spirulina* 17% from 91 to 150 d/a (C6/S17) and V- Casein 6% from 30 to 90 days and Casein 17% from 91 to 150 d/a (C6/C17). We investigated the muscle total protein and DNA contents as well as the protein synthesis and degradation to infer on muscle growth and on muscle protein metabolism, respectively. The alkaline phosphatase enzyme (APE) activity was determined as an index of cell activity.

**RESULTS:** The C6 group presented lower total protein and DNA contents in the soleus muscle (g/100g) if compared to the other groups (Anova two-way test, Bonferroni post-hoc;  $P < 0.05$ ). The nutritional recovery, using both diets, re-established these parameters (Total Protein Contents: C6=1.4 $\pm$ 0.2; C6/S17=2.6 $\pm$ 0.3; C6/C17=2.5 $\pm$ 0.2; S17=3.5 $\pm$ 0.4; C17=3.5 $\pm$ 0.3; DNA Contents: C6=0.139 $\pm$ 0.014; C6/S17=0.149 $\pm$ 0.014; C6/C17=0.145 $\pm$ 0.013; S17=0.147 $\pm$ 0.009; C17=0.148 $\pm$ 0.012). *Spirulina* and casein diets were able to reduce protein degradation (pmol/mg.h<sup>-1</sup>) (C6=457.6 $\pm$ 49.4; C6/S17=338.2 $\pm$ 28.4; C6/C17=344.3 $\pm$ 48.3; S17=290.4 $\pm$ 17.1; C17=294.8 $\pm$ 32.3), to reduce APE activity (mU/g) (C6=8.4 $\pm$ 1.4; C6/S17=6.4 $\pm$ 1.3; C6/C17=6.2 $\pm$ 1.5; S17=6.6 $\pm$ 1.2; C17=6.8 $\pm$ 1.5) and to increase the protein synthesis (pmol/mg.h<sup>-1</sup>) (C6=26.4 $\pm$ 4.0; C6/S17=35.4 $\pm$ 4.1; C6/C17=34.3 $\pm$ 3.5; S17=34.1 $\pm$ 4.2; C17=33.7 $\pm$ 4.1) in the soleus muscles of the previously malnourished rats.

**CONCLUSION:** *Spirulina* proved to be an adequate protein source to recovery malnourished rats, since the soleus muscle APE activity was restored to control levels concomitant to the re-establishment of the protein and DNA contents, the increase of the protein synthesis and the decrease of the protein degradation rates.

**Intake Of Water-soluble Protein During An Interval Of Repeated Strenuous Exercises Can Improve Serum Myoglobin Levels**

Chiaki Sanbongi<sup>1</sup>, Seigo Baba<sup>1</sup>, Hisataka Ambe<sup>2</sup>, Takeshi Oyama<sup>3</sup>, Kenichi Suijo<sup>4</sup>, Yuki Sakamoto<sup>2</sup>, Katsura Takahara<sup>2</sup>, Mihoko Ishizaka<sup>1</sup>, Kunihiro Kurihara<sup>1</sup>, Yoshiharu Fujieda<sup>2</sup>. <sup>1</sup>Meiji Seika Kaisha, Ltd., Tokyo, Japan. <sup>2</sup>Tokyo Gakugei University, Tokyo, Japan. <sup>3</sup>Gunma Prefectural Maebashi Nishi High School, Gunma, Japan. <sup>4</sup>Tokyo Medical University, Tokyo, Japan.  
Email: Chiaki\_sanbongi@meiji.co.jp  
(No relationships reported)

Many athletes consume protein both immediately after exercise and before sleeping to build up the body and to recover from strenuous exercise. Little is known about the effects of protein supplementation during exercise because protein can have a bitter taste. Recently, athletes have been consuming a sports drink containing good tasting and rapidly absorbed water-soluble protein, without evidence of any obvious benefit.

**PURPOSE:** To determine whether intake of water-soluble protein during exercise has a favorable effect on muscle damage, performance, and soreness.

**METHODS:** Japanese trained male athletes ( $n=7$ ) performed two sessions of high intensity cycle ergometer exercise. In each session, subjects did five repetitions of 10 s of maximal intensity riding interrupted by 50 s of resting. Subjects consumed protein (14.1 g/400 mL) either during exercise or immediately after exercise. Blood lactic acid, serum myoglobin, CK, and LDH were measured pre- and post-exercise. Perceived muscle soreness and psychological mood change (Profile of Mood State: POMS) were investigated.

**RESULTS:** Serum myoglobin, CK, and LDH increased significantly 2 h after exercise. Intake of water-soluble protein during exercise (relative to protein intake after exercise) decreased myoglobin, CK, and LDH. POMS scores (fatigue, total scores) were also improved.

**CONCLUSIONS:** In contrast to supplementation after exercise, supplementation during exercise attenuated post-exercise muscle damage and fatigue. The results suggest that ingestion of protein during exercise may be important.

(No relationships reported)

Many studies have revealed the effects of supplementing protein on endurance exercise performances or attenuating muscle damage derived from resistance training, whereas the evidences of protein supplementation for strenuous intermittent exercise are still insufficient.

**PURPOSE:** To investigate the effects of a protein beverage on anaerobic performances and muscle damage through double-blind manner.

**METHODS:** Subjects consisted of 7 Japanese male collegiate athletes (age; 21.4 ± 0.5yrs, height; 176.9 ± 4.8cm, weight; 70.2 ± 5.8kg) underwent twice the same intermittent anaerobic exercise protocol on the different 2 days under supplementing either water-soluble protein of 14.1g or placebo in crossover research design. Both on the 1<sup>st</sup> and the 2<sup>nd</sup> day, all the participants accomplished repetitive high-intensity sprint exercises composed of 2 sessions, and consumed protein or placebo before and after the 1<sup>st</sup> session. Each session included 5 bouts of 10 sec. cycle pedaling with maximal efforts at the workload of 0.075 kp. per body weight and 50 sec. intervals. Measuring serum myoglobin, CK and LDH was done before and after exercise to evaluate muscle damage.

**RESULTS:** ANOVA revealed significant differences in both anaerobic powers and changing patterns of serum myoglobin level. In contrast to the condition of taking placebo, subjects demonstrated not only higher achievement of total power outputs (6856 ± 669 vs. 6730 ± 693 watts, p<0.05) but also lower serum myoglobin concentrations at 2-hour (39.0 ± 10.8 vs. 52.0 ± 16.3 ng/ml, p<0.05) and 3-hour (33.8 ± 8.9 vs. 44.3 ± 14.3 ng/ml, p<0.05) after exercise under supplementing protein.

**CONCLUSIONS:** Supplementing water-soluble protein can improve repetitive highly-demanding anaerobic performance with suppressed serum myoglobin elevation.

(No relationships reported)

Historically, research on BCAAs has been conducted to determine its effects on central fatigue, peripheral fatigue, and most recently its effects on cell-signaling properties leading to an increase in protein synthesis. In relation to high intensity activities, such as resistance exercise, few published data exist investigating the short-term effects of BCAA supplementation on resistance exercise performance.

**PURPOSE:** To determine the effect of BCAA supplementation on total workout volume achieved during an acute bout of lower-body resistance exercise in comparison to a placebo.

**METHODS:** In a randomized, double blind, placebo controlled design, 14 recreationally active males were divided into a BCAA (n = 7) and a placebo (n = 7) group (BCAA = 25.6 ± 4.7 yrs, 180.7 ± 6.6cm, 89.1 ± 10.7 kg; placebo = 20.0 ± 0.8 yrs, 174.5 ± 6.2cm, 80.1 ± 11.6 kg). The participants ingested either 80 mg/kg of BCAAs divided into 2 equal doses or a similar tasting placebo in conjunction with a lower body resistance exercise (RE) bout. The RE bout consisted of 4 sets of leg press followed by 4 sets of knee extension at 80% 1RM to failure. Only those participants who were able to achieve a minimum of 8 repetitions at 80% of 1RM on every set were included in the analysis. However, all participants were required to attain volitional fatigue. Rest periods between sets and exercises were approximately 150 seconds. Supplementation was administered 30 minutes prior and immediately before RE. Total lower-body workout volume between groups was analyzed via an independent samples t-test using SPSS for Windows version 15.0.

**RESULTS:** Data are reported as means ± standard deviation. Total lower-body workout volume for the BCAA and placebo groups was 18,754 ± 1,573 kg and 18,260 ± 6,519 kg, respectively. Independent samples t-test revealed that there were no significant differences between the two groups ( $t_{(12)} = .169$ ,  $p = .869$ ).

**CONCLUSION:** At a dosage of 80 mg/kg of bodyweight, it appears that BCAA supplementation does not increase total lower-body workout volume at an intensity of 80% 1RM to volitional exhaustion during an acute bout of resistance exercise.

**2315 Board #203 May 28 2:00 PM - 3:30 PM****Leucine Associated With Exercise Reduces Body Weight And Improves The Lipid Profile Of Obese Rats**

Francisco L. Tores-Leal, Miriam Fonseca-Alaniz, Daiana Vianna, Gabriela F. Teodoro, Ivanir S. Pires, Mariana D. Capitani, Lucas C. Pantaleão C. Pantaleão, José Donato Jr, Julio Tirapegui. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

Leucine, as an essential amino acid and activator of mTOR (mammalian target of rapamycin), promotes protein synthesis and suppresses protein catabolism. However, the effect of leucine associated with exercise on weight loss and improvement on cholesterol metabolism remains unclear, and whether leucine has beneficial effects as a long-term dietary supplement has not been examined.

**PURPOSE:** To evaluate the effect of leucine associated with exercise on weight loss and metabolism of cholesterol in rats previously submitted to a high-fat diet.

**METHODS:** Initially fifteen Sprague-Dawley rats were to fed with high-fat diet for 15 weeks. Subsequently, they were distributed in two groups, exercise group (EG) (n = 8) and exercise + leucine (GEL) (n = 7). Both groups rats were submitted to a swimming exercise for 60 minutes per day for 6 weeks, and GEL rats received supplementation with 5% of leucine. After 21 weeks the animals were sacrificed and samples for analysis were collected. Test t was done for statistical analysis with p<0.05.

**RESULTS:** There was a significant variation in body weight of GEL compared with GE (-32.50 ± 37.05 vs. 30.87 ± 7.82 respectively; p<0.03), equivalent to -6.15% vs. 1.73%. In addition, GEL compared with the GE showed a significant increase in HDL-c (43.46 ± 5.81 vs 32.34 ± 12.27 respectively; p<0.04). The values of triglycerides (TG), total cholesterol and ratio of triglycerides to HDL-cholesterol (TG/HDL-c) showed no significant difference, 88.19 ± 20.03 (GEL) vs. 98.42 ± 33.12 (GE), p>0.490; 69.89 ± 17.30 (GEL) vs. 60.04 ± 12.06 (GE), p>0.218; 2.06 ± 0.40 (GEL) vs 2.64 ± 0.60 (GE), p>0.060; respectively.

**CONCLUSIONS:** The results of this study suggest that exercise when combined with supplementation with leucine favors the loss of body weight and increases the fraction of HDL-C in rats previously submitted to a high-fat diet via multiple mechanisms.

**2316 Board #204 May 28 2:00 PM - 3:30 PM****Effect Of Leucine And Exercise On Fat And Metabolism Of Glucose In Previously Obese Rats**

Gabriela F. Teodoro, Francisco L. Torres-Leal, Miriam Fonseca-Alaniz, Daiana Vianna, Ivanir S. Pires, Mariana D. Capitani, Lucas C. Pantaleão, José

Donato Jr, Marcelo M. Rogero, Fábio B. Lima, Julio Tirapegui. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

Several studies show evidence that supplementation with leucine favors reducing body fat in animals submitted to various experimental conditions, including food restriction and high fat diet. However, the effect of supplementation with leucine associated with exercise in animals submitted to high-fat diet remains poorly informed, as well, the effects of these interventions on reversion of the deleterious effects on metabolism of glucose caused by the high fat diet.

**PURPOSE:** To evaluate the effect of supplementation with leucine associated with exercise in body fat and in the metabolism of glucose in rats previously submitted to high-fat diet.

**METHODS:** Initially thirty Sprague-Dawley rats were fed with high-fat diet for 15 weeks. Subsequently, they were distributed into control group (CG) (n = 7), leucine group (LG) (n = 8), exercise group (EG) (n = 8) and group exercise + leucine (GEL) (n = GEL 7). CG and EG were fed with AIN-93M diet, and LG and GEL were supplemented with 5% of leucine. EG and GEL were exposed to 60 minutes per day of swimming exercise for 6 weeks. After 21 weeks the animals were sacrificed and samples for analysis were collected. Two-way ANOVA was performed for statistical analysis with  $p < 0.05$ .

**RESULTS:** When compared the factors exercised vs. sedentary and leucine vs. control, there was a significant difference in the sum of deposits of visceral fat ( $p < 0.022$  and  $p < 0.034$ , respectively). The same results were observed between LG vs. CG ( $6.01 \pm 1.18$  vs.  $7.79 \pm 2.18$   $p < 0.026$ ) and GEL vs. LG ( $6.14 \pm 0.78$  vs.  $7.79 \pm 2.18$ ,  $p < 0.019$ ). Significant differences were found among the factors exercised vs. sedentary ( $p < 0.011$ ) and leucine vs. control ( $p < 0.047$ ) for the morphometry of adipose tissue. The same was observed between the CG vs. LG ( $288.05 \pm 53.54$  vs.  $380.26 \pm 120.02$ ,  $p < 0.029$ ) and GEL vs. LG ( $269.49 \pm 36.70$  vs.  $380.26 \pm 120.02$ ,  $p < 0.010$ ). On the other hand there was no significant difference in insulin and HOMA index.

**CONCLUSIONS:** The results of this study suggest that supplementation with leucine does not reduce body fat nor the volume of adipocytes. Moreover, the effects of the association between leucine and exercise are attributed primarily to the exercise.

Supported by FAPESP, 07/59291-3 and 07/51964-9.

**2317 Board #205 May 28 2:00 PM - 3:30 PM**

**Protein In Food Versus A Dietary Supplement After Strength Training In Collegiate Football Athletes**

Rochelle D. Kirwan, M.S., Lindsay K. Kordick, Shane McFarland, Denver Lancaster, Mary P. Miles, Ph.D., FACSM. *Montana State University, Bozeman, MT.*

(No relationships reported)

Many athletes believe the utilization of protein supplements will increase their lean body mass while improving their overall performance. Many also believe meeting their established protein requirements through dietary intake alone can be difficult and even impossible without incorporating protein supplementation.

**PURPOSE:** The purpose of this study was to determine if muscle hypertrophy and strength gains differed between athletes consuming protein from dietary sources compared to those consuming protein in an exercise recovery supplement.

**METHODS:** Performance measures (bench press, back squat, hang clean, 10 yard sprint, and vertical jump) and body composition were compared in redshirt football players (age  $18.6 \pm 0.7$  years) who completed an eleven week protocol of weight training followed by either protein in supplement form (S, n=6, 28 grams protein) or protein in foods (NS, n=9, 8-28 grams protein) 3 days/week. Subjects completed 3-day diet records to determine macronutrient intake and had DEXA scans to determine body composition both pre- and post-training.

**RESULTS:** Without inclusion of the post-workout protein intake, both groups had similar protein intakes in their diets. Similar increases ( $P=0.003$ ) in lean body mass were measured in the S ( $72.2 \pm 6.6$  to  $73.0 \pm 6.3$  kg) and NS groups ( $69.3 \pm 8.6$  to  $70.9 \pm 8.8$  kg). No significant differences were found between the two groups in performance variables. For example, bench press increased ( $P=0.01$ ) from  $114 \pm 15$  to  $120 \pm 16$  kg in the S group and from  $111 \pm 12$  to  $116 \pm 13$  kg in the NS group.

**CONCLUSION:** The consumption of protein in the form of a recovery supplement shake did not offer any performance or lean body mass advantages over consumption of protein in the form of food.

**2318 Board #206 May 28 2:00 PM - 3:30 PM**

**Dietary-energy/protein Optimum For N-balance And Muscle Hypertrophy During Two Weeks Of Resistance Training**

Nailza Maesta, Fabio L. Orsatti, Roberto C. Burini. *Unesp Medical School, Botucatu, Brazil.*

Email: nmaesta@uol.com.br

(No relationships reported)

In a previous paper, dietary-protein needs for better muscle hypertrophy during 2-week resistance training were found to be between 1.5 and 2.5 g/kg/d (Maesta et al. Rev. Bras. Med. Esporte 2008). However, not only total energy adequacy but also energy-yielding nutrients are important.

**PURPOSE:** To determine adequate energy and the energy-yielding nutrient (CHO/Fat) ratio for N-balance and related muscle-mass gain in training body builders.

**METHODS:** forty-two healthy young men (18-35yrs), without exogenous anabolics and at least two years of body-building training were assessed at baseline (MO) for food intake, anthropometry (calculation of body fatness-BF and muscle mass-MM) and urinary nitrogen excretion (for N-balance, NB). The assessment was repeated after four weeks (M1) with a diet of 1.8g prot/kg/d and different proportions of kcal/prot and CHO/Fat along with a unique 6-day/wk resistance-training protocol. Statistics between groups and among moments were performed by ANOVA and Student's t test along with regression analysis (Pearson) with  $p=0.05$ .

**RESULTS:** Total energy intake correlated positively with NB ( $r=0.69$ ), BW ( $r=0.59$ ), MM ( $r=0.41$ ) and BF ( $r=0.34$ ), with  $\geq 30$  kcal/g protein giving greater gain of both MM and NB (than  $< 30$  kcal/g prot) without BF gain. Dietary CHO showed a strong positive relationship and dietary-fat a negative relationship with NB and MM. Dietary CHO/Fat (calorie) ratio  $> 6$  resulted in better MM gain (2.2kg) and BF loss (-1.1%) for the same BW.

**CONCLUSION:** For the best MM gain and NB during a short period of resistance training, the recommended diet would provide  $\sim 1.8$ g prot/kg/d,  $\geq 30$  kcal/g/prot in a proportion of CHO/Fat calories  $\geq 6$ .

**Performance In The Heat Of Previously Fed Subjects Is Unaffected By Carbohydrate Or Protein Ingestion**

Aline R. Gomes<sup>1</sup>, Camila Nassif<sup>2</sup>, Danusa D. Soares<sup>1</sup>, Emerson S. Garcia<sup>1</sup>. <sup>1</sup>Federal University of Minas Gerais, Belo Horizonte, Brazil. <sup>2</sup>Charles Sturt University, Bathurst, Australia.

Email: alinets4@yahoo.com

(No relationships reported)

It has been suggested that exercise performance in the heat might be limited by central mechanisms. One of the proposed mechanisms associates increased central serotonergic activity to the onset of fatigue. Different nutritional strategies have been used in an attempt to decrease central serotonergic activity thus improving performance.

**PURPOSE:** To evaluate carbohydrates (CHO) or protein (PTN) ingestion effects on self-paced time trial performance in the heat when subjects were previously fed.

**METHODS:** Ten male subjects ( $26 \pm 1$  yrs;  $64.5 \pm 2.4$  kg; peak power output  $323 \pm 13$  W;  $\dot{V}O_{2max}$   $70.7 \pm 2.8$  mL  $O_2 \cdot kg^{-1} \cdot min^{-1}$ ) were asked to cycle 60 km as fast as possible in an environmental chamber (dry temperature  $32^\circ C$ ; 50% RH). Trials included four 1-km all-out sprints: after 14, 29, 44 and 59 km. Participants were randomly subject to three

different trials, during which they ingested: 1) water (H<sub>2</sub>O); 2) H<sub>2</sub>O+capsules containing a powder mixture of glucose and sucrose (CHOc 6.0%, 1.32g/kg body wt); 3) H<sub>2</sub>O+capsules containing a powder of whey-protein isolate (PTNc 3.9%, 0.85g/kg body wt). Both of trials with capsules were run on a double-blind fashion. Ingestion of fluids in all trials occurred at 5<sup>th</sup>, 15<sup>th</sup>, 30<sup>th</sup>, 45<sup>th</sup> and 55<sup>th</sup> km. Blood samples were collected through a catheter from a superficial forearm vein at pre-exercise period and at 9<sup>th</sup>, 24<sup>th</sup>, 39<sup>th</sup>, 54<sup>th</sup> and 60<sup>th</sup> km. Data (mean  $\pm$  SE) were analysed using a factorial ANOVA with repeated measures and a LSD *post-hoc* test where significant main effects were observed ( $p \leq 0.05$ ).

**RESULTS:** No differences in time taken to complete trials for either the 60 km (CHOc 137.5  $\pm$  6.1 min; PTNc 143.2  $\pm$  8.8 min vs H<sub>2</sub>O 138.4  $\pm$  5.3 min) or the 1-km all-out sprints were observed. Serum free fatty acids were higher at 54 km in H<sub>2</sub>O and in PTNc (0.73  $\pm$  0.10 and 0.68  $\pm$  0.06 mmol/L, respectively) when compared to CHOc (0.58  $\pm$  0.07 mmol/L). From km 9 to the end of exercise, the TRP/BCAA ratio was lower in CHOc and PTNc (0.085  $\pm$  0.009 and 0.073  $\pm$  0.009, respectively) than in H<sub>2</sub>O (0.117  $\pm$  0.014). Serum prolactin and rating of perceived exertion in all treatments increased in the same fashion.

**CONCLUSION:** Ingestion of CHOc and PTNc did not improve self-paced time trial performance in the heat and probably did not affect central serotonergic activity in previously fed subjects.

Email: paul\_la\_bounty@baylor.edu

(No relationships reported)

**PURPOSE:** To determine the effect of leucine supplementation, as compared to a placebo, on total lower-body workout volume achieved following an acute bout of heavy resistance exercise.

**METHODS:** In a randomized, double blind, placebo controlled design, 11 recreationally active males were randomized into either a leucine supplementation group (20.8  $\pm$  2.4 yrs; 182.2  $\pm$  2.4 cm; 83.0  $\pm$  6.0 kg) or a placebo group (20.0  $\pm$  0.8 yrs; 174.5  $\pm$  6.2 cm; 80.1  $\pm$  11.6 kg). The participants ingested either 40 mg/kg of leucine (n = 4) divided into 2 equal doses or a placebo (n = 7) and then performed a lower body resistance exercise (RE) bout. Supplementation was administered 30 minutes prior, and immediately before RE. The RE bout consisted of 4 sets of leg press followed by 4 sets of knee extension at 80% 1RM to failure. Only those participants who were able to accomplish a minimum of 8 repetitions at 80% of 1RM on every set were included in the analysis. However, all participants were required to attain volitional fatigue. Rest periods between sets and exercises were approximately 2.5 minutes. Total lower-body workout volume between groups was analyzed using an independent samples t-test utilizing SPSS for Windows version 16.0.

**RESULTS:** Data are reported as means  $\pm$  standard deviation (SD). Total lower-body workout volume after leucine and placebo administration was 22584  $\pm$  1954 kg and 18260  $\pm$  6519 kg, respectively. Independent samples t-test revealed there were no significant differences between the two groups  $t_{(9)} = 1.268$ ,  $p = .237$ .

**CONCLUSIONS:** At a dosage of 40 mg/kg of bodyweight, leucine does not appear to increase total lower-body workout volume at an intensity of 80% 1RM to volitional exhaustion to a greater extent than an acute bout of resistance exercise alone.

**Power Capabilities Of Elite Bicycle Motocross (BMX) Racers During Field Testing In Preparation For 2008 Olympics.**

Christopher W. Herman<sup>1</sup>, Stephen J. McGregor<sup>1</sup>, Hunter Allen<sup>2</sup>, Erik M. Bollt<sup>3</sup>. <sup>1</sup>Eastern Michigan University, Ypsilanti, MI. <sup>2</sup>Peaks Coaching Group, Bedford, VA. <sup>3</sup>Clarkson University, Potsdam, NY.

Email: chrisherma40@hotmail.com

(No relationships reported)

**PURPOSE:** Bicycle motocross (BMX) was a recent addition to the medal sports at the 2008 Summer Olympics and there is little information regarding the physiological demands of the sport. Specifically, the power capabilities of this population and demands of the discipline in the field have yet to be defined. Considerations include i) multiple heats of maximal effort and ii) gear ratios for supercross (Olympic) style courses. The purpose of this study was to test the effects of gear, trial and starting grade on performance of Olympic-caliber BMX racers in controlled field tests.

**METHODS:** Procedures were approved by Eastern Michigan's HSRC in which five elite male BMX racers from the 2008 US Olympic selection pool (including two Olympic medalists) performed controlled field testing over a 7 day period on their racing bicycles equipped with custom portable power meters (PM; SRM, CO). Tests included seven starts for three different gear combinations (-1, 0, +1) and two start conditions (Flat; FS vs Supercross; DS). Data collected from PM included power (W), relative power (W/kg), and cadence (CAD). Timing systems (ProGate, IL) were used to record performance time (PT) from start to 6 and 20m to mimic start conditions at the Olympic venue, while a paved surface was used as opposed to dirt to stabilize testing conditions. MANOVA and ANOVA were used to analyze dependent variables (SPSS, IL;  $\alpha=0.05$ ).

**RESULTS:** PT for DS were faster than LS to both 6 m and 20 m, respectively ( $p<0.001$ ), despite the fact that power was not different. Of note, peak power occurred within 6 m (2087 $\pm$ 156.8 W; 1.6 s) vs 20 m (1688 $\pm$ 193.5 W; 2.7 s) ( $p<0.001$ ), which was confirmed in tests on a full mock Olympic course. This is in contrast to a recent report in elite BMX racers from lab studies (Zabala, et al.) where PP occurred at  $>4$  s. For LS there was a significant effect for gear on PT to both 6 m and 20 m ( $p<0.001$ ), but not power. There was no effect for trial. For DS, there was an effect of gear on CAD with peak occurring in 6 m (212 $\pm$ 3.5, 207 $\pm$ 5.0, 203 $\pm$ 5.1) vs 20 m (174 $\pm$ 9.9, 173 $\pm$ 8.9, 169 $\pm$ 7.6), for -1, 0 and +1, respectively, but not power or time.

**CONCLUSION:** Study results may help future coaching and training decisions for Olympic-caliber BMX racers. Notably, the observation of peak power within the first 2 s in field studies contrasts lab data, and demonstrates the importance of field testing.

**Intensity Of Brazilian Official Soccer Games**

Joao C. Dias, Ph.D.<sup>1</sup>, Daniel B. Coelho, M.S.<sup>2</sup>, Lucas de A C F Mortimer, M.S.<sup>2</sup>, Luciano A. Condessa, M.S.<sup>2</sup>, João C B Marins, Dr.<sup>3</sup>, Danusa D.

Soares, Dr.<sup>2</sup>, Silami-Garcia Emerson, Ph.D.<sup>2</sup>. <sup>1</sup>UNI-BH, Belo Horizonte, MG, Brazil. <sup>2</sup>UFMG, Belo Horizonte, MG, Brazil. <sup>3</sup>UFV, Viçosa, MG, Brazil.

Email: diasjc@hotmail.com

(No relationships reported)

Soccer seems to be a high intensity intermittent activity, which varies with the players' position and category (age). The intensity during a soccer game can be assessed by several

variables, but heart rate (HR) is recommended as a practical way. No studies were found in which a great number of players were analyzed during some Brazilian official games.

**PURPOSE:** To evaluate the intensity of official soccer games in different positions using heart rate.

**METHODS:** Subjects from a Brazilian soccer club included male categories under 17 years old (n=26) and 20 (n=18) (U-17 and U-20, respectively); mean  $\pm$  SD; age 16.4 $\pm$ 0.5 and 18.2 $\pm$ 0.7 yr; body mass (BM), 68.1 $\pm$ 4.2 and 70.3 $\pm$ 4.9 kg; height, 175 $\pm$ 7 and 178 $\pm$ 8 cm; body fat, 9.5 $\pm$ 2 and 8.9 $\pm$ 1.4%; and VO<sub>2</sub>max 56.1 $\pm$ 2.0 and 59.2 $\pm$ 3.0 mL·O<sub>2</sub><sup>-1</sup>·min<sup>-1</sup>. Maximum HR (HRmax) was determined as the greatest HR achieved during game, or all out running 1000 m or 2400 m. HR was registered each 5 seconds during 14 official games using a set of HR monitors (Polar Electro Oy, Team System, Finland) and analyzed with respective program. Indirect VO<sub>2</sub>max was predicted from 2400 m running. Percentage of HRmax (%HRmax) was used to express players' effort. Zones of intensity were established regarding %HRmax: 1 (<70%); 2 (70-85%); 3 (85-90%); 4(90-95%); 5(95-100%). HR at the onset of blood lactate accumulation (OBLA) was determined using few 1000 m increasing speed running to achieve 4mM (Accusport Blood Lactate Analyzer).

**RESULTS:** Maximum heart rate (HRmax) was 201 $\pm$ 9 and 198 $\pm$ 7 bpm for the U-17 and U-20 categories, respectively. No differences were found between categories during the study (p>0.05). The mean intensity of the soccer game was 84 $\pm$ 5 %HRmax. The percentage of time spent in zones 1 to 5 during the games were respectively 6, 39, 24, 23, 8%. Forwards and the side-backs remained more time in zone1. Forwards were in zone2 more time than others. The mid-fielders achieved the greater percentage of time spent in zone3 and 4. The wing-backs were the ones who spent more time in zone5. OBLA was 87  $\pm$  5 %HRmax. The percentage of time of game spent above the OBLA intensity was 52  $\pm$  20%.

**CONCLUSIONS:** About two thirds of the game happened at high and one third at very high intensity heart rate responses. Mid fielders achieved greater intensities. The study demonstrated that professional Soccer is a high intensity intermitted activity.

**The Relationship Between Power And Lean Body Mass To Sport-specific Skills Of College Baseball Players**

David J. Szymanski, Jessica M. Szymanski, Kelly A. Brooks, Michael T. Braswell, Andrew T. Britt, Hung-Sheng Hsu, Hannah E. Lowe, Erica G. Taylor, Kristina L. Weil. *Louisiana Tech University, Ruston, LA.*  
Email: dszyman@latech.edu

(No relationships reported)

Baseball is an anaerobic, power sport. Players need to perform the skills of hitting, throwing, and running explosively. Research suggests that these baseball-specific skills can be predicted from fitness and performance tests. Player profiles created with these types of data are of considerable interest to college baseball coaches because it greatly enhances the recruiting process. If coaches had information that may help predict successful baseball skill performance, they could possibly do a better job of recruiting players for scholarships. This could ultimately help teams win more games.

**PURPOSE:** To determine the relationship of various physiological characteristics to sport-specific skills of college baseball players.

**METHODS:** Thirty-seven members of an NCAA Division I men's baseball team (age = 19.7  $\pm$  1.3 yr) volunteered to be evaluated. Tests included percent body fat, lean body mass (LBM), grip strength, upper (1RM bench press and 1-arm dumbbell row) and lower body (1RM squat) strength, rotational power (medicine ball side toss), leg power (vertical jump), running speed (10, 30, 60 yd sprint), throwing velocity (TV), bat velocity (BV), and batted-ball velocity (BBV).

**RESULTS:** Correlation coefficients were calculated for all variables by utilizing a correlation matrix from raw scores. Significant (p < 0.05) and moderately high positive relationships were indicated between BV and BBV (r = 0.70); 60 yd sprint and 30 yd sprint (r = 0.77), 10 yd sprint (r = 0.70). Significant and moderately positive relationships were indicated between BV and vertical jump (r = 0.58), LBM (r = 0.43); medicine ball side toss and BV (r = 0.50), TV (r = 0.49), BBV (r = 0.45); 1RM squat and 1RM bench press (r = 0.58). Significant and moderately negative relationships were indicated between 60 yd sprint and vertical jump (r = -0.57). Coefficients of determination for all variables were also calculated. Of particular interest was BV and BBV (r<sup>2</sup> = 0.49), vertical jump (r<sup>2</sup> = 0.34), medicine ball side toss (r<sup>2</sup> = 0.25), LBM (r<sup>2</sup> = 0.18); medicine ball side toss and TV (r<sup>2</sup> = 0.24), BBV (r<sup>2</sup> = 0.20); 60 yd sprint and 30 yd sprint (r<sup>2</sup> = 0.59), 10 yd sprint (r<sup>2</sup> = 0.49), VJ (r<sup>2</sup> = -0.32).

**CONCLUSION:** Results suggest that strength training programs designed to improve baseball player's performance should emphasize increasing leg power, rotational power, and LBM.

**Physiological Changes Across A 3 Month Sprint Racing Season In Master Level Rowers**

Tricia N. Blocher, Gretchen Casazza. *University of California Davis, Davis, CA.*

Email: tnblocher@ucdavis.edu

(No relationships reported)

**PURPOSE:** The aim of this study was to determine the physiological and performance changes in response to 3 months of specific training for sprint racing (1000 meter course) in master level rowers.

**METHODS:** On three occasions over a 3 month period, nine male rowers (44.9  $\pm$  1.7 yrs, 184.3  $\pm$  2.4 cm) participated in a maximal effort, graded exercise test on the rowing ergometer. Blood lactate concentration, heart rate, oxygen consumption (VO<sub>2</sub>) and rating of perceived exertion were recorded at each three minute stage, during a 30 second rest period, throughout the exercise test and at 3 and 6 minutes of an active recovery. Body composition, maximal vertical jump, core strength, hamstring flexibility and the profile of mood states questionnaire (POMS) were also measured at baseline and 3 months of training. Additionally, a 2000m performance test was performed 1 day apart from the graded exercise testing.

**RESULTS:** Three months of sprint training resulted in a decrease (p < 0.05) in body fat, fat mass and waist circumference and an increase in fat free mass (72.5  $\pm$  3.8 vs. 73.5  $\pm$  3.7 kg) and thigh circumference. The 3-month training program did not change vertical jump, core strength, peak [lactate], [lactate] during recovery, VO<sub>2</sub>peak or 2000m performance, but did improve hamstring flexibility. After 3 months of training the athletes were able to produce more power at lactate threshold (1 mmol/L above baseline) (218  $\pm$  9.5 vs. 243  $\pm$  12.1 watts), at 4 mmol/L of lactate (245  $\pm$  11.2 vs. 262  $\pm$  16.4 watts) and at the onset of blood lactate accumulation (OBLA) (274  $\pm$  12.2 vs. 299  $\pm$  14.7 watts).

**CONCLUSIONS:** Three months of sprint training resulted in increased fat free mass, hamstring flexibility and power at lactate threshold, 4 mmol/L of lactate and at OBLA in master level rowers.

**Physiological Responses To Running In Trained Male Collegiate And Master Level Distance Runners**

Nicole Swanson, Robert Pritchett, Vince Nethery, Ryan Perkins, Amber Green, Leo J. D'Acquisto. *Central Washington University, Ellensburg, WA.*

Email: swansonn09@gmail.com

(No relationships reported)

Performance for running events requiring a substantial aerobic energy contribution (i.e., 10 km) declines gradually from the early 20's to 50 yr, with a more pronounced decrease between 51 and 65 yr, followed by an exponential decrement thereafter (Tanaka, et al. (2003).

**PURPOSE:** This study examined the physiological responses to running in similarly trained male collegiate (C) (n=11; 20+1 yr) and master level (M) (n=9; 45+5yr) distance runners.

**METHODS:** Oxygen uptake (open-circuit spirometry, Parvo-Medic), heart rate (HR; telemetry), and blood lactate (YSI) responses to a series of submaximal (11.3, 12.9, 14.5,

and 16.1 km·hr<sup>-1</sup>) and one maximal run to volitional exhaustion were recorded. Body composition was also assessed (skinfolds).

**RESULTS:** Collegiate runners had a greater VO<sub>2</sub> max (60.9±2.2 vs 58.3±2.6 ml·kg<sup>-1</sup>·min<sup>-1</sup>), a higher HR max (193±6 vs 178±7 bpm), and a faster maximal running speed (19.8±0.7 vs 19.0±0.9 km·hr<sup>-1</sup>) compared to masters runners (P<0.05). However, peak blood lactate was similar (C=9.6±.8, M=10.6±2.6 mM) (P>0.05). At a fixed blood lactate of 4 mM, C had a slightly faster running speed than M (16.7±1.2 vs 15.5±1.6 km·hr<sup>-1</sup>) (P=0.09). HR was higher during the submaximal runs for C compared to M (P<0.05), while an ordinal interaction was found between age category and running speed for oxygen uptake (P<0.05) with M having higher VO<sub>2</sub> values at 14.5 and 16.1 km·hr<sup>-1</sup>. Although body weight was the same for each group (C=67.1±7.2, M=65.4±3.2 kg), the percent adipose tissue was lower for C (6.9±1.1%) compared to M (11.8±2.8%) (P<0.05).

**CONCLUSION:** The collegiate runners were characterized by a greater maximal aerobic power, better running economy, and tendency to sustain a faster running speed at a given metabolic load. Declines in physiological responses still occur with the aging process despite maintenance of training and competitive running.

**Physiological And Anthropometric Characteristics Of The Italian National Women Rugby Union Team**

Giorgio Da Lozzo<sup>1</sup>, Veronica Ceradini<sup>1</sup>, Gabriela De Roia<sup>1</sup>, Annalisa De Cesaro<sup>2</sup>, Silvia Pogliaghi<sup>1</sup>. <sup>1</sup>Università di Verona, Verona, Italy. <sup>2</sup>Federazione Italiana Rugby, Roma, Italy.

Email: silvia.pogliaghi@univr.it

(No relationships reported)

**PURPOSE:** The aim of this study was to provide up to date normative data on selected, laboratory-based, functional and anthropometric variables of elite rugby union women players.

**METHODS:** 11 forwards (FW) and 11 backs (BK) from the Italian National team, regularly engaged in elite training and international competitions were tested in March 2007. We measured body mass, stature, % body fat and lean body mass (5-site plicometry), maximum oxygen consumption (incremental cycling test to exhaustion) and lower extremities power (vertical jumping test: squat, SJ, and countermovement jump, CMJ). Mean and standard deviation were calculated in FW and BK and in positional subgroups (i.e. front row FW: props, locks; back row FW: flankers, number 8, hooker; inside BK: fly-half, centre; outside BK: wings, full back). Data were compared by t test and Bonferroni correction (significance p< 0.05).

**RESULTS:** The athletes were 24±4 years old with a 9±6 years playing experience. Results are presented in the table. \* and § indicate, respectively, a significant difference between FW and BK and within forwards and backs subgroups.

group	#	mass (Kg)	stature (m)	fat (%)	lean mass (Kg)	VO2max (l*min-1)	VO2max (ml*Kg- l*min-1)	SJ (cm)	CMJ (cm)
FW	11	71±12*	1.68±0.1*	24±6	53±5*	3.0±0.4*	43±5	26±4*	29±3
BK	11	63±6	1.63±0.1	24±4	47±4	2.7±0.5	43±5	24±3	29±4
FR FW	5	79±14§	1.71±0.1§	28±6§	56±5§	3.1±0.3	41±6	25±2	28±2
BR FW	6	65±5	1.64±0.0	22±6	51±3	2.9±0.4	44±5	27±5	30±4
I BK	6	64±6	1.63±0.1	26±4	47±4	2.8±0.5	42±7	23±3	29±3
O BK	4	61±7	1.63±0.1	22±4	48±5	2.6±0.3	42±2	24±4	29±5

**CONCLUSION:** The study provides normative functional and anthropometric data for elite female rugby union players, with special reference to positional role. Role differences appear between forwards and backs and between forwards subgroups, suggesting that differences in physical requirements, related to playing positions, are similar for men and women. This normative database can support coaches for talent selection and to guide training to match the playing position demands. Furthermore, periodic monitoring of a variety of playing populations is necessary to quantify and compare the rapidly evolving demands of this game.

**2327 Board #215 May 28 3:30 PM - 5:00 PM**

**Impact Of Visual Training On Complex Visual Reaction Time In Athletes**

Sandra M. Rossi, Aldo F. Longo, Nestor A. Lentini, Víctor M. Paris, José L. Tripodi. *Exercise Physiology Laboratory, National Sport High Performance Center (CeNARD), Buenos Aires, Argentina.*

(No relationships reported)

Visual information is very important in competitive sports because of the velocity and selectivity of the tactical decisions that are needed to make.

**PURPOSE:** The aim of this study was to evaluate the impact of visual training on complex visual reaction time (CVRT) in athletes, to test the hypothesis that specific and systematic visual stimulation contributes to changes over a short period of time.

**METHODS:** A before and after design was used. Forty-one female and 33 male athletes (19 ± 5 yr, mean ± SD) who belonged to individual and team sports volunteered to take part in this study. A PC-based visual training program was performed within 5 weeks, with a training frequency of 3 sessions per week. Every session lasted 30 min and included the following visual skills: Saccadic Movements, Follow-up Visual Field, Stereopsis, Fusion, Peripheral Visual Field and Taquitoscope. Progressive incremental levels of complexity were stipulated for the training. Specific software was used to assess CVRT in both pre and post training tests. The evaluation of CVRT consisted of showing on a PC screen a sequence of 5 randomly-timed visual stimuli in the course of ~30 s, 3 of them (positives) to be responded by means of pressing the enter key on a keyboard, which was located under the dominant hand. Punishments of 200 ms were automatically added in case of failed responses. The subjects repeated the test 4 times, with rest intervals of 1 min. The average time of the 12 outputs was taken into account for the pre-post comparison. The training sessions and the tests took place at the same time of day (± 2 h). A paired t-test was used to determine the significance of the difference between the performances before and after training.

**RESULTS:** Statistical analysis revealed that visual training produced a significant decrease (p<0.05) in CVRT (335.6 ± 4.6 to 271.3 ± 4.0 ms, mean ± SE; 95% CI for the difference: 57.2 to 71.4). All subjects had higher performances in the post training test.

**CONCLUSIONS:** These results showed that visual training produced improvement in CVRT over a short period of time. It would be advisable to design field tests to evaluate the effect of the visual perceptual and visual motor interventions on the performance of the athletes in sports situations.

**Evaluation Of Yo-Yo Intermittent Recovery And Hoff Tests In Female Collegiate Athletes**

Clayton Nicks, Michael Mangum. *Columbus State University, Columbus, GA.* (Sponsor: Kent D. Johnson, FACSM)

Email: nicks\_clayton@colstate.edu

(No relationships reported)

The Yo-Yo Intermittent Recovery and Hoff tests are field tests that can be used to predict performance in soccer players. However, the physical requirements of these tests are

uniquely different and there is limited data on their usefulness for female soccer players.

**PURPOSE:** It was the purpose of this study to evaluate the Yo-Yo Intermittent Recovery and Hoff tests as they relate to each other and to maximal oxygen consumption in collegiate female soccer players.

**METHODS:** Fifteen female soccer athletes from an NCAA Division II university team volunteered to participate in this study. Anthropometric measurements of height, weight, and body mass index (BMI) were recorded. The athletes performed levels 1 and 2 of the Yo-Yo Intermittent Recovery test (YY1 and YY2) and a modified, 7-minute version of the Hoff test (HT). Maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ) was determined utilizing an open circuit technique during a graded treadmill protocol to voluntary exhaustion. Individual tests were performed at least 3 days apart to avoid residual fatigue. Pearson's  $r$  was calculated to determine the linear association between test results, laboratory results, and anthropometric data.

**RESULTS:** Age, height, and weight (Mean  $\pm$  SD) were  $19.6 \pm 1.29$  years,  $1.65 \pm .07$  m, and  $63.8 \pm 6.9$  kg, respectively. Performances in the field tests were: YY1 =  $840 \pm 311.2$  m, YY2 =  $260 \pm 67.9$  m, and HT =  $1032.9 \pm 80.5$  m.  $\text{VO}_{2\text{max}}$  averaged  $46.1 \pm 4.5$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$  while mean BMI was  $23.4 \pm 2.3$  kg/m $^2$ .  $\text{VO}_{2\text{max}}$  was significantly related to performance in the YY1 ( $r = .84$ ,  $p = .001$ ) and YY2 ( $r = .70$ ,  $p = .012$ ), but was not significantly related to HT ( $r = .37$ ,  $p > .05$ ). BMI was inversely related to YY1 ( $r = -.64$ ,  $p = 0.025$ ) and YY2 performance ( $r = -.62$ ,  $p = 0.018$ ), but did not relate to HT ( $r = -.07$ ,  $p = .82$ ). In addition, we observed significant relationships between YY1 and HT ( $r = .64$ ,  $p = 0.025$ ) and between YY1 and YY2 ( $r = .86$ ,  $p = 0.001$ ).

**CONCLUSIONS:** YY1 and YY2 were strongly associated with aerobic power and inversely related to BMI, reinforcing the concept that these are primarily fitness tests. Similarly, that HT was not strongly associated with aerobic power or BMI suggests that it is measuring something other than fitness, presumably sport specific skill.

**2329      Board #217      May 28      3:30 PM - 5:00 PM**  
**Circulatory Strain And Hydration Status Of Cyclists Competing In Le Tour De Langkawi**

Cheong Hwa Ooi<sup>1</sup>, Joshua Philip<sup>1</sup>, Naziah Dollah<sup>1</sup>, Marilyn Ong<sup>1</sup>, Razali Makhtar<sup>1</sup>, Martin William Thompson<sup>2</sup>. <sup>1</sup>National Sports Institute of Malaysia, Kuala Lumpur, Malaysia. <sup>2</sup>The University of Sydney, Sydney, Australia.

Email: cheonghwa@isn.gov.my

G. Olcina presenting

(No relationships reported)

**PURPOSE:** To investigate the circulatory strain and hydration status of cyclists in Le Tour de Langkawi - a 10-day cycling tour event covering a total distance of ~1,150 km in Malaysia.

**METHODS:** Six male elite cyclists (age  $24.5 \pm 5.7$  yr; mass  $61.6 \pm 4.7$  kg; stature  $1.68 \pm 0.04$  m,  $\text{VO}_{2\text{max}}$   $66.6 \pm 3.8$  mL $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ; HR $_{\text{max}}$   $185 \pm 4$  bpm) gave their informed consent to take part in the study. Prior to the tour,  $\text{VO}_{2\text{max}}$  and HR $_{\text{max}}$  were determined via an incremental cycling test to volitional fatigue on a cycle ergometer. Before the start of each stage body mass was measured and a HR monitor was strapped to each cyclist. At the end of each race stage the cyclists were reweighed and total body mass loss was used as an indicator of dehydration. The HR data was analyzed to determine the relative percentage of HR $_{\text{max}}$  (% HR $_{\text{max}}$ ) sustained throughout the tour. Five different % HR $_{\text{max}}$  were defined as follow: Recovery (<60% HR $_{\text{max}}$ ), Easy (60-69% HR $_{\text{max}}$ ), Moderate (70-79% HR $_{\text{max}}$ ), Hard (80-89% HR $_{\text{max}}$ ), Intense (>90% HR $_{\text{max}}$ ). The ambient temperature and relative humidity were recorded during each day of the tour.

**RESULTS:** The final stage of the race was cancelled due to heavy rain. Cyclists maintained a mean HR of 148 bpm over the 9 days duration of the event, although there was a considerable range of HR response throughout the tour. A total of 8.7 hours (31.6%) of the time racing in the tour was classified as "Hard" to "Intense" in terms of the HR response (>80% HR $_{\text{max}}$ ). Body mass of cyclists was significantly ( $P < 0.01$ ) lower at the end of each race stage with an observed mean stage body mass loss of  $1.6 \pm 0.6$  kg. In addition, total body mass loss was correlated to the distance of each stage ( $P < 0.05$ ). Mean maximum daily ambient temperature and relative humidity for the tour was  $37.2 \pm 3.8$  °C and  $60.9 \pm 20.1$  % rh.

**CONCLUSIONS:** This study found a significant mean 2.6% body mass deficit across all stages of the tour. Most of this loss can be attributed to the thermal stress of the hot-humid environment and associated sweat production. Increasing dehydration coupled with periods of intense physical effort contributed to a high mean heart rate of 80% HR $_{\text{max}}$  despite the cooling effect of airflow and availability of fluid. Part of this elevated HR response may be attributed to the well documented cardiovascular drift that is associated with prolonged exercise in hot conditions.

**2330      Board #218      May 28      3:30 PM - 5:00 PM**  
**Rhythmic Gymnastics On Different Levels Of Qualification. A Comparative Study.**

Luciana Menezes<sup>1</sup>, Paulo Dantas<sup>2</sup>, José Fernandes Filho<sup>3</sup>. <sup>1</sup>UTAD, Rio de Janeiro, Brazil. <sup>2</sup>UFRN, Natal, Brazil. <sup>3</sup>UFRJ, Rio de Janeiro, Brazil.

Email: lucianasmenezes@hotmail.com

(No relationships reported)

Rhythmic gymnastics is a sport that can be characterized for having athletes that achieve international status before becoming adults. Teenagers have a intensive training program in a period which can be associated to hormonal changes an body growing.

**PURPOSE:** To compare the structural, chronological and physical variables differences between Rhythmic gymnastics athletes from different levels of qualification.

**METHODS:** The sample was composed by the brazilian rhythmic team (international level)  $n = 07$ , National gymnasts (10 first places in the brazilian adult nationals)  $n = 10$ , State gymnasts (07 first places in the Rio de Janeiro state adult competition)  $n = 07$ . For the evaluation of the physical qualities the following protocols were used: coordination (test of coordination of Burpee), flexibility (goniometry test), explosive power (test of vertical impulse - Sargent jump). The statistic descriptive procedure used was the Shapiro wilk, and the inferencial one was the one-way ANOVA with Sheffe's post hoc. The study established  $p \leq 0.05$  to statistic significance.

**RESULTS:** showed significant statistic differences in the variables age between the international level and the other two ( $16.2 \pm 1.49$ ;  $13.7 \pm 1.25$ ;  $13.8 \pm 1.34$ ) and high between the international and the state gymnasts ( $162.2 \pm 6.87$ ;  $156.6 \pm 3.27$ ;  $155.6 \pm 2.93$ ). There were no significant statistic differences between the groups for weight ( $44.2 \pm 5.06$ ), Burpee ( $4.7 \pm 0.53$ ), Sargent jump ( $37.7 \pm 4.00$ ), Leg goniometry ( $33.0 \pm 11.20$ ).

**CONCLUSION:** Differences in age can be explained for Nationals and State championships allow juniors to participate. Most evaluated gymnasts narrated not having the menarch period yet or being late (after 15 years). At the same time, the best results in National and State competitions were achieved by the juniors. These results may be related to the late maturational period, considering that the presence of the strogenio hormone affects the athletes performance. In this study, there was found no difference for the physical variables, this way, the qualification difference is due to the thecnical and specific levels.

**Urinary Androgens And Corticosteroids Changes In Elite Cyclists After High Intensity Efforts**

Diego Muñoz, Fermin Toribio, Concepcion Robles, Javier Brazo, Rafael Timon, Guillermo Olcina, Marcos Maynar. University of Extremadura, Caceres, Spain.

Email: diegomun@unex.es

G. Olcina presenting

(No relationships reported)

Some research has shown that high intensity exercise induces physiological stress which alter hormonal profile. Urinary excretion of these hormones and its metabolites can be used in order to evaluate physical exercise load. Cortisol's metabolites and cortisone are determined for assess catabolic status, while testosterone and its metabolites as well as

suprarenal androgens are in relation with anabolic status.

**PURPOSE:** the aim of this study is to analyze if high intensity efforts provokes changes in urinary steroids profile in endurance trained subjects.

**METHODS:** Twenty male cyclists participated in this study (age:  $23.83 \pm 2.32$  years; height:  $176.00 \pm 3.65$  cm; weight:  $66.94 \pm 3.59$  kg; body fat %:  $8.57 \pm 1.22$ ;  $\text{VO}_2$  max:  $65.53 \pm 9.35$  ml/kg/min). The trial performed was an incremental ergometric test until exhaustion. Urine samples were collected before and after the test. All tests were conducted in a physiology laboratory, room temperature was  $23 - 25^\circ\text{C}$ , humidity was  $45 - 55\%$ . Urinary samples were analyzed by gas chromatography techniques in order to determine testicular androgens, suprarenal androgens and corticosteroids values. Sample urinary density was in the range of  $1.005 - 1.025$  g/mL, pH was between the normal range of  $4.7 - 7.8$ . Creatinine levels of all samples were determined in order to report the steroid concentrations relative to this urinary parameter. The Wilcoxon test was performed for statistical analysis. A  $p < 0.05$  was used to determine statistical significance.

**RESULTS:** We obtained statistically significant decreases ( $p < 0.05$ ) in testosterone ( $37.5 \pm 16.5$  to  $29.2 \pm 10.9$  ng/mg creatinine), androsterone  $2460.7 \pm 933.4$  to  $2004.8 \pm 819.3$  ng/mg creatinine), total testicular androgens ( $3709.3 \pm 1503.1$  to  $2960.7 \pm 772.3$  ng/mg creatinine), androstenedione ( $32.1 \pm 13.7$  to  $10.4 \pm 4.4$  ng/mg creatinine), total suprarenal androgens ( $229.16 \pm 120.3$  to  $154.5 \pm 134.3$  ng/mg creatinine) and in DHEA/THC ( $0.11 \pm 0.02$  to  $0.07 \pm 0.01$  ng/mL) and DHEA/THC<sub>ol</sub> ( $0.13 \pm 0.02$  to  $0.10 \pm 0.02$  ng/mL) ratios.

**CONCLUSION:** Results suggest that the decline in urinary excretion is due to a decline in the clearing of androgens by the liver because of the reduction in hepatic perfusion that accompanies intense exercise. The DHEA/THC y DHEA/THC<sub>ol</sub> ratios are some markers of the subjects' anabolic/catabolic status following the exercise session.

**Comparison Of Walking Energy Expenditure On Field Tracks With And Without Poles**

João M. Brito<sup>1</sup>, Victor M. Reis<sup>2</sup>, Renato Fernandes<sup>1</sup>, Hugo Louro<sup>1</sup>, Aldo Costa<sup>3</sup>. <sup>1</sup>ESDRM, Rio Maior, Portugal. <sup>2</sup>Universidade Trás-os-Montes e Douro, Vila Real, Portugal. <sup>3</sup>Universidade da Beira Interior, Covilhã, Portugal.

Email: jbrito@esdrm.pt

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effects of poles on the walking energy expenditure. The metabolic responses were examined for two walking condition: poles ( $W_{WP}$ ) and non-poles ( $W_{NP}$ ).

**METHODS:** Twenty healthy males volunteers walked at a self-selected pace in a 821 m pedestrian level ground field track (age  $22.70 \pm 2.89$  years; body weight  $77.90 \pm 11.19$  Kg; height  $176.55 \pm 5.90$  cm; body fat percentage  $14.59 \pm 5.99\%$ ). The subjects completed each trail in a randomized order. Return to metabolic rest values was respected between trails. The heart rate (HR), oxygen consumption ( $\text{VO}_2$ ) and energy expenditure (EE) were continuously recorded by a portable telemetric system. Rating of perceived exertion (RPE) was measured at the end of each trial by the modified Borg scale (1-10). The telemetric poles were adjusted individually to each subject.

**RESULTS:** Significant differences were found ( $P \leq 0.05$ ) in the comparisons  $W_{NP}$  vs  $W_{WP}$  for HR and walking speed. Mean walking speed was lower in the  $W_{WP}$ .

**CONCLUSIONS:** The results indicate that the use of walking poles does not increase the metabolic and perceptive demands ( $\text{VO}_2$ , EE and RPE) but do increase HR response. The use of poles does not seem to be an optimal strategy to influence the improvement of the physical fitness when walking on field level ground.

**2333 Board #221 May 28 3:30 PM - 5:00 PM**  
**Effects Of Doms On Basketball Players' Shooting Accuracy, Flexibility, Jump Height, Hand Speed And Agility**

Jacob D. Galloway, Charilaos Papadopoulos, Tim Burnham, Robert Pritchett. Central Washington University, Ellensburg, WA.

Email: jgalloway@sacdt.com

(No relationships reported)

Basketball players' success is largely dependent on physical conditioning and their ability to execute sport specific skills. Basketball players experience the effect of weight training induced delayed-onset muscle soreness (DOMS) and believe that negatively affects their playing ability.

**PURPOSE:** The purpose of this study was to examine the effects of weight training induced DOMS on several basketball specific tests.

**METHODS:** Fourteen college basketball players (9 males and 5 females) were recruited. Shooting accuracy, leg and shoulder flexibility, jump height, hand speed, agility, and perceived pain were assessed on days 1 and 2. On day 2, after the testing, the subjects performed a full-body weight training to induce DOMS. Twenty-four hours (24-h) and 48 hours (48-h) post DOMS, participants performed the same tests and soreness evaluation. Blood samples were collected prior to, half an hour, 24-h and 48-h after weight training induced DOMS and analyzed for creatine kinase (CK). A one-way repeated measure ANOVA was used to determine the effect of DOMS on shooting ability, flexibility, hand speed, agility, jump height, CK, and perceived pain throughout the three days of the study.

**RESULTS:** There was no significant difference in shooting percentage ( $P = 0.31$ ), agility ( $P = 0.39$ ), and hand speed ( $P = 0.22$ ) at any time. Leg flexibility significantly ( $P < 0.05$ ) decreased between pre and 24-h post weight training induced DOMS. At 48-h post DOMS, leg and shoulder flexibility and jump height were significantly decreased compared to pre-weight training values. Pain, measured with a visual analogue scale, significantly increased ( $P < 0.05$ ) during stretch and palpation for all muscle groups (gluteus and quadriceps, chest and triceps, back and biceps) except the abdominal, from pre-weight training to 24-h and peaked at 48-h after weight training. Average CK levels at 24-h and 48-h were significantly higher than the pre-weight training values.

**CONCLUSION:** These results in this population of college basketball players revealed that weight training induced DOMS does not negatively affect basketball players' shooting ability even though pain was significantly increased post weight-training. However, weight training induced DOMS may have an impact on their jumping ability and flexibility 48-h after weight training.

**Comparison Of Different Drop Jump Heights On Vertical Jump Performance In Elite Team Handball Players**

Douglas P. Marin<sup>1</sup>, Donizete Xavier Oliveira<sup>2</sup>, Paulo Barbosa Freitas Junior<sup>3</sup>, Luiz Moura Junior<sup>2</sup>, Adriano Aparecido Santos<sup>1</sup>, Gustavo Pereira Barbosa<sup>4</sup>, Ana Maria Forti Barela<sup>2</sup>, José Angelo Barela<sup>5</sup>. <sup>1</sup>Metodista University of São Paulo, São Paulo, Brazil. <sup>2</sup>Cruzeiro do Sul University, São Paulo, Brazil. <sup>3</sup>University of Delaware, Delaware, DE. <sup>4</sup>Metodista University of São Paulo, São Paulo, Brazil. <sup>5</sup>Cruzeiro do Sul University, São Paulo, Brazil.

Email: douglas.marin@metodista.br

(No relationships reported)

**INTRODUCTION:** Studies have shown that when compared to other kinds of vertical jump, drop jumps (DJ) can increase maximal jump height. However, landing from high levels can be detrimental to bone and joint structures and cause long-lasting injuries.

**PURPOSE:** To examine the effects of different drop heights on the performance of drop jump in Brazilian elite team handball players.

**METHODS:** Nine male team handball players (body mass  $90.7 \pm 12.1$  kg; body height  $184.3 \pm 8.9$  cm) were asked to drop from boxes 40, 60, and 80 cm high, and immediately perform a vertical jump as higher as possible. No arm swing was allowed. A force plate (Kistler - Model 9286A) was used to measure the vertical component of ground reaction force (GRF<sub>v</sub>), recorded by a customized LabView, which was also employed to calculate landing peak force (LPF1) and time to peak (TPF1) after the drop, contact time (CT), jump height (JH), and landing peak force (LPF2) and time to peak (TPF2) after the subsequent vertical jump.

**RESULTS:** Except for LPF1 there were no effect of dropping height (40, 60, and 80 cm) on TPF1, CT, JH, LFP2, and TPF2. The landing peak force (LFP1) after the drop jump was lesser when the participants dropped from 40 cm (DJ 40) when compared to dropping from other heights (DJ 60 and DJ 80).

		LPF1 (N)	TPF1 (ms)	CT (ms)	JH (cm)	LPF2 (N)	TPF2 (ms)
DJ 40	Mean	2850.9 *	28.7	482.4	36.4	6831.5	49.1
	SD	1343.1	13.3	87.1	8.3	2461.7	12.8
DJ 60	Mean	4877.7	25.9	483	36.2	6600.4	51.9
	SD	1470.5	14.9	122.9	7.4	1308.1	19.8
DJ 80	Mean	5421.1	18.3	525.9	35.3	5751.8	47.3
	SD	1823.6	12.6	93.9	7.8	1415.9	17.4

\* p < 0.05 among DJ conditions.

**CONCLUSION:** The results indicate that, no matter from what height the participants dropped, the final outcome (jump height) is similar. However, dropping from a higher place generates more peak force, and consequently, more stress in bones and joints structures. In conclusion, dropping from 40 cm can be more effective (same performance outcome and lower bone and joints overloads) than from higher heights.

**2335 Board #223 May 28 3:30 PM - 5:00 PM**  
**Anaerobic Power Profiles In Track And Field**

Michael J. Johnson, Steven J. Albrechtsen. *University of Wisconsin, Whitewater, WI.*  
Email: albrechs@uww.edu  
*(No relationships reported)*

**PURPOSE:** To evaluate the importance of lower body and upper body anaerobic power in relation to performance in track and field events where the importance and development of anaerobic power varies substantially from event to event.

**METHODS:** Thirty-two collegiate track and field athletes performed a standard Wingate Anaerobic Test to evaluate lower body anaerobic power (AnP-L) followed by a modified Wingate Anaerobic Test to evaluate upper body anaerobic power (AnP-U). Each athlete's personal records were converted to standardized values using the IAAF Scoring Tables of Athletics and the standardized values were correlated with AnP-L and AnP-U.

**RESULTS:** The highest levels of peak AnP-L were achieved in short sprints, 200 and sprint hurdles (9.78 W/kg, 9.76 W/kg, 9.62 W/kg). The lowest levels of peak AnP-L were achieved in 5,000/10,000, 1,500/Mile and 800 (8.17 W/kg, 8.34 W/kg, 8.92 W/kg). The highest levels of average AnP-L were achieved in horizontal jumps, 200 and short sprints (7.75 W/kg, 7.68 W/kg, 7.67 W/kg). The lowest levels of average AnP-L were achieved in 5,000/10,000, vertical jumps, 800 and 1,500/Mile (6.74 W/kg, 7.14 W/kg, 7.18 W/kg, 7.18 W/kg). The highest levels of peak AnP-U were achieved in 400, sprint hurdles and 200 (3.34 W/kg, 3.31 W/kg, 3.30 W/kg). The lowest levels of peak AnP-U were achieved in 5,000/10,000, 800 and 1,500/Mile (2.35 W/kg, 2.77 W/kg, 2.79 W/kg). The highest levels of average AnP-U were achieved in sprint hurdles, 200 and horizontal jumps (2.65 W/kg, 2.59 W/kg, 2.53 W/kg). The lowest levels of average AnP-U were achieved in 5,000/10,000, 1,500/Mile and 800 (1.98 W/kg, 2.23 W/kg, 2.29 W/kg). Peak AnP-L correlated most with performance for 1,500, 800, sprint hurdles, 200 and 400 (0.93, 0.90, 0.68, 0.59, 0.51). Average AnP-L correlated most with performance for 1,500/Mile, 800, 400, 200 and short sprints (0.97, 0.91, 0.80, 0.64, 0.39). Peak AnP-U correlated most with performance in vertical jumps and 1,500/Mile (0.75, 0.34). Average AnP-U correlated most with performance in 800, 1,500/Mile, horizontal jumps and 400 (0.96, 0.92, 0.57, 0.40).

**CONCLUSIONS:** The results suggest that anaerobic power may be a secondary consequence of training in a wide range of track and field events, but that excessive emphasis should not be placed on the development of anaerobic power for track and field events.

**2336 Board #224 May 28 3:30 PM - 5:00 PM**  
**Active And Passive Ranges Of Motion Of Collegiate Division I Soccer And Baseball Players.**

Sandro R. Freitas<sup>1</sup>, Jakob L. Vigren<sup>2</sup>, Mick Joseph<sup>2</sup>, Disa L. Hatfield<sup>2</sup>, Jeff S. Volek<sup>2</sup>, Maren S. Fragala<sup>2</sup>, Jen Y. Ho<sup>2</sup>, William J. Kraemer, FACSM<sup>2</sup>.

Email: pt.sandrefreitas@gmail.com  
*(No relationships reported)*

**PURPOSE:** Kicking (soccer) and throwing (baseball) are ballistic tasks in which athletes may have specific flexibility profiles for the predominant joint used for each sport. The purpose of this study was to examine and compare active and passive ranges of motion (ROM) of the hip and shoulder joints for the dominant and non-dominant limbs of soccer and baseball players.

**METHODS:** Collegiate Division I soccer (n=10) and baseball (n=6) players (20.7±1.6 and 20.7±1.6 years; 179 ± 6 and 178 ± 6 cm; 79.3 ± 9.1 and 83.5 ± 14.5 kg for soccer and baseball players, respectively) volunteered for this study. Active and passive ROM, as well as the difference between end range of active and passive (D<sub>pass</sub>) motion were determined for: shoulder horizontal abduction (SHAB), shoulder horizontal adduction (SHAD), hip extension (HE), hip flexion (HF), and hip extension, abduction, and external rotation (Patrick's test).

**RESULTS:** Sport specific significant differences were found between the dominant and non-dominant limbs. Soccer players had a higher active HE in their dominant leg compared with the non-dominant leg (p<0.01); no differences were found in HF and PT. Baseball players demonstrated less active (p<0.001) and passive (p<0.05) SHAD and a greater active (p<0.05) and less D<sub>pass</sub> SHAB (p<0.05) in the dominant arm compared to the non-dominant arm.

**CONCLUSIONS:** Baseball and soccer players have specific flexibility profiles for the predominant joint used in their sport.

**2337 Board #225 May 28 3:30 PM - 5:00 PM**  
**The Effect Of Compression Socks On Recovery After A 30-sec Wingate Test**

John D. Smith<sup>1</sup>, Timothy D. Heden<sup>2</sup>, Mark D. Applegate<sup>3</sup>. <sup>1</sup>TAMU-Kingsville System Center San Antonio, San Antonio, TX. <sup>2</sup>Southern Illinois University Edwardsville, Edwardsville, IL. <sup>3</sup>St. Louis Community College, St. Louis, MO.  
Email: jdsmith@tamuk.edu  
*(No relationships reported)*

Compression socks appear to work by reducing venous pooling and improving deeper tissue oxygenation, and may also increase the ejection fraction of the calf muscle pump thereby possibly increasing circulation. Increasing the venous circulation may facilitate an increase in metabolic waste clearance. No research has been conducted on the effects

of compression socks during recovery after exercise.

**PURPOSE:** To examine heart rate (HR), oxygen consumption ( $\text{VO}_2$ ), perceived exertion (RPE) and lactate clearance after a 30-sec Wingate test.

**METHODS:** A Polar HR transmitter interfaced with a True One 2400 (ParvoMedics) metabolic analyzer and a Borg's 6-20 scale was used to collect HR,  $\text{VO}_2$ , RER and RPE of 17 subjects ( $28.6 \pm 9.0$  yrs,  $175.2 \pm 7.3$  cm,  $73.3 \pm 8.0$  kg,  $18.7 \pm 7.4$  %BF,  $44.7 \pm 9.6$  ml kg<sup>-1</sup> min<sup>-1</sup>  $\text{VO}_{2\text{max}}$ ) immediately after the Wingate test and 3, 6, and 10 min after, while cycling at 35%  $\text{VO}_{2\text{max}}$ . An Accutrend lactate analyzer was used to determine venous blood lactate at these same time points. Participants served as their own controls in this counter balanced design, once with and once without the knee-high graduated compression sock (OxySocks: 18-22 mmHg).

**RESULTS:** RMANOVA revealed no significant differences between the trials in any of the variables,  $p > .05$  (Table 1). A paired  $t$ -test did not reveal a significant difference in total work without ( $16349.7 \pm 323$  Joules) and with ( $15969.8 \pm 329$  Joules) the sock.

Table 1. Physiological and perceptual responses with and without compression socks after a 30-sec Wingate test						
		Pre	Wingate	3-min Post	6-min Post	10-min Post
HR (b/min)	NoSock	68.6±12.4	177.9±14.4	136.6±15.0	127.3±13.6	126.7±15.6
	Sock	71.9±9.98	179.7±13.2	138.0±12.9	130.3±12.4	128.9±12.0
VO2 (ml.kg.min-1)	NoSock	3.8±0.8	35.4±6.9	21.6±5.7	18.4±4.6	17.2±3.7
	Sock	4.1±0.9	34.7±8.1	20.8±5.6	20.0±5.5	17.6±5.2
Lactate (mmol/L)	NoSock	2.2±.04	9.8±3.2	11.8±2.8	10.5±2.9	8.6±2.8
	Sock	2.2±.05	9.1±2.5	11.9±1.9	10.5±2.3	9.0±2.8
RER	NoSock	.87±.09	1.15±.09	1.17±.10	.99±.08	.88±.06
	Sock	.88±.08	1.17±.10	1.20±.12	.99±.09	.88±.04
RPE	NoSock	----	17.0±2.3	10.9±1.4	9.0±1.5	8.1±1.3
	Sock	----	16.9±3.1	11.3±1.6	9.7±1.7	8.3±1.8

Note: Means ± SD

**CONCLUSIONS:** This study does not provide evidence that compression socks effect physiological or perceptual variables during recovery after a 30-sec Wingate test.

## 2338 Board #226 May 28 3:30 PM - 5:00 PM Effect Of One Session Of Hydrotherapy In The Physical Qualities In Soccer Players

Ana M. Pardo Márquez<sup>1</sup>, Andrea Ávila Bogotá<sup>2</sup>, Alexander Niño<sup>3</sup>, Mauricio Serrato<sup>4</sup>, Camilo E. Povea<sup>5</sup>. <sup>1</sup>Universidad el Bosque, Bogotá, Colombia. <sup>2</sup>Universidad el Bosque, Bogota, Colombia. <sup>3</sup>Compensar, Bogotá, Colombia. <sup>4</sup>Centro de Alto Rendimiento en Altura, Bogota, Colombia. <sup>5</sup>Fundación Cardio Infantil, Bogotá, Colombia.

Email: guayita@hotmail.com

A. Avila Bogota presenting

(No relationships reported)

One of the fundamental principles of the modern training lies in a suitable balance between the stimulation caused by the loads of training and the later recovery. For this purpose, there have been created multiple modalities that try to accelerate the process of recovery from physical exercise; one of those is the hydrotherapy, nevertheless its use is based generally on anecdotal information more than in controlled studies.

**PURPOSE:** To assess the immediate effects of hydrotherapy in some physical qualities (strength, speed, jump capacity) and subjective perception of fatigue, in soccer players.

**METHODS:** During a clinical Pseudo-experimental research, the strength (isokinetic force), speed (40 meters sprint), jump capacity (Bosco's test) and subjective sensation of fatigue were measured in 7 soccer players for three non consecutive days: an initial evaluation (base); 16 hours later to a football match and after one session of 30 minutes of hydrotherapy (hydrotherapy); and 16 hours later to a football match without hydrotherapy (not hydrotherapy). The players were their own controls. The averages of the values obtained with the hydrotherapy and not hydrotherapy were compared with the base results.

**RESULTS:** The players were slower in the final speed (time in seconds from 20 to 40 meters) in the situation of not hydrotherapy compared with the base ( $2.40 \pm 0.10$  vs.  $2.35 \pm 0.10$  seconds,  $p < 0.05$ ); the maximum force of quadriceps diminished more in not hydrotherapy than in hydrotherapy with regard to the base ( $172.29 \pm 36.39$  vs.  $190.14 \pm 27.67$  Newton · meter,  $p < 0.05$ ); the explosive force increased in the hamstrings of the right knee with the session of hydrotherapy ( $137.14 \pm 26.94$  vs.  $120.57 \pm 21.19$  N·m of base,  $p < 0.05$ ); the players improved in the subjective perception of the physical condition after a session of hydrotherapy post game ( $30.4 \pm 13.96$  vs.  $26.81 \pm 16.55$  %,  $p < 0.05$ ).

**CONCLUSIONS:** A session of hydrotherapy immediately after a football match reduces the negative impact of a physical load over some qualities as the speed and the strength. The subjective perception of the physical condition improves after a session of hydrotherapy. The answers to a session of hydrotherapy were individual and did not generate adverse effects in the studied subjects.

## 2339 Board #227 May 28 3:30 PM - 5:00 PM Reliability Of The Power Profile Test: Assessing The Performance Capacity Of Road Cyclists

Marc J. Quod<sup>1</sup>, David T. Martin<sup>1</sup>, Paul B. Laursen<sup>2</sup>, Christopher J. Gore, FACSM<sup>1</sup>. <sup>1</sup>Australian Institute of Sport, Canberra, Australia. <sup>2</sup>Edith Cowan University, Perth, Australia.

Email: marc.quod@ausport.gov.au

(No relationships reported)

Successful road cyclists tend to produce numerous high-intensity efforts between 5 s and 10 min in duration. Quantification of the maximal power output that can be produced for progressively longer durations (Critical Power Tests) typically involve maximal efforts produced over multiple days. The Power Profile (PP) is a 60 min laboratory test

designed to assess the power producing capacity of competitive cyclists over a range of durations that compare directly with those typically experienced during mass start road racing.

**PURPOSE:** To establish the reliability of the PP test.

**METHODS:** 16 competitive cyclists (mean  $\pm$ SD, 21.5  $\pm$ 2.2 y, 70.6  $\pm$ 6.8 kg,  $\text{VO}_{2\text{peak}}$  4.9  $\pm$ 0.5 L.min<sup>-1</sup>) who had no prior experience with the test protocol completed two PP tests that were separated by >24 h and < 7 d. Cyclists were tested on a custom-built wind-braked ergometer and completed 7 maximal efforts of 6, 6, 15, 30, 60, 240 and 600 s duration incorporating active recovery periods of 54, 174, 225, 330, 480 and 600 s respectively. Cyclists were instructed to produce the highest average power output possible for each effort. Power output was continuously monitored (5Hz) with a dynamically-calibrated torque meter.

**RESULTS:** Average ( $\pm$ SD) maximal mean power for the PP were typical of nationally competitive male road cyclists (5s-1075  $\pm$ 135 W; 15s-865  $\pm$ 93 W; 30s-664  $\pm$ 70 W; 60s-519  $\pm$ 60W; 240s-375  $\pm$ 39W; 600s-329  $\pm$ 33W). The average  $\pm$ SD (range) Change in Mean, Typical Error and ICC between Test 1 and 2 for the 6 efforts lasting from 6 s - 600 s were 1.7  $\pm$ 1.6% (-0.2-3.9%); 3.6  $\pm$ 0.8% (2.3-4.5%) and 0.90  $\pm$ 0.03 (0.88-0.96) respectively. In addition, the Typical Error for the total work (kJ), anaerobic work capacity (kJ) and critical power (W) was 2.2%, 8.8% and 2.9%, respectively.

**CONCLUSIONS:** The reliability of the PP test is similar to other tests that require maximal efforts across similar durations. In addition, changes in average power for maximal sprints in the PP need to be greater than 3.3-6.4% to be considered "real" at the 68% level of confidence. These reliability data for the PP test suggest that this test is suitable for quantifying both anaerobic and aerobic power producing capacities of cyclists that are relevant to road cycling competition.

**Variability In High Intensity Activities In Premier League Soccer**

Warren Gregson<sup>1</sup>, Valter Di Salvo<sup>2</sup>, Greg Atkinson<sup>1</sup>, Barry Drust<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>University Institute of Movement Sciences, Rome, Italy. (Sponsor: Keith George, FACSMM)

Email: W.Gregson@ljmu.ac.uk

(No relationships reported)

Traditional reliability checks on performance analysis systems tend to involve two observations made on the same player in the same game. Such an analysis does not include between-match variability, which would be present in any longitudinal or large scale cross-sectional soccer research. Few attempts to date have been made to provide a detailed analysis of this variation in key match performance activities in soccer.

**PURPOSE:** To determine the between-match variability in high-intensity running activity in elite soccer players and the influence of playing position and team success.

**METHODS:** A total of 7355 individual match work-rate observations were undertaken on 563 outfield players (median of 8 games per player; range = 1-57 games) competing in the English Premier League from 2003/2004 to 2005/2006 using a novel computerised tracking system (Prozone®, Leeds, England). Between-match coefficients of variation (CV) and associated 95% confidence intervals (CI) were calculated and compared between different player positions and team success levels using a general linear model.

**RESULTS:** The mean CV for high speed running and sprint distance covered during a game was 16.2  $\pm$  0.3% (95%CI = 15.7-16.8%) and 30.8  $\pm$  0.5% (95%CI = 29.9-31.7%) respectively. This variability was generally lower for attacking players but higher for defenders. The variability in number of sprints during a game was larger for sprints of greater distance (< 5m mean CV of 14.5  $\pm$  0.3%, 95%CI = 14.0-15.0%; 15-20m, 64.4  $\pm$  1.4%, 95%CI = 62.1-66.6%). Differences between levels of team success were small, although players from more successful teams showed less between-match variability in the number of sprints of 10-15m in length.

**CONCLUSIONS:** Match-to-match variability in performance characteristics of elite soccer players is high and not dependent on team success. This inherent variability means that research requires large sample sizes in order to detect real systematic changes in performance characteristics.

**Maximal Oxygen Consumption Values In Female Ice Hockey Players**

Christine Durham<sup>1</sup>, Niall M. Moyna, FACSM<sup>2</sup>, Carena S. Winters<sup>1</sup>. <sup>1</sup>Chatham University, Pittsburgh, PA. <sup>2</sup>Dublin City University, Dublin, Ireland.

Email: cwintershart@chatham.edu

(No relationships reported)

Aerobic metabolism contributes significantly to the energy demands of ice-hockey. Using an on-ice testing protocol Durocher et al., (J. Strength and Cond Res, 22, 1327-31, 2008) reported a maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ) value of 40.1  $\pm$  1.0 ml.kg<sup>-1</sup>.min<sup>-1</sup> in Division III female college hockey players. Due to the difficulties inherent in using on-ice testing procedures, the majority of aerobic tests involving ice-hockey players have used either a treadmill or cycle ergometer.

**PURPOSE:** To compare  $\text{VO}_{2\text{max}}$  values obtained during a treadmill running and a cycle ergometer test to previously published values obtained using an on-ice testing protocol.

**METHODS:**  $\text{VO}_{2\text{max}}$  was measured at the mid-point of the season using an incremental treadmill and cycle ergometer protocol in 12 female (Age 19.5  $\pm$  1.6 y; mean  $\pm$  SD) Division III college hockey players. The treadmill and cycle ergometer tests were undertaken on different days and were performed in a counter-balanced order. Oxygen uptake was measured using open circuit spirometry (MAX-II metabolic cart) and heart rate was continuously monitored using a Polar heart rate monitor.

**RESULTS:** Maximal heart rate (193.0  $\pm$  9.7 vs. 182.1  $\pm$  7.8 beats.min<sup>-1</sup>) and  $\text{VO}_{2\text{max}}$  (46.6  $\pm$  4.4 vs. 41.2  $\pm$  5.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>) were higher (p<0.001) in the treadmill running than the cycle ergometer test. There was a trend (p<0.09) toward a higher rating of perceived exertion at maximal exercise in the cycle test than the treadmill test.

**CONCLUSION:** When compared to gender and age based norms the  $\text{VO}_{2\text{max}}$  values for the ice-hockey players in the present study are in the 80<sup>th</sup> percentile, or average category. In Division III female college hockey players the  $\text{VO}_{2\text{max}}$  determined during a cycle ergometer test is similar to the value obtained using an on-ice protocol. In contrast, the  $\text{VO}_{2\text{max}}$  determined using a treadmill protocol overestimates the  $\text{VO}_{2\text{max}}$  obtained using an on-ice protocol.

---

**2342 Board #230 May 28 3:30 PM - 5:00 PM**  
**Determinants Of Maximal Aerobic Power In Trained Cyclists**

Daryl L. Parker, Roy Salgado, Roberto Quintana, Irvin E. Faria, FACSM. CSU Sacramento, Sacramento, CA.

Email: parkerd@csu.edu

(No relationships reported)

Peak aerobic power ( $\text{W}_{\text{max}}$ ) from a graded exercise test (GXT) is a strong predictor of cycling performance. Peak power is highly correlated with  $\text{VO}_{2\text{max}}$ , suggesting that  $\text{VO}_{2\text{max}}$  is a strong predictor of performance. However,  $\text{VO}_{2\text{max}}$  has typically only been shown to be a moderate predictor of performance, therefore factors other than  $\text{VO}_{2\text{max}}$  are likely contributing to  $\text{W}_{\text{max}}$ . Other factors that contribute to performance are the ventilation threshold, respiratory compensation point (VT1, VT2) and economy.

**PURPOSE:** This investigation was conducted to determine the roles that  $\text{VO}_{2\text{max}}$ , VT1, VT2, and economy play in the contribution of aerobic power. **SUBJECTS:** Fifty four (female n=9) trained cyclists served as subjects for this investigation. Subjects ranged from seasoned professionals to novice competitors.

**METHODS:** Each subject underwent a sub-maximal exercise bout at 200W (female = 150W) to determine cycling economy. Following the sub-maximal test each subject underwent a GXT to volitional fatigue for the determination of  $\text{VO}_{2\text{max}}$ , VT1 and VT2. The GXT protocol began at 70W and increased 35W.min<sup>-1</sup> until an rpm >70 could not longer be maintained. Expired gas was collected throughout the GXT. All  $\text{VO}_2$  variables were expressed in L.min<sup>-1</sup> and economy was expressed as WL<sup>-1</sup>.min<sup>-1</sup>. **ANALYSIS:** Stepwise multiple regression was used to model the variables contributing to  $\text{W}_{\text{max}}$ . Variables entered into the analysis were  $\text{VO}_{2\text{max}}$ ,  $\text{VO}_2$  at VT1,  $\text{VO}_2$  at VT2, and economy.

**RESULTS:** The  $\text{VO}_2$  at VT2 entered the regression model first (b = 0.567) followed by  $\text{VO}_{2\text{max}}$  (b = 0.431) and economy (b = 0.105). The  $\text{VO}_2$  at VT1 did not enter the regression model. The model significantly explained the variance in  $\text{W}_{\text{max}}$  (p= 0.00) with a multiple R<sup>2</sup> of 0.935.

**CONCLUSION:** The analysis indicates that  $\dot{V}O_{2\max}$ ,  $\dot{V}O_2$  at VT2, and economy each contribute uniquely to  $W_{\max}$ , but  $\dot{V}O_2$  at VT1 does not.

**2343 Board #231 May 28 3:30 PM - 5:00 PM**  
**Dynamic Warm-up Optimizes Sprint Performance In Collegiate Track Athletes**

Donovan S. Conley, FACSM, Kelly J. Brink, Peter J. Ray, Tammy K. Evetovich, FACSM. *Wayne State College, Wayne, NE.*  
(No relationships reported)

Previous research has shown that passive stretching negatively affects sprint performance (Nelson, A.G. et al., *J. Sports Sci.* 23:449-454, 2005) however, the affect of other stretching or warm-up methods on sprint performance is unclear.

**PURPOSE:** To compare the effects of no warm-up (NW), low volume proprioceptive neuromuscular facilitation stretching (LVPNFS), high volume proprioceptive neuromuscular facilitation stretching (HVPNFS), static stretching (SS), and dynamic warm-up protocols (DW) on 36.7 m sprint performance in National Collegiate Athletic Association Division II track athletes.

**METHODS:** Ten male healthy trained collegiate track athletes (mean  $\pm$  SD, age=20.9  $\pm$  0.97 y, height=183.6  $\pm$  5.9 cm, mass=78.96  $\pm$  7.29 kg, body fat=6.3  $\pm$  0.97 %) volunteered to participate in the study. Subjects completed each of 5 randomly assigned warm-up protocols to include: 1) NW, 2) LVPNFS, 3) HVPNFS, 4) SS and, 5) DW prior to 36.7 m sprint performance. Two and 5 sets of stretching were completed for the low and high volume PNF protocols respectively. The PNF stretching protocols used a contract (5 sec at 75% maximum effort) - relax (10 sec) - stretch (10 sec at moderate tension) sequence that targeted calf, hamstring, and quadriceps muscle groups. The static stretching protocol included 2 sets of the same stretching exercises held for 20 sec. The DW protocol consisted of high knees, gluteus maximus kicks, lunges, leg swings, and dynamic quadriceps and hamstring stretches. The best of two timed 36.7 m sprints was used to determine sprint performance following each protocol. One min rest was provided after each warm-up protocol and 3-5 min rest was given between sprints. A minimum of 48 h was required between testing sessions.

**RESULTS:** Repeated measures one-way ANOVA analysis with Tukey post-hoc tests indicated that average 36.7 m sprint performance using DW (4.860  $\pm$  0.131 sec) was significantly ( $p < 0.05$ ) lower than NW (4.953  $\pm$  0.184 sec), LVPNFS (5.079  $\pm$  0.148 sec), HVPNFS (5.043  $\pm$  0.185 sec), and SS (5.054  $\pm$  0.172 sec) warm-up methods.

**CONCLUSIONS:** We conclude that performing DW prior to a maximal effort 36.7 m sprint is significantly better than NW, LVPNFS, HVPNFS, and SS warm-up methods. The data from this project suggests that a dynamic warm-up protocol should be used to optimize sprint performance in collegiate track athletes.

**High Reliability Of Jump Performance Assessed With A Linear Transducer In Elite Track And Field Athletes**

Mário C. Marques<sup>1</sup>, Juan J. González-Badillo<sup>2</sup>. <sup>1</sup>University of Beira Interior/CIDESD, Covilhã, Portugal. <sup>2</sup>University Pablo de Olavide, Seville, Spain.  
Email: mariomarques@mariomarques.com  
(No relationships reported)

Although the countermovement vertical jump (CMJ) has been extensively used, data about reliability parameters on a large subject sample (~50) of elite athletes are limited.

**PURPOSE:** To determine the reliability of CMJ performance in a large sample of track and field top athletes using a linear transducer.

**METHODS:** A group of 48 elite male sprinters and long-jumpers volunteered to participate in this study. Subjects performed three trials with 3 minutes of rest between each CMJ. This was accomplished by measuring jump performance using a linear transducer and a force platform simultaneously. The relationships between force-time dependent variables and CMJ performance were examined during the concentric phase using a Smith machine.

**RESULTS:** The present study demonstrated high intraclass correlations (ICC) values for maximum rate of force development (RFD<sub>max</sub>) accessed with linear transducer, however, the coefficient of variation (CV) was somewhat high (15-17%). Nevertheless, ICC of peak force (PF) and the maximum power measured with force platform were very high. The maximum negative velocity presents a somewhat smaller but likewise high degree of stability, although the CV is slightly high (9.9%). The trial-to-trial reliability of the CMJ measured by the force platform gave an ICC of 0.87-0.97 for PF, maximum power and maximum negative velocity. Similar ICCs of 0.93-0.98 for RFD<sub>max</sub>, PF, and for rate of force development at PF were observed by the linear transducer. The CVs were 3.6-17% and 5.8-9.9% with force platform and with linear transducer, respectively.

**CONCLUSIONS:** The present findings showed that the calculations derived from the linear transducer synchronized with a force platform were very similar and hence provided evidence of the reliability of this method in elite track and field athletes. Moreover, this method suggests that the linear position transducer offers a cost-effective, versatile, and valid means for the measurement of force in track and field top athletes.

**Prescription For Aerobic High-Intensity Interval Training By Means Of Incremental Exercise Tests Markers**

Gerhard Tschakert<sup>1</sup>, Werner Groeschl<sup>1</sup>, Günther Schwabberger<sup>2</sup>, Serge P. von Duvillard, FACSM<sup>3</sup>, Peter Hofmann<sup>1</sup>. <sup>1</sup>Karl-Franzens-University and Medical University Graz, Graz, Austria. <sup>2</sup>Medical University Graz, Graz, Austria. <sup>3</sup>University of Salzburg, Salzburg, Austria.  
Email: gerhard.tschakert@uni-graz.at  
(No relationships reported)

There is no standardized model described in literature for exercise prescription of aerobic high-intensity interval training (HIT). From a theoretical point of view it appears to be reasonable to prescribe aerobic HIT by means of individual markers determined from incremental exercise tests (IET): mean workload just below Lactate Turn Point 2 (LTP<sub>2</sub>) (consistent with maximal lactate steady state), recovery workload just below LTP<sub>1</sub> (optimal rate of lactate elimination) and workload at P<sub>max</sub> applying a defined workload duration (t<sub>w</sub>) and a calculated recovery duration (t<sub>rec</sub> = t<sub>bel</sub> (P<sub>LTP2</sub> - P<sub>max</sub>) / (P<sub>LTP1</sub> - P<sub>LTP2</sub>)). The LTP Concept and the Lactate Shuttle Theory were used as the scientific base for this study.

**PURPOSE:** To determine if the regulation of aerobic HIT by means of LTP<sub>1</sub>, LTP<sub>2</sub> and P<sub>max</sub> leads to a blood lactate steady state representing a consistent way of exercise prescription of aerobic HIT.

**METHODS:** Five young healthy male sports students (age: 24.6  $\pm$  1.5 yrs; Ht: 185.2  $\pm$  2.3 cm; Wt: 76.1  $\pm$  5.3 kg;  $\dot{V}O_{2\max}$ : 57.8  $\pm$  8.5 ml·kg<sup>-1</sup>·min<sup>-1</sup>) participated in the study. A maximal IET (40W; 20W·min<sup>-1</sup>) and subsequently 2 interval tests (IT) as aforementioned with workload durations of 20s and 30s and calculated recovery time were performed on an electronically braked cycle ergometer (Monark 839E, Monark, Sweden). Sessions were randomly assigned and interspersed by at least two separate days to ensure sufficient recovery between tests. Heart rate (PE4000, Polar Electro, Finland) and gas exchange variables (ZAN800, ZAN, Germany) were obtained at rest, throughout exercise and during recovery. Blood lactate concentration (Biosen S-line, EKF Diagnostik, Germany) was obtained from blood samples collected from ear lobe at rest, after each interval and during recovery.

**RESULTS:** During the last 20min, mean blood lactate values in the 30s-IT (7.0  $\pm$  1.5 mmol·l<sup>-1</sup>) were higher than in 20s-IT (5.5  $\pm$  1.1 mmol·l<sup>-1</sup>), but a lactate equilibrium was seen in this time period at each single test except for one 30s-test.

**CONCLUSION:** Due to the fact that during the last 20min 9 of 10 IT led to a blood lactate steady state, it may be suggested that setting aerobic HIT by means of LTP<sub>1</sub>, LTP<sub>2</sub> and P<sub>max</sub> obtained in IET is a consistent model of exercise prescription for aerobic HIT if workload durations of no longer than 30s are applied.

## Analysis Of The Efficacy Of Different Stretching Applications And Their Relation To Delayed Onset Muscle Soreness (DOMS).

Priscila Z. Candido<sup>1</sup>, Gerseli Angeli<sup>1</sup>, Donald Kirkendall, FACSM<sup>2</sup>, Turibio Leite Barros<sup>1</sup>. <sup>1</sup>UNIFESP, São Paulo, Brazil. <sup>2</sup>Duke University, Durham, NC.

Email: cemaife@uol.com.br

(No relationships reported)

The use of stretching to increase flexibility, prevent injuries and decrease muscle pain, has been widely studied, but there are large divergences in the literature in relation to the time and duration of stretching.

**PURPOSE:** To evaluate if a stretching program is effective for attenuating the signs and symptoms of delayed onset muscle soreness (DOMS) caused by eccentric exercising.

**METHODS:** For 25 days, 33 active male individuals (between 20 and 31 years of age) underwent two sets of tests (AV<sub>1</sub> and AV<sub>2</sub>) and eccentric exercises (EE<sub>1</sub> and EE<sub>2</sub>) in order to trigger DOMS. AV<sub>1</sub> was performed before, 24h, 48h and 72h after EE<sub>1</sub> and consisted of: measurement of the range of motion (ROM) of knee flexion, thigh perimeter and subjective perception of pain. EE<sub>1</sub> was performed on the first day and consisted of four series of 12 repetitions of eccentric exercises on a leg extension machine at the level of 80% of one maximum repetition. After that, a 17-day stretching program began. After these 17 days, the volunteers were randomly assigned into three groups. Group A did not perform stretching, group B did one 10-second repetition of stretching and group C did three repetitions of 30 seconds. Following this, each group underwent a new set of evaluations and eccentric exercises (AV<sub>2</sub> and EE<sub>2</sub>) that followed the same patterns as used for AV<sub>1</sub> and EE<sub>1</sub>.

**RESULTS:** After the stretching program, there was decreased muscle pain. Group A reported less pain than did the other groups.

**CONCLUSIONS:** The stretching program decreased DOMS and increased the ROM. Furthermore, performing a stretching program without doing stretching immediately before the exercise is more effective for attenuating DOMS.

#### Ultra-marathon Runners Have The Biggest Hearts: Fact Or Fiction?

Robert Shave<sup>1</sup>, Darren Warburton<sup>2</sup>, David Oxborough<sup>3</sup>, Ben Esch<sup>2</sup>, Jessica Scott<sup>2</sup>, Tim Noakes, FACSM<sup>4</sup>, Keith George, FACSM<sup>5</sup>. <sup>1</sup>Brunel University, Middlesex, United Kingdom. <sup>2</sup>University of British Columbia, Vancouver, BC, Canada. <sup>3</sup>University of Leeds, Leeds, United Kingdom. <sup>4</sup>University of Cape Town, Cape Town, South Africa. <sup>5</sup>Liverpool John Moores, Liverpool, United Kingdom.

Email: rob.shave@brunel.ac.uk

(No relationships reported)

Physiologic eccentric hypertrophy (left ventricular end-diastolic diameter [LVDd]  $\geq$  55mm) has been well documented in endurance-trained individuals. Traditionally, cycling, rowing and cross-country skiing have been associated with the "athlete heart syndrome." Nagashima et al. (2003) reported LVDd to be beyond normal limits in a considerable number of ultra-marathon runners (mean LVDd of 61mm), with 11% of those tested having LVDd greater than 70mm.

**PURPOSE:** The purpose of this investigation was to assess whether ultra-marathon runners have physiological cardiac hypertrophy to the magnitude and prevalence that has been previously reported.

**METHODS:** A total of 105 (26 female) ultra-marathon runners (Age =  $43.3 \pm 9.3$  years (range 24-76 years)) underwent M-mode echocardiography to assess LVDd, interventricular septal thickness (IVS) and posterior wall thickness (PWT). LV mass (LVM) was calculated as:  $0.8 (1.04(LVDd + IVS + PWT)^3 - LVDd^3) + 0.6$ . Body surface area (BSA) was estimated ( $71.84 (\text{height}^{0.725} * (\text{weight}^{0.425})) / 10000$ ), and LVM index (LVMI) was calculated as  $LVM / BSA^{1.5}$ . All participants were recruited from the Western States Endurance Run (160km), or the Comrades Ultra-Marathon (89km). Participants with known cardiovascular disease or hypertension (systolic  $>140$ mmHg, diastolic  $>90$ mmHg) were excluded from the analyses.

**RESULTS:** On average, the athletes ran  $92.1 \pm 32.1$  km/week and had trained for  $15.4 \pm 10.2$  yrs. The average resting heart rate was  $58 \pm 10$  beats/minute, while systolic and diastolic blood pressures were  $116 \pm 10$  and  $76 \pm 9$  mmHg respectively. Mean fractional shortening was  $40.2 \pm 6.1$  %, while LVDd was  $51.4 \pm 4.1$  mm (range: 42 to 61 mm). LVDd exceeded the upper normal limits ( $\geq$  55mm) in 27 (26%) athletes. Mean IVS was  $10.3 \pm 1.7$  mm (range: 6 to 14 mm) and mean PWT was  $9.4 \pm 1.6$  mm (range: 6 to 13 mm). Average LVM was  $192.5 \pm 42.2$  g (range: 105 to 320g), and LVMI was  $76.6 \pm 13.2$  g/m<sup>3</sup> (range: 45 to 114g/m<sup>3</sup>).

**CONCLUSIONS:** Our results suggest that although some (26%) ultra-marathon runners have evidence of eccentric hypertrophy, the frequency and magnitude of hypertrophy are not as great as previously reported. Importantly, only our highest LVDd was equivalent to the mean value reported previously in ultra-marathon runners.

---

### 2348 Board #236 May 28 2:00 PM - 3:30 PM

#### Maintenance Of Total Body Water Despite Body Weight Loss During An Ultramarathon

Tamara D. Hew-Butler<sup>1</sup>, Nicholas Tam<sup>2</sup>, Heinrich Nolte<sup>3</sup>, Timothy D. Noakes, FACSM<sup>2</sup>. <sup>1</sup>Arizona State University, Tempe, AZ. <sup>2</sup>University of Cape Town, Cape Town, South Africa. <sup>3</sup>ERGOnomics TEChnologies, Pretoria, South Africa.

Email: tamara.hew@overhydration.org

(No relationships reported)

**PURPOSE:** To determine if: 1) body weight loss equates to total body water loss during prolonged endurance exercise and 2) plasma sodium, osmolality and volume are maintained with ad libitum food and fluid intakes, despite significant ( $>2\%$ ) bodyweight loss from pre to post race.

**METHODS:** Ten athletes participating in an 80km mountain footrace consented to bodyweight (BW), venous blood and saliva measurement 2-days, immediately pre- and post-race. Changes (D) in body mass, plasma sodium and potassium concentration, osmolality and volume were determined. Changes in total body water (TBW) were quantified using deuterium oxide. Food and fluid were allowed ad libitum and quantified by researchers stationed at 13 checkpoints.

**RESULTS:** 8 subjects completed the 80km footrace with a mean finishing time (mean  $\pm$  SD) of  $691.4 \pm 51.8$  minutes (range: 583 - 769.2) and fluid intake of  $4.8 \pm 0.9$  L (range: 3.5 - 6.1). A significant decrease was noted between D in % BW loss versus D in % TBW loss immediately post-race minus 2-days pre-race ( $-3.5 \pm 1.4\%$  BW vs.  $-1.1 \pm 1.2\%$  TBW;  $p < 0.05$ ). Significant differences were noted between the D in % BW loss in both the post- minus immediately pre-race condition ( $-4.7 \pm 4.1\%$ ) and the post- minus 2-day pre-race condition ( $-3.5 \pm 1.4\%$ ) when compared with the pre- minus the 2-days pre-race condition ( $+1.5 \pm 3.1\%$ ;  $p < 0.05$ ). No significant differences were noted in the D in plasma sodium concentration or plasma volume when the three testing conditions were compared.

**CONCLUSIONS:** TBW, plasma sodium, plasma osmolality and plasma volume were maintained during an 80km mountain footrace despite significant (4-5%) BW loss. These preliminary data suggests that recommendations to replace 100% BW losses during prolonged endurance running may promote TBW dysregulation that is worthy of further, more robust and stringent investigation.

**Energy Intake And Expenditure During An Ultra Endurance Event - Race Across America**

Andrew T. Hulton<sup>1</sup>, Ian Lahart<sup>2</sup>, Karen L. Williams<sup>1</sup>, Richard Godfrey<sup>3</sup>, Sarah Charlesworth<sup>4</sup>, Hannah Twigg<sup>5</sup>, Mat Wilson<sup>5</sup>, Andy Lane<sup>5</sup>, Charlie Pedlar<sup>6</sup>, Greg Whyte, FACSM<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>University College Birmingham, Birmingham, United Kingdom. <sup>3</sup>Brunel University, Brunel, United Kingdom. <sup>4</sup>University of British Columbia, British Columbia, BC, Canada. <sup>5</sup>Wolverhampton University, Wolverhampton, United Kingdom. <sup>6</sup>English Institute of Sport, St Mary's University, London, United Kingdom.

Email: a.t.hulton@ljamu.ac.uk

(No relationships reported)

Energy Expenditure (EE) was measured with doubly labelled water (DLW) technique during heavy sustained exercise with an official finishing team in the Race Across America (RAAM). Energy Intake (EI) was also calculated to produce an energy deficit for the total race. EE has not previously been reported during the RAAM using the DLW technique which is the gold standard method for EE in free living humans, and used to validate other methods of EE.

**PURPOSE:** To determine the EE of athletes participating in the RAAM and to examine the energy intake throughout such a demanding ultra endurance event.

**METHODS:** A team of 4 cyclists (age: 38.25 ± 5.68 yr; height: 182.25 ± 8.18 cm; weight: 80.75 ± 6.60 kg) were used as consenting subjects, and completed the race in an intermittent fashion to maintain a high intensity and to encourage recovery between exercise bouts. To determine EE the DLW method was employed. Urine samples were collected prior to consumption of the DLW on the race morning, 2 hours post drink, then every 24 hours after and a final sample on completion of the race. All samples were analysed by isotope ratio mass spectrometry. EI was analysed using a dietary analysis package (Microdiet) following completion of food diaries by the support team.

**RESULTS:** The team completed the race in 6 days 10 hours and 51 minutes, finishing in third place in the 4 man team event. Total EE was found to be 44,941.75 kcals (ranging from 40,376 - 47,418 kcals) with an average daily EE 6420.25 kcals (ranging from 5768 - 6774 kcals). Total EI from all food and drink consumed was calculated at 29,505.5 kcals (ranging from 24,698 - 35,386 kcals) with an average daily EI of 4215.025 kcals (ranging from 3528.3 - 5055 kcals). This resulted in an energy deficit of 15,361.25 kcals (ranging from 11,878 - 18,237 kcals) with an average daily energy deficit of 2205.2 kcals (ranging from 1696.9 - 2605.3 kcals).

**CONCLUSIONS:** The high EE, three times that of a typical EI for males, highlights the need for correct and practical dietary strategies and challenges nutritionists to devise high energy diets that not only contain the correct macronutrient balance, but are also palatable to the cyclists, thus encouraging a high EI. The findings from this study can aid future cyclists, coaches and nutritionist participating in the RAAM and other ultra endurance events.

(No relationships reported)

**PURPOSE:** Maintaining body water and blood electrolyte concentrations within a normal range is critical for athletes in ultra-endurance events. This study examined the relationships between body mass, total body water, and blood electrolyte values before and after a 161-km ultra-marathon run.

**METHODS:** Measurements were made on runners of the 2008 Rio Del Lago 161-km trail run, which included body height & mass, bioimpedance spectroscopy, and electrolyte concentrations. These measurements were made the day before the race on 72 of the 109 starters, and immediately post-race on the 44 participants who finished. Analyses were performed by t-test to compare pre- and post-race body mass, total body water (TBW), blood concentrations of sodium and potassium, hematocrit (Hct), and hemoglobin (Hgb).

**RESULTS:** Height and age of the study participants (mean±SD) were 188.9±8.6 cm and 53±8.2 years. Mean (±SD) pre-race values among all finishers for body mass (70.4±10.8 kg) and TBW (43.3±7.3 L) were not significantly different from those immediately after the race (68.1±10.6 kg and 42.9±7.7 L). Among finishers whose electrolytes were measured, there were significant differences before and after the race. Pre-race blood sodium (139±2.0 mmol/L, range 135-143 mmol/L, n=27) decreased significantly by the end of the race (135±4.9 mmol/L, range 123-148 mmol/L, p<0.001, n=40). Twenty one participants (53%) were clinically hyponatremic (sodium 145 mmol/L) at the end of the race. Potassium concentration increased significantly from pre- to post-race (4.9±0.4 mmol/L, range 3.9-5.7 mmol/L; 5.4±0.8 mmol/L, range 4.2-6.9 mmol/L, p<0.001). Similarly, pre-race measurements of Hct (47.8±5.1 PCV) and Hgb (16.2±1.7 g/dL) decreased (p=0.02) by the end of the race (45.4±4.6 PCV and 15.4±1.6).

**CONCLUSIONS:** Even though body mass and TBW were maintained during the race, electrolyte, Hct, and Hgb concentrations changed significantly. Changes in serum electrolyte, Hct and Hgb concentrations suggest additional research is needed to more fully understand and evaluate changes in these parameters during ultra-endurance events and the potential physiological effects.

**Historical Analysis Of The Western States 100-mile Endurance Run: 1974 Through 2007**

Martin D. Hoffman, FACSM<sup>1</sup>, Jacob Wegelin<sup>2</sup>. <sup>1</sup>University of California Davis Medical Center and VA Northern California Health Care System, Sacramento, CA. <sup>2</sup>Virginia Commonwealth University, Richmond, VA.

Email: martin.hoffman@va.gov

(No relationships reported)

**PURPOSE:** To summarize data on the Western States 100-Mile Endurance Run (WSER) since its inception in 1974, including the characteristics of participants, relationship of performance to age and sex, and changes over time in runner demographics and performance.

**METHODS:** Name, age, sex and finish time of each WSER finisher 1974-1985 and of all starters and finishers 1986-2007 were obtained from published race results. Name, age and sex discrepancies from year to year for repeat runners were reconciled through line-by-line examination of the data.

**RESULTS:** A total of 6462 finishes at the WSER were accounted for by 3459 individuals (84% men) from 1974 through 2007. The proportion of starters who were women increased from 10-12% in 1986-88 to 20-22% since 2001. Starters ranged in age from 18 to 75 years, and finishers ranged from 18 to 71 years. Mean (±SD) ages of participants were 44±9 years for men and 42±8 for women. The average age of men starting the race increased (p<0.001) from 41 in 1986 to 47 in 1999, then leveled off. Average age of women starters increased but remained about 3 years younger than men (p<0.001). The increase in average age of starters was accounted for by increasing (p<0.02) participation among women ≥40 years of age, increasing (p≤0.001) participation among men ≥50 years of age, and decreasing (p<0.0001) participation among men <50 years of age. Since 1974, ages of the top performers have increased (p≤0.002) for both sexes to the upper 30's. Finish times among men, when examined across different age groups and performance levels (top-5 or all finishers), showed no change between 1986 and 2007. However, the top-5 women finishers in the 30-39 and 40-49 year age groups have shown improvements (p<0.01) across this time period.

**CONCLUSIONS:** Participation in the WSER has increased among women and older athletes, and the ages of the fastest runners at the WSER have gradually risen to the extent

that the fastest runners at the WSER are now older than the fastest marathoners. In contrast to what has been observed for men, the performances among the top women have improved over the last two decades at the WSER.

**Impact Of Ambient Temperature On Performance In A 161-km Ultramarathon Run**

Kevin Fogard<sup>1</sup>, Martin D. Hoffman, FACSM<sup>2</sup>, Marcel Fraix<sup>3</sup>, Jacob Wegelin<sup>4</sup>. <sup>1</sup>VA Northern California Health Care System, Sacramento, CA. <sup>2</sup>University of California Davis Medical Center and VA Northern California Health Care System, Sacramento, CA. <sup>3</sup>Western University of Health Sciences, Pomona, CA. <sup>4</sup>Virginia Commonwealth University, Richmond, VA.  
Email: kevin.fogard@va.gov  
(No relationships reported)

**PURPOSE:** The effect of ambient temperature on performance in ultramarathon runs has not been previously examined. The present work makes such an analysis relative to a 161-km ultramarathon run over mountain trails.

**METHODS:** Race results for the Western States Endurance Run from 1986 through 2007 were compiled along with minimum, mean, and maximum local ambient temperatures on the day of each run. Two separate generalized linear mixed-effects regression models were computed to assess the degree to which (1) probability of finishing and (2) finish times of finishers were related to ambient temperature, while adjusting for sex, age, and starter's previous WSER experience. Coefficients were reported with respect to a temperature difference of 5°C. Only one of minimum, mean, and maximum temperature was used in models; for reporting, the single measure of temperature was chosen which provided the best fit.

**RESULTS:** Race day ambient temperatures ranged from 11 to 22°C (minimums), 14 to 30°C (means), and 16 to 38°C (maximums). Unadjusted finish rates ranged from 51% to 80%. Due to outliers in mean and maximum temperatures, minimum temperature was found to provide the best fit in regression. After adjustment for covariates, a temperature decrease of 5°C was found to be associated with a 34% increased chance ( $p=0.026$ ) of finishing for individuals who either had never started since 1986 or had finished every run they started, and with a 61% increased chance ( $p=0.036$ ) of finishing for those who had dropped out in the past. Among men who finished, a temperature decrease of 5°C was associated with a 24 minute decrease ( $p<0.01$ ) in average finish time. Women averaged 78 minutes slower than men but their finish time only decreased 7.4 minutes with a temperature decrease of 5°C (both  $p<0.01$ ).

**CONCLUSIONS:** Elevated temperatures during a 161-km trail ultramarathon run adversely affect finish rates and finish times, but affect finish times less strongly for women than for men.

**Analysis Of Factors Affecting The Probability Of Finishing The Western States 100-mile Endurance Run**

Jacob Wegelin<sup>1</sup>, Martin D. Hoffman, FACSM<sup>2</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, VA. <sup>2</sup>University of California Davis Medical Center and VA Northern California Health Care System, Sacramento, CA.  
Email: jwegelin@vcu.edu  
(No relationships reported)

**PURPOSE:** Determine factors associated with finishing the Western States 100-Mile Endurance Run (WSER).

**METHODS:** Name, age, sex and finish or drop-out information was obtained for each runner starting the WSER from 1986 through 2007. Generalized linear mixed-effects models were computed to assess the degree to which the probability of a starter finishing a race was related to starter's sex, age, previous WSER experience, and to ambient race day temperature. Separate relationships between age and probability of finishing were computed in the lower quartile (18-38 years), interquartile (38-50 years) and upper quartile (>50 years). WSER experience was categorized as never previously started, started in the past and finished each run started, started in the past and finished at least once and dropped out at least once, and started in the past and never finished.

**RESULTS:** There were a total of 8282 starts and 5276 finishes from 1986 through 2007. Yearly finish rates ranged from 51% to 80%. There was no effect of age across 18-38 years, but from 38-50 years an increase in age was associated with decreased probability of finishing and the association was stronger for >50 years (both  $p<0.001$ ). Specifically, men were 46% more likely to finish at age 38 than 50, and 6 times more likely to finish at age 50 than 72. Men and women 18-38 years of age had no difference in probability of finishing, but women's probability of finishing decreased more quickly than men's across ages 38-50 ( $p=0.01$ ). Specifically, 50 year old men were 70% more likely to finish than 50 year old women. Over age 50, the decrease was parallel for men and women. New starters since 1986, and those who had finished every race they started since 1986, were 28% more likely ( $p<0.001$ ) to finish than those who had ever dropped out of the race since 1986. Increased ambient temperature was associated with a decreased probability ( $p=0.026$ ) of finishing. Starters who had previously dropped out of the race were more likely ( $p=0.036$ ) to drop out in high temperatures than those who either had always finished or had never started since 1986.

**CONCLUSIONS:** Factors adversely associated with finishing the WSER include increasing age, being female >38 years of age, having previously dropped out of the race, and higher ambient temperatures.

**Historical Analysis Of Participation And Performance In 100-mile Ultramarathon Runs In North America: 1974-2008**

June C. Ong<sup>1</sup>, Martin D. Hoffman, FACSM<sup>2</sup>, Gary Wang<sup>3</sup>. <sup>1</sup>University of California Davis Medical Center, Sacramento, CA. <sup>2</sup>University of California Davis Medical Center and VA Northern California Health Care System, Sacramento, CA. <sup>3</sup>Independent Researcher, Corte Madera, CA.  
Email: june.ong@ucdmc.ucdavis.edu  
(No relationships reported)

**PURPOSE:** To document changes in participation and performance in 100-mile (161-km) ultramarathon running competitions in North America from 1974 to 2008.

**METHODS:** Results were tabulated for all 161-km running races in North America between 1974 and 2008 from which results could be identified. Regression analyses were used to examine changes across time. ANOVA was used to compare the fastest finish times across age groups.

**RESULTS:** From 1974 through 2007, a total of 29,617 finishes were identified which were accounted for by 8969 different individuals (83% men). There was exponential growth in the total number of finishes as well as the number of different individuals finishing these races. The number of 161-km ultramarathon running races in North America has also risen exponentially since 1980, with there being 53 such events in 2008. The proportion of finishes accounted for by women has increased to the current level of nearly 20%. Finishers ranged in age from 15-75 years, and women were significantly ( $p<0.0001$ ) younger than men ( $41\pm 8$  vs.  $43\pm 9$  years). Mean ages generally increased ( $p<0.0001$ ) across years for both men and women, but dropped after 2004 among men so that ages in 2007 averaged 44 and 43 years, respectively. The general increase in average age of finishers was accounted for by proportional increases among those  $\geq 40$  years of age and decreases among those <40 years of age for men; and proportional increases among those in the 40-59 year age range and decreases among those <30 years of age for women. Overall finish rates have increased slightly ( $p<0.002$ ) over the last 30 years to approximately 60%. Runners in the 30-39 year age group achieved the fastest finish times. Over the last 30 years, the average age of winners has increased ( $p\leq 0.01$ ) for both sexes to approximately 38 years. On the whole, the fastest women were 22% slower than the fastest men, and this difference has not changed in the last 20 years.

**CONCLUSIONS:** Participation in 161-km running competitions in North America increased exponentially from the 1970's, and though participation among women grew, men have remained dominant in terms of quantity and speed. The age range of finishers was quite wide, and the average age of finishers and winners has increased to the mid-40's and upper-30's, respectively.

Hoffman, FACSM<sup>4</sup>. <sup>1</sup>University of California Davis Medical Center, Sacramento, CA. <sup>2</sup>University of California, Davis, Davis, CA. <sup>3</sup>USDA, ARS Western Human Nutrition Research Center, Davis, CA. <sup>4</sup>University of California Davis Medical Center and VA Northern California Health Care System, Sacramento, CA.  
Email: alison.ganong@ucdmc.ucdavis.edu

*(No relationships reported)*

**PURPOSE:** Previous work has demonstrated considerable variability in body mass index (BMI) among top finishers in a 161-km trail ultramarathon. The present study further examines anthropometric characteristics of runners participating in a 161-km trail ultramarathon and compares body composition with running performance.

**METHODS:** Height, weight, and percent body fat from bioimpedance spectroscopy measurements were made on 72 of 109 starters of the 2008 Rio Del Lago 161-km trail run. Correlation analyses were used to compare body characteristics with finish time, and ANOVA and effect sizes were used to compare characteristics of finishers with non-finishers.

**RESULTS:** Mean ( $\pm$ SD) BMI ( $\text{kg/m}^2$ ) was  $24.8 \pm 2.7$  (range 19.1-32.2) for the men and  $21.2 \pm 2.1$  (range 18.1-26.7) for the women. Among the five fastest participants in the study, BMI values were  $22.9 \pm 2.7$  (range 19.5-26.9) for men and  $20.3 \pm 2.0$  (range 18.1-22.9) for women. Percent body fat values for men and women were  $17 \pm 5$  (range 5-35) and  $21 \pm 6$  (range 10-29) among all participants, and  $11 \pm 3$  (range 6-14) and  $20 \pm 5$  (range 14-27) among the fastest five participants. Of the 72 athletes in the study, 45 (35 men, 10 women) finished the run. Among the men, there was a significant positive correlation ( $p=0.002$ ) between finish time and percent body fat. There was also a trend ( $p=0.06$ ) among the men towards a significant positive relationship between finish time and BMI. Of the 10 female finishers in the study, there was no significant relationship ( $p=0.5$ ) between finish time and BMI, but there was a trend ( $p=0.06$ ) towards a negative correlation between finish time and percent body fat. ANOVA revealed no difference in BMI and percent body fat values between finishers and non-finishers for either sex, however, effect sizes for percent body fat were moderate for men ( $d=0.52$ ; mean 19 vs. 24 for finishers vs. non-finishers) and large for women ( $d=0.85$ ; mean 16 vs. 19 for finishers vs. non-finishers).

**CONCLUSIONS:** Despite wide variations in BMI and percent body fat among the ultramarathon participants, the faster men tended to have lower BMI and percent body fat values than the slower men, and those who finished tended to have lower BMI and percent body fat values than non-finishers within both sexes.

**Self-selected Exercise Intensity Decreases But Perception Of Effort Remains Constant During A Cycle Time-trial At Altitude**

B A. Beidleman, S R. Muza, FACSM, C S. Fulco, E Lammi, J E. Staab, A Cymerman. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Stephen Muza, FACSM)

*(No relationships reported)*

Self-selected exercise intensity during a time-trial is regulated within the brain by peripheral sensory feedback (e.g., perception of effort) and the anticipated workload remaining (Abbiss, 2008).

**PURPOSE:** To determine whether a decrease in arterial oxygen saturation ( $\text{SaO}_2$ ) during an acute exposure to altitude affects self-selected exercise intensity and perception of effort during a cycle time trial.

**METHODS:** Twenty-six male lowlanders of similar age ( $22 \pm 1$  yr; mean  $\pm$  SE), weight ( $81 \pm 4$  kg), and sea-level (SL) peak oxygen uptake ( $47.6 \pm 1.9$  ml/kg/min) first completed a maximal effort 720 kJ cycle time-trial at SL and then again within 4 h of exposure to either 3000 m ( $n=6$ ), 3500 m ( $n=8$ ) or 4300 m ( $n=12$ ) altitude in a hypobaric chamber.  $\text{SaO}_2$ , heart rate (HR), and rating of perceived exertion (RPE) were measured every 5-min during the cycle time-trial and the respective overall means were calculated. The overall mean work rate and altitude-specific percent of maximum work rate ( $\% \text{WR}_{\text{max}}$ ) maintained during the time-trial were calculated for each altitude.

**RESULTS:** Time-trial performance (min) was impaired ( $p<0.05$ ) by  $\sim 32\%$  from SL values ( $73 \pm 5$ ) to 3000 m ( $97 \pm 10$ ), by  $\sim 38\%$  from SL to 3500 m ( $104 \pm 9$ ) and by  $\sim 65\%$  from SL to 4300 m ( $120 \pm 7$ ).  $\text{SaO}_2$  (%) was decreased ( $p<0.05$ ) from SL values ( $97 \pm 1$ ) at 3000 m ( $87 \pm 1$ ), 3500 m ( $83 \pm 1$ ) and 4300 m ( $74 \pm 1$ ). HR (beats/min) did not change from SL values ( $165 \pm 3$ ) at 3000 m ( $150 \pm 5$ ) or 3500 m ( $150 \pm 4$ ), but was decreased ( $p<0.05$ ) at 4300 m ( $148 \pm 3$ ).  $\% \text{WR}_{\text{max}}$  did not change from SL values ( $60 \pm 2\%$ ) at 3000 m ( $53 \pm 3\%$ ), but was decreased ( $p<0.05$ ) at 3500 m ( $50 \pm 3\%$ ) and 4300 m ( $46 \pm 3\%$ ). RPE did not change from SL values ( $14 \pm 1$ ) at any altitude. The decrease in  $\% \text{WR}_{\text{max}}$  was correlated ( $r=0.40$ ;  $p<0.05$ ) to the decrease in  $\text{SaO}_2$  with increasing altitude.

**CONCLUSION:** These results demonstrate that during an acute exposure to altitude, self-selected exercise intensity (e.g.,  $\% \text{WR}_{\text{max}}$ ) is decreased proportional to the decrease in  $\text{SaO}_2$  during a cycle time trial but perceived exertion is maintained around 14 (i.e., somewhat hard to hard) regardless of altitude. Funding provided by US Army MPMC ATO IV.MD2006.01. Authors' views not official US Army or DoD policy.

**2357 Board #2 May 29 8:00 AM - 9:30 AM**  
**Maximal Oxygen Consumption Changes After Altitude Training: Role Of Ventilatory Acclimatization**

Daniel P. Wilhite, Abigail S. Laymon, James M. McKenzie, Elizabeth A. Lundgren, Robert F. Chapman. *Indiana University, Bloomington, IN.* (Sponsor: Timothy Mickleborough, FACSM)

Email: dpwilhit@indiana.edu

*(No relationships reported)*

With chronic altitude training, ventilatory acclimatization often results in an increase in maximal exercise ventilation. The added respiratory muscle work may contribute to the  $\text{VO}_2\text{max}$  increase seen in many elite endurance athletes after altitude training.

**PURPOSE:** To determine the contribution of respiratory muscle oxygen consumption to the change in  $\text{VO}_2\text{max}$  after altitude training.

**METHODS:** Seven elite endurance runners (6 M, 1 F;  $\text{VO}_2\text{max}$  M,  $70.6 \pm 4.5$  ml/kg/min,  $\text{VO}_2\text{max}$  F,  $64.7$  ml/kg/min) participated in a 28 day altitude training intervention in Flagstaff, Arizona, elevation 2150m, following a "live-high, train-low" training model.  $\text{VO}_2\text{max}$  and  $\text{VEmax}$  were measured 2-9 days prior to departure for altitude and 1-2

days after returning to sea level. Respiratory muscle  $\text{VO}_2$  ( $\text{VO}_{2\text{rm}}$ ) was estimated using the equations of Aaron et al (1992).

**RESULTS:**  $\text{VO}_{2\text{max}}$  increased from  $4.67 \pm 0.71$  L/min pre-altitude to  $4.86 \pm 0.81$  L/min post-altitude ( $p=0.016$ ).  $\text{VE}_{\text{max}}$  increased from  $169.7 \pm 23.5$  L/min pre-altitude to  $183.1 \pm 26.1$  L/min post-altitude ( $p=0.045$ ).  $\text{VO}_{2\text{rm}}$  increased from  $484 \pm 67$  mL/min during maximal exercise pre-altitude to  $522 \pm 64$  mL/min post-altitude.

**CONCLUSIONS:** Of the 210 mL/min increase in  $\text{VO}_{2\text{max}}$  with altitude training, an estimated 38 mL/min or 18.2% of the whole body increase in  $\text{VO}_{2\text{max}}$  came from the increased metabolic cost of ventilation. These results suggest that ventilatory acclimatization plays a role in maximal oxygen consumption improvements with altitude training. It is unknown if a) the added respiratory  $\text{VO}_2$  after altitude training effectively limits the potential magnitude of locomotor  $\text{VO}_{2\text{max}}$  increase, or b) if  $\text{VO}_{2\text{max}}$  would change over time at sea level as ventilatory acclimatization decays. These issues may be of importance to elite endurance athletes, regarding the timing of key competitions after an altitude training camp.

**2358      Board #3      May 29      8:00 AM - 9:30 AM**  
**Effect Of Altitude On Hiking Performance While Carrying A Weighted Backpack**

J E. Staab, B A. Beidleman, S R. Muza, FACSM, C S. Fulco, E Lammi, A Cymerman. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

*(No relationships reported)*

Athletic performances lasting longer than ~1 hr can be impaired by as much as 30% to 70% at 3000 m to 4300 m from sea level (Fulco, 1998). However, the magnitude of impairment while hiking with a backpack at such altitudes has never been quantitated.

**PURPOSE:** To determine at altitude if the relative performance impairments while hiking with a weighted backpack are similar to those observed during athletic performances.

**METHODS:** Twenty-eight male lowlanders of similar age ( $22 \pm 1$  yr; mean  $\pm$  SE), weight ( $82 \pm 4$  kg), and SL peak oxygen uptake ( $47 \pm 1$  mL/kg/min) completed a 8-km, 5% grade maximal effort, simulated hike on a treadmill while carrying a 16-kg backpack at sea level (SL) and again after 24-h exposure to 3000 m ( $n=6$ ), 3500 m ( $n=8$ ) or 4300 m ( $n=14$ ) altitude in a hypobaric chamber. Heart rate (HR), arterial oxygen saturation ( $\text{SaO}_2$ ) and rating of perceived exertion (RPE) were measured every 5-min during the hike and the respective overall mean values were calculated.

**RESULTS:** Seven of the volunteers exposed to 4300 m could not complete the hike and their data were excluded. Hike performance (min) was impaired ( $p<0.05$ ) by ~13% from SL ( $81 \pm 2$ ) to 3000 m ( $92 \pm 3$ ), by ~19% from SL ( $74 \pm 3$ ) to 3500 m ( $88 \pm 3$ ) and by ~24% from SL ( $81 \pm 2$ ) to 4300 m ( $100 \pm 3$ ).  $\text{SaO}_2$  (%) was decreased ( $p<0.05$ ) from SL values ( $96 \pm 1$ ) at 3000 m ( $84 \pm 1$ ), 3500 m ( $80 \pm 1$ ), and 4300 m ( $72 \pm 1$ ). HR (beats/min) and RPE did not change from SL values ( $160 \pm 4$ ;  $13 \pm 1$ ) at either 3000 m ( $158 \pm 3$ ;  $14 \pm 1$ ), 3500 m ( $156 \pm 3$ ;  $14 \pm 1$ ), or 4300 m ( $153 \pm 3$ ;  $13 \pm 1$ ), respectively.

**CONCLUSION:** These results indicate that the performance impairments at altitude that occur when hiking with a weighted backpack are smaller than those that occur during athletic events. The most likely reason for this difference is a narrowed range of movement speed due to a change in body position imposed by carrying the weighted backpack. Funding provided by US Army MPMC ATO IV.MD2006.01. Authors' views not official US Army or DoD policy.

**2359      Board #4      May 29      8:00 AM - 9:30 AM**  
**Running Economy Changes After Altitude Training: Role Of Ventilatory Acclimatization**

Elizabeth A. Lundgren, Daniel P. Wilhite, Abigail S. Laymon, James M. McKenzie, Robert F. Chapman. *Indiana University, Bloomington, IN.*

(Sponsor: Timothy Mickleborough, FACSM)

Email: elundgre@indiana.edu

*(No relationships reported)*

Several recent studies suggest that chronic altitude training may cause changes in submaximal oxygen uptake in elite endurance runners. Ventilatory acclimatization with altitude training may increase respiratory muscle work, confounding the measurement and interpretation of running economy.

**PURPOSE:** To determine if potential running economy changes after altitude training can be explained by changes in ventilatory factors.

**METHODS:** Six elite male distance runners ( $\text{VO}_{2\text{max}} 70.6 \pm 4.5$  mL/kg/min) completed a 28 day altitude training intervention in Flagstaff, Arizona, elevation 2150m, following a "live high - train low" training model. Running economy and expired ventilation (VE) were measured 2-9 days prior to departure to altitude and 1-2 days after return to sea level. Running economy was determined from  $\text{VO}_2$  measured in the final minute of 3 minute stages at 3 constant submaximal treadmill speeds of 291, 301, and 311 m/min. Respiratory muscle  $\text{VO}_2$  ( $\text{VO}_{2\text{rm}}$ ) was estimated using the equations of Aaron et al (1992).

**RESULTS:** Post-altitude  $\text{VO}_2$  was higher at each submaximal workload ( $\text{DVO}_2$  pre- to post-altitude range 2.3 - 3.2 mL/kg/min;  $p$  range 0.037 - 0.115). Post altitude VE was significantly higher at each submaximal workload ( $\text{DVE}$  pre- to post-altitude range 7.5 - 12.7 L/min;  $p$  range 0.016 - 0.021). Estimated  $\text{VO}_{2\text{rm}}$  accounted for 12.3 %, 11.0 %, and 14.2 % of the increase in whole body  $\text{VO}_2$  at each of 3 submaximal workloads after altitude training.

**CONCLUSIONS:** Submaximal  $\text{VO}_2$  increased in our elite athlete cohort after chronic altitude training. Although ventilation increased post-altitude, the estimated metabolic cost of ventilation explained 11.0 - 14.2% of the  $\text{VO}_2$  increase. The source of the remaining submaximal  $\text{VO}_2$  change after altitude training remains unknown.

**Running Economy Changes After Altitude Training: Role Of Running Mechanics**

Abigail S. Laymon, Elizabeth A. Lundgren, James M. McKenzie, Daniel P. Wilhite, Robert F. Chapman. *Indiana University, Bloomington, IN.*

(Sponsor: Joel Stager, FACSM)

Email: aslaymon@indiana.edu

*(No relationships reported)*

The oxygen cost of running at submaximal workloads is influenced in large part by individual differences in running mechanics. Several recent studies suggest that chronic altitude training may cause changes in submaximal oxygen uptake in elite endurance runners. Whether any change in running economy after altitude training is due to altered running mechanics is undetermined.

**PURPOSE:** To determine if potential running economy changes after altitude training can be explained by changes in biomechanical factors.

**METHODS:** Six elite male distance runners ( $\text{VO}_{2\text{max}} 70.6 \pm 4.5$  mL/kg/min) completed a 28 day altitude training intervention in Flagstaff, Arizona, elevation 2150m, following a "live high - train low" training model. Running economy and gait parameters were measured 2-9 days prior to departure to altitude and 1-2 days after returning to sea level. Running economy was determined from  $\text{VO}_2$  measured in the final minute of 3 minute stages at 3 constant submaximal treadmill speeds of 291, 301, and 311 m/min. To measure variables related to running mechanics, subjects completed separate 30 second stages at constant treadmill speeds of 300, 315, 330, 345, and 360 m/min. Each running stage was separated by a period of standing rest. Wireless tri-axial 10g accelerometer devices, sampling at 1024 Hz, were securely attached to the laces of each shoe. Values of ground contact time, stride time, swing time, stride length, and stride frequency were determined from accelerometric output corresponding to foot strike and toe-off events obtained from a minimum of 25 consecutive steps.

**RESULTS:** Post-altitude  $\text{VO}_2$  was higher at each submaximal workload ( $\text{DVO}_2$  pre- to post-altitude range 2.3 - 3.2 mL/kg/min;  $p$  range 0.037 - 0.115;  $n = 6$ ). No significant differences were found in ground contact time, stride time, swing time, stride length or stride frequency at any speed after altitude training.

**CONCLUSIONS:** Changes in running economy in elite endurance runners after chronic altitude training are not due to altitude mediated changes in running mechanics.

**What Is The Effect Of Moderate Altitude (ma) On Olympic Running Performance: Perplexing Findings?**

Anthony A. Sucec. *San Diego State Univ., San Diego, CA.* (Sponsor: Larry Verity, FACSM)  
Email: tsucec@msn.com  
(No relationships reported)

Several approaches have been employed to ascertain the effect of MA, ~ 2,300 m, on running performance. A common method has been to compare a MA time to a sea level SL mark, such as winning times for the Mexico City Olympics (MCO) to SL marks such as the previous Olympiad. Another technique has been to measure run marks of a sample at SL and then at MA. The former method is limited due to the questionable validity of using an extreme, single measure as a representative effect, while the latter approach has, generally, been restricted to small samples and has been confined to distance events.

**PURPOSE:** To determine the effect of MA on times for events without hurdles, by comparing the best times during the MCO with the best SL marks for the same individuals and season.

**METHODS:** Run events, listed below, were analyzed to determine run times and the % difference, SL time - MCO time, (%D) for the first ~32 finishers/event (n= 297). Only 211 SL times could be validated for the MCO entries (26.4±5.1/event) or 70.5 % of the MCO sample. Additionally, %D scores were regressed over finish place and the slope (b) was tested for significance at p <0.05.

**RESULTS:** The mean MCO and SL times (in s) were as follows (in m):100=10.23/10.18; 200=20.59/ 20.67; 400=45.78/46.14; 800=108.10/ 107.10; 1,500=231.25/220.73; 5,000= 880.53/821.66; 10,000=1828.08/1719.66; marathon= 9296.11/8362.66. The mean %D from 100 m to the marathon were, respectively, -0.48; 0.40; 0.78; -0.93; -4.77; -7.17; -6.20; -11.24. Only the 100 and 200 m sprints were unaffected by MA. The regression analysis revealed that, with the exception of the 100 m, %D was related to finish position, as r ranged from -.43 to -.78 with b ranging from -0.04 to -0.31 %D. Only the b for the 100 m was not different from no slope, p=0.21.

**CONCLUSION:** The findings for the 100 and 200 m do not support single data point reports, as no differences (p > 0.05) were found for %D. However, the direction of the effect for the 400 m, 5, 10 km and marathon were in agreement, though the magnitude of the differences was considerably smaller compared to the this report. The 800 and 1500 m results yielded opposite effects, as the latter event displayed a smaller effect (1.5 vs -4.8 %). The major finding is that the order of finish is related to the %D, and informs as to why the size of the %D is smaller when MA winners are compared to SL winners.

**Relationship Between Total Hemoglobin Mass And Aerobic Performance Of Sea Level Residents Exposed To 2210m**

Jeffrey L. Nelson<sup>1</sup>, Brandon K. Doan<sup>1</sup>, Ben Ryan<sup>2</sup>, Al Wile<sup>1</sup>, William C. Byrnes, FACSM<sup>2</sup>, Michael D. Brothers<sup>1</sup>. <sup>1</sup>*U.S. Air Force Academy Human Performance Lab, USAF Academy, CO.* <sup>2</sup>*University of Colorado, Boulder, CO.*  
Email: Jeffrey.Nelson@usafa.edu  
(No relationships reported)

It is reported that up to 70% of aerobic performance is related to O<sub>2</sub> carrying capacity as measured by total hemoglobin mass (THM). However, the relationship between THM and performance among sea level (SL) subjects following acute and chronic residence at moderate altitude (MA) has not been examined.

**PURPOSE:** To examine the relationship between THM and 1.5 mile run time acutely and after 6 and 10 weeks of chronic MA exposure among SL and MA subjects at the U.S. Air Force Academy (USAF). We hypothesized that a significant correlation would exist between THM and 1.5 mile run time acutely, that former SL subjects would display a significant increase in THM and improved run time chronically, and these changes would correlate significantly.

**METHODS:** 66 male and female freshman subjects (55 SL, 11 MA) aged 18.1 ± 0.3 years completed a 1.5 mile run 1 day after in-processing USAFA (2210m) as part of a standard fitness test. THM was measured within 72 hours of arrival utilizing the optimized CO re-breathing protocol. This 1.5 mile run and THM assessment was repeated following 6 and 10 weeks of chronic residence at USAFA.

**RESULTS:** Acutely, all hematological variables examined correlated significantly (p<0.01) with aerobic performance among SL subjects (R = -0.37 to -0.70), with THM predicting 49% of the variability observed. After 6 and 10 weeks at MA, cadets from SL displayed a 5% and 8.5% gain in THM, and 12.7% and 15.8% improvement in 1.5 mile run time, respectively, and all hematological variables again correlated significantly (p<0.05; R = -0.31 to -0.71). However, the change (D) in these blood values vs. D-run time among SL subjects after +6 weeks resulted in non-significant correlations, and only D-THM and D-erythrocyte volume correlated significantly at +10 weeks (R = -0.41, p<0.01). No significant correlations occurred among MA controls.

**CONCLUSIONS:** While strong correlations existed between blood values and run time, they explained less than half of the variability. Significant improvements in performance were seen chronically, yet blood adaptations accounted for only 16% of this variability. Other adaptations besides THM may be needed for improved aerobic performance and MA acclimatization. Disclaimer: the views expressed are the authors and do not reflect the official policy/position of the USAF, the DoD, or the US Government.

**2363 Board #8 May 29 8:00 AM - 9:30 AM**  
**Effect Of Iron Supplementation On Hematological Adaptations To Moderate Altitude Among Former Sea Level Females**

Christina Minares<sup>1</sup>, Julia McGregor<sup>1</sup>, Chris Ruth<sup>1</sup>, Elizabeth Terry<sup>2</sup>, Jeffrey L. Nelson<sup>2</sup>, Brandon K. Doan<sup>2</sup>, Michael D. Brothers<sup>2</sup>. <sup>1</sup>*Air Force Research Labs, Brooks City-Base, TX.* <sup>2</sup>*US Air Force Academy Human Performance Lab, USAF Academy, CO.* (Sponsor: William C. Byrnes, FACSM)  
(No relationships reported)

Previous research at the U.S. Air Force Academy (USAF) has suggested that more than 37 weeks may be required for complete hematological acclimatization to moderate altitude (MA), but this lengthy time may have been confounded by insufficient iron stores and/or intake.

**PURPOSE:** To further elucidate the time requirement for hematological adaptations and the effect of iron supplementation, a double blind, placebo controlled study was designed. 18 female subjects' (9 iron, 9 placebo) total hemoglobin mass (THM), erythrocyte volume (EV), plasma volume (PV), and total blood volume (BV) were measured acutely and chronically at USAFA--a unique and well-controlled military installation--to quantify the long term hematological adaptations to MA (2210m). We hypothesized that SL females supplemented with iron would display significantly faster gains in THM and EV compared to the placebo controls.

**METHODS:** 18 incoming female freshman subjects were provided with either 100mg ferrous sulfate or placebo (corn starch) upon arrival at USAFA to be taken daily. THM was assessed within the first 72 hours of in-processing USAFA, and again after +6 and +10 weeks of chronic MA exposure utilizing the optimized CO re-breathing protocol. During this same assessment, a controlled, seated venipuncture was conducted and EV, PV, and total BV was calculated with this additional data.

**RESULTS:** Although both cohorts displayed a significant (p<0.001) increase (+11-12%) in THM and EV following 10 weeks of chronic MA, there were no significant differences in relative THM (9.3 ± 0.7 vs. 9.4 ± 0.7 g/kg) or EV (27.2 ± 1.4 vs. 27.5 ± 1.9 ml/kg) between cohorts.

**CONCLUSIONS:** Chronic exposure to 2210m resulted in significant increases in THM and EV, but daily supplementation for 10 weeks with 100mg ferrous sulfate failed to enhance hematological adaptation among this population of former SL residents.

2364 Board #9 May 29 8:00 AM - 9:30 AM

**Hemoglobin Mass And Erythrocyte Volume Adaptations After 10 Weeks Of Altitude In Sea Level Females**

Julia McGregor<sup>1</sup>, Christina Minares<sup>1</sup>, Chris Ruth<sup>1</sup>, Andrea Pinchak<sup>1</sup>, Michael F. Zupan<sup>1</sup>, Jeffrey L. Nelson<sup>2</sup>, Michael D. Brothers<sup>2</sup>. <sup>1</sup>U.S. Air Force Research Labs, Brooks City-Base, TX. <sup>2</sup>U.S. Air Force Academy Human Performance Lab, USAF Academy, CO. (Sponsor: William C. Bymes, FACSM)

(No relationships reported)

Previous research from the U.S. Air Force Academy (USAF) has suggested that significant altitude-related hematological adaptations are required for former sea level (SL) males exposed to moderate altitude (MA), but more precise hematological measurements such as total hemoglobin mass (THM) have not occurred--especially among SL female subjects.

**PURPOSE:** To assess hematological adaptations to MA, THM, erythrocyte volume (EV), plasma volume (PV), and total blood volume (BV) were measured in SL females acutely and chronically at USAFA (2210m). We hypothesized that SL females would display significant gains in all hematological parameters over time.

**METHODS:** 18 SL female subjects' (age 18.3 ± 0.4 years) THM was assessed within the first 72 hours of in-processing USAFA, and after +6 and +10 weeks of chronic MA exposure utilizing the optimized CO re-breathing protocol. During these same assessments, a controlled, seated venipuncture was conducted and EV, PV, and total BV was calculated utilizing the THM data, hemoglobin concentration, and hematocrit. Relative THM values were compared to the average THM values measured among upper-class USAFA females that had resided at MA for 2+ years (n=20).

**RESULTS:** Former SL females had a significant (p<0.001) 12.5% increase in THM (1.1 ± 0.6 g/kg) and 10.8% increase in EV (2.7 ± 1.0 ml/kg) following 10 weeks of chronic MA versus acute values. However, neither BV (+1.9 ± 6.1 ml/kg; p=0.36) nor PV (-0.7 ± 5.3 ml/kg; p=0.86) changed significantly from acute values. SL subject's THM was significantly (p<0.01) lower acutely (-14.0%, or -1.4 g/kg) and following +6 weeks of MA exposure (-5.9%, or -0.6 g/kg; p<0.05) compared to MA controls, but was not significant at week 10.

**CONCLUSIONS:** Chronic exposure to 2210m combined with military training resulted in significant increases in THM and EV which required 10 weeks to reach the hematological values of long-term MA females. Disclaimer: the views expressed are those of the authors and do not reflect the official policy or position of the United States Air Force, the Department of Defense, or the US Government.

2365 Board #10 May 29 8:00 AM - 9:30 AM

**Altitude-related Difference In Hemoglobin Mass And Blood Volumes Upon Acute Exposure To Moderate Altitude**

Michael D. Brothers<sup>1</sup>, Jeffrey L. Nelson<sup>1</sup>, Brandon K. Doan<sup>1</sup>, Matt Lorenz<sup>2</sup>, Michael F. Zupan<sup>3</sup>, William C. Bymes, FACSM<sup>4</sup>. <sup>1</sup>U.S. Air Force Academy Human Performance Lab, U.S. Air Force Academy, CO. <sup>2</sup>University of Colorado, Colorado Springs, CO. <sup>3</sup>Air Force Research Laboratory, Brooks City-Base, TX. <sup>4</sup>University of Colorado, Boulder, CO.

Email: michael.brothers@usafa.edu

(No relationships reported)

Research from the U.S. Air Force Academy (USAF) has suggested that significant altitude-related hematological differences exist between moderate altitude (MA) and sea level (SL) residents acutely exposed to MA (2210m), but these studies did not distinguish between differences due to variations in total hemoglobin mass (THM) versus plasma volume.

**PURPOSE:** To assess acute differences in THM plus erythrocyte (EV), plasma (PV), and total blood (BV) volumes between incoming SL (<300m) and MA (>1800m) male freshmen USAFA cadets. We hypothesized that MA subjects would have significantly more THM, EV, PV and BV.

**METHODS:** Within 72 hours of MA exposure, a resting seated venipuncture (Hb concentration & hematocrit) and the optimized CO re-breathing protocol (THM) were performed on 56 incoming male freshmen. EV, PV, and total BV were calculated utilizing THM data, hemoglobin concentration, and hematocrit.

**RESULTS:** Although there were no differences in hemoglobin concentration (14.82 ± 1.19 vs. 14.69 ± 1.22 g/dL), cadets from MA had significantly (p < 0.01) higher THM (12.01 ± 0.71 vs. 11.30 ± 0.97 g/kg; +6.3%), and significantly (p < 0.05) greater EV (35.25 ± 2.23 vs. 33.38 ± 2.78 ml/kg; +5.6%) and BV (89.69 ± 8.91 vs. 84.86 ± 6.85 ml/kg; +5.7%). For PV, the magnitude of the difference (5.8%) between MA (54.44 ± 7.87) and SL (51.47 ± 5.74 ml/kg) was similar and approached significance (p < 0.07).

**CONCLUSIONS:** Long-term (2+ years) residence at MA results in significant hematological acclimatization which increases nearly all hematological parameters compared to SL residents of similar fitness.

**Relation Between Measured And Ideal Weight, Body And Life Satisfaction, And Fitness Levels Of Adolescents**

Scott B. Martin, Christy A. Greenleaf, Trent A. Petrie, Priscilla L. Connors. *University of North Texas, Denton, TX.*

Email: Scott.Martin@unt.edu

(No relationships reported)

The state of Texas enacted legislation requiring public schools to conduct comprehensive health-related physical fitness evaluations on students in grades 3-12 each year.

**PURPOSE:** To examine the relation between middle school students' measured weight, self-reported ideal weight, body satisfaction, life satisfaction, and achieving the "Healthy Fitness Zone" (HFZ) standards of the *FITNESSGRAM*® physical fitness testing program in Texas.

**METHODS:** Students are considered to be in the HFZ if they achieve health-related standards on each of six tests (aerobic capacity, abdominal strength, upper body strength, trunk extensor strength, flexibility, and body composition), with the standards adjusted for their age and gender. The PACER, curl-up, push-up, trunk-lift, sit and reach, and BMI were given. Students also completed self-report measures that assessed their psychosocial health. The difference between measured weight and self-reported ideal weight was computed for each participant. Of the 448 middle school students who participated in the study, 121 achieved the HFZ standards whereas 327 did not achieve the HFZ standards for all six tests.

**RESULTS:** A 2 (gender) by 2 (HFZ) MANOVA was conducted using their measured and ideal weight difference, body satisfaction, and general life satisfaction as dependent measures. Results revealed main effects for gender and HFZ. Girls had a greater difference between their measured and ideal weight than boys. They were also less likely to be

satisfied with their bodies than boys. Those who achieved the HFZ standard for all six tests had smaller differences between their measured and ideal weight than those who did not achieve the HFZ standard. In addition, those who achieved the HFZ standard were more likely to be satisfied with their body and life in general than those who did not achieve the HFZ standard.

**CONCLUSIONS:** Middle school students who were objectively judged to be physically fit were more satisfied with their weight, body, and life in general than those who were less fit. Recognizing that those who do not achieve the HFZ standards may be dissatisfied with their fitness performance and their weight, bodies, and possibly their life in general may help physical educators develop multifaceted strategies to improve both the physical and psychosocial health of students.

**Body Mass Index And Perceptions Of Body Among Chinese University Students In Hong Kong.**

Robert SK NG<sup>1</sup>, Violette FP LIN<sup>2</sup>. <sup>1</sup>*The Hong Kong Polytechnic University, Hong Kong, China.* <sup>2</sup>*Food and Environment Hygiene Department, Hong Kong, China.*

Email: sarobert@inet.polyu.edu.hk

(No relationships reported)

**PURPOSE:** The prevalence of both obesity and eating disorders are on the rise worldwide, especially in the young. This study explored the relationship between different weight status as measured by body mass index (BMI) and the perception of body image and health among university students.

**METHODS:** Students were recruited from different universities in Hong Kong to fill in a Chinese self-administered questionnaire. Respondents had to match 9 men (and women) drawings of different sizes with words such as sickly, healthy, underweight, and obese. They also recorded their current and ideal body images. BMI was calculated using self-reported weight and height. Body image discrepancy (BID) was the difference between ideal and current body images selected from the 9-figure rating scale. Spearman's rho correlation analyses were conducted separately for men and women.

**RESULTS:** As the pilot of a large scale survey, 71 men (mean age 21.8±2.0 years) and 79 women (mean age 21.6±1.8 years) took part in the study. The mean BMIs were 21.7±3.5 and 19.7±2.7 kg/m<sup>2</sup> for men and women respectively. For men, 23.9% dissatisfied with their shapes, 28.2% wanted to be thinner whereas 33.8% wanted to be fatter. For women, 43.0% dissatisfied with their body shapes, 45.6% wanted to be thinner whereas 22.8% wanted to be fatter. BID was negatively correlated with BMI in men (r=-.578) and women (r=-.548). Most overweight men and women (BMI >23.0) and underweight men (BMI <18.5) did not describe the skinny figure as sickly, whereas most underweight women described the skinny figure as sickly. In the perception of "healthiest", overweight and underweight men perceived the fatter male figures as the healthiest; but slimmer female figures as the healthiest. Overweight and underweight women perceived the fatter female figures as the healthiest; but slimmer male figures as the healthiest.

**CONCLUSIONS:** The study indicates that an increase in BMI aggravates an increase in BID. Weight status influenced the gender perception of the healthiest figure. Overweight people tended to regard slim as healthy in opposite gender, but for the same gender fat is healthy. The study highlights a need for interventions to help young adults develop a healthy and realistic body image and healthy ways to manage their weight.

**The Effects Of Healthy Lifestyle Intervention On Body Dissatisfaction And Weight Concerns In Minority Girls**

Norma Olvera<sup>1</sup>, Kendall McCarley<sup>2</sup>, Stephanie Kellam<sup>1</sup>, Jessica McLeod<sup>1</sup>, Jill A. Bush, FACSM<sup>3</sup>. <sup>1</sup>*University of Houston, Houston, TX.* <sup>2</sup>*University of Denver, Denver, CO.* <sup>3</sup>*University of Towson, Maryland, MD.*

Email: nolvera@uh.edu

(No relationships reported)

**PURPOSE:** The primary aim of this study was to assess the effect of a family-based healthy lifestyle intervention titled BOUNCE on body dissatisfaction and weight concerns in overweight minority girls.

**METHODS:** Thirty-eight Hispanic and African American girls aged 8-14y (11.5±1.4y) and their mothers aged 26-39y (39.3+ 6.5y) participated as part of a pilot study of a healthy lifestyle intervention to promote physical activity and physical fitness. Most of the participating girls (85%) were categorized as being overweight (BMI >95%) and 15% were at risk for overweight (BMI >85<95). Similarly, most of mothers were categorized as being overweight (41%) or obese (53%). Girls completed body dissatisfaction and weight concerns measures at baseline and after a 4-week intervention.

**RESULTS:** The BOUNCE healthy lifestyle summer intervention had a significant decrease in girls' body dissatisfaction ( $p < .0005$ ) pre-post intervention, but no significant differences in weight concerns were observed pre and post-intervention.

**CONCLUSIONS:** This is one of the few studies to assess the effects of a healthy lifestyle intervention on body image and weight concerns in preadolescent Hispanic and African American girls. Body dissatisfaction was positively influenced by the intervention.

**A Preliminary Survey Of College Cheerleaders For Symptoms Of Eating Disorders**

Judy R. Wilson, FACSM, Wendy Williams, Mark D. Ricard. *University of Texas @ Arlington, Arlington, TX.*

Email: jrwilson@uta.edu

(No relationships reported)

**INTRODUCTION:** While some may not consider cheerleading a sport, it still shares some of the same pressures as those sports that require a low body weight. An emphasis on maintaining a low body weight raises the potential for the occurrence of eating disorders among those participating in this activity.

**PURPOSE:** The purpose of this study was to use the Eating Disorders Inventory-2 (EDI-2) to evaluate the potential for eating disorders among college cheerleaders.

**METHODS:** Participants were 28 college cheerleaders from four universities. All participants were asked to fill out the Eating Disorder Inventory-Symptoms Checklist (EDI-SC) and the EDI-2 anonymously and return the packets to a sealed box. The questionnaires were then coded and analyzed to provide descriptive information regarding the participants and the subscales of the EDI-2. Descriptive statistics were used to characterize the potential for eating disorders among college cheerleaders. Independent t-tests were used to compare subjects with eating disorders to those without eating disorders.

**RESULTS:** The 28 college cheerleaders were all females with an average age of 19.5 yrs (± 1.6) and an average height and weight of 63.3 in (± 2.9) and 122 lbs (± 16.2), respectively. The mean for the highest weight (excluding pregnancy) was 127 lbs (± 17.6) and included a female who currently weighed 173 lbs with a height of 67 in. The means of all of the subscales fell within the normal ranges for college females with the exception of the "Maturity Fears" subscale. A mean value of 2.7 is considered appropriate for college females, while in the current study the "Maturity Fears" subscale indicated a mean value of 5.0. Individual profiles of the subscales were determined for each of the 28 participants. This led to the separation of seven of the original group of 28 cheerleaders into a subgroup with symptoms of disordered eating. The subscales of the high disordered eating group were significantly different ( $p < 0.05$ ) from the low disordered eating group with the exception of the Perfectionism and Maturity Fears subscales.

**CONCLUSIONS:** Twenty five percent of the cheerleaders sampled were identified as having an eating disorder. This finding suggests that cheerleaders may comprise a group that includes those with eating disorders.

**2370 Board #15 May 29 9:00 AM - 10:30 AM**

## A Comparison Of Body Dissatisfaction And Obligatory Exercise Among Certified Fitness Instructors And Regular Exercisers

Shala E. Davis, FACSM, Kate Hodnik, Paula Parker, Gregory B. Dwyer, FACSM. *East Stroudsburg University, East Stroudsburg University, PA.*  
(No relationships reported)

**INTRODUCTION:** Literature suggests that fitness professionals may feel additional pressure to meet societal expectations related to body image which may lead to greater risk of body dissatisfaction and obligatory exercise.

**PURPOSE:** The purpose of the present study was to compare body dissatisfaction (BD) and obligatory exercise (OE) among certified fitness instructors and regular exercisers. **SUBJECTS:** There were 68 total subjects who participated in the study, 48 (mean age: 20.8 + 2.3) of those subjects (42 female and 6 male) were from the general population of exercisers, and 20 (mean age: 25.8 + 3.9) were certified fitness professionals (18 female, 2 male) including group exercise instructors and personal trainers.

**METHODS:** All subjects completed a modified Body Dissatisfaction subscale of the EDI-2, the Obligatory Exercise Questionnaire, and the Body Contour Rating (BCR) scale in a private environment. Subjects also provided demographic data on exercise history, current exercise habits, and menstrual history.

**RESULTS:** No significant difference ( $p>0.05$ ) was found in body dissatisfaction between the general exercisers (mean BD= 28.4) and the certified professionals (mean BD= 29.5). No significant difference ( $p>0.05$ ) was found in obligatory exercise between the general exercisers (mean OE= 27.5) and the certified professionals (mean OE= 28.7). The BCR scale revealed similar physique misperceptions between the general exercisers (less than 25% were satisfied with current figure) and certified fitness professionals (less than 12% were satisfied with current figure).

**CONCLUSION:** Although previous literature has suggested that fitness professionals may be at greater risk of body image and excessive exercise, the present study demonstrated that the certified fitness professional were less satisfied with their physique and preferred to have physiques that were not realistic.

### 2371 Board #16 May 29 9:00 AM - 10:30 AM Alexithymia Is Related To Disordered Eating, Exercise Dependence, And Depression In Young Adults

Jennifer Bossard, Wayne C. Miller, FACSM. *George Washington University, Washington, DC.*  
Email: [wmiller@gwu.edu](mailto:wmiller@gwu.edu)  
(No relationships reported)

Alexithymia is a psychological construct that describes one's inability to distinguish between physical feelings and emotions, and one's inability to express their emotions. The prevalence of alexithymia is generally higher in eating disorder and depression patients than in controls. Alexithymia has not been studied in people with exercise dependence.

**PURPOSE:** The aims of this study were to examine the association between alexithymia and exercise dependence, disordered eating, and depression; and to see if exercise dependence is more prevalent in people with alexithymia than not.

**METHODS:** Subjects were men and women between 18-40 y. Each subject completed the following diagnostic tools: TAS-20 (Alexithymia), EDI (Eating Disorder Inventory), EDS (Exercise Dependence Scale), and the BDI (Beck Depression Inventory).

**RESULTS:** Alexithymia is positively related ( $p<0.0001$ ) to disordered eating ( $r=0.61$ ), depression ( $r=0.59$ ), and exercise dependence ( $r=0.41$ ). 93% of those with alexithymia are depressed, while 100% of those with exercise dependence are depressed. 40% of those with exercise dependence are alexithymic. Eating Disorder Inventory ( $p<0.001$ ), Beck Depression Inventory ( $p<0.003$ ), and Exercise Dependence Scale ( $p<0.03$ ) scores are higher in those with alexithymia than without. The prevalence of alexithymia (18%) is higher in the sample than eating disorders (5%,  $p<0.003$ ), less than the prevalence of depression (58%,  $p<0.001$ ), and the same as that of exercise dependence (6%). Exercise dependence is higher ( $p<0.01$ ) in those with alexithymia (14%) than those without (5%). Exercise dependence is higher ( $p<0.004$ ) in those with depression (28%) than those without (3%).

**CONCLUSION:** Alexithymia, exercise dependence and eating disorders are significantly related. A person's inability to identify and express his/her emotions may pre-dispose him/her to an eating or exercise disorder.

*Supported by the Department of Exercise Science at George Washington University*

### 2372 Board #17 May 29 9:00 AM - 10:30 AM Body Image Perceptions Among Female Weight Lifters

Karen M. Skemp-Arlt, Richard P. Mikat, FACSM. *University Wisconsin La Crosse, La Crosse, WI.*  
Email: [skemp.kare@uwlax.edu](mailto:skemp.kare@uwlax.edu)  
(No relationships reported)

Muscle Dysmorphia (MD) has been recognized as a disorder associated with body dissatisfaction and is especially prevalent among the exercising/athletic population, however, little is known about MD among female weight lifters.

**PURPOSE:** The purpose of the study was to measure body image perceptions particularly comparing the levels of MD among competitive and non-competitive female weight lifters.

**METHODS:** The Muscle Dysmorphia Inventory (MDI) was used to assess body image perceptions and the characteristics of muscle dysmorphia among the groups. This 27-item self-report survey has been validated in previous research and was designed for the assessment of behavioral and psychological characteristics associated with MD. The MDI contains 6 subscales and each subscale uses a 6-point Likert scale ranging from "never" (=1) to "always" (=6). Higher subscale scores represent a greater association with MD characteristics. Participants included 15 competitive and 15 non-competitive female weight lifters (mean age = 22). Data collection was done using a combination of paper and web-based surveys. MANOVA was used to measure differences between groups in all subscales.

**RESULTS:** Results indicated significant differences between competitive and noncompetitive weightlifters on the diet and exercise subscales ( $p<.01$ )\*.

MDI Subscales	Competitive (Mean Total $\pm$ SD)	Noncompetitive (Mean Total $\pm$ SD)	MANOVA p-values
Dietary Behavior	19.17 $\pm$ 5.90	11.47 $\pm$ 3.98	0.000*
Supplement Use	8.07 $\pm$ 5.68	5.47 $\pm$ 2.29	0.111
Physique Protection	10.13 $\pm$ 2.88	11.20 $\pm$ 6.25	0.553
Exercise Dependence	16.47 $\pm$ 3.54	12.40 $\pm$ 2.26	0.001*
Body size/symmetry	10.67 $\pm$ 3.83	9.33 $\pm$ 4.70	0.402
Pharmacology Use	3.00 $\pm$ 0.00	3.73 $\pm$ 2.58	0.280

**CONCLUSIONS:** Results of this study indicate that competitive female weight lifters exhibit greater behavioral characteristics associated with MD than do their non-competitive counterparts and suggest they may be at risk for this disorder. Awareness of the behavioral signs associated with MD by coaches, trainers, and health professionals is important for communication and intervention purposes.

---

**2373 Board #18 May 29 9:00 AM - 10:30 AM**  
**Body Image Perceptions Related To Muscle Dysmorphia Among Competitive And Non-competitive Male Weight Lifters**  
Richard P. Mikat, FACSM, Karen Skemp-Arlt. *Univ. of Wisconsin-La Crosse, La Crosse, WI.*  
Email: mikat.rich@uwlax.edu  
(No relationships reported)

Muscle Dysmorphia (MD) is a psychological disorder associated with body dissatisfaction. The current literature shows a prevalence of MD among competitive male weight lifters, however, little is known about MD among non-competitive male weight lifters.

**PURPOSE:** The purpose of this study was to measure and compare body image perceptions related to MD among competitive and non-competitive male weight lifters.

**METHODS:** The Muscle Dysmorphia Inventory (MDI) was used to assess body image perceptions and the characteristics of muscle dysmorphia among men in both competitive and non-competitive groups. Each subscale score of the MDI was calculated by summing all item scores within the subscale. Higher scores were associated with greater risk for MD. Participants included 38 competitive and 38 non-competitive male weight lifters (mean age = 24). MANOVA was used to measure differences between groups in all subscales.

**RESULTS:** Both competitive and non-competitive male weightlifters exhibited relatively high MDI subscale scores and no significant differences in MDI subscale scores were found between groups ( $\alpha = 0.05$ , see table below).

MDI Subscales	Maximum Possible Score	Competitive (Total Mean $\pm$ SD)	Noncompetitive (Total Mean $\pm$ SD)	MANOVA p-values
Dietary Behavior	30	18.74 $\pm$ 5.17	17.47 $\pm$ 5.77	0.318
Supplement Use	24	13.55 $\pm$ 4.48	12.95 $\pm$ 5.68	0.607
Physique Protection	36	12.55 $\pm$ 4.71	13.03 $\pm$ 4.35	0.650
Exercise Dependence	24	17.34 $\pm$ 3.50	15.61 $\pm$ 4.50	0.064
Body size/symmetry	30	18.79 $\pm$ 5.92	17.16 $\pm$ 6.59	0.260
Pharmacology Use	18	3.26 $\pm$ 0.83	3.45 $\pm$ 1.11	0.414

**CONCLUSION:** All weightlifters in this study had similarly high MDI subscale scores which place them at risk for MD. Additionally, no apparent differences in MDI subscale scores between competitive and non-competitive male weightlifters were found indicating that both groups have similar MD risks. These findings should encourage coaches, trainers, and fitness and health professionals to become aware of the behavioral signs associated with MD and to look for these signs in all male weight lifters under their supervision.

**2374 Board #19 May 29 9:00 AM - 10:30 AM**  
**Affective Responses To Dexa Images And Body Composition Analysis**  
Mark D. Faries, Cathrine S. Boroff, Matthew Stults-Kolehmainen. *University of Texas-Austin, Austin, TX.* (Sponsor: John Bartholomew, FACSM)  
Email: faries@mail.utexas.edu  
(No relationships reported)

Dual-energy X-ray absorptiometry (DEXA) has become a widely used method for estimation of body composition, including bone mineral density, muscle mass and fat mass. In addition to body composition results, DEXA also provides users with full body two-dimensional images; one of their skeleton and one of their soft tissue. It is unknown what affective responses incur upon finding out one's own body composition, along with seeing these images of self.

**PURPOSE:** To examine the affective responses to viewing DEXA images after body composition analysis, and whether or not body fat percentage (BF%) moderates such responses.

**METHODS:** 111 participants (female,  $n = 73$ ; male,  $n = 38$ ;  $21.09 \pm 3.56$  yrs) were randomly assigned to either a control (NO IMAGE,  $n = 55$ ) or experimental group (IMAGE,  $n = 56$ ). Both groups completed a demographic questionnaire and the Positive Affect Negative Affect Scale (PANAS) prior to the DEXA scan. Participants then completed a DEXA scan, and were told their measured total body fat percentage along with norms (women 21-32%, men 8-19%). At this point, the IMAGE group was allowed to view their own produced DEXA images, while the NO IMAGE group was kept from seeing their images. Immediately following the DEXA scan, all participants completed a post-PANAS. Changes in positive affect (PA) and negative affect (NA) were separately investigated using 3-way repeated measures ANOVA (condition, gender & BF%).

**RESULTS:** There was a main effect of time on PA, decreasing from  $3.18 \pm .78$  to  $2.83 \pm .87$  ( $p < 0.01$ ), as well as both genders and BF% categories (in norm-desired range vs. above range) decreasing significantly ( $p < 0.01$ ). No within-subjects interaction effects were found. For NA, there were no main effects of time, condition or gender, although a significant interaction effect with BF% was found. There was a significant increase in NA for those whose BF% was greater than the desired range ( $1.47 \pm .54$  to  $1.58 \pm .62$ ,  $p < 0.05$ ), while there was a non-significant effect of time on NA for those who BF% was in the desired range ( $1.58 \pm .57$  to  $1.51 \pm .68$ ,  $p > 0.05$ ).

**CONCLUSIONS:** It appears that finding out one's own BF% may not be as benign as thought, with decreases in PA overall, in both genders and BF% categories, while NA increases in overweight individuals. Viewing DEXA images do not differentially influence affective responses.

**2375 Board #20 May 29 9:00 AM - 10:30 AM**  
**Male Athletes, Fitness Media, And Post-exercise Psychological Affect**  
Ann Wertz Garvin, Adam Crowley, Robert Schilt, Sean Dill. *University of Wisconsin Whitewater, Whitewater, WI.*  
Email: garvina@uww.edu  
(No relationships reported)

Fitness magazines with images of the lean muscular body type characteristic of athletes, dominate the reading materials provided at exercise facilities. Preliminary research suggests that exposure to this type of image may have negative psychological consequences related to increased anxiety and reduced mood in women and non athlete males.

**PURPOSE:** The purpose of this investigation was to quantify the effects of fitness media exposure on the psychological affect of male athletes; athletes whose BMI and physical aesthetics are in alignment with the idealized fitness images in popular press.

**METHODS:** Male athletes ( $N=95$ ) were recruited, counterbalanced and randomly assigned to conditions within a Solomon-multi-group design. Participants were provided with either a Men's Health and Fitness (fitness images), a National Geographic (no fitness images) or no-magazine control condition. All athletes engaged in 30-min of cycle ergometry at a self-selected intensity. State anxiety (STAI) and mood state (POMS) were measured in half the cases before exercise, and in all cases within 3-min following

exercise. This design allows for speculation regarding pre-test sensitization and expectancy, as well as, group differences in the post exercise condition. Data were analyzed with a series of repeated measures ANOVAs and dependent t-tests on post-test scores.

**SUMMARY OF RESULTS:** Collapsed across conditions (viewing a fitness magazine, non fitness magazine or no magazine control) state anxiety and global mood state were associated with significant improvements ( $P < .001$ ) from pre- to post- exercise. Viewing popular media with or without fitness images did not appear to impact the dependent variables measured when compared to controls. While this trend was recorded in the subscales of the POMS (depression and tension) it appears that pre-test sensitization may have effected post-test outcomes in these specific variables.

**CONCLUSIONS:** Results indicate that athletes experience similar positive psychological benefit from acute exercise as has been previously documented in exercise literature. From this investigation, it appears viewing popular magazines with or without idealized fitness images has little effect on post-exercise psychological affect when compared to controls in the non-clinical athletic male sample.

Email: [torresmc@mailbox.sc.edu](mailto:torresmc@mailbox.sc.edu)

(No relationships reported)

**PURPOSE:** Assess collegiate band administrators and auxiliary unit instructors regarding eating disorders: (a) knowledge, (b) educational program attendance, and (c) confidence scores of knowledge responses.

**METHODS:** An online questionnaire was distributed to NCAA Division I, II, and III university band administrators ( $n = 175$ ) and instructors ( $n = 150$ ) of auxiliary units (majorettes, dance line, color guard). Response rates were: administrators (34.9%,  $n = 61$ ), instructors (29.3%,  $n = 44$ ), total response rate (32.3%,  $n = 105$ ). An eating disorder questionnaire assessed [attendance at educational programs] about eating disorders, knowledge, and confidence levels of responses across five domains of etiology, identifying signs/symptoms, management/ treatment, risk factors, and prevention and education. The survey included 30 true-false questions each followed by a 4-point Likert-type scale assessing respondents' personal confidence levels for each answer.

**RESULTS:** Percentages for those administrators and instructions who reported ever attending a session were: administrators (13.1%), instructors (40.9%), overall (24.8%). Overall, instructors' knowledge score ( $71.9\% \pm 9.5\%$ ) was significantly ( $p = 0.03$ ) better than administrators ( $67.9\% \pm 9.3\%$ ). Individual domain scores were not significantly different between groups, but instructors demonstrated higher confidence levels (2.6 vs. 3.2,  $p \leq 0.01$ ) for correct responses in the identification of signs/symptoms, management/treatment (2.7 vs. 3.1,  $p = 0.04$ ), and risk factor (2.6 vs. 3.2,  $p = 0.02$ ) domains. Confidence levels in etiology and prevention and education were not significantly different.

**CONCLUSIONS:** While instructors demonstrated greater eating disorder knowledge (vs. administrators), scores were low in both groups. Because knowledge scores were lower in the group with a lower attendance record, educational intervention may offer a viable avenue for improving knowledge. Results emphasized the need for improving educational levels of administrators and auxiliary unit instructors on eating disorder knowledge.

**Early Participation in Cardiac Rehabilitation Exercise Programming Further Improves Aerobic Capacity Post Myocardial Infarction**

Tyler G. Threlfall<sup>1</sup>, Trina Hauer<sup>1</sup>, Dr. Ross Arena, FACSM<sup>2</sup>, Karen Parker<sup>3</sup>, Debra Lundberg<sup>3</sup>, Dr. David Goodhart<sup>3</sup>, Dr. Mouhieddin Traboulsi<sup>3</sup>, Dr. Sandeep Aggarwal<sup>1</sup>. <sup>1</sup>Cardiac Wellness Institute of Calgary, Calgary, AB, Canada. <sup>2</sup>Virginia Commonwealth University, Richmond, VA. <sup>3</sup>Calgary Health Region, Calgary, AB, Canada.

Email: [tthrelfall@cwic.ca](mailto:tthrelfall@cwic.ca)

(No relationships reported)

Aerobic capacity is an important outcome of exercise based cardiac rehabilitation (CR) programs as it is a strong predictor of cardiac related death. Following a myocardial infarction (MI), engaging in aerobic exercise CR programming improves aerobic capacity, however, optimal timing of this programming remains controversial.

**PURPOSE:** To determine if there are differences in aerobic capacity between subjects who engage in early compared to usual timing of aerobic exercise CR programming post MI.

**METHODS:** One hundred and one patients diagnosed with a low risk (CADILLAC score 0-2) ST elevation MI participated in this analysis. Fifty three subjects (91% male, age:  $56.1 \pm 9.1$  years) were allocated to the Early Exercise arm, while forty eight subjects (81% male, age:  $56.9 \pm 10.5$  years), identified retrospectively and matched for Early Exercise criterion, served as the Usual Care comparison group. All subjects participated in a 12 week outpatient CR aerobic exercise program and underwent maximal exercise treadmill stress testing using BRUCE protocol, at baseline and at completion of their program.

**RESULTS:** The following results are reported Early Exercise versus Usual Care group throughout. The time between MI event and baseline exercise testing was significantly shorter in the Early Exercise group ( $11.7 \pm 14.6$  vs.  $61.5 \pm 33.3$  days,  $p < 0.001$ ). Baseline peak metabolic equivalent (MET) level was not significantly different ( $8.3 \pm 1.8$  vs.  $7.8 \pm 1.8$  METs,  $p = 0.25$ ) between groups. While both groups experienced a significant improvement in post CR peak MET level ( $p < 0.001$ ) the mean change was significantly greater in the Early Exercise group ( $1.4 \pm 0.98$  vs.  $0.76 \pm 1.1$  METs,  $p < 0.005$ ).

**CONCLUSION:** The results of the present investigation are consistent with the vast body of previous literature demonstrating CR leads to a significant improvement in aerobic capacity. However, the mean improvement in aerobic capacity was significantly greater in the Early Exercise group compared to subjects entering Usual Care outpatient CR according to a more traditional initiation of exercise time-line. Hypotheses for this outcome include: 1) Less sedentary lifestyle-induced deconditioning following hospital discharge in the Early Exercise group and 2) Early cardiac follow-up care post MI leading to improved exercise compliance.

Email: robert.berent@aon.at  
(No relationships reported)

Cardiac rehabilitation and secondary prevention (CR) services have become recognized as a significant component in the continuum of care for persons with cardiovascular disease (CVD), undergone cardiac surgery or suffer from heart failure. The role of CR services in the comprehensive secondary prevention of CVD events is well documented and has been promoted by various health care organizations and position statements.

**PURPOSE:** We investigated the 16-months effect of CR in cardiac patients readmitted to CR.

**METHODS:** 408 patients (60±10 years) underwent cycle ergometry, blood sampling, and fasting glucose tests at the beginning, the end of 21±2 days of the exercise program and at readmission after 488±116 days. Maximal oxygen uptake (VO<sub>2</sub>max) was estimated from the maximal watts (W) achieved. The CR program consisted of cycling for 17±4 min 6.0 x wk and daily walking for 45 min at 60-70% of the maximal individual heart rate (HR<sub>max</sub>).

**RESULTS:** Blood cholesterol, LDL-C, TRIGs, and the body mass index (BMI) fell significantly during CR, -12%, -17%, -19 %, and -2%, respectively. Resting blood pressure, maximal performance, VO<sub>2</sub>max and the HR recovery in 1 minute improved significantly (P<0.001). Fasting glucose was unchanged. After readmission BMI, lipids (blood cholesterol, LDL-C, TRIGs) and resting blood pressure as traditional cardiovascular risk factors were increased significantly, +5%, +22%, +28%, +32%, +4%, respectively, although medication was unchanged. Exercise performance was comparable to discharge and was not significantly different.

**CONCLUSION:** During CR exercise performance and cardiovascular risk factors improved. However, readmission revealed an increase in BMI, lipids and resting blood pressure although physical fitness remained unchanged in comparison to discharge. Thus, lifestyle modification as a part of secondary prevention in CVD was changed in terms of exercise behaviors, but lifestyle trends are still a cause for concern in cardiac patients, as is the lack of any improvement in blood-pressure management, and the fact that most CHD patients are still not achieving the cholesterol goal of less than 200 mg/dl. Whether reinforcement of CR sessions or other strategies to enhance long-term adherence to lifestyle changes could attenuate the observed attrition in benefits needs further study.

**Accuracy Of Ambulatory Heart Rate Monitoring During Exercise In Patients With Coronary Artery Disease.**

Josephine M. Said. William Beaumont hospital, Royal Oak, MI.  
Email: jsaid@beaumonthospital.com  
(No relationships reported)

Accuracy of Ambulatory Heart Rate Monitoring During Exercise in Cardiac Patients With and Without Arrhythmias

Josephine Said, Amanda Sprinkle, Barry Franklin, FACSM, Adam deJong. William Beaumont Hospital, Royal Oak, MI

Although the accuracy of ambulatory heart rate (HR) monitoring has been reported in healthy populations, few data are available in patients with coronary disease.

**PURPOSE:** The accuracy of contemporary HR monitors was evaluated during prescribed exercise in phase 2/3 coronary patients (n=17) with and without a history of bundle branch block (n=3), atrial fibrillation (n=3), and atrial/ventricular arrhythmias (n=6), using simultaneous ECG-telemetry monitoring as the criteria measure. Mean ± SD age, body mass index, and estimated cardiorespiratory fitness was 57.8 ± 9.5 years, 26.0 ± 3.6 kg/m<sup>2</sup>, and 10.3 ± 2.3 metabolic equivalents.

**METHODS:** Our protocol assessed exercise HRs at 60-80% HR<sub>max</sub> using an elliptical trainer and a stationary cycle ergometer equipped with sensor (gripping) HR monitors versus ambulatory monitoring (Polar®). Patients performed a 5-min warm-up, and 5-7 min on a sensor HR equipped elliptical trainer and stationary cycle ergometer, in randomized order, while ECG-telemetry monitored.

**RESULTS:** A comparison of HR responses obtained from the 2 different exercise devices versus simultaneous ambulatory and ECG-telemetry is shown below.

Exercise Device	Sensor HR	Ambulatory HR	ECG-Telemetry HR
Cycle ergometer	113.5 ± 15.2	113.9 ± 5.0	113.6 ± 15.1
Elliptical trainer	119.7 ± 11.9	119.8 ± 13.2	121.5 ± 11.8

All of the paired differences were examined using paired t-tests. None were significantly different.

**CONCLUSIONS:** Contemporary ambulatory monitors and exercise equipment provide accurate measures of HR during exercise in coronary patients with and without conduction anomalies and/or atrial and ventricular arrhythmias.

**2381 Board #26 May 29 8:00 AM - 9:30 AM**  
**Evaluation Of A Simple Intervention To Increase Self-efficacy For Independent Exercise In Cardiac Rehabilitation Participants**

Sherry A. Barkley<sup>1</sup>, Matthew D. Vukovich, FACSM<sup>2</sup>. <sup>1</sup>Augustana College, Sioux Falls, SD. <sup>2</sup>South Dakota State University, Brookings, SD.  
Email: sherry.barkley@augie.edu  
(No relationships reported)

While benefits of exercise after a cardiac event are well documented, participation in and adherence to cardiac rehabilitation (CR) programs is often low.

**PURPOSE:** To test the effectiveness of a self-efficacy coaching intervention (SCI): a simple theory-based behavioral intervention to increase self-efficacy for independent exercise as well as independent exercise behavior in CR patients. It was hypothesized that persons receiving the SCI treatment (T) would have higher levels of self-efficacy for exercise and greater participation in independent exercise than those in an attention control (C) group.

**METHODS:** People referred to a hospital-based CR program by their physician were invited to participate in the study (N = 65). Participants were assigned to either T or C groups which were randomly designated by class time. The SCI was administered every two weeks by CR staff as a supplement to standard CR care. Patients in the T group received coaching about independent exercise, patients in the C group received coaching matched for time and technique but covering information about healthy eating. Self-efficacy for independent exercise was assessed at the beginning and end of the supervised CR program with an Exercise Self-Efficacy (ESE) scale and a Barriers Self-Efficacy (BARSE) scale. Participation in independent exercise was determined by self-report with activity logs. Outcome differences between and within T and C groups were analyzed through one-way ANOVA.

**RESULTS:** Differences between groups were not statistically significant (p > .10) for any outcome variable. Significant within groups changes (p < .05) were seen for BARSE change in the T group, and for independent exercise change in both groups. Analysis of covariance suggested an independent effect of gender on change in ESE and BARSE scores, and an independent effect of previous exercise on exercise change.

**CONCLUSIONS:** This study adds to the limited body of knowledge about theory-based interventions in CR programs and takes an important step in translating self-efficacy theory into a simple, practical application that will promote maintenance of lifestyle changes in this population. Further study is needed to see if the changes translate into maintenance of independent exercise behavior after completion of a formal CR program.

**2382 Board #27 May 29 8:00 AM - 9:30 AM****Utilizing A 12-minute Walk Test To Assess Progress In A Cardiac Rehabilitation Population**

Suresh Koneswaran<sup>1</sup>, Debra Boardley<sup>2</sup>, Dalynn T. Badenhop, FACSM<sup>1</sup>, Angela Burkett<sup>1</sup>, Abby Steigerwalt<sup>1</sup>. <sup>1</sup>University of Toledo Medical Center, Toledo, OH. <sup>2</sup>University of Toledo, Toledo, OH.

Email: sureshkoneswaran@hotmail.com

(No relationships reported)

Measuring a patient's ability to walk for a distance over a specific time period is a simple and cost-effective means of assessing functional improvement in cardiac patients.

**PURPOSE:** To determine the significance of the 12-minute walk test (12MWT) in a population of cardiac rehabilitation patients, with specific regards to improvement in distance walked.

**METHODS:** Data were collected from 586 patients (402 men, 184 women) who completed a 12MWT prior to and upon completion of a phase II cardiac rehabilitation program. Age, gender, and primary diagnosis in 4 categories were used to examine 12-minute distance walked (12MWD), measured in feet, using repeated measures ANOVA with Tukey's post hoc test when group differences were significant.

**RESULTS:** Men (3105 + 695) walked further than women (2610 + 701) in the pre-program 12MWT ( $p < .001$ ). Both men and women improved walk distance in the post 12MWT ( $p < .001$ ) but there was not a significant difference between men and women ( $p = .052$ ). Considering age groups, all groups increased distance walked from pre to post ( $p < .001$ ). Post 12MWD in those < 45 years of age (3829 + 958) and those 45-60 (3686 + 958) did not differ significantly ( $p = .89$ ). Patients < 45 years old increased significantly more (603) than patients > 75 years old (311) ( $p < .001$ ). There were no significant differences between diagnoses in mean distance walked prior to cardiac rehabilitation. By diagnosis category (Coronary Artery Bypass Graft Surgery, Myocardial Infarction, Stable Angina, and Other), all groups improved over time ( $p < .001$ ). However, after cardiac rehabilitation, there was a significant change in distance walked between myocardial infarction patients (489) and stable angina patients (315), myocardial infarction patients improving more ( $p = .013$ ).

**CONCLUSIONS:** Upon completion of a cardiac rehabilitation program, all patients regardless of gender, age, and diagnosis significantly improved their 12MWD. This test may be particularly useful to small medical centers and outpatient clinics that desire to evaluate improvement in functional capacity, but do not have access to conventional treadmill tests.

**2383 Board #28 May 29 8:00 AM - 9:30 AM****Aerobic Exercise Training Affects Vascular Endothelial And Cardiac Diastolic Functions In Coronary Artery Disease**

Levent Soyer, Sadi Sanli Kurdak, Mesut Demir, Kerem Tuncay Ozgunen, Medih Celiktas, Cigdem Zeren, Ozlem Ayse Ornek, Esmeray Acarturk, Mehmet Kanadası. *Cukurova University Medical Faculty, Adana, Turkey.*

(No relationships reported)

Endothelial dysfunction is an early manifestation of coronary artery disease (CAD). The heart, as a specialized form of vessel, has an endothelial system which is forming the composition of endocardium. Therefore, endothelial dysfunction may impair the diastolic functions of the heart. The beneficial effect of aerobic exercise on endothelium may also improve the diastolic functions.

**PURPOSE:** The aim of this study was to investigate the effect of aerobic exercise training on vascular endothelial and cardiac diastolic functions.

	Pre Exercise	Post Exercise
Plasma Homocystein (umol/L)	11.86 ± 1.29	14.53 ± 0.93*
Microalbuminuria (mg/L)	14.90 ± 3.04	10.3 ± 3.78*
Flow Mediated Dilatation (%)	10.38 ± 3.61	12.97 ± 3.38*
<b>Mitral Flow</b>

E' (m/s) ± Early diastolic velocity	0.181 ± 0.009	0.161 ± 0.001*
A' (m/s) ± Atrial systolic velocity	0.279 ± 0.030	0.171 ± 0.008*
E' (m/s) ± Ventricular systolic velocity	0.143 ± 0.008	0.131 ± 0.007
E/E'	3.512 ± 0.255	4.242 ± 0.299*

**METHODS:** Eleven patients (8 males and 3 females, mean age 57±2) with stable CAD were included to the study. Blood and urine samples were taken to calculate plasma homocystein (PH) and instant microalbuminuria levels, respectively. Doppler echocardiographic measurements and the amount of brachial flow mediated dilatation (FMD) were achieved. Patients were trained for four weeks with moderate intensity treadmill exercise, regarding the 50% of peak oxygen uptake. All laboratory and echocardiographic examinations were repeated after the training protocol. Paired sample t-test was used to evaluate the level of significance, and p values < 0.05 were accepted as significant.

**RESULTS:** Transmittal peak velocities evaluated by pulsed wave Doppler, tissue Doppler velocities, FMD and laboratory results are summarized in table.

Table \* = indicates the significant difference ( $p < 0.05$ )

**CONCLUSIONS:** Moderate intensity level of exercise improved both endothelial and diastolic functions in patients with CAD. Regular exercise may be an important tool in the CAD treatment protocol. Wide range studies might be helpful to explain the relation of both entities.

(No relationships reported)

Oxidative stress, endothelial cell activation, inflammation and plaque stability are now recognized as important contributors to explain the incidence of atherosclerosis in metabolic syndrome. In this respect it is suggested matrix metalloproteinase (MMP-9) independently predict early risk of cardiovascular disease. Fortunately, recent studies have reported regular exercise may reduce proinflammatory status in patients with metabolic syndrome. On the contrary little attention has been paid regarding plaque destabilization.

**PURPOSE:** For the reasons already mentioned this study was designed to determine the influence of exercise on serum levels of total matrix metalloproteinase-9 (MMP-9) in adult women with metabolic syndrome

**METHODS:** Sixty adult women with metabolic syndrome according to the criteria reported by the National Cholesterol Education Program Adult Treatment Panel III volunteered for this study. Forty-five were randomly included in experimental group to perform a 12-week aerobic training program, 3 days/week, consisting of warm up (10-min), main part (20-35-min [increasing 5 minutes each 3 weeks]) at a work intensity of 60-75% of peak heart rate (increasing 5% each 3 weeks) and cool-down (10min). Control group included 15 age, sex and BMI-matched women with metabolic syndrome that will not perform any program. Written informed consent was obtained. Further our protocol was approved by an institutional ethic committee. Serum total MMP-9 concentration was measured by ELISA, using a commercially available kit (R&D Systems) twice: 72-hours before starting the program (pre-test) and after its ending (post-test).

**RESULTS:** When compared to baseline serum total MMP-9 concentration was decreased significantly after our 12-week protocol ( $886.3 \pm 15.1$  vs  $609.7 \pm 13.2$  ng/ml;  $p < 0.05$ ). No changes were reported in controls.

**CONCLUSIONS:** A 12-week training program decreased serum total MMP-9 concentration in adult women with metabolic syndrome. Further studies on this topic are required.

(No relationships reported)

The clustering of multiple coronary artery disease (CAD) risk factors in the same individual, commonly referred to as the metabolic syndrome is extremely prevalent in westernized societies. Accordingly the examination of the effect of modifying environmental influences (e.g. exercise) is warranted. In this respect, increasing attention has been paid to plasma proteins that originate from adipose tissue, especially adiponectin, which exhibits potent anti-inflammatory and anti-atherosclerotic effects.

**PURPOSE:** The present study was designed to determine the influence of regular exercise on plasmatic adiponectin levels in young male adults with metabolic syndrome.

**METHODS:** Sixty adult men with metabolic syndrome according to the criteria reported by the National Cholesterol Education Program Adult Treatment Panel III volunteered for this study. Forty-five were randomly included in experimental group to perform a 12-week aerobic training program, 3 days/week, consisting of warm up (10-min), main part (20-35-min [increasing 5 minutes each 3 weeks]) at a work intensity of 60-75% of peak heart rate (increasing 5% each 3 weeks) and cool-down (10-min). Control group included 15 age, sex and BMI-matched men with metabolic syndrome that will not perform any program. Written informed consent was obtained. Further our protocol was approved by an institutional ethic committee. Plasma adiponectin was assessed using a commercially available radioimmunoassay kit (HADP-61HK) 72-hours before starting the program (pre-test) and 72-hours after its ending (post-test).

**RESULTS:** When compared to baseline IL-6 levels were decreased significantly after being exercised ( $6.3 \pm 1.2$  vs  $8.0 \pm 1.4$  pg/ml;  $p < 0.05$ ). On the contrary no changes were reported in controls

**CONCLUSIONS:** It may be concluded regular exercise may increase plasmatic adiponectin levels in young male adults with metabolic syndrome. Further studies on this topic are still required.

(No relationships reported)

It is widely accepted P-selectin is a cell-surface adhesion molecule involved in leukocyte rolling and attachment that has been studied in various inflammatory and pro-thrombotic disorders. In fact P-selectin is increased in patients with early atherosclerosis or those with manifest atherosclerotic disease. Fortunately regular exercise may reduce circulating levels of cardiovascular inflammatory markers in patients with metabolic syndrome.

**PURPOSE:** Accordingly this study was designed to determine the influence of exercise on soluble plasmatic P-selectin levels in women with metabolic syndrome.

**METHODS:** Sixty adult women with metabolic syndrome according to the criteria reported by the National Cholesterol Education Program Adult Treatment Panel III volunteered for this study. Forty-five were randomly included in experimental group to perform a 12-week aerobic training program, 3 days/week, consisting of warm up (10-min), main part (20-35-min [increasing 5 minutes each 3 weeks]) at a work intensity of 60-75% of peak heart rate (increasing 5% each 3 weeks) and cool-down (10-min). Control group included 15 age, sex and BMI-matched women with metabolic syndrome that will not perform any program. Written informed consent was obtained. Further our protocol was approved by an institutional ethic committee. Circulating levels of soluble P-Selectin were measured with an enzyme-linked immunosorbent assay (ELISA) using monoclonal antibodies (Parameter, R&D Systems) twice: 72-hours before starting the program (pre-test) and after its ending (post-test).

**RESULTS:** When compared to baseline soluble P-Selectin concentration was not decreased significantly after our 12-week protocol based on exercise ( $131.6 \pm 8.1$  vs  $126.8 \pm 7.7$  ng/ml;  $p > 0.05$ ). On the contrary, no changes were reported in controls.

**CONCLUSION:** A 12-week aerobic training program did not change significantly circulating levels of soluble plasmatic P-Selectin in women with metabolic syndrome. Further studies on this topic are required.

**2387 Board #32 May 29 8:00 AM - 9:30 AM**  
**Exercise With Arb Improved Metabolic Syndrome Risk Factors And Exercise-induced Cardio-renal Disorganization In Oletf Rats**

Yuka Nagashima, Daisuke Shindo, Masato Suzuki. *The Jikei University School of Medicine, Tokyo, Japan.*  
(No relationships reported)

**PURPOSE:** Exercise is one of the treatments for hypertension. However, our previous study showed no antihypertensive effects of exercise in Otsuka Long-Evans Tokushima Fatty (OLETF) rats. Exercise activates sympathetic nervous activity and renin-angiotensin-aldosterone system, which may lead to cardio-renal disorganization, via elevated blood pressure (BP) or direct actions of angiotensin II (Ang II). This study investigated the effects of combination treatment with exercise and Ang II receptor blocker (ARB) on metabolic syndrome (MS) risk factors and morphological findings of the heart and kidney in OLETF rats.

**METHODS:** Male OLETF rats were assigned to exercise (Ex, n = 7), ARB (ARB, n = 8), exercise with ARB (Ex & ARB, n = 8), and sedentary control (Sed, n = 9) groups. Exercise was performed by using a rotatory wheel. ARB, telmisartan (10 mg/kg/day), was blended in a powdered feed. Body weight, BP, and urinary albumin excretion were measured during the treatment. Oral glucose tolerance test was performed before and after the treatment. After the treatment, the heart, kidney, skeletal muscles, visceral fat, and subcutaneous fat were removed and weighed. Interstitial myocardial fibrotic area (IMFA) of the heart and glomerular area (GA) and mesangial area (MA) of the kidney were measured using an imaging analyzer.

**RESULTS:** In both the Ex and Ex & ARB groups, body weight and visceral fat weight (g/kg) were reduced, skeletal muscle weight (g/kg) was increased, and the glucose,

HbA1c, TC, TG, and LDL-C levels were improved significantly compared with those of the Sed group. However, BP of the Ex group was significantly higher than that of the Ex & ARB and ARB groups. The heart weight (g/kg) and urinary albumin excretion in the Ex group were significantly higher than those of the Sed group, while the Ex & ARB group showed a non-significant increase in these variables. In addition, BP correlated significantly with heart weight, IMFA, kidney weight, and MA.

**CONCLUSION:** The single treatment with exercise didn't have antihypertensive effects, while it improved MS risk factors such as visceral fat, glucose intolerance, and dyslipidemia. On the other hand, the combination treatment with exercise and ARB could lower elevated BP, improved MS risk factors, and inhibited exercise-induced cardiac hypertrophy and albuminuria in OLETF rats.

**2388 Board #33 May 29 8:00 AM - 9:30 AM**  
**Relationship Between Regional Adiposity And Risk For Cardiovascular Disease In College Aged Students**

Laura Swan, David Q. Thomas, FACSM, Karen K. Dennis, Ashley Reum, Lindsay Gallovitch. *Illinois State University, Normal, IL.*  
(No relationships reported)

Studies stress the importance of body fat distribution when determining risk for cardiovascular and metabolic diseases, often citing adiposity in the trunk as a main indicator for these health problems. However, risk factors in college aged individuals have not been thoroughly investigated.

**PURPOSE:** To determine the relationship between regional adiposity and risk for cardiovascular disease in college aged students.

**METHODS:** Fifty male and female students (mean age 20.4 years, SD  $\pm 1.19$ ) participated in the study. Institutional Review Board approval was obtained. After each subject completed an informed consent, medical health history, and a cardiac risk evaluation worksheet, physical measurements (height and weight for calculation of BMI, waist and hip circumference for calculation of WHR, as well as both peripheral and truncal skinfolds) were obtained. Each subject also underwent air displacement plethysmography (ADP) testing for assessment of body fat percentage.

**RESULTS:** Descriptive statistics (means and standard deviations) were calculated for all data and Pearson Product-Moment Correlations were used to determine the relationship between regional adiposity and cardiac risk. The entire sample showed a significant correlation between waist circumference ( $r = 0.34$ ) and BMI ( $r = 0.34$ ) with cardiac risk. Men showed a significant correlation between peripheral skinfolds ( $r = 0.47$ ), body fat percentage ( $r = 0.49$ ), and cardiac risk, while women did not show any significant relationships.

**CONCLUSIONS:** There appears to be a significant relationship between cardiac risk and body composition in this population. The strongest relationships were found for the male subjects. No relationship was found between truncal skinfolds and cardiac risk. This may be due to the low relative risk in subjects of this age group. Future research is necessary to explore why body composition was not related to cardiac risk in female subjects and to determine at what age truncal adiposity becomes related to cardiac risk.

**Obstructive Sleep Apnea Alters Exercise Blood Pressure Responses in Normal Weight Men**

Laura J. Newsome, Adrian Aron, William G. Herbert, FACSM. *Virginia Tech, Blacksburg, VA.*  
Email: lnewsome@vt.edu  
(No relationships reported)

In adult obstructive sleep apnea (OSA), severity of the disorder generally increases in proportion to the degree of obesity. OSA severity is also correlated to the increase in resting blood pressure and the onset of hypertension. Apneas caused by upper airway collapse lead to repetitive sympathetic activations, arousals, and fragmented sleep. These 'events' appear fundamental to the mechanisms by which OSA independently contributes to development of hypertension (Nieto *et al.* JAMA, 2000). Exaggerated blood pressure during exercise has been shown in some studies to predict future development of hypertension; recent studies have demonstrated exercise responses are altered in the presence of OSA. Since OSA is generally associated with overweight or obese individuals, little is known about exercise blood pressure responses in normal-weight subjects.

**PURPOSE:** To determine whether mild OSA alters exercise systolic and diastolic blood pressure responses in normal-weight young men.

**METHODS:** Eight normal-weight men with mild OSA [apnea-hypnea index (AHI: Mean  $\pm$  SD) =  $8.0 \pm 2.8$  events/hr; body mass index (BMI) =  $21.8 \pm 1.5$  kg/m<sup>2</sup>; age =  $22.1 \pm 2.9$  years] and seventeen control men without OSA (AHI =  $1.9 \pm 1.1$  events/hr; BMI =  $22.4 \pm 1.6$  kg/m<sup>2</sup>; age =  $21.1 \pm 2.1$  years) completed a maximal graded cycle ergometer exercise test (GXT). During the GXT, blood pressure (BP), heart rate (HR), rating of perceived exertion (RPE), respiratory exchange ratio (RER), and oxygen consumption (VO<sub>2</sub>pk) were measured throughout.

**RESULTS:** Age, BMI, resting HR and BP, mean arterial pressure (MAP) were not different between men with and without OSA. During exercise in the OSA group, mean systolic BP was 5 to 11% lower ( $p \leq 0.05$ ) at all intensities, whereas diastolic BP in the OSA group was lower only at submaximal intensities ( $p \leq 0.05$ ). At peak exercise, maximal endpoints for HR, RPE, RER, and VO<sub>2</sub>pk were not different between the groups.

**CONCLUSION:** Normal weight OSA subjects have a unique response to GXT, characterized by blunted BP responses, which are different than the exaggerated BP responses previously reported for overweight adults with OSA. This unexpected result requires further research to understand the mechanistic differences in OSA in the absence of obesity.

*Parts of the research were Supported by a grant from ResMed Corporation, San Diego, CA.*

**Cross Tolerance Effect Of Endurance Training Against In Vitro Cardiac Mitochondrial Dysfunction In Diabetes**

Antonio Ascensao<sup>1</sup>, Jose A. Lumini<sup>1</sup>, Paulo J. Oliveira<sup>2</sup>, Cláudia V. Pereira<sup>2</sup>, José Magalhães<sup>1</sup>. <sup>1</sup>Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>Centre for Neurosciences and Cell Biology, University of Coimbra, Coimbra, Portugal. (Sponsor: FCT grants SFRH/BPD/4225/2007; SFRH/BD/30906/2006, FACSM)  
Email: aascensao@fade.up.pt  
(No relationships reported)

Cardiac dysfunction characterizing diabetes has been associated with mitochondrial impairments. On the other hand, endurance training (ET) provides protection against cardiac mitochondrionopathies.

**PURPOSE:** To analyze the effects of ET on cardiac mitochondrial dysfunction caused by streptozotocin (STZ) treatment, particularly on the susceptibility to mitochondrial permeability transition pore (mPTP) opening.

**METHODS:** Twenty four adult male Wistar rats were randomly divided into sedentary (Sed), sedentary STZ (single dose, 50 mg/kg, i.p.), ET (14 wk treadmill running, 60 min/day, 25m/min) and ET+STZ (TSTZ). After STZ injection (18 wk), isolated heart mitochondria were used for in vitro oxygen consumption and transmembrane potential (D $\Psi$ ) assessment using malate-pyruvate (MP) and succinate plus rotenone (SR). Cyclosporin A (CyA)-sensitive mitochondrial osmotic swelling and Ca<sup>2+</sup> fluxes were also measured to study mPTP opening susceptibility.

**RESULTS:** In sedentary groups, STZ treatment resulted in decreased state 3 ( $165.6 \pm 6.8$  vs  $136.7 \pm 5.7$  natomO/min/mg;  $p < 0.05$ ), respiratory control ratio ( $9.9 \pm 0.4$  vs  $4.9 \pm 0.3$ ;  $p < 0.05$ ), CCCP-induced uncoupled respiration ( $394.4 \pm 7.1$  vs  $277.8 \pm 6.3$  natomO/min/mg;  $p < 0.05$ ), oligomycin-inhibited respiration ( $115.8 \pm 6.6$  vs  $74.9 \pm 7.8$  natomO/min/mg;  $p < 0.05$ ) and increased state 4 ( $16.7 \pm 0.6$  vs  $27.3 \pm 2.5$  natomO/min/mg;  $p < 0.05$ ), D $\Psi$  with endogenous substrates ( $185.9 \pm 2.9$  vs  $194.9 \pm 1.4$  mV;  $p < 0.05$ ) and lag phase ( $70.0 \pm 2.1$  vs  $112.0 \pm 2.1$  s;  $p < 0.05$ ) (MP). It decreased both state 3 ( $394.3 \pm 7.1$  vs  $276.7 \pm 7.9$ ;  $p < 0.05$ ) and state 4 ( $117.0 \pm 4.0$  vs  $75.4 \pm 3.9$ ;  $p < 0.05$ ) with SR. STZ treatment decreased CyA-sensitive Ca<sup>2+</sup> uptake ( $250.8 \pm 4.8$  vs  $220.8 \pm 1.4$  nmol/mg;  $p < 0.05$ ) and release ( $64.8 \pm 7.0$  vs  $47.9 \pm 3.4$ ;  $p < 0.05$ ), despite the increased swelling amplitude ( $3.5 \text{E}6 \pm 1.9 \text{E}5$  vs  $4.1 \text{E}6 \pm 3.7 \text{E}4$  AU;  $p < 0.05$ ) in sedentary groups. The respiratory and D $\Psi$  parameters impaired by STZ treatment were reverted by ET (STZ vs TSTZ). ET increased

mitochondrial Ca<sup>2+</sup> uptake (220,8±1.4 vs 273,1±3.7; p<0,05) and decreased Ca<sup>2+</sup> release (47,9±3.4 vs 30,1±2.1; p<0,05) in diabetic animals.

**CONCLUSION:** ET reverted the impaired heart mitochondrial respiratory function caused by STZ and decreased the susceptibility to mtPTP opening.

FCT grants SFRH/BPD/4225/2007; SFRH/BD/30906/2006.

**2391 Board #36 May 29 8:00 AM - 9:30 AM**

**Effects Of Exercise Training On Arterial Stiffness And Vasoactive Hormonal Levels Of Normotensive Young Women At High Familial Risk Of Hypertension**

Emmanuel G. Ciolac, Edimar A. Bocchi, Luiz A. Bortolotto, Júlia M. Greve, Guilherme V. Guimarães. *University of São Paulo, Medical School, Sao Paulo, Brazil.*

Email: egciolac@hcnet.usp.br

(No relationships reported)

**BACKGROUND:** Offspring of essential hypertensive parents (OHT) are at high risk of future hypertension and subsequent cardiovascular diseases. Whether alterations on arterial stiffness and vasoactive hormonal levels precede the increase in blood pressure (BP) is not well established. Moreover, there is little information about the effects of exercise training (ET) in OHT.

**PURPOSE:** To evaluate arterial stiffness and vasoactive hormonal levels in normotensive women OHT, as well as the effects of ET on these variables.

**METHODS:** First, we studied 44 healthy sedentary young women aged 19 to 30 years: 15 had two hypertensive parents (OHT<sub>2</sub>), 17 had one hypertensive parent (OHT<sub>1</sub>), and 12 had no hypertensive parents (ONT). Ambulatory BP monitoring (ABPM), arterial stiffness (carotid-femoral pulse wave velocity [PWV]), and nor-epinephrine (NE) and epinephrine (EPI) levels at rest, immediately after (exercise) and ten minutes after (recovery) a graded exercise test were evaluated. Second, the OHT women were randomly assigned to ET (OHT<sub>ex</sub>; 40 minutes walking or running at 70% of VO<sub>2PEAK</sub> three times-a-week) or control (OHT<sub>con</sub>) group, and had their ABPM, PWV, NE and EPI levels analyzed after 16 weeks of follow-up.

**RESULTS:** ABPM was not different between groups at baseline. However, PWV was 7.2% and 11.7% higher in OHT<sub>2</sub> than OHT<sub>1</sub> and ONT, respectively (p ≤ 0.01). Rest, exercise and recovery NE were 37.9% to 47.9% higher in OHT<sub>2</sub> than ONT (p ≤ 0.003), while rest and recovery NE were 36% and 26.5% higher in OHT<sub>1</sub> than ONT (p ≤ 0.047). Exercise EPI were also higher in OHT<sub>2</sub> than ONT (p ≤ 0.047), and recovery EPI were higher in OHT<sub>2</sub> than OHT<sub>1</sub> and ONT (p ≤ 0.01), respectively. On the other hand, ET reduced PWV (p = 0.01) and basal NE (p = 0.003) in OHT<sub>ex</sub> to levels similar to those of ONT. OHT<sub>ex</sub> also showed tendency toward reduction (p = 0.06) in exercise NE after exercise training. PWV, NE and EPI did not change in OHT<sub>con</sub> after follow-up.

**CONCLUSIONS:** Arterial stiffness and vasoactive hormonal levels were increased in normotensive women offspring of hypertensive parents, but were reduced by exercise training to levels similar to those of women without familial history of hypertension. These results suggest that exercise training may have a potential role in the management of an inherited hypertensive disorder.

**2392 Board #37 May 29 8:00 AM - 9:30 AM**

**Decreasing Superoxide Within The Nucleus Tractus Solitarius Partially Corrects Skeletal Muscle Mechanoreflex Overactivity In Hypertension**

Megan N. Hawkins, Anna K. Leal, Jere H. Mitchell, FACSM, Scott A. Smith. *UT Southwestern Medical Center, Dallas, TX.*

Email: megan.hawkins@utsouthwestern.edu

(No relationships reported)

In hypertension, the blood pressure (BP) response to exercise is abnormally elevated. We have previously demonstrated that overactivity of the skeletal muscle mechanoreflex (MMR) plays a significant role in generating this exaggerated BP response to exercise. Yet the mechanisms underlying MMR overactivity remain unknown. Sensory information elicited by activation of the MMR is processed within the nucleus tractus solitarius (NTS) of the medulla oblongata. In normotensive rats, nitric oxide (NO) within the NTS is known to buffer MMR function. Recent evidence suggests the production of reactive oxygen species in the NTS, specifically superoxide (a NO scavenger), is increased in hypertension. Therefore, augmentations in superoxide production could reduce the NO available for biological activity. This may reduce the buffering capacity of NO in hypertension resulting in MMR overactivity.

**PURPOSE:** To determine the effects of endogenously produced superoxide on MMR activity in male normotensive Wistar-Kyoto (WKY; n=4) and Spontaneously Hypertensive (SHR; n=5) rats.

**METHODS:** The MMR was selectively activated by passively stretching hindlimb skeletal muscle before and after the microdialysis of the superoxide dismutase mimetic, tempol (30 μM) in the NTS. Superoxide dismutase is the endogenous enzyme responsible for the breakdown of superoxide.

**RESULTS:** Activation of the MMR by stretch resulted in significantly larger increases in mean BP in SHR (58±5 mmHg) than WKY (22±3 mmHg). In both groups, dialysis of tempol reduced the BP response to stretch. Interestingly, the magnitude of the tempol-induced decrease in BP in response to MMR activation was larger in SHR (-24±6 mmHg) compared to WKY (-7±4 mmHg). Despite this larger effect, the stretch-induced augmentation in BP in SHR treated with tempol was greater than the BP increase elicited by stretch in untreated WKY.

**CONCLUSIONS:** The results demonstrate that endogenously produced superoxide modulates MMR activity in both WKY and SHR animals. Further, the findings suggest that decreasing superoxide within the NTS can partially correct the exaggerated BP response to activation of the MMR in SHR. As such, the data are consistent with the concept that increases in superoxide production within the NTS contribute to MMR dysfunction in hypertension.

**Phase I Cardiac Rehabilitation, Physical Activity Levels And Exercise Capacity In Coronary Artery Disease Patients**

Fernando Ribeiro<sup>1</sup>, Madalena Teixeira<sup>2</sup>, Fátima Miranda<sup>2</sup>, Alberto J. Alves<sup>1</sup>, Mónica Pinho<sup>2</sup>, Cristina Azevedo<sup>2</sup>, José A. Duarte<sup>1</sup>, José Oliveira<sup>1</sup>.

<sup>1</sup>University of Porto, Faculty of Sport, Research Centre in Physical Activity, Health and Leisure, Porto, Portugal. <sup>2</sup>Vila Nova de Gaia Hospital Centre, Vila Nova de Gaia, Portugal.

Email: fernando.silva.ribeiro@gmail.com

(No relationships reported)

Previous studies have determined the amount of physical activity (PA) in patients with coronary artery disease (CAD) enrolled in phase II/III cardiac rehabilitation programs (CRP). However, it must be highlighted that the number of patients that reach the phase II/III of CRP is smaller than the potential candidates, since a minority of eligible patients actually enrol CRP. In this sense, the information given in phase I in-hospital CRP is paramount to the adoption of an active lifestyle. Additionally, a positive relationship between daily PA and exercise capacity is established in healthy adults. To date, no studies exist in CAD patients, where direct measurements of VO<sub>2</sub> and accelerometers have been used to study the relationship between exercise capacity and daily PA.

**PURPOSE:** To analyze the habitual PA levels of CAD patients after a phase I CRP and its relation to exercise capacity.

**METHODS:** Forty-three consecutive, sedentary, patients (36 male; age: 54.5 ± 11.1 yrs; weight: 79.6 ± 15.6 kg; height: 168 ± 8.0 cm; BMI: 28.2 ± 4.9 kg/m<sup>2</sup>) with recent history of first myocardial infarction (65% percutaneous coronary intervention) were recruited. Assessment included cardiopulmonary graded exercise testing and PA measured

objectively during seven consecutive days by accelerometry. During hospitalization patients received counseling concerning the deleterious effects of cardiovascular risk factors on health and strategies for their management. All the assessment procedures were conducted six weeks after hospital discharge (none of the patients was enrolled in a phase II CRP at that time).

**RESULTS:** The average daily amount of light, moderate, and vigorous PA was, respectively,  $595.8 \pm 114.6$  min,  $38.7 \pm 29.7$  min, and  $0.73 \pm 2.3$  min. The number of 10-minute bouts of moderate-intensity PA was  $0.75 \pm 0.90$ . Mean peak oxygen uptake was  $31.9 \pm 7.4$  mL/min/kg and exercise time averaged  $9.26 \pm 2.23$  min. Only PA of moderate-intensity was significantly related to peak oxygen uptake ( $r = 0.348$ ,  $p = 0.02$ ) and exercise time ( $r = 0.359$ ,  $p = 0.01$ ).

**CONCLUSIONS:** The information provided in a phase I CRP led patients to perform enough moderate-intensity PA to meet health-related recommendations. Importantly, exercise capacity was only related to PA of moderate-intensity. Thus, emphasis should be given to the improvement of moderate intensity PA.

Email: s-crouse@tamu.edu

(No relationships reported)

Blood N-terminal pro-brain natriuretic peptide (NT-proBNP), a known marker for heart failure, is released from ventricles in response to stretch of cardiomyocytes.

**PURPOSE:** Cardiac patients (68 women, 296 men, aged  $63 \pm 11$  yr) were categorized by echo-derived ejection fraction (EF) into 4 groups (EF >55%, 45 - 55%, 30 - 44%, <30%), then studied for changes in NT-proBNP and training effects before and after  $25 \pm 4$  days of residential cardiac rehabilitation.

**METHODS:** Exercise training consisted of 6 x wk cycle ergometry for 14 - 22 min (mean  $17 \pm 4$  min), and daily walking for 45 min at 60 - 70% maximal heart rate (HRmax). Nutrition, diet, and pharmacologic prescriptions were initiated when indicated.

**RESULTS:** see table.

EF (%)	Rehab Status	NT-proBNP (pg.mL <sup>-1</sup> )	VO2max (mL.min <sup>-1</sup> )	Rest HR (bpm)
>55%	Before	726±996	1870±557	73±14
	After	470±569*	2083±567*	66±13*
45-55%	Before	796±768	1815±549	73±13
	After	573±511*	2059±585*	69±11*
30-44%	Before	1607±1882	1872±523	75±14
	After	1278±1140*	1984±517*	73±13
<30%	Before	2761±2098	1651±503	80±16
	After	1574±1138*	1930±569*	74±15*

Table . \* indicates  $p < 0.05$  for difference from before cardiac rehab

In addition to changes with training, NT-proBNP was significantly greater before rehab training in patients with EF <30% and EF 30-44% than those with higher EF. This remained true after training in spite of significant NT-proBNP reductions in all EF groups.

**CONCLUSIONS:** These significant findings in only 25 days suggest a relatively powerful effect of short-term exercise training to improve myocardial function in cardiac patients regardless of initial EF, and to at least partially ameliorate the symptoms of ventricular systolic and diastolic insufficiency.

**The Impact Of Exercise Training On Oxidative Stress In Spinal Cord-injured Individuals**

Noortje T.L. van Duijnhoven<sup>1</sup>, Evelyn Hesse<sup>2</sup>, Thomas Janssen, FACSM<sup>3</sup>, Marc Knippenberg<sup>4</sup>, Peter Scheffer<sup>5</sup>, Maria Hopman, FACSM<sup>1</sup>. <sup>1</sup>Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands. <sup>2</sup>ETH, Zurich, Switzerland. <sup>3</sup>Research Institute MOVE, Amsterdam, Netherlands. <sup>4</sup>AZ Maastricht, Maastricht, Netherlands. <sup>5</sup>VU Medical Centre, Amsterdam, Netherlands.

(No relationships reported)

Spinal cord-injured (SCI) individuals have a high prevalence of morbidity and mortality due to cardiovascular diseases, which is unlikely explained by traditional CVD risk factors. Recent studies suggest that an imbalance in (anti)oxidative status is associated with an increased cardiovascular risk. However, little is known about the (anti)oxidative balance in SCI.

**PURPOSE:** To compare baseline levels of oxidative stress and antioxidative capacity in SCI individuals and able-bodied (AB) subjects, and to assess acute and long-term effects of functional electrical stimulation (FES) exercise on oxidative stress and antioxidative capacity in SCI individuals.

**METHODS:** Venous blood was taken from SCI ( $n=9$ ;  $41 \pm 9$  years) and age-matched AB subjects ( $n=9$ ;  $42 \pm 10$  years) to examine oxidative stress through malondialdehyde (MDA) levels, while superoxide dismutase (SOD) and glutathione peroxidase (GPx) enzyme levels represented anti-oxidative capacity. Subsequently, SCI subjects performed an 8 week FES exercise training period. Blood was taken after the first and last FES exercise session to examine the acute effect of FES exercise. Baseline blood samples before the last FES exercise session were used to assess the chronic effect of FES exercise.

**RESULTS:** Baseline levels of MDA, SOD and GPx were not different between SCI and AB subjects. Both, a single bout of FES exercise and 8 weeks of FES exercise training, had no effect on MDA, SOD and GPx levels.

**CONCLUSIONS:** The preserved (anti)oxidative status in SCI suggests that the increased prevalence for CVD in SCI is unlikely explained by (anti)oxidative imbalance. In contrast with previous studies in AB, we found no changes in (anti)oxidative status after acute and long-term FES exercise in SCI. Possibly, the stimulus induced by FES exercise is insufficient to change (anti)oxidative status in SCI individuals.

**2396 Board #41 May 29 8:00 AM - 9:30 AM**

**No Acute Exercise Effect On Inflammatory And Oxidative Stress Markers In Lean And Obese Children.**

Teresa A. Sharp, Sara D. Mathews, Cherith A. Gordon, Nancy F. Krebs, Tracy J. Horton. *Univ. of Colorado Denver, Aurora, CO.*  
Email: Teresa.Sharp@UCDenver.edu  
(No relationships reported)

Elevated biomarkers of inflammation and oxidative stress are associated with increased relative risk of cardiovascular disease in adults. The impact of obesity, diet, and acute exercise on these markers in young children are unknown.

**PURPOSE:** To determine the effect of obesity and/or acute exercise (EX) on fasting and post-meal inflammatory and oxidative stress markers in pre- and early-pubertal children.

**METHODS:** We studied the effects of a high-fat test meal on inflammatory markers (CRP, IL-6, TNF $\alpha$ ) and oxidized LDL (ox-LDL) in 23 children (Tanner 1-3, 10 $\pm$ 2yrs, 11 lean/12 obese, 11M/12F) during 2 separate study days of rest (RST) or EX (random order) each preceded by 3 days of diet/exercise control. The afternoon prior to the study day (5pm) subjects rode a cycle ergometer (25 min @ 65% max HR) or rested for the same time period. The following morning (7:30am) a milkshake test meal (50% fat, 20% protein and 30% carbohydrate) was consumed. Subjects remained resting during the study day. Blood was drawn before and after the EX bout, and before and 3 times after the test meal (6 samples EX, 5 samples RST). Main effects of group, condition, and group x condition were tested by repeated measures ANOVA; alpha set at  $p < 0.05$ .

**RESULTS:** As expected, obese were heavier ( $p < 0.0001$ ) with higher fat mass ( $p < 0.0001$ ) than lean. Fasting CRP ( $1.12 \pm 0.84$  vs  $0.13 \pm 0.11$  mg/L,  $p < 0.01$ ), IL-6 ( $97 \pm 81$  vs  $40 \pm 39$  pg/ml,  $p < 0.05$ ) and ox-LDL ( $54 \pm 12$  vs  $40 \pm 12$  U/L,  $p < 0.05$ ) were greater in obese than lean, but fasting or post-meal TNF $\alpha$  did not differ by group. EX had no effect on pre- or post-meal levels of these biomarkers, nor did the test meal change concentrations from fasted values.

**CONCLUSIONS:** Obese had greater fasting CRP, IL-6 and ox-LDL than lean children. Neither EX nor a high-fat meal changed these markers in lean or obese children. The lack of change in these markers in response to the meal suggests that acute consumption of high dietary fat does not increase these markers above levels seen due to obesity alone, and that increased levels of inflammation and oxidative stress are related to chronic obesity. These data have important chronic health implications for children with elevated adiposity, and suggest that long-term behavior modification strategies are necessary for reversal of this detrimental condition.

(No relationships reported)

Research is needed to clarify the meaning of CRP concentrations in healthy, younger, non-obese individuals.

**PURPOSE:** To determine whether anthropometric characteristics, physical activity, cardiorespiratory fitness, diet, and variables related to metabolic syndrome (e.g. blood lipids, glucose, insulin, inflammation markers) differ across CRP tertile groups in healthy, young, non-obese adults.

**METHODS:** This was a cross-sectional study in which 42 non-obese men and women (18-27 y) were assessed using a VO<sub>2</sub>max test for cardiorespiratory fitness, bio-impedance analysis (BC-418 8 contact electrode) for total and regional body composition, ActiGraph accelerometry for 7 days physical activity assessment, a 110 item Block 2005 Food Frequency Questionnaire (FFQ) for dietary intake patterns, two fasting blood draws for analysis of CRP, blood lipids, interleukin-6 (IL-6), soluble tumor necrosis factor receptor-1 (sTNFR1), glucose, insulin, and homeostatic model assessment (HOMA) for estimation of insulin resistance and beta-cell function.

**RESULTS:** CRP concentrations ranged from 0.150-0.304, 0.324-1.115, and 1.127-11.836 mg·dl<sup>-1</sup> for Low, Average, and High CRP tertiles, respectively. The groups had similar proportions of men and women, anthropometric characteristics, blood lipids, IL-6, sTNFR1, physical activity, and HOMA variables (even though blood glucose was higher in the Low compared to High group). VO<sub>2</sub>max was higher in the Average compared to the High CRP group. Similarly, estimates from the FFQ were indicative of a higher quality diet, primarily in the form of increased dairy consumption, in the Average ( $2.7 \pm 1.5$  servings/day) compared to the High CRP ( $1.2 \pm 0.4$  servings/day) groups. Consistent with the higher intake of dairy was a higher ( $P < 0.05$ ) intake of calcium, retinol, Vitamins A and D, and a lower overall glycemic index in the Average compared to High CRP group.

**CONCLUSIONS:** Higher dairy consumption and cardiorespiratory fitness were the variables differentiating young, healthy non-obese individuals between Average and High CRP tertiles. Anti-inflammatory effects of increased dairy consumption have been identified in previous research.

**Carbohydrate And Protein Intake Before, During, And After Exercise: Are Active Women Following Current Recommendations?**  
Lynn A. Cialdella-Kam, Katherine Lewis, Melinda M. Manore, FACSM, Lanae M. Joubert. *Oregon State University, Corvallis, OR.*  
(No relationships reported)

Optimal intakes of Carbohydrate (CHO) and Protein (PRO) prior, during, and after exercise can yield improved exercise performance, recovery from exercise, and adaptations to training. Recommendations for active individuals have been developed based on research examining the relationship between dietary intake and exercise. To our knowledge, only one study has examined whether active women follow these recommendations.

**PURPOSE:** To determine if CHO and PRO intake in active women before, during, and after exercise meet current recommendations.

**METHODS:** Secondary analysis data analysis was performed on young, aerobically trained women ( $n=17$ , age =  $26 \pm 4$ y,  $>420$  min·wk<sup>-1</sup> of exercise), who participated in a study examining the relationship between physical activity (PA) and blood homocysteine levels. PA was assessed using 7-d PA records. CHO and PRO intake were assessed using 7-d weighed food records. Unpaired t-tests ( $\alpha=0.05$ ) were used to determine if mean CHO and PRO intakes (g·kg<sup>-1</sup> or total g·d<sup>-1</sup>), timing (min before/after exercise), and frequency (number of meals after exercise) were different from recommendations.

**RESULTS:** It is recommended that active individuals consume 150-300g of CHO in the 2-4h prior to exercise and 60g·h<sup>-1</sup> of CHO during exercise bouts  $>1$ h. Results showed that 74% of the time women consumed a pre-exercise meal before exercise. When food was consumed prior to exercise, the mean CHO intake was 74g, which is less than current recommendations ( $p < 0.0001$ ). The mean duration of the exercise bouts was 70 min, with 38% lasting  $>1$ h. Only 19% of the women who exercised  $>1$ h consumed CHO during exercise (mean CHO intake = 51g). Post-exercise recommendations for active individuals are to consume 1.0-1.2 g·kg<sup>-1</sup>·h<sup>-1</sup> of CHO and 0.3-0.4 g·kg<sup>-1</sup>·h<sup>-1</sup> of PRO every 30-60 min after exercise for 5h. 91% of the time, the women consumed at least one meal after exercise (1.6 post-exercise meals). However, the first meal was not consumed until 81 min after completion of exercise. The mean CHO intake was also below recommendations (0.45 g·kg<sup>-1</sup>·h<sup>-1</sup> of CHO,  $p=0.0009$ ) but PRO intake was not significantly lower (0.14 g·kg<sup>-1</sup>·h<sup>-1</sup> of PRO,  $p=0.21$ ).

**CONCLUSION:** Although recommendations for CHO and PRO intake before, during, and after exercise have been published, the active women in this study did not adhere to current

(No relationships reported)

Mozambique is a southeastern African nation in the beginning stages of major socioeconomic changes which will result in changes in infrastructure and in diet and exercise patterns that will alter the disease profile of the nation from predominantly infectious diseases and nutrition-related health problems associated with poverty, such as stunting, to nutrition-related chronic diseases and health problems that arise as abject poverty abates, such as obesity and diabetes. It is of interest to determine to what extent the better economic climate in Mozambique during the last decade may have altered the foods available to rural children of Calanga and/or affected their nutrition status.

**PURPOSE:** To describe the quality of foods consumed by rural children in Mozambique in relation to their nutrition status.

**METHODS:** A descriptive, cross-sectional study of children in a rural farming region on the southeast coast of Mozambique lacking adequate access to roads, electricity, health services, sanitation and water was completed. Dietary information for 271 children was evaluated using the Mozambican Diet Assessment Tool (MDAT). Children, ages 5 to 18 y, were measured for height and weight to calculate nutrition status according to international norms.

**RESULTS:** Data demonstrated a high prevalence of stunting: more than one-fourth of both boys and girls. Only 4 children were classified as overweight. Food records showed that 49% of diets were of low or very low quality as estimated by the MDAT index. Children classified as wasted with low weight-for-height, were more likely to have reported diets of low or very low quality ( $p=0.05$ ). Diet quality improved if the child had consumed lunch at school.

**CONCLUSIONS:** Low quality diets may be a major factor underlying the poor nutrition status of the children of Calanga.

Supported by funds from the World Bank Quick Impact Fund through the Higher Education -I Project of the Ministry of Science and Technology.

**Determination Of The Glycemic Index Of Selected Chinese Traditional Foods Using Different Glucose Analyzers**

Stephen H.S. Wong, FACSM, Fenghua Sun, Yajun Chen, Yajun Huang. *The Chinese University of Hong Kong, Hong Kong, China.*

Email: hsswong@cuhk.edu.hk

(No relationships reported)

**PURPOSE:** To determine the glycemic index (GI) of 4 Chinese traditional foods and compare the agreement between portable glucose monitoring system (PoG) and the YSI glucose analyzer in determining the GI of the test foods.

**METHODS:** Thirteen healthy adults (8 males and 5 females, age:  $26.0 \pm 1.3$  y, BMI:  $21.5 \pm 0.6$  kg·m<sup>-2</sup>) volunteered to participate the experiment. All subjects were required to refrain from alcohol consumption and vigorous physical activities 24h before test. After 10-14h overnight fast, the subjects consumed either reference (50g anhydrous glucose) or test foods containing 50g of available carbohydrate. The food included baked barbecued pork puff (BBPP), fried rice in Yangzhou-style (FRYS), fried fritter (FF), and "Mai-lai" cake (MLC). The finger-prick blood samples were collected immediately before, 15, 30, 45, 60, 90, and 120min after food consumption, and were analyzed with portable glucometer (Glucometer Elite, Bayer Diagnostics, Japan) and YSI glucose analyzer (YSI 1500, USA). The GI was calculated by expressing the incremental area under the blood glucose response curve (IAUC) for each test food as a percentage of each subject's average IAUC for the glucose.

**RESULTS:** The mean glucose concentrations measured by PoG were higher than that measured by YSI ( $5.58 \pm 0.05$  vs.  $5.39 \pm 0.05$  mmol·L<sup>-1</sup>,  $P<0.01$ ). However, there were no differences in average IAUC ( $136.3 \pm 8.3$  vs.  $135.8 \pm 7.7$  mmol·min·L<sup>-1</sup>) and GI ( $62.7 \pm 4.6$  vs.  $68.8 \pm 4.6$ ) between PoG and YSI. There were no differences in the mean within-subject CV for the 13 subjects between IAUC<sub>YSI</sub> and IAUC<sub>PoG</sub> ( $47.3 \pm 6.5$  vs.  $47.9 \pm 3.2$  %), GI<sub>YSI</sub> and GI<sub>PoG</sub> ( $47.9 \pm 7.4$  vs.  $52.8 \pm 3.1$  %). Bland-Altman plots showed that the 95% limits of agreement for IAUC was -74.6 to 73.6 mmol·min·L<sup>-1</sup>, and for GI values was -45 to 57. No differences were observed in the mean GI values of the 4 food items determined by YSI and PoG (BBPP:  $57 \pm 7$  vs.  $54 \pm 8$ ; FRYS:  $79 \pm 7$  vs.  $73 \pm 9$ ; FF:  $74 \pm 9$  vs.  $69 \pm 11$ ; MLC:  $66 \pm 12$  vs.  $54 \pm 9$ ).

**CONCLUSIONS:** The PoG and YSI glucose analyzer produced similar results in determining the GI of 4 Chinese traditional foods.

**2401 Board #46 May 29 8:00 AM - 9:30 AM**

**Assessment Of Dietary Intake In Elite Ethiopian Distance Runners**

Lukas Y. Beis<sup>1</sup>, Lena Willkomm<sup>1</sup>, Ramzy Ross<sup>1</sup>, Zeru Bekele<sup>2</sup>, Bezabhe Wolde<sup>2</sup>, Yannis P. Pitsiladis<sup>1</sup>. <sup>1</sup>University of Glasgow, Glasgow, United Kingdom. <sup>2</sup>Addis Ababa University, Addis Ababa, Ethiopia.

Email: l.beis.1@research.gla.ac.uk

(No relationships reported)

Explanations for the astonishing success of Kenyan and Ethiopian distance runners include unique dietary intake. Previous studies found the diet of elite Kenyan endurance runners met most recommendations for endurance athletes for macronutrient intake but not for fluid intake (e.g. Onywera et al. Int J Sports Nutr 14: 709-719, 2004).

**PURPOSE:** The aim of the present study was to assess the food and macronutrient intake of elite Ethiopian long-distance runners during a period of intense training at altitude and prior to major competition.

**METHODS:** The dietary intake of 10 (8 male, 2 female) highly-trained Ethiopian long distance runners, living and training at high altitude (~2400 m above sea level) was assessed during a 7 day period of intense training prior to competition using the standard weighed intake method. Training was also assessed using an activity/training diary.

**RESULTS:** Body mass was well maintained over the assessment period (pre:  $56.7 \pm 4.3$  kg vs. post:  $56.6 \pm 4.2$  kg,  $P = 0.54$ ; mean  $\pm$  standard deviation). The diet comprised of  $3194 \pm 329$  kcal and was high in carbohydrate ( $64.3 \pm 2.4\%$ ,  $545 \pm 49$  g,  $9.7 \pm 0.9$  g/kg); fat and protein intake was  $23.3 \pm 2.1\%$  ( $83 \pm 14$  g) and  $12.4 \pm 0.6\%$  ( $99 \pm 13$  g,  $1.8 \pm 0.2$  g/kg), respectively. The diet consisted mainly of vegetable sources (~88%) with the remaining small contribution from meat sources. Fluid intake comprised mainly of water ( $1751 \pm 583$  ml,  $0.54 \pm 0.15$  ml/kcal), while no fluids were consumed before or during training with only modest amounts following training.

**CONCLUSION:** As previously found in elite Kenyan endurance runners, elite Ethiopian runners met dietary recommendations for endurance athletes for macronutrient intake but not for fluid intake.

**2402 Board #47 May 29 8:00 AM - 9:30 AM**

**Dietary Intake And Metabolic Markers In Athletes With Spinal Cord Injury Compared With Sedentary Non-disabled**

Mina C. Mojtahedi, Rudy J. Valentine, Ellen M. Evans, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Email: mojtahed@illinois.edu

(No relationships reported)

Although well studied in many populations, data on dietary habits of people with spinal cord injury (SCI), especially athletes, and the relation to metabolic markers compared to the able-bodied (AB) population is lacking.

**PURPOSE:** To assess nutrient intake and associations between metabolic markers in SCI athletes compared with sedentary AB controls.

**METHODS:** Paraplegic athletes (n = 14, 7 women; duration of injury 16.5±5.7 yrs, injury level T5-L5) were compared with 16 sedentary, age- and BMI-matched AB (8 women) controls. Fasting lipids, insulin (INS) and glucose (GLU) were assessed via 2-h oral glucose challenge with area under the curve (AUC) and HOMA calculated. Dietary intake was obtained from 3-day food diaries. Body composition was assessed with DXA.

**RESULTS:** Metabolic markers and nutrient intakes did not differ between SCI and AB. Trunk fat mass was lower in SCI than in AB (5.7±1.6kg, 7.7±2.0kg; p<0.01). In SCI, dietary fat intake (% of energy) was related (all p<0.05) to INS-AUC (r=0.58), total cholesterol (r=0.59), LDL (r=0.96) and HDL (r=0.56). Fiber intake was related to fasting INS (r=0.75) and HOMA (r=0.72). After controlling for trunk fat, % dietary fat remained related to LDL (r=0.56) and fiber remained related to fasting INS (r=0.86) and HOMA (r=0.83). In AB, daily energy intake was related to fasting GLU (r=0.50). Protein intake (% of energy) was related to GLU-AUC (r=0.63), INS-AUC (r=0.62), and HDL (r=0.49). Carbohydrate intake (grams) was related to fasting GLU (r=0.56), and GLU-AUC (r=0.46). Fiber was related to HOMA (r=0.49); and saturated fat to HOMA (r=0.51). After controlling for trunk fat in AB, energy intake remained associated with fasting GLU (r=0.48), % protein intake with GLU- and INS-AUC (r=0.59, 0.56), and carbohydrate intake (grams) with fasting GLU (r=0.58).

**CONCLUSIONS:** Despite greatly differing physical activity levels, dietary intake was similar in SCI athletes and sedentary AB controls; however, associations between nutrients and metabolic markers differed between SCI and AB such that dietary fat intake appears to negatively and fiber favorably impact SCI compared to AB. Conversely, protein and carbohydrate intake had greater implications for AB metabolic profiles. Trunk fat mass appeared to explain most correlations between markers and nutrients in SCI, but not in AB.

**2403      Board #48      May 29      8:00 AM - 9:30 AM**  
**Nutritional Strategies Of Ncaa Division Iii Female Volleyball Players: Pre-season V. In-season**

Lana Brand, Whitney Sparby, Kelley Holmes, Lindsey Quale, Mark Blegen, FACSM. *College of St. Catherine, St. Paul, MN.*  
(No relationships reported)

Appropriate nutritional strategies play an important role in the success of all athletes. By consuming adequate and appropriate amounts of kilocalories (kcal), macronutrients, and micronutrients, athletes placing themselves in a position to positively influence body composition, glycogen storage, and recovery. However, due to varying demands placed on today's collegiate athletes, athletes may not be engaging in proper nutritional strategies throughout the year.

**PURPOSE:** The purpose of this study was to determine if there was a difference between pre-season and in-season nutrition among NCAA Division III female volleyball players.

**METHODS:** Ten (N = 10) NCAA Division III female volleyball players participated in this study. Subjects recorded their diets for three days (both pre-season and in-season) after receiving instruction from certified personnel. The three day diet records were analyzed for kcal, macronutrient, and micronutrient consumption.

**RESULTS:** Dependent samples t-tests identified no significant differences (p <0.05) between pre-season and in-season nutrition in terms of kcals consumed (2231 ± 1097 vs. 2275 ± 445 kcal), carbohydrates (286 ± 45 vs. 319 ± 88 grams), fat (61 ± 23 vs. 71 ± 15 grams), or protein (72 ± 23 vs. 74 ± 15 grams). Also, there were no significant differences identified among micronutrients.

**CONCLUSION:** The results of this study show that nutritional strategies among NCAA Division III female volleyball players do not differ when comparing pre-season to in-season. These results indicate that the various physiological demands placed on these athletes do not alter nutritional strategy.

**2404      Board #49      May 29      8:00 AM - 9:30 AM**  
**Pre-season Nutritional Status Of Ncaa Division Iii Female Volleyball Players**

Whitney Sparby, Lana Brand, Kelley Holmes, Lindsey Quale, Mark Blegen, FACSM. *College of St. Catherine, St. Paul, MN.*  
(No relationships reported)

Proper consumption of macro- and micronutrients, along with adequate amounts of energy (kilocalories) are essential for athletic performance. Pre-season training, typically time intensive and physiologically demanding further emphasize the need for proper nutritional strategies.

**PURPOSE:** The purpose of this study was to investigate the pre-season macro- and micro-nutrient consumption patterns of NCAA Division III female volleyball players who attend an all female institution.

**METHODS:** Ten (N=10) NCAA Division III female volleyball players participated in this study. Subjects completed a three day diet record after receiving instructions from certified personnel.

**RESULTS:** Energy intake (kcal) fell within the recommended values for athletes (2443.2 ± 966.8 kcal). Vitamin C intake (106.8 ± 66 mg) represented 142% of Recommended Daily Intake (RDI), while vitamin E (7.9 ± 4 mg) and potassium (2.6 ± 0.971 g) represented 52% and 57% of RDI, respectively. Sodium intake was 222% of RDI (3323.3 ± 1229 mg).

**CONCLUSION:** The nutritional status of NCAA Division III female volleyball players in this study demonstrates both over- and under-consumption of micronutrients. Left unabated these consumption patterns could possibly lead to dietary induced deficiencies thus impacting performance.

---

**2405      Board #50      May 29      8:00 AM - 9:30 AM**  
**Pre-season Nutritional Status Of Ncaa Division Iii Female Swimmers**

Kelley Holmes, Lindsey Quale, Lana Brand, Whitney Sparby, Mark Blegen, FACSM. *College of St. Catherine, St. Paul, MN.*  
(No relationships reported)

Adequate amounts of kilocalories (kcal), macronutrients, and micronutrients in the diet are important for athletic success. However, the demands of schoolwork and outside activities may cause stress and could lead athletes to consume an insufficient amount of both kcals and nutrients. If an athlete does not consume the appropriate amount of both kcals and nutrients it may negatively impact their athletic performance.

**PURPOSE:** This study was designed to determine if NCAA Division III female swimmers were adequately meeting the Daily Recommended Intakes (DRI) Guidelines.

**METHODS:** Fifteen (N=15) female NCAA Division III swimmers completed three day diet records. The records were analyzed for kcal, macronutrient, and micronutrient consumption.

**RESULTS:** Total energy intake was 2346.6 ± 425.8 kcal, representing 92% of the DRI. Carbohydrate consumption was 316.8 ± 43.2 g, representing 110% of the current DRI. Similarly, the consumption for protein was 94.2 ± 28.0 g (144% of DRI) while fat consumption was 78.4 ± 28.7 g (135% of DRI). Vitamin D consumption was 4.54 ± 3.18 µg and vitamin E consumption was 6.20 ± 3.61 mg, representing 91% and 41% of the DRI, respectively.

**CONCLUSION:** The results of this study show that NCAA Division III female swimmers are deficient in specific micronutrients while consuming too much fat and protein. These dietary practices, followed habitually, could lead to decrements in performance. Appropriate nutritional strategies should be incorporated in pre-season training to maximize swimming performance.

**The Relationship Between Reported Dietary Intake And Time Spent In Sedentary Behaviors.**

Brandy-Joe Milliron, Kathleen Woolf, Shauna Salvesen, Mark Johnson, Mallory Adams. *Arizona State University, Mesa, AZ.*  
Email: brandyjoe@gmail.com  
(No relationships reported)

The protective effects of regular physical activity on the human body have been well-documented. Unfortunately, our society has moved toward a more sedentary lifestyle. Physical inactivity (time spent sitting, watching television, working at the computer, and playing computer games) and physical activity may both be independently associated with obesity and chronic disease. Poor dietary choices could exacerbate the deleterious effects that are already associated with physical inactivity. Previous research has typically utilized self-reported measures of sedentary behaviors (SED).

**PURPOSE:** To examine the relationship between dietary intake and time spent in SED in normal weight (n=25), overweight (n=22), and obese (n=27) women between the ages of 25 and 40 y. This study design quantified SED by the use of accelerometers.

**METHODS:** Seventy-two young women (age 32±5 y; BMI 28.1±6.6 kg/m<sup>2</sup>) completed 7-day weighed food records (The Food Processor SQL). Participants wore an accelerometer (Kenz Lifecorder) for seven days and kept a log noting time to bed and time awake. Time (minutes/day) spent in four activity levels (inactive, light, moderate, vigorous) was determined. Sleep time (minutes) was subtracted from the inactive category. SED was defined as inactive - sleep time. Descriptive statistics and partial correlations were computed using SPSS version 15.

**RESULTS:** Participants reported consuming 2045±486 kcal/d, 52±6 % energy from carbohydrate, 20±6 % energy from sugar, 34±5 % energy from fat, and 11±2 % energy from saturated fat. Participants (n=72) spent an average of 635±105 minutes in sedentary behaviors per day. Participants of normal weight, overweight, and obese weight categories spent an average of 615±82, 630±137, and 659±95 respectively in sedentary behaviors. Controlling for age, positive partial correlations were found between 7-day average SED (minutes/day) and folate density (mcg DFE/1000 kcal) (P<0.01), and SED and iron density (mg/1000 kcal) (P<0.05). No other relationships between SED and dietary intake were observed in this study.

**CONCLUSION:** Time spent in SED was only associated with iron density and folate density. Thus, an increased time spent in SED was not associated with poor dietary choices.

### Dietary Intake And Energy Expenditure In Spanish Road Cyclist During Competition And Training

Raul Bescos<sup>1</sup>, Piero Galilea<sup>2</sup>, Bonet Jessica<sup>1</sup>, Jordi Porta<sup>1</sup>. <sup>1</sup>INEFC, University of Barcelona, Barcelona, Spain. <sup>2</sup>High Performance Centre, Sant Cugat, Spain.

Email: raul.bescos@inefc.net

(No relationships reported)

**PURPOSE:** To assess the dietary intake and energy expenditure during training and competition in cycling

**METHODS:** 11 male high level road cyclists (mean ± SD; age: 24.2 ± 2.9 years; BMI: 21.8 ± 1.0 kg·m<sup>-2</sup>) performed at the beginning of season a progressive laboratory test, after 5-min warm-up at 100W, initial stage started at 130W and workload was increased by 30 W every 3 min until exhaustion. All subjects after received detailed instructions registered three days dietary record during competition with various stages and training period. In addition, cyclists reported mean heart rate (HR) and time duration of training and competition. Nutrient composition were analyzed using the software Regal®. Energy Expenditure (EE) was obtained with the exponential equations relationship between HR and oxygen consumption (VO<sub>2</sub>). The total VO<sub>2</sub> was then recalculated to kcal based on the assumption that for each litre of oxygen uptake, about 5 kcal was produced. The basal metabolic rate (BMR) in litres (O<sub>2</sub>/min) was calculated by multiplying the weight of the person in kg by 0.0035. Student *t* test was used to compare energy and nutrient intake during training and competition period.

**RESULTS:** Significant differences were found in energy, carbohydrate, iron, thiamin and niacin intake between training and competition period (table 1).

**CONCLUSIONS:** Inadequate eating behaviour was showed during training and competition. Also, insufficient replenishment of glycogen stores can affect dramatically in performance of the cyclist mainly during competition.

Note: Mean ± SD; EE: Energy Expenditure; EI: Energy Intake; * P<0.05		
	Training	Competition
Energy (kcal-day-1)	3279 ± 759	4024 ± 482 *
Carbohydrate (kcal-day-1)	375 ± 86	520 ± 102 *
Protein (g-day-1)	174 ± 41	198 ± 27
Lipids (g-day-1)	116 ± 40	131 ± 20
Iron (mg-day-1)	17.7 ± 6.9	20.4 ± 7.5 *
Thiamin (mg-day-1)	2.1 ± 0.8	2.9 ± 1.3 *
Niacin (g-day-1)	40.2 ± 19.8	53 ± 19.6 *
Total EE (included BMR) (kcal-day-1)	4619 ± 831	4869 ± 668
Differences between EI vs EE	71%	83%

### No Relationship Between Youth's Physical Activity And Changes In Insulin, Leptin, Cortisol And Growth Hormone

Kristin S. Ondrak, Robert G. McMurray, FACSM, A.C. Hackney, FACSM, Joanne S. Harrell. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Email: kondrak@unc.edu

(No relationships reported)

**PURPOSE:** The interrelationships among changes in habitual physical activity (PA) and changes in insulin, leptin, cortisol and growth hormone (GH) are complex, particularly in youth, and studies have not considered the influence of change in weight status on these relationships. This investigation determined the association between changes in these hormones and PA over two years in youth who were normal weight and became overweight, were overweight and normalized their weight, or simply maintained their weight status.

**METHODS:** Data were collected from 120 youth at baseline (mean age 9.8 years) and two years later. Participants were selected from a larger cohort to represent the following: normal weight ( $>5^{\text{th}}$  and  $<85^{\text{th}}$  BMI percentile) or overweight ( $\geq 85^{\text{th}}$  BMI percentile) at both time points, normal weight that became overweight and overweight that became normal weight. Fasting, morning plasma leptin, cortisol, GH and insulin were measured via radioimmunoassay. Habitual physical activity (PA) was assessed via questionnaire. Partial correlations and multiple regression analyses were used to determine the relationship between changes in insulin and changes in leptin, cortisol, GH, PA and BMI percentile, while controlling for race and sex. Additionally, correlations were computed between change in PA and changes in leptin, cortisol and GH.

**RESULTS:** Change in insulin was related to change in BMI percentile ( $r=0.25$ ,  $p<0.05$ ) and change in leptin ( $r=0.29$ ,  $p<0.05$ ), but was not related to changes in cortisol ( $r=-0.08$ ) or GH ( $r=0.16$ ) ( $p>0.05$ ). Likewise, change in PA over the two year period was not related to changes in any of the hormones ( $p>0.05$ ). Multiple regression analyses revealed that change in leptin accounted for 9% of the variance in insulin change, while change in BMI percentile accounted for 4% of the variance ( $p<0.05$ ); no other variables were significant.

**CONCLUSIONS:** In this sample of youth, changes in or maintenance of weight status over a two year period appears to only impact the association between hormonal changes in insulin and leptin. Thus, weight status has a stronger association with the insulin-leptin relationship than does habitual physical activity.

**Hormonal Markers And Physical Performance During A Peak-taper Cycle In Elite Track And Field Athletes.**

Arnold G. Nelson, FACSM<sup>1</sup>, Jason B. Winchester<sup>2</sup>, Laura K. Stewart<sup>1</sup>, Michael H. Stone<sup>3</sup>. <sup>1</sup>LSU, Baton Rouge, LA. <sup>2</sup>George Mason University, Manassas, VA. <sup>3</sup>East Tennessee State University, Johnson City, TN.

Email: anelso@lsu.edu

(No relationships reported)

**PURPOSE:** To investigate the relationship between physical performance and testosterone and cortisol following short term alterations in training volume and intensity.

**METHODS:** Five male qualifiers for the 2006 NCAA D-I national track and field meet took part. At study start, they had just finished a peaking training phase prior to competition in a NCAA regional meet. Peaking involved a 2 week elevation in training volume/intensity, followed by 1 week reduction in training volume/intensity prior to the regional and national meets. Testing occurred immediately prior to beginning the peaking phase (pre), to the onset of the taper cycle (mid), and to leaving for the national meet (post). For each athlete, all tests were performed at the same time of day, on the same day of the week, and with a minimum of 48 h prior rest. The performances tested were broad jump (BJ) and mid-thigh pull. Testosterone (T) and cortisol (C) were determined from saliva samples. Samples were analyzed in duplicate via ELISA.

**RESULTS:** Free T (nmol/L) went unchanged throughout the study (pre=  $9.7 \pm 1.5$ , mid=  $9.6 \pm 1.2$ , post=  $10.8 \pm 1.6$ , mean  $\pm$  std. dev). On the other hand, free C (nmol/L) rose significantly ( $p<0.05$ ) at mid, but returned to pre levels at post (pre=  $18.5 \pm 3.7$ , mid=  $22.2 \pm 3.7$ , post=  $15.8 \pm 2.3$ ). T/C ratio was also increased at mid but returned to pre at post (pre=  $.5 \pm .3$ , mid=  $.4 \pm .1$ , post=  $.7 \pm .2$ ). Additionally, significant correlations were observed between T and BJ, peak force (PF), and rate of force development (RFD) for pre ( $r=.54$ ,  $.42$ ,  $.59$ ), mid ( $r=.44$ ,  $.62$ ,  $.57$ ), and with BJ and RFD during post ( $r=.56$ ,  $.53$ ). Significant negative correlations were observed between C and BJ and RFD during pre ( $r=-.44$ ,  $-.47$ ), and with RFD during mid ( $r=-.51$ ), and post ( $r=-.50$ ). Significant correlations were observed between T/C and BJ and RFD during pre ( $r=.64$ ,  $.68$ ), with PF during mid ( $r=.64$ ), and with BJ, PF, and RFD during post ( $r=.68$ ,  $.71$ ,  $.74$ ).

**CONCLUSIONS:** Athletes increasing training volume for 2 weeks showed a significant increase in [C]. When training volume was tapered, [C] decreased accordingly. However, [T] showed no significant alterations to either the sudden increase in the training or the tapering and cessation of training. In addition, T, C, and T/C shared significant relationships with the physical performance indicators of BJ, PF, and RFD.

**Testosterone to Cortisol Ratio Shows Strong Relationship With Adaptation to a Strength and Power Training Regimen in American-style Collegiate Football Players**

Jason B. Winchester<sup>1</sup>, Arnold G. Nelson, FACSM<sup>2</sup>, Laura K. Stewart<sup>2</sup>, Michael H. Stone<sup>3</sup>. <sup>1</sup>George Mason University, Manassas, VA. <sup>2</sup>Louisiana State University, Baton Rouge, LA. <sup>3</sup>East Tennessee State University, Johnson City, TN.

(No relationships reported)

**PURPOSE:** Previous research has demonstrated strong correlation between hormonal markers and physical performance. The purpose of this study was to examine the relationship that hormonal markers shared with performance measures and to establish whether or not alterations in performance were reflected through shifts in hormone profile.

**METHODS:** Twenty-two freshman collegiate American-style football players were recruited this study (Age =  $18.41 \pm 0.73$  years; Mass =  $107.60 \pm 22.97$  kg; and Height =  $188.31 \pm 6.71$  cm). Ten collegiate males were recruited as an experimental control (Age =  $19.01 \pm 0.81$  years; Mass =  $91.45 \pm 17.12$  kg; and Height =  $168.94 \pm 7.12$  cm). Performance testing included peak isometric force (PF), rate of force development (RFD), broad jump (BJ), and vertical jump (VJ). Hormone values included free testosterone (T), cortisol (C), and testosterone to cortisol ratio (T/C), measured via enzyme-linked immune assay. Following initial testing, treatment group subjects participated in seven weeks of strength and power training. Control group subjects were instructed not to participate in strength or power training during the course of the study. Statistical analysis was performed using a Pearson product-moment correlation and reliability was determined via interclass correlation (ICC). A paired t-test was used to compare pre-post means between the performance variables of PF and RFD within groups. An additional paired t-test was performed examining pre-post means of the BJ and VJ tests. A final paired t-test was performed to compare the pre-post means of the hormonal markers T, C, and T/C. The level of significance was set at  $p<0.05$ , and was adjusted to cover for multiple comparisons using a Bonferroni adjustment.

**RESULTS:** Significant correlations were observed between pre T/C and percent improvements in performance variables pre-post (BJ =  $3.8\%$   $r=0.59$ , PF =  $16.8\%$   $r=0.62$ , RFD =  $20.1\%$   $r=0.67$ , VJ =  $4.1\%$   $r=0.64$ ).

**CONCLUSIONS:** The results of this study suggest that the hormonal markers T, C, and T/C share significant correlation with indices of strength and power performance and that these relationships are sensitive to alterations in strength and power performance capabilities. Practitioners wishing to monitor training and adaptation may wish to consider the use of such hormonal markers in their participants.

**Acute Regulation Of Igf-1 By Differential Binding Protein Expression, Inhibition, And Proteolysis**

Gordon Fisher, Byron Foster, David D. Pascoe, FACSM. Auburn University, Auburn, AL.

Email: grdnfs@gmail.com

(No relationships reported)

**INTRODUCTION:** Strong evidence supports the roles of Insulin Growth Factor Binding Proteins (IGFBPs) in regulating Insulin Growth Factor 1 (IGF-1) bioavailability and individual regulation dynamics. A large percentage of circulating IGF-1 is bound in a ternary complex consisting of IGF-1, IGFBP-3, and hepatically-produced acid labile subunit. IGF-1 bound in binary complexes with IGFBP-1, -2, -4, -5, and -6 constitute an additional 4% of circulating IGF-1, the remainder is 'free' IGF-1. This free fraction of IGF-1 is able to bind to type 1 IGF receptor and elicit biological effects. Exercise (EX) combined with proper post-EX nutrition elicits metabolic signals that would serve to maximize bioavailability of free, dissociable IGF-1.

**PURPOSE:** This study investigated differential contributions of IGFBPs on bioavailability of IGF-1 and the individual regulation of each of these binding proteins in exercising humans.

**METHODS:** Eight recreationally-active college-aged males completed three identical high-intensity interval training protocols followed by each of three randomly ordered post-EX nutritional protocols: 1) non-caloric placebo; 2) carbohydrate-only (0.85 g/kg lbw); and 3) essential amino acid/carbohydrate (0.35 g/kg and 0.5 g/kg lbw). Blood samples were obtained pre-EX, immediately post-EX, 10 min intervals for 80 min post-EX, and 20 min intervals until 160 min post-EX. Blood samples were analyzed for growth hormone, free IGF-1, insulin, hematocrit, hemoglobin, plasma amino acid concentrations, and matrix metalloproteinase (MMP) activity. Analytes were compared relative to baseline and across conditions using repeated measures ANOVA. Total area under the curve was calculated for insulin and analyzed using one-way ANOVAs with repeated measures on condition. *A priori* significance level was  $p < 0.05$ .

**RESULTS:** Significant post-EX increases in free IGF-1 concentrations were observed only for essential amino acid/ carbohydrate group. Additionally, significant increases in post-EX MMP activity were observed in all groups.

**CONCLUSION:** Results indicate that post-EX macronutrient ratio is a determinant of free concentrations of IGF-1 and high-intensity EX results in increased MMP activity.

**Plasma Free Testosterone, Regional Fat Mass And Plasma Leptin Concentration In Men**

Teresa Fuentes, Amelia Guadalupe-Grau, Hugo Olmedillas, Safira Delgado-Guerra, Jesús Gustavo Ponze-González, David Morales-Álamo, Lorena Rodríguez-García, Borja Guerra, José Antonio López-Calbet, Cecilia Dorado. *University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain.*

Email: fuentes.teresa@gmail.com

(No relationships reported)

There is an inverse correlation between serum leptin and testosterone levels in men which could be explained by either an effect of testosterone on leptin secretion or by an indirect effect of testosterone in fat mass.

**PURPOSE:** To determine if the association between serum free testosterone and leptin concentrations is independent of fat mass and its regional distribution in men.

**METHODS:** Two hundred and fifty-nine healthy and physically active men, aged  $29.1 \pm 7.4$  years and with a percentage of body fat of  $19.5 \pm 7.3\%$  participated in this investigation. Fasting serum concentrations of leptin and free testosterone were assessed with ELISA and body composition with DEXA.

**RESULTS:** The percentage of body fat mass was associated with leptin (spearman  $r = -0.87$ ,  $P < 0.001$ ), free testosterone ( $r = -0.31$ ,  $P < 0.001$ ), and free testosterone with leptin ( $r = 0.24$ ;  $P < 0.01$ ). In addition, the percentage of fat accumulated in the trunk region was correlated with serum leptin ( $r = 0.70$ ,  $P < 0.001$ ) and free testosterone ( $r = -0.29$ ;  $P < 0.001$ ). However, when controlling for the percentage of body fat, there was no relationship between free testosterone and leptin.

**CONCLUSIONS:** Circulating levels of leptin and free testosterone are inversely associated and this relationship can be explained by the fat-reducing effects of serum free testosterone.

Supported by grants from Ministerio de Educación y Ciencia, Spain (BFU2006-13784/BF1 and DEP2006-56076-C06-04/ACTI).

**2413 Board #58 May 29 9:00 AM - 10:30 AM**  
**Serum Myostatin And IGF-I Status In Cancer Patients With And Without Cachexia**

Jeremy Baker, Michael Bembien, FACSM, Penny Hopkins, Vanessa Sherk, Debra Bembien, FACSM. *University of Oklahoma, Norman, OK.*

(No relationships reported)

Cancer cachexia is a syndrome involving weight loss, anorexia, loss of skeletal muscle, and body fat which results in lowered quality of life and survival rate for cancer patients.

**PURPOSE:** The purpose of this study was to examine serum myostatin and IGF-I levels in patients with cancer cachexia to determine if these hormones are involved in cancer associated weight loss.

**METHODS:** Subjects were divided into three groups: healthy age-matched controls (CON;  $n = 11$ ); weight stable cancer patients (NWL;  $n = 10$ ) and cancer patients (WL;  $n = 10$ ) who had lost at least 10% of their pre-diagnosis normal weight. Serum was analyzed via a western blot protocol for myostatin protein and by IRMA for IGF-I concentrations. Body composition was assessed using a multi-compartment model using DXA (mineral), Bod Pod (body density) and bio-impedance spectrum (BIS) analyzer (body water).

**RESULTS:** Physical characteristics were not significantly different between groups. WL had a weight loss of 20.46 kg from their pre-cancer normal weights. Body composition variables were not significantly different between groups except that intra-cellular water was significantly lower ( $p < 0.01$ ) in WL than in C. Myostatin and IGF-I levels were not significantly different ( $p > 0.05$ ) between the groups (Table 1). Myostatin was positively related to METs per week ( $r = 0.697$ ,  $p = 0.03$ ) in WL, which may be the result of myostatin production being stimulated by glucocorticoid release at higher levels of activity. IGF-I did show a positive correlation to the percentage of weight change from normal weight in WL ( $r = 0.71$ ,  $p = 0.02$ ).

**CONCLUSION:** Our findings suggest that there are mechanisms other than myostatin involved in cancer cachexia.

Table 1. Myostatin (Myo) and IGF-I Levels (Mean  $\pm$  SE)

Variable	NWL (n=10)	WL (n=10)	CON (n=11)
Myo (ng/ml)	$2.75 \pm 0.36$	$2.61 \pm 0.70$	$3.23 \pm 0.74$
IGF-I (ng/ml)	$216.1 \pm 29.9$	$259.4 \pm 34.7$	$185.1 \pm 19.7$

**Effects Of rhGH On Selected Markers Of Altered Health Status In Trained Sportsmen**

Richard J. Godfrey, FACSM<sup>1</sup>, Anthony Blazevich<sup>2</sup>, Mariann Rand-Weaver<sup>1</sup>, Cristiana Velloso<sup>3</sup>, Pierre Bouloux<sup>3</sup>, Stephen Harridge<sup>3</sup>, Geoffrey Goldspink<sup>3</sup>. <sup>1</sup>Brunel University, London, United Kingdom. <sup>2</sup>Edith Cowan University, Perth, Australia. <sup>3</sup>University College London, London, United Kingdom.

Email: richard.godfrey@brunel.ac.uk

(No relationships reported)

Recombinant human growth hormone (rhGH) is used illicitly by some athletes as a means of improving sports performance. Exogenous administration of growth hormone is believed by athletes to reduce body fat and increase muscle mass. There are health risks associated with exogenous administration of rhGH. These include risk of diabetes, joint pain, skeletal changes and hepatomegaly. Some evidence also suggests a link between exogenous rhGH and changes in insulin sensitivity and cardiovascular risk.

**PURPOSE:** The aim of this work was to examine selected measures of the healthy *mileu* that may be altered in favour of pathology as a consequence of the illicit use of rhGH in sport. Accordingly, the analytes, leptin, adiponectin and IL-6 are examined as indices of potential pathologic change.

**METHODS:** Following the provision of written informed consent fourteen male undergraduates entered the study (Mean  $\pm$  sd; age  $22.5 \pm 2.3$  years, weight  $93.6 \pm 5.9$  kg). Each had a minimum of three years resistance training experience and, upon entry to the study, were regularly participating in a minimum of two resistance training sessions per week. A six week standardised, supervised, resistance training program comprising three sessions per week was implemented. Participants were tested on two occasions: T1

following 4 weeks of training and T2 following two further weeks of training plus either rhGH 0.1 IU/kg/day or placebo administration. The testing sessions involved the use of an acute high resistance exercise test of 4-8 sets of 10 repetitions leg-press at 80% of maximal voluntary contraction with 90 seconds rest between sets. This took place at the same time in the morning for each participant, in the fasted state and following insertion of a cannula in a radial vein. Blood samples were taken at rest, and at 5 and 60 minutes post exercise.

**RESULTS:** In the experimental group there was a large (300-fold,  $p < 0.001$ ) increase in exercise induced IGF-1 secretion compared with the control group. Hence administration of rhGH was demonstrated to have physiological efficacy. Despite this, there was no difference in either leptin, adiponectin or IL-6 when comparing experimental and control groups.

**CONCLUSION:** Any negative health-related changes in insulin sensitivity and cardiovascular risk are not mediated by leptin, adiponectin or IL-6.

**Insulin-like Growth Factor 1 And Insulin-like Growth Factor Binding Proteins 1 And 3 During A Competitive College Cross-country Season**

Matthew D. Vukovich, FACSM, Kevin J. Bjerke, Mary K. Thum, Allison J. Gauer, Andrew R. Creer. *South Dakota State University, Brookings, SD.*  
Email: matt.vukovich@sdsstate.edu  
(No relationships reported)

The effect of exercise training on the IGF system remains equivocal. Some research indicates a negative effect of exercise training on the IGF system, while others report a positive effect.

**PURPOSE:** To determine the effects of 10wks of training in male (XCM) and female (XCF) collegiate cross-country runners on insulin-like growth factor-I (IGF-I), IGF binding protein 1 (IGFBP-1) & IGFBP-3.

**METHODS:** 8 male & 18 female collegiate runners & 9 male (CONM) & 10 female (CONF) active controls volunteered to participate in the 10wk study. Blood samples were obtained at baseline, 5 & 10 weeks. IGF-I, IGFBP-1, & IGFBP-3 were determined by ELISA. Diet records were obtained from all subjects for the 3d prior to blood collection.

**RESULTS:** Weekly running distance remained relatively constant through the 10wks (males: baseline,  $92 \pm 29$  km; 5wk,  $95 \pm 24$  km; 10wk,  $82 \pm 16$  km; females: baseline,  $69 \pm 16$  km; 5wk,  $77 \pm 13$  km; 10wk,  $68 \pm 11$  km). Energy intake at baseline was higher in runners (Males,  $3465 \pm 1370$  kcals, females  $2128 \pm 722$  kcals) than controls (males,  $2350 \pm 650$  kcals; females,  $1808 \pm 404$  kcals) due to higher carbohydrate (runners: males,  $479 \pm 204$  g; females,  $304 \pm 117$  g; controls males,  $275 \pm 85$  g; females,  $256 \pm 61$  g) & protein intake in runners (runners: males,  $125 \pm 30$  g; females,  $83 \pm 34$  g; controls: males,  $100 \pm 45$  g; females,  $77 \pm 25$  g). Energy, carbohydrate & protein consumption remained constant for the duration of the study for all groups. Baseline IGF-I (XCF,  $296 \pm 86$ ; XCM,  $335 \pm 87$ ; CONF,  $342 \pm 38$ ; CONM,  $342 \pm 61$  ng/mL) was not different among the groups & did not change over time. Baseline IGFBP-3 (XCF,  $2124 \pm 204$ ; XCM,  $1762 \pm 79$ ; CONF,  $1827 \pm 119$ ; CONM,  $1751 \pm 100$  ng/mL) was not different among the groups and did not change over time. Baseline IGFBP-1 was different among groups (XCF,  $52 \pm 22$ ; XCM,  $38 \pm 13$ ; CONF,  $40 \pm 7$ ; CONM,  $30 \pm 16$  ng/mL). IGFBP-1 was lower ( $P < 0.05$ ) at 5wk (XCF,  $33 \pm 22$ ; XCM,  $25 \pm 11$  ng/mL) & 10wk (XCF,  $32 \pm 14$ ; XCM,  $22 \pm 11$  ng/mL) compared to baseline in male & female runners. There was no change in IGFBP-1 in controls at 5wk (CONF,  $42 \pm 22$ ; CONM,  $24 \pm 14$  ng/mL) or 10wk (CONF,  $49 \pm 19$ ; CONM,  $27 \pm 22$  ng/mL).

**CONCLUSIONS:** A 10wk season of cross-country running had little effect on IGF-I and IGFBP-3. The decline in IGFBP-1 is unlikely related to negative energy or protein balance; as the runners remained weight stable. The change in IGFBP-1 requires further investigation.

---

**The Effects Of Mouthpiece Use During Endurance Exercise On Lactate And Cortisol Levels**

Dena P. Garner, Erica McDivitt. *The Citadel, Charleston, SC.*  
(No relationships reported)

Protective mouthpieces have been used in a variety of sports to decrease the risk of orofacial injury. However, there is limited research on the physiological effects of mouthpiece use during exercise.

**PURPOSE:** To investigate the possible effect on lactate and cortisol levels when wearing and not wearing a mouthpiece, the wEdge (Bite-Tech Corp).

**METHODS:** Subjects ( $n=24$ ), age 18-24, ran at 75 -85% of their maximal heart rate for 30 minutes on 2 separate trials, being randomly assigned the use of the mouthpiece on 1 of the 2 trials. Lactate levels were assessed before, 15 and 30 minutes during, and post 10 minutes exercise. Subjects provided a passive drool sample before and after each exercise bout to assess salivary cortisol levels.

**RESULTS:** Lactate data indicated a significant difference between wearing and not wearing the mouthpiece at 30 minutes exercise ( $p$ -value = 0.024). Mean lactate levels at 30 minutes with the mouthpiece was 4.01 mmol/L versus 4.92 mmol/L without the mouthpiece. Mean cortisol levels showed no significant difference between wearing and not wearing the mouthpiece ( $p$ -value= 0.111). However, there was a trend towards lower mean cortisol levels with use of the mouthpiece (0.1484 ug/dL) versus no mouthpiece (0.2201 ug/dL).

**CONCLUSION:** This study suggests that use of a mouthpiece may reduce lactate and cortisol increases and thereby improve exercise performance.

**Association Of Exercise-induced Salivary Cortisol To Exertional Perception And Affect**

Jeanette M. Garcia, Elizabeth F. Nagle, FACSM, Robert J. Robertson, FACSM, Deborah J. Aaron, FACSM. *University of Pittsburgh, Pittsburgh, PA.*  
Email: jmg12@pitt.edu  
(No relationships reported)

**PURPOSE:** To examine the relation between cortisol levels and both exertional perceptions and exercise induced changes in affect during a bout of exercise.

**METHODS:** 13 males and 20 females (mean age  $30.5 \pm 1.2$  yrs) participated in this investigation. Salivary cortisol was measured at baseline (C1), 5 minutes after a submaximal (C2) and maximal (C3) treadmill protocols, and 30 minutes following the maximal treadmill test (C4). Affect was measured using the Total Mood Disturbance score (TMD) calculated from the Profile of Mood States (POMS) at baseline (TMD1), 5 min post submaximal test (TMD 2), 5 min post maximal test (TMD 3), and 30 minutes post maximal test (TMD 4). Ratings of perceived exertion (RPE) were assessed with the OMNI Walk/Run Scale during treadmill exercise for legs (RPE-L), chest and breathing (RPE-C), and overall body (RPE-O). Partial correlations were used to examine the association among cortisol values, affect, and RPE.

**RESULTS:** For males, there was a positive correlation between the D in TMD 1 to TMD 3 and the D in C1 to C3 ( $r=0.62$ ,  $p < 0.05$ ) and the D in C1 to C4 ( $r=.77$ ,  $p < 0.01$ ). For females, positive correlations were found between the D in C1 to C4 and RPE-L ( $r=0.53$ ,  $p < 0.05$ ), RPE-C ( $r=0.58$ ,  $p < 0.01$ ), and RPE-O ( $r=0.56$ ,  $p < 0.05$ ).

**CONCLUSION:** Findings suggest that increased post exercise cortisol levels are associated with a negative mood shift following a maximal treadmill test in males and higher perceived exertion during a maximal treadmill test in females. Examining the physiological and psychological responses to exercise may assist with the development of improved strategies to increase exercise adoption and adherence.

## A Meta-analysis Of Biomarkers Associated With The Overtraining Syndrome

Alissa Donaldson, Frank Wyatt, Tyler Fagan, Elise Brown. *Midwestern State University, Wichita Falls, TX.*

Email: alissa.donaldson@gmail.com

(No relationships reported)

Overtraining (OT) syndrome has been investigated extensively with little agreement as to reliable markers for detection. A meta-analytic review is a procedure designed to compile studies in an area with hopes of reaching a consensus view.

**PURPOSE:** The purpose of this meta-analysis was to provide summary quantitative findings of biomarkers (i.e., blood) associated with the overtraining syndrome.

**METHODS:** A meta-analytic research design was utilized to investigate selected studies allowing for a coding process to record data. Thirteen studies met inclusion/exclusion criteria. Biomarkers included samples taken with subjects in normal (N) condition and during OT. These biomarkers were the following: glutamine (um), glutamate (um), cortisol (nmol<sup>-1</sup>), IL-6 (nm), testosterone (mg\*dL<sup>-1</sup>), total cholesterol (mg\*dL<sup>-1</sup>), glucose (mg\*dL<sup>-1</sup>), leptin (ng\*mL<sup>-1</sup>), hematocrit (%), hemoglobin (g\*L<sup>-1</sup>), norepinephrine (pg\*mL<sup>-1</sup>), epinephrine (pg/ml), creatine kinase (u\*L<sup>-1</sup>). To determine magnitude of difference between N and OT, the effect size calculation of  $M_2 - M_1 / SD_1$  was used where  $M_2$  is the mean of the OT sample,  $M_1$  was the mean of the N sample and  $SD_1$  is the standard deviation of the N sample.

**RESULTS:** Combined sample size (N) was 238 subjects with the mean time in OT of 6.6 (weeks). The following are mean (SD) of combined subject demographics: height (cm) 175.4 (2.4); weight (kg) 71.7 (2.6); body fat (%) 11.8 (0.9); age (y) 23.5 (2.03);  $VO_{2max}$  (ml\*kg<sup>-1</sup>\*min<sup>-1</sup>) 55.4 (0.8). Mean (SD) biomarker changes from N to OT were the following: Glutamine -56.3 (-2); glutamate 49.7 (2); cortisol -89.7 (-12.2); IL 6 -0.52 (0.12); testosterone -88.9 (-30); cholesterol 4.6 (-1.6); glucose -13.3 (1.9); leptin 0.15 (-0.11); hematocrit -0.83 (-0.4); hemoglobin -20; norepinephrine 36 (-4.1); epinephrine -2.2 (-3.5); creatine kinase 29.2 (8.5). Effect size calculations for the above biomarkers were considered large for the following: glutamine (-4.02), glutamate (8), cortisol, (-1.4), IL 6 (-5.2), glucose (-1.1).

**CONCLUSION:** From this analysis, the noted biomarker changes and direction of change (+, -) indicates considerable immune-suppression and increased stress with athletes experiencing the OT syndrome.

### Determining If *N. Micropus* Is A Viable Animal Model For The Study Of Type 2 Diabetes

James A. Eldridge<sup>1</sup>, Diane Post<sup>1</sup>, Joey Schenkman<sup>1</sup>, Craig Spellman<sup>2</sup>. <sup>1</sup>The Univ. of Texas at the Permian Basin, Odessa, TX. <sup>2</sup>Texas Tech University Health Science Ctr. Permian Basin, Odessa, TX. (Sponsor: Tinker D. Murray, PhD, FACSM, FACSM)

Email: eldridge\_j@utpb.edu

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if wild caught *N. micropus* would exhibit signs of type of type 2 diabetes when fed a high fat, high carbohydrate diet.

**METHODS:** Twenty *N. micropus* were captured from several field locations and brought into the lab. Initial blood samples of blood glucose, bone mineral density (BMD) and body fat percentage (%BF) were collected. The animals were fed a modified western high fat, high CHO diet. Beginning in the seventh week, the animals began exhibiting signs of distress, including increased fluid intake, loss of appetite, and polyuria. Upon death, a second blood glucose, BMD and %BF were collected along with tissue samples of the livers, pancreata, and kidneys. A repeated measures analysis of variance was run to determine differences between pre and post data.

**RESULTS:** The repeated measures analysis of variance revealed significant differences between pre-test and post-test glucose levels ( $F = 71.77$ ,  $p < 0.05$ ) and %BF ( $F = 10.1$ ,  $p < 0.05$ ). There were no significant differences between the experimental pre-test and the field control blood glucose values ( $t = 0.332$ ,  $p > 0.05$ ) or %BF ( $t = 1.08$ ,  $p > 0.05$ ). The livers of the experimental animals contained a statistically significant greater number of lipid droplets compared to the livers of the field control animals ( $F = 5.05$ ,  $p < 0.05$ ). The glomerular space of the kidneys in the experimental animals was significantly smaller than the space in the field control animals ( $F = 7.71$ ,  $p < 0.05$ ). H & E staining of pancreata from the experimental animals showed disruption of the lobular groups, a loss of the secretory and centroacinar cells due to lipid infiltration, and no islets could be identified.

**CONCLUSIONS:** Results of our study show that when *N. micropus* is placed on a high fat, high CHO diet, they rapidly develop symptoms of type 2 diabetes similar to those observed in humans. They have hyperglycemia, develop fatty deposits in the liver similar to non-alcoholic liver disease and the glomerulus swells resulting kidney damage. The pancreata shows a disruption of the lobular groups, a loss of the secretory and centroacinar cells due to lipid infiltration, and the destruction of the Islet of Langerhans. These results suggest that *N. micropus* can be developed in to a useful small animal model for the study of type 2 diabetes.

### Menstrual Cycle Disruptions In Female Soldiers During Military Training: Impact Of Body Weight And Composition

James P. McClung<sup>1</sup>, J. Philip Karl<sup>1</sup>, Nina S. Stachenfeld, FACSM<sup>2</sup>, Sonya J. Cable<sup>3</sup>, Kelly W. Williams<sup>3</sup>, Bradley C. Nindl, FACSM<sup>1</sup>, Harris R. Lieberman<sup>1</sup>, Andrew J. Young, FACSM<sup>1</sup>. <sup>1</sup>US Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>John B. Pierce Laboratory and Yale University School of Medicine, New Haven, CT. <sup>3</sup>Experimentation and Analysis Element, Directorate of Basic Combat Training, Fort Jackson, SC.

(Sponsor: Dr. Andrew Young, FACSM)

(No relationships reported)

Menstrual cycle disruptions (MCDs) have been reported in populations experiencing increased physical activity and may be associated with poor health outcomes. The prevalence and etiology of MCDs have not been studied in enlisted female Soldiers during military training.

**PURPOSE:** In this study we investigated the prevalence of MCDs during military basic combat training (BCT), and the relationship between altered menstrual function and changes in body weight (BW) and composition. We hypothesized that female Soldiers who lost weight during BCT may develop MCDs.

**METHODS:** Survey questions regarding menstrual cycling were administered to 163 Soldier volunteers ([mean  $\pm$  SD] age = 21  $\pm$  4 yrs) immediately before and following the 9-wk BCT course. At both timepoints, measured BW was used to calculate body mass index (BMI), and skinfold thickness was used to calculate body fat percentage.

**RESULTS:** Following the 9-wk BCT course, 73.6% of volunteers reported that they had stopped menstruating regularly since arriving at BCT. Pre-BCT BW was lower ( $p < 0.05$ ) in individuals that reported MCDs (61.5  $\pm$  8.8 kg) as compared to those who did not (ND, 64.8  $\pm$  8.9 kg). The ND group had a greater ( $p < 0.05$ ) BCT-induced change in BW (-1.4  $\pm$  3.3 kg) than the MCD group (0.2  $\pm$  3.4 kg). Likewise, the ND group demonstrated a greater ( $p < 0.05$ ) BCT-induced change in BMI (-0.54  $\pm$  1.2 kg\*m<sup>-2</sup>) than the MCD group (0.06  $\pm$  1.3 kg\*m<sup>-2</sup>). There was no difference in body fat percentage between the MCD and ND groups at either timepoint.

**CONCLUSION:** Menstrual cycle disruptions are prevalent in female Soldiers following BCT. Starting BW, but not body fat percentage, appears to be associated with MCDs during the training period. Contrary to our hypothesis, volunteers reporting MCDs did not lose weight, suggesting that weight loss per se does not appear to affect menstrual function during BCT. Future studies should determine the impact of MCDs on Soldier health and performance during military training.

### Estrogen And Exercise Effects On The Recovery Of Atrophic Skeletal Muscle

Marybeth Brown, FACSM, J Andries Ferreira. *University of Missouri, Columbia, MO.*

Email: brownmb@health.missouri.edu

(No relationships reported)

Estrogen deficient women do not show as much improvement with rehabilitation as men. Several studies have indicated that the recovery of atrophic skeletal muscle does not occur or is delayed in female rats that are estrogen (E2) deficient. There is also evidence that E2 is anabolic, stimulating protein synthesis. The PURPOSE of this study was to determine extent of recovery of atrophic skeletal muscle in E2 deficient rats that were allowed to spontaneously cage recover from induced atrophy or exercised during recovery.

**METHODS:** 55 female rats age 5 mos were randomly placed into 4 groups:

1) control, 2) Hindlimb unweighted (HLU), 3) cage ambulation recovery and 4) exercise. Initially, all rats were ovariectomized and allowed to recover pre-surgery weight (~3 wks). 38 rats were HLU for 4 weeks to induced muscle atrophy; 13 were sacrificed at the end of HLU. Remaining animals were exercised daily for 14 days (rehabilitation activity and ladder climbing with resistance) after HLU or cage recovered for 14 days.

**RESULTS:** HLU resulted in significant atrophy in soleus, plantaris, gastrocnemius, tibialis anterior and Quads. Unexpectedly, ambulation recovery rats showed a strong trend toward return of muscle mass compared to control values whereas exercise rats did not. Means  $\pm$  sem of 2 locomotor muscles are presented. (Plantaris: Con: 396mg $\pm$ 10, HLU: 294 $\pm$ 5, Recov: 363 $\pm$ 9, Exercise: 306 $\pm$ 9; Gastroc: Con 1850 $\pm$ 40, HLU 1353 $\pm$ 45, Recov 1661 $\pm$ 37, Exercise 1371 $\pm$ 43). Recovery of muscle force lagged behind the recovery of mass in the exercise and cage ambulation groups as follows: (Plantaris Po: Con 312g $\pm$ 10, HLU 256 $\pm$ 21, Recov 292 $\pm$ 20, Exerc 226 $\pm$ 14; Lateral Gastroc: Con 407 $\pm$ 13, HLU 335 $\pm$ 29, Recov 332 $\pm$ 15, Exerc 309 $\pm$ 20). Cross-sectional area (CSA) data reflect the same trend as muscle mass with recovery rats showing an increase in CSA toward baseline and exercise rats failing to increase fiber size. Central nuclei were present in muscles from exercise rats, suggesting damage.

**CONCLUSIONS:** Exercise may be detrimental in an E2 deficient organism. Results may explain why E2 deficient women do not show as robust an increase in mass and strength with exercise as men.

#### **Hypothalamic-pituitary-adrenal Axis And The Sympathetic-adrenomedullary System Responses During Heat Acclimation In Sedentary Males**

Heather E. Wright, Tom M. McLellan, FACSM. *Defence Research & Development Canada-Toronto, Toronto, ON, Canada.*

Email: Heather.Wright@drdc-rddc.gc.ca

(No relationships reported)

Previous research suggests that the release of HPA and SAS stress hormones are functionally linked to the increase in core temperature during exercise and heat stress exposure. Yet, heat acclimation is known to increase tolerance time and the core temperature tolerated during uncompensable heat stress (UHS), and reduce physiological strain. It would be of interest, therefore, to know whether the HPA and SAS hormone response following heat acclimation is reduced at any given level of thermal strain.

**PURPOSE:** To examine the HPA and SAS stress hormone responses in sedentary males during 9 days of exposure to UHS.

**METHODS:** Nine sedentary males (Mean $\pm$ SE:  $\text{VO}_{2\text{peak}}$  = 51.7 $\pm$ 1.9 mL $\cdot$ kgLBM $^{-1}\cdot$ min $^{-1}$ , 17 $\pm$ 2% fat) walked to exhaustion (EXH) on 9 days (over 2 consecutive weeks) on a treadmill (4.5 km $\cdot$ h $^{-1}$ , 2% incline) in 40°C and 30% R.H., wearing combat clothing and a protective hooded overgarment. At rest (PRE; prior to heat) and at a  $T_{re}$  of 38, 38.5, 39°C, and EXH venous blood samples were obtained. COR, GH, and ACTH were determined by chemiluminescence and NE and E by gas chromatography/mass spectrometry.

**RESULTS:** Although  $T_{re}$  EXH was not different from Day 1 (38.8 $\pm$ 0.1°C) to 9 (39.1 $\pm$ 0.1°C), time to EXH increased from 95 $\pm$ 8 to 145 $\pm$ 13 min. Significant increases were observed from PRE to EXH for COR (357.0 $\pm$ 8.5 to 491.3 $\pm$ 18.8 nmol $\cdot$ L $^{-1}$ ), ACTH (4.7 $\pm$ 0.2 to 21.7 $\pm$ 1.9 pmol $\cdot$ L $^{-1}$ ), NE (1.9 $\pm$ 0.0 to 4.7 $\pm$ 0.0 nmol $\cdot$ L $^{-1}$ ), and E (208.4 $\pm$ 3.5 to 547.5 $\pm$ 18.9 pmol $\cdot$ L $^{-1}$ ) that were unaffected by heat acclimation. No differences also were observed between Day 1 and 9 from Pre to 39°C for COR, ACTH, NE, and E ( $p \leq 0.1$ ). However, GH EXH on Day 1 (9.9 $\pm$ 1.7 mIU $\cdot$ mL $^{-1}$ ) was significantly greater than Days 5, 6, and 9 (6.5 $\pm$ 0.9, 6.4 $\pm$ 0.9, and 7.7 $\pm$ 0.2 mIU $\cdot$ mL $^{-1}$ , respectively).

**CONCLUSION:** Nine days of exertional heat acclimation improved the GH stress response, yet COR, ACTH, NE, and E remained temperature driven. Funded by a DRDC Technology Investment Fund.

### **2423 Board #68 May 29 8:00 AM - 9:30 AM**

#### **The Relationship Between Plasma Volume Changes Following Heat Acclimation And Thermotolerance During Uncompensable Heat Stress In Sedentary Males**

Tom M. McLellan, FACSM<sup>1</sup>, Heather E. Wright<sup>2</sup>. <sup>1</sup>DRDC Toronto, Toronto, ON, Canada. <sup>2</sup>York University, Toronto, ON, Canada.

Email: tom.mclellan@drdc-rddc.gc.ca

(No relationships reported)

Sedentary individuals can not tolerate the same increase in rectal temperature ( $T_{re}$ ) during uncompensable heat stress (UHS) compared with endurance trained subjects, partially due to intestinal ischemia and endotoxin leakage that occurs with the redistribution of splanchnic blood flow. Heat acclimation (HA) may be an adaptive strategy for these individuals to increase plasma volume and delay endotoxin leakage, thus increasing thermotolerance during UHS.

**PURPOSE:** The purpose was to examine the relationship between plasma volume (PV) changes and thermotolerance during UHS following 9 days of HA in sedentary males.

**METHODS:** Seven sedentary males (mean $\pm$ SD: 28 $\pm$ 7 y, 75.3 $\pm$ 8.0 kg,  $\text{VO}_{2\text{peak}}$  = 42 $\pm$ 6 mL $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ) walked to exhaustion on a treadmill (4.5 km $\cdot$ h $^{-1}$ , 2% grade) in 40°C and 30% R.H. wearing combat clothing and a protective hooded overgarment on 9 days (over 2 consecutive weeks). PV was determined prior to beginning HA using Indocyanine Green<sup>TM</sup> and resting hematocrit and hemoglobin values measured on subsequent days were used to calculate the change in PV.

**RESULTS:** PV increased significantly over the 9 days from 49.6 $\pm$ 9.0 to 53.3 $\pm$ 10.3 mL $\cdot$ kg $^{-1}$ . The change in  $T_{re}$  from beginning to end of the UHS also increased significantly over the 9 days from 1.94 $\pm$ 0.38 to 2.37 $\pm$ 0.3°C owing to both a significant reduction in resting  $T_{re}$  from 36.83 $\pm$ 0.32 to 36.59 $\pm$ 0.26°C and a non-significant increase ( $p < 0.08$ ) in  $T_{re}$  at exhaustion (38.76 $\pm$ 0.4 to 38.95 $\pm$ 0.31°C). Total heat storage increased significantly from 6.7 $\pm$ 1.3 to 8.0 $\pm$ 1.2 kJ $\cdot$ kg $^{-1}$ . However, PV changes were not related to changes in heat storage or the changes in initial or final core temperatures during UHS.

**CONCLUSION:** Although 9 days of HA induced an expansion of PV in these sedentary males, these changes were not directly related to the increase in heat storage that occurred. Funded by a Defence R&D Canada Technology Investment Fund and the US Navy Office of Naval Research.

### **2424 Board #69 May 29 8:00 AM - 9:30 AM**

#### **Heat And Run, Genomic And Morphological Aspects Of Adaptation In The Rat's Heart**

Einat Kodesh<sup>\*1</sup>, Assi Saamn<sup>1</sup>, Ronen Beer<sup>2</sup>, Dan Gilon<sup>2</sup>, Michal Horowitz<sup>1</sup>. <sup>1</sup>Hebrew University, Jerusalem, Israel. <sup>2</sup>Hadassah University Hospital, Jerusalem, Israel. (Sponsor: D.S.Moran, FACSM)

(No relationships reported)

**INTRODUCTION:** Heat acclimation (AC) and exercise training (EX) individually improves mechanical and metabolic performance of the isolated rat's heart. Combined heat acclimation and exercise training (EXAC) demonstrates an interactive/additive effect, manifested by greater systolic pressure generation than that shown by either alone. Given the opposing adaptive requirements of the two stressors, the underlying mechanisms of the combined EXAC affect is as yet unknown.

**PURPOSE:** 1. *in vivo* assessment of the physiological adaptation to the stressors 2. determining global genomic responses using gene profiling analyses 3. linking physiological and genomic responses.

**METHODS:** Rats were divided into: AC, EXAC (30d, 34°C), C, EX (30d, 24°C) groups. For Exercise training a progressive treadmill protocol was applied; *In vivo* cardiac performance was monitored using Echocardiography; global genomic response of homeostasis associated genes was detected using cDNA microarray.

**RESULTS:** Increased thickness of posterior and septum walls coincidentally with decreased chamber diameter was demonstrated in EX and EXAC groups. Longer duration of left ventricular ejection and circumferential fiber shortening, implying decreased contractile velocity was evident in the heat treated groups. Gene profiling demonstrated transcript upregulation in a stress specific manner. Focusing on metabolic, transport, stress and signaling GO categories, we demonstrated that EX and EXAC upregulated 37 and 43% (in metabolic) while AC and EXAC upregulated 25 and 21% (in transport) genes. Other categories changed similarly in all groups.

**CONCLUSION:** Exercise training was manifested in morphological changes; chronic heat overrode exercise training mediated contractile response. Principally, both stressors upregulated gene expression. Different gene profiles were detected, however, following the various treatments. Training affected metabolic pathways (most pronouncedly in the EXAC) while exposure to heat induced changes in genes linked to transport, EC coupling mechanism and cytoprotection. Concerted gene upregulation in all functional categories, in EXAC only, may account for the advantage in pressure generation seen in this group.

**Effect Of Elevated Local Temperature On Cutaneous Vasoconstrictor Responsiveness In Humans**

Jonathan Wingo<sup>1</sup>, David A. Low<sup>2</sup>, David M. Keller<sup>3</sup>, R Matthew Brothers<sup>1</sup>, Manabu Shibasaki<sup>4</sup>, Craig G. Crandall, FACSM<sup>1</sup>. <sup>1</sup>*Institute for Exercise and Environmental Medicine, Dallas, TX.* <sup>2</sup>*Brunel University, Uxbridge, Middlesex, United Kingdom.* <sup>3</sup>*University of Texas at Arlington, Arlington, TX.*

<sup>4</sup>*Nara Women's University, Nara, Japan.*

Email: jewingo@tx.rr.com

(No relationships reported)

Cutaneous vascular conductance (CVC) increases in response to local skin heating. While attenuation of vasoconstrictor responsiveness due to local heating has been demonstrated, the mechanism(s) responsible for this attenuation remain unclear. Nitric oxide has been shown to at least partially contribute to this response, but other mechanisms also may be involved.

**PURPOSE:** To test the hypothesis that local heating diminishes cutaneous vasoconstrictor responsiveness through a nitric oxide independent mechanism by altering post-synaptic reactivity to norepinephrine. A follow-up protocol tested the hypothesis that local heating attenuates the pre-synaptic release of neurotransmitters that cause vasoconstriction, also via non-nitric oxide mechanisms.

**METHODS:** Protocol I: in 8 subjects, CVC was assessed while increasing doses of norepinephrine (via intradermal microdialysis) were administered at adjacent sites separately heated to 34 and 40 °C. Protocol II: in an identical but separate protocol, in 7 subjects, CVC was assessed while increasing doses of tyramine, which causes release of neurotransmitters from adrenergic nerves, were administered. At each site for both protocols, nitric oxide synthesis was inhibited (via microdialysis administration of *N*<sup>G</sup>-nitro-L-arginine methyl ester) and flow was matched (via microdialysis administration of adenosine), leaving temperature as the only variable different between sites.

**RESULTS:** For both protocols, non-linear regression analysis revealed no difference (*P* > 0.05) in the effective drug concentration causing 50% of the vasoconstrictor response. Minimum CVC (protocol I, mean ± SD: 6.3 ± 2.0 and 9.0 ± 4.0 %CVC<sub>peak</sub>; protocol II: 19.3 ± 9.3 and 20.5 ± 11.9 %CVC<sub>peak</sub> at the 34 and 40 °C sites, respectively) was not different between sites.

**CONCLUSION:** Independent of nitric oxide, local skin heating to 40 °C does not attenuate adrenergically-mediated cutaneous vasoconstriction through pre- or post-synaptic mechanisms.

**Comparison Of Invasive And Non-invasive Measures Of Arterial Blood Pressure In Heat Stressed Humans.**

Manabu Shibasaki<sup>1</sup>, Thad E. Wilson<sup>2</sup>, Niels H. Secher<sup>3</sup>, Craig G. Crandall, FACSM<sup>4</sup>. <sup>1</sup>*Nara Women's University, Nara, Japan.* <sup>2</sup>*Ohio University College of Osteopathic Medicine, Athens, OH.* <sup>3</sup>*Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.* <sup>4</sup>*University of Texas Southwestern Medical Center at Dallas, Dallas, TX.* (Sponsor: CraigCrandall@texashealth.org, FACSM)

Email: shiba@cc.nara-wu.ac.jp

(No relationships reported)

Arterial blood pressure is an important variable when evaluating physiological responses to whole-body heat stress. The Finometer™ is commonly used to evaluate this parameter because of its non-invasive and continuous measurement attributes. However, it is unknown whether the Finometer™ accurately tracks arterial blood pressure during heat stress.

**PURPOSE:** To test the hypothesis that the Finometer™ accurately assesses arterial blood pressure in heat stressed individuals, when compared to arterial blood pressure obtained via direct cannulation.

**METHODS:** 17 subjects underwent whole-body heat stress sufficient to increase internal temperature at least 1 °C. Arterial blood pressure was measured via brachial artery cannulation and via the volume-clamp method of the Finometer™. Two min averages of mean arterial blood pressure (MAP) were obtained while subjects were normothermic and after whole-body heat stress. Data were analyzed via 2 way repeated measures ANOVA with main factors of device (i.e., artery cannulation and Finometer™) and thermal status (normothermia and heat stress).

**RESULTS:** Whole-body heat stress reduced MAP when evaluated with both devices. However, a significant interaction from the ANOVA was identified (*P* < 0.001). Further analysis demonstrated that the reduction in MAP to the heat stress was almost two fold greater when evaluated with the Finometer™ (13.9 ± 8.0 mmHg; mean ± SD), relative to direct arterial cannulation (7.3 ± 4.6 mmHg; *P* < 0.001).

**CONCLUSIONS:** These data suggest that caution should be taken when evaluating MAP during heat stress when solely relying upon Finometer™ derived values. Other measures of MAP, such as direct cannulation or auscultation of the brachial artery, should be considered when measuring blood pressure in heat stressed individuals. Sponsored by NIH HL61388 & HL84072

**Mechanisms Of Orthostatic Intolerance During Passive Heat Stress**

Luke C. Wilson, James D. Cotter, Jui-lin Fan, Rebekah A I Lucas, Kate N. Thomas, Philip N. Ainslie. *University of Otago, Dunedin, New Zealand.*

(Sponsor: Nancy Rehrer, FACSM)

Email: willu061@student.otago.ac.nz

(No relationships reported)

Passive heat stress has been shown to cause orthostatic intolerance. The role of potential mediators remains unclear but should include factors that affect cerebral perfusion directly or indirectly. **PURPOSE:** To determine the roles of hyperthermic-induced hypocapnia and hypotension on orthostatic intolerance during graded hyperthermia.

**METHODS:** Eight healthy young males, resting supine in a water-perfused suit, were progressively heated in 1.0°C (oesophageal) increments from normothermia to +2°C. At each thermal state, orthostatic tolerance was assessed using progressive lower body negative pressure to -45 mm Hg or to pre-syncope. During all procedures, blood flow velocity in the middle cerebral artery (MCAv; transcranial Doppler ultrasound), mean arterial pressure (MAP), heart rate (HR) and the partial pressure of end-tidal carbon dioxide (PETCO<sub>2</sub>) were measured continuously.

**RESULTS:** All subjects tolerated +1°C, whereas only six subjects reached +2°C. During orthostatic stress, pre-syncope occurred in one participant at +1°C, and in four at +2°C. Heating alone reduced mean MCAv ( $-11 \pm 5\%$ ), MAP ( $-11 \pm 5$  mm Hg) and PETCO<sub>2</sub> ( $-7 \pm 5$  mm Hg), and elevated HR ( $21 \pm 5$  b/min; all  $P < 0.05$ ), but responses were alinear, except for heart rate. The entire drop in MAP across the range of heating occurred before 1°C, whereas the majority of the drop ( $\sim 68\%$ ) in MCAv occurred above 1°C. Orthostatic stress at normothermia did not reduce PETCO<sub>2</sub>, MAP or mean MCAv. Orthostatic stress reduced MCAv during heat stress; at +1°C this was related to the reduction in MAP only ( $r^2 = 0.72$ ;  $P = 0.008$ ), whereas at +2°C it was related to PETCO<sub>2</sub> only ( $r^2 = 0.77$ ;  $P = 0.049$ ).

**CONCLUSIONS:** Hypotension and hypocapnia both mediate (pre)syncope during passive heat and orthostatic stress, but in different patterns. Some hypotension develops at modest hyperthermia, whereas hypocapnia occurs more at higher temperatures and is associated with much lower cerebral perfusion and tolerance.

**The Effects Of Reduced End-tidal Carbon Dioxide Tension On Cerebrovascular Conductance During Heat Stress**

R Matthew Brothers, Jonathan E. Wingo, Kimberly A. Hubing, Craig G. Crandall, FACSM. *Institute for Exercise and Environmental Medicine, Dallas, TX.*

Email: robertbrothers@texashealth.org

(No relationships reported)

**PURPOSE:** Passive heat stress reduces arterial carbon dioxide (PaCO<sub>2</sub>) partial pressure as reflected by 3 to 5 mmHg reductions in end-tidal carbon dioxide tension (PETCO<sub>2</sub>). Heat stress also reduces cerebrovascular conductance (CBVC) by up to 30%. While PaCO<sub>2</sub> is a strong regulator of CBVC, it is unlikely that the relatively small changes in PETCO<sub>2</sub> during heating are solely responsible for the reductions in CBVC. The aim of this study was to test the hypothesis that PaCO<sub>2</sub>, referenced by PETCO<sub>2</sub>, is not the sole regulator of CBVC during heat stress.

**METHODS:** Mean arterial blood pressure (MAP), PETCO<sub>2</sub>, middle cerebral artery blood velocity (MCAV<sub>mean</sub>), and calculated CBVC (MCAV<sub>mean</sub> / MAP) were assessed in 7 healthy individuals, each wearing a water-perfused suit during three separate conditions performed sequentially 1) normothermia (NT), 2) control passive heat stress (HS), and 3) passive heat stress with PETCO<sub>2</sub> clamped at the normothermic level (HS + Clamp) using a computer controlled sequential gas delivery breathing circuit (Respiract™).

**RESULTS:** MAP was similar between the three thermal conditions (NT:  $85 \pm 9$ ; HS:  $84 \pm 10$ ; HS + Clamp:  $84 \pm 10$  mmHg;  $P = 0.46$ ). HS increased internal temperature (NT:  $36.9 \pm 0.2$ ; HS:  $38.3 \pm 0.4$  °C;  $P < 0.001$ ) while it decreased PETCO<sub>2</sub> (NT:  $40.7 \pm 2.6$ ; HS:  $34.8 \pm 4.6$  mmHg;  $P < 0.001$ ). MCAV<sub>mean</sub> (NT:  $58.7 \pm 4.5$ ; HS:  $40.8 \pm 8.3$  cm·s<sup>-1</sup>;  $P < 0.001$ ), and calculated CBVC (NT:  $0.70 \pm 0.1$ , HS:  $0.49 \pm 0.1$  CBVC units;  $P < 0.001$ ). During HS + Clamp internal temperature remained similar to that during the HS condition (HS + Clamp:  $38.5 \pm 0.4$  °C;  $P = 0.31$ ). HS + Clamp successfully restored PETCO<sub>2</sub> to the NT level (HS + Clamp:  $40.8 \pm 2.5$ ;  $P = 0.99$ ) and increased MCAV<sub>mean</sub> (HS + Clamp:  $50.1 \pm 5.4$  cm·s<sup>-1</sup>;  $P = 0.002$ ) and CBVC (HS + Clamp:  $0.6 \pm 0.1$  CBVC units;  $P = 0.008$ ) relative to HS however both variables remained reduced relative to NT ( $P = 0.005$  and  $0.03$ ; for MCAV<sub>mean</sub> and CBVC, respectively).

**CONCLUSIONS:** These results indicate that heat stress induced reductions in PaCO<sub>2</sub>, as referenced by PETCO<sub>2</sub>, contribute to the decrease in MCAV<sub>mean</sub> and CBVC however other factors (possibly elevated sympathetic nerve activity) are also involved in mediating this response.

**Does Exercise Intensity Modulate The Thermoregulatory Responses To Intermittent And Continuous Exercise?**

Barry Drust, Steven Jones, Helen Jones, Warren Gregson, Greg Atkinson. *Liverpool John Moores University, Liverpool, United Kingdom.* (Sponsor: A.M.Batterham, FACSM)

Email: B.Drust@ljmu.ac.uk

(No relationships reported)

Evidence for differences in thermoregulatory strain between intermittent (INT) and continuous exercise (C) performed at the same average exercise intensity is inconclusive. This uncertainty may be a consequence of the specific nature of the exercise protocol performed and/or the site of core temperature measurement.

**PURPOSE:** To determine the impact of exercise intensity on the thermoregulatory responses to INT and C.

**METHODS:** Seven male subjects (Age  $25 \pm 2$  yrs; Height  $1.80 \pm 0.70$  m; Body mass  $77.1 \pm 8.0$  kg; VO<sub>2max</sub>  $49.6 \pm 5.9$  mL·kg<sup>-1</sup>·min<sup>-1</sup>) volunteered to participate. Each subject completed 30 min bouts of INT with a 1:1 (45s:45s) exercise:rest ratio at two different intensities (Bout 1: INT<sub>100</sub>, 100% VO<sub>2max</sub>; Bout 2: INT<sub>50</sub>, 50% VO<sub>2max</sub>). Subjects also completed 2 x 30 min bouts of C at the same average exercise intensities as in INT (Bout 1: C<sub>100</sub>, 50% VO<sub>2max</sub>; Bout 2: C<sub>50</sub>, 25% VO<sub>2max</sub>). All exercise trials were completed in a randomised order at  $18 \pm 2$  °C on a cycle ergometer. Oesophageal, rectal, mean skin temperature and heart rate were monitored throughout exercise. Subjective ratings of thermal comfort and perceived exertion were recorded at 5 min intervals throughout exercise. Data were analysed using a 3-factor repeated measures general linear model.

**RESULTS:** Increases in rectal temperature were significantly greater (95% CI = 0.03 to 0.31,  $P = 0.005$ ) in INT<sub>100</sub> ( $0.6 \pm 0.1$  °C) and INT<sub>50</sub> ( $0.2 \pm 0.1$  °C) than during C<sub>100</sub> and C<sub>50</sub> ( $0.4 \pm 0.2$  °C and  $0.1 \pm 0.1$  °C respectively). Changes in oesophageal temperature were sensitive to increases in exercise intensity ( $P = 0.001$ ) but were not significantly different (95% CI = -0.30 to 0.29,  $P = 0.761$ ) between INT and C (INT<sub>100</sub>  $0.8 \pm 0.3$  °C; INT<sub>50</sub>  $0.3 \pm 0.3$  °C; C<sub>100</sub>  $0.8 \pm 0.3$  °C; C<sub>50</sub>  $0.2 \pm 0.4$  °C). All other variables were significantly affected by exercise intensity ( $P < 0.05$ ) but not exercise pattern.

**CONCLUSION:** We have observed a site-dependent variation in the thermoregulatory strain associated with moderate duration INT exercise performed in compensable environmental conditions. Exercise pattern is an important determinant of the thermoregulatory response to exercise irrespective of the exercise intensity employed.

**Impact Of Prior Heat Stress On Subsequent Aerobic Exercise Performance**

Robert W. Kenefick, FACSM, Laura J. Palombo, Brett R. Ely, Daniel A. Goodman, Samuel N. Cheuvront, FACSM, Michael N. Sawka, FACSM. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

Email: Robert.Kenefick@us.army.mil

(No relationships reported)

The impact of prior heat exposure on subsequent aerobic exercise-heat performance has not been studied. However, recent research shows that despite returning to normothermia, residual effects persisted during an orthostatic challenge.

**PURPOSE:**To determine if prior heat exposure degrades subsequent aerobic exercise performance in the heat.

**METHODS:**Eighteen non-heat acclimated males established their baseline aerobic exercise performance in temperate conditions (4 practice trials; 22°C) and then were divided into two (n=8) groups. One group (EUH<sub>PH</sub>; VO<sub>2peak</sub>, 44.4 ± 6 ml·kg<sup>-1</sup>·min<sup>-1</sup>) was tested after 90 minutes of recovery (22°C) from 3 hr of intermittent light intensity (< 30% VO<sub>2peak</sub>) exercise-heat (50°C) exposure where sweat losses were matched with fluid intake (3.5 ± 0.5 L) to maintain euhydration. The other group (EUH; VO<sub>2peak</sub>, 46 ± 5 ml·kg<sup>-1</sup>·min<sup>-1</sup>) was tested while euhydrated without prior exercise-heat exposure. Aerobic performance was determined from a 30-min cycling pre-load (50% VO<sub>2peak</sub>) followed by a 15 min time trial in 40°C. Total work during the 15-min performance time trial in EUH and EUH<sub>PH</sub> was compared, as were the percentage changes from their best practice trial.

**RESULTS:**Volunteers were euhydrated (plasma osmolality <290 mOsm·kg<sup>-1</sup>) and normothermic prior to each aerobic exercise performance trial. Therefore, the 90 rest was sufficient to recover from hyperthermia (core temperature elevation of 1.4 ± 0.5°C). Heart rate and core temperature were not different (p>0.05) between groups at any time point during exercise. Total work was not different (p>0.05) at baseline or between EUH (150.5 ± 28.3kJ; 2.0 ± 0.3 kJ·kg<sup>-1</sup>) and EUH<sub>PH</sub> (160.3 ± 24.0 kJ; 1.8 ± 0.2 kJ·kg<sup>-1</sup>) exercise-heat trials. The percent change in total work relative to baseline was not different (p>0.05) between EUH (-18.7 ± 9.2%) and EUH<sub>PH</sub> (-15.0 ± 7.8%).

**CONCLUSIONS:** If hydration and body temperatures recover, prior exercise-heat exposure does not result in a greater degradation in aerobic exercise performance in the heat compared to heat exposure alone.

**High Solar Radiation Degrades Thermoregulatory Model Performance in Highly Fit Runners**

David W. DeGroot, Matthew R. Ely, Brett R. Ely, Laurie A. Blanchard, Scott J. Montain, FACSM, Samuel N. Cheuvront, FACSM. *USARIEM, Natick, MA.*

Email: david.degroot@us.army.mil

(No relationships reported)

Solar radiation can add up to 1000 W/m<sup>2</sup> to the heat load that needs to be dissipated in order to maintain heat balance. The effect of solar radiation on models of human thermoregulation during self-paced outdoor running is unknown but suspected to increase model error.

**PURPOSE:** To evaluate the accuracy of a model of thermoregulation in highly fit runners during high and low solar radiant loads.

**METHODS:** On day 1, 5 runners (3 male, 2 female) completed a self-paced 8K run on a 400m outdoor track. On day 2, 5 different runners (2 male, 3 female) completed the same run. Core temperature was measured via telemetry pill (T<sub>pill</sub>). Dry bulb temperature (29.4±0.5 vs 30.2±0.3°C) and relative humidity (62±3 vs. 61±2%) were similar, while black globe (31.3±1.8 vs. 38.3±1.5°C, p<0.01) and mean radiant (38.2±6.4 vs. 70.5±4.5°C, p<0.01) temperatures were significantly higher on day 2. The Initial Capability Decision Aide (ICDA) model was used to predict T<sub>c</sub>. Non-parametric Bland-Altman analyses were performed to assess model performance, in which the proportion of predicted T<sub>c</sub> values within 0.20°C of actual was calculated.

**RESULTS:** The mean 8K time was lower for day 1 (1639±114 vs. 1858±126s, p<0.05) though final T<sub>c</sub> (40.4±0.3 vs. 40.3±0.3°C) was similar. The model predicted 70% of T<sub>c</sub> values within 0.20°C of actual values during day 1 (low solar radiation) conditions but only 27% during day 2 (high solar radiation) conditions. Model predicted metabolic rate was similar between groups (9.7±1.7 vs 9.7±2.7 METS, p=0.98).

**CONCLUSIONS:** These results indicate that high solar radiation degrades ICDA thermoregulatory model performance. Alternative methods for quantifying solar radiation may yield improved model results.

(No relationships reported)

**INTRODUCTION:** During physical training in the heat, extreme metabolic heat storage manifests (pending on the individual features) as a rise in body core temperature (T<sub>c</sub>).

Individuals, previously exposed to heat exhaustion/stroke and demonstrating an earlier/faster T<sub>c</sub> and heart rate rise within a cohort study, are defined as "heat intolerant" (HI). Whether HI is a transient phenotypic or genotypic response is yet unknown.

**PURPOSE:** To investigate whether HI and heat tolerant (HT) subjects differ in their lymphocyte gene profile.

**METHODS:** 68 healthy young male volunteers, 1-3 months post-exertion heatstroke, underwent a heat tolerance test (HTT), consisting of walking on a treadmill for 2h at a speed of 5 km·h<sup>-1</sup> and 2% grade in a climatic chamber (40°C, 40% relative humidity). T<sub>c</sub>, T<sub>skin</sub> (3 sites), and heart rate were continuously monitored and recorded. Blood samples were drawn before, at the end of the HTT and after 1h of recovery in an air-conditioned room (23°C). Global gene profile of 6 HT and 6 HI lymphocytes RNA samples (2 pools per group) was detected and analyzed using two-color gene chips and bioinformatic tools.

**RESULTS:** According to the HTT, 10 subjects were diagnosed as HI and 58 subjects as HT. T<sub>c</sub> at the end of HTT was elevated by 1.4 and 0.77°C in the HI and the HT subjects, respectively. T<sub>skin</sub> vs. T<sub>c</sub>, indicative of skin blood flow, implied a HI sluggish response (vs. HT) (P<0.01). Two different gene chip experimental paradigms indicated differences in gene profiles of the HI vs. the HT group, prior to and following recovery from HTT. Basal differences in biological functional categories among the groups included genes associated with immune responses, stress (e.g., apoptotic pathways), transport, molecular processes (DNA and RNA regulation and organization) and metabolism.

**CONCLUSIONS:** This study (as well as our previous reports) characterizes a distinct HI physiological phenotype. This characterization of the HI phenotype demonstrates a differential genomic profile found even prior to heat stress tests, adding a novel category to the defined reasons for potential congenital HI.

(No relationships reported)

Exertional heat illness is a significant morbidity and mortality risk in individuals exercising in hot, humid environmental conditions. The third leading cause of death in US high school athletes, it is of considerable concern to the sports medicine team.

**PURPOSE:** This study investigated the relationship between subjective symptom scores and gastrointestinal temperature, T<sub>gi</sub>, in elite football athletes during two a day practices in the heat and humidity of southern Florida.

**METHODS:** 66 division I collegiate football athletes participated in this study over two years of two a day preseason practices. Athletes ingested T<sub>gi</sub> temperature thermistors preceding each practice and were evaluated by a validated symptom questionnaire, the Heat Illness Symptom Index (HISI), following each practice.

**RESULTS:** 5552 data points were obtained on 66 athletes, covering an average of 4.4 hours per player. The data was collected over 25 early preseason practices, 12 am practices and 13 pm practices. Each player was monitored for an average of four practices. Statistically significant correlation was seen between multiple variables and Tgi. Time elapse ( $p<.0001$ ), was obviously a predictor of core temperature elevation, but also player position group ( $p=0.0003$ ), BMI ( $p=0.0001$ ), symptom score of same practice ( $p<0.0001$ ), symptom score of the preceding practice ( $p<0.0001$ ), and rating of perceived exertion ( $p<0.0001$ ).

**CONCLUSION:** HISI scores following each practice were predictive of core temperature elevations in the the following practice ( $p=0.0001$ ). Those at highest risk of elevated core temperature the following practice were those that ranked in the fourth (highest) quartile on HISI score ( $p=0.0001$ ). The HISI can be a valuable, simple tool in identifying those at risk of elevated core temperature in football athletes exercising in the heat.

(No relationships reported)

Exertional heat illness is one of the most important health problems of athletes who have to train and compete in hot and humid environmental conditions. To our knowledge there are no published data that reflect the effects of heat strain on soccer players under extreme heat conditions.

**PURPOSE:** The aim of this study was to evaluate the effect of a competitive soccer match played at high environmental temperature and humidity on serum electrolytes, serum biochemistry and serum osmolality.

**METHODS:** 21 soccer players aged  $20 \pm 2$  y (mean  $\pm$  SD) with  $\dot{V}\text{O}_{2\text{max}}$  of ( $60.9 \pm 5.1$  ml/kg/min) volunteered to join this study. During the match, the ambient temperature and humidity were  $34.3 \pm 0.6$  °C and  $64 \pm 2$  %, respectively. Blood samples were withdrawn from an antecubital vein 5 hours before and immediately after the game. Thermosensor pills were used for body temperature measurements. Paired sample t-test was used to evaluate the level of significance, and p values  $< 0.05$  were accepted as significant.

**RESULTS:** Significant increases were found after the game in BUN ( $14.9 \pm 3.3$  vs  $19.5 \pm 3.9$  mg/dL), creatinine ( $0.9 \pm 0.1$  vs  $1.5 \pm 0.2$  mg/dL), Na ( $143 \pm 2$  vs  $145 \pm 3$  mmol/L), K ( $4.5 \pm 0.4$  vs  $5.3 \pm 0.4$  mmol/L). The highest body temperature recorded during the game was  $39.5 \pm 0.6$  °C. Players had opportunities to consume plain water ad libitum during the game, but post-match serum osmolality values were significantly higher than pre-match values ( $293 \pm 11$  vs  $285 \pm 12$  mosm/kg;  $p < 0.05$ ). The hematocrit ( $48.7 \pm 3.0$  vs  $49.2 \pm 3.0$  %) and hemoglobin values ( $16.1 \pm 1.2$  vs  $16.3 \pm 1.2$  g/L) were used to calculate % plasma volume change ( $-2.1 \pm 7.4$  %).

**CONCLUSIONS:** Even though the players consumed plain water ad libitum during the game, increased serum osmolality may emphasize the effects of thermal stress during a soccer match under extreme heat and humidity. Significantly increased BUN and creatine values may indicate dehydration-induced reduced renal perfusion. Playing soccer under extreme heat and humidity requires special care for the players in terms of heat stress and accompanying biochemical changes.

(No relationships reported)

Soccer teams may sometimes be obliged to play under difficult environmental conditions. Indoor laboratory measurements may underestimate the associated thermoregulatory heat stress.

**PURPOSE:** To evaluate the heat stress responses of players during soccer matches played in different environmental temperatures and humidity.

	Temperature (°C)	Humidity (%)	Peak Body Core Temperature (°C)	Sweat Loss (L)	Dehydration (%)
April	$23 \pm 0$	$39 \pm 3$	$39.0 \pm 0.4$	$1.9 \pm 0.4$	$1.3 \pm 1.1$
June	$34 \pm 1^*$	$38 \pm 2$	$39.3 \pm 0.3$	$2.8 \pm 0.4^*$	$2.3 \pm 0.7^*$
July	$36 \pm 0^{**}$	$61 \pm 1^*$	$39.6 \pm 0.4^*$	$2.8 \pm 0.6^*$	$2.0 \pm 0.7$

**METHODS:** Non-acclimatized soccer players ( $n=15$ ,  $21 \pm 2$  y,  $\dot{V}\text{O}_{2\text{max}} = 62.5 \pm 7.1$  ml/min/kg, due to different

reasons some players could not played in all three matches, missing players replaced by other non acclimatized players) played 3 matches in different environmental conditions (Table) Players ingested telemetric core temperature (Tc) sensors prior to each match. Body weight, fluid intake, and urine volume were measured to determine % dehydration and sweat loss volume.

**RESULTS:** Temperature and humidity in July was significantly higher than April. In all cases the peak Tc was recorded in the first half of the game. Peak Tc recorded in the July match was significantly higher than the April match. Sweat loss volume was calculated as a function of mass loss, the amount of urine production and the amount of water consumed. The amount of sweat lost in June and July was higher than April. The amount of dehydration in June was than April.

\*: significantly different than April value

#: significantly different than June value

**CONCLUSIONS:** In all matches peak body core temperature values recorded in the first half were higher than peak temperature values in the second half. Post-match temperature measurements may under-estimate peak match core temperature values. Hyperthermia may occur in football players in games played at high ambient temperatures.

(No relationships reported)

Low to moderate doses of physiologic stressors, including heat, cold, and exercise have been shown experimentally to induce HSP72. However, the effect of dehydration on HSP72 expression has not been previously examined.

**PURPOSE:** The present study evaluates the effect of mild dehydration on HSP72 expression during 90 minutes of continuous exercise.

**METHODS:** Three male subjects (mean  $\pm$  SD; ht, 177.7  $\pm$  9.5 cm, wt 70.7  $\pm$  8.6 kg, BF%, 7.8  $\pm$  1.4%; cycle VO<sub>2</sub> pk 53.0  $\pm$  3.6 ml/kg/min<sup>-1</sup>) performed two cycling bouts at 70% VO<sub>2</sub> pk (37.1  $\pm$  2.5 ml/kg/min<sup>-1</sup>) in a temperate environment (21.8  $\pm$  0.8°C, RH 42  $\pm$  1 %) for 90 minutes. In one condition subjects were provided water for 48 hours prior to exercise testing to ensure euhydration, while in the other subjects were voluntarily dehydrated. Nude bodyweight and urine osmolality were measured both pre and post exercise. During exercise core temperature, oxygen consumption, and power output were measured every 15 minutes. HSP72 was measured in peripheral blood mononuclear cells separated from blood samples taken pre and 1 hour post exercise. Western blot was used to quantify HSP72, with pretest levels being normalized to 1.0 for each condition to increase interpretation.

**RESULTS:** There were no differences ( $p > 0.05$ ) in peak core temperature (38.99  $\pm$  0.15 vs. 38.74  $\pm$  0.25°C), exercise induced change in bodyweight (1.8  $\pm$  0.7 vs. 1.8  $\pm$  0.8%), power output (185  $\pm$  2 vs. 186  $\pm$  5 W), or oxygen consumption (36.9  $\pm$  3.2 vs. 36.4  $\pm$  2.4 ml/kg/min<sup>-1</sup>) between the dehydrated and euhydrated conditions, respectively. Urine osmolality was greater in the dehydrated condition both pre (808  $\pm$  159 vs. 163  $\pm$  78 mosm/kg;  $p < 0.001$ ) and post exercise (908  $\pm$  189 vs. 302  $\pm$  66 mosm/kg;  $p < 0.001$ ). Following exercise HSP72 expression in the euhydrated condition was 47% lower than the dehydrated condition. Although this difference was large, variability in dehydrated subjects post exercise HSP72 values prevented us from showing a significant difference ( $p = 0.14$ ).

**CONCLUSION:** Preliminary findings ( $n = 3$ ) indicate that mild dehydration may not be sufficient to induce HSP72 during an acute bout of exercise. Whether this trend will remain with greater  $n$  size remains to be determined.

(No relationships reported)

Although extensive research has analyzed the stress inducible HSP72, a confounding variable has been the inter-subject variability existing at baseline. It remains to be determined whether greater experimental control can increase uniformity of basal HSP72 expression.

**PURPOSE:** The present study evaluates whether increasing control of subject diet, hydration, physical activity, and environmental exposure will reduce variation in HSP72.

**METHODS:** Four male subjects (mean  $\pm$  SD; ht, 176.8  $\pm$  8 cm; wt, 74.6  $\pm$  10.4 kg; age, 25  $\pm$  3 yrs) repeated two experimental conditions in a counterbalanced order. In the confined condition (CC) subjects became hospital inpatients for 48 hours. Caloric intake (60% CHO, 15% PRO, 25% FAT) was set according to current dietary reference intakes (activity factor = 1.4). Fluid and caffeine intake were controlled to ensure euhydration. Subjects were restricted to the hospital, ensuring they remained sedentary and were not exposed to UV light. In the wild condition (WC) subjects were on the honor system to follow the same guidelines, mimicking a traditional HSP72 protocol. HSP72 was measured in peripheral blood mononuclear cells separated from blood samples taken 1 hour post prandial at the beginning (Pre) and end (Post) of each condition. Western blot was used to quantify HSP72, with pretest levels being normalized to 1.0 for each condition to aid interpretation.

**RESULTS:** Following CC subjects were more hydrated than in WC (urine osmolality = 166  $\pm$  64 mosm/kg vs 850  $\pm$  154 mosm/kg;  $p < 0.01$ ). HSP72 was not different ( $p > .05$ ) from WC.

**CONCLUSION:** Preliminary data ( $n = 4$ ) reveal a difference in both intersubject and intrasubject variability following CC, but at this time these differences are not statistically significant.

Email: tgillum@unm.edu

(No relationships reported)

Heat shock proteins (Hsp) are a ubiquitous family of proteins known to have cytoprotective functions. Previous data has shown that serum Hsp72 is known to increase in response to exercise, but the response and time course of intracellular Hsp72 in peripheral blood mononucleated cells (PBMCs) during exercise has yet to be critically examined.

**PURPOSE:** To measure the intracellular Hsp72 response in PBMCs to cycle ergometry. We hypothesized that Hsp72 will increase throughout the exercise bout.

**METHODS:** Three healthy, active (VO<sub>2</sub> pk 53.0  $\pm$  3.6 ml/kg/min) males (BW 70.7  $\pm$  8.6 kg) participated in this study. Subjects were confined to the hospital for the 48 hrs prior to exercise to minimize variance by standardizing activity, diet, hydration, & UV exposure. Cycle ergometry consisted of 90 min at 70% VO<sub>2</sub> max in a thermo-neutral environment (21.8  $\pm$  0.8°C, 44.2%  $\pm$  1.0 RH). Subjects consumed 125 mL of water every 15 min. Blood samples were collected pre, 30, 60, and 90 min, along with 1 hr post. Western blot was used to quantify the presence of Hsp72 in PBMCs during and after exercise.

**RESULTS:** Core temperature reached 38.63  $\pm$  .19°C during exercise and subjects body weight decreased 1.8  $\pm$  0.8%. In all three subjects, Hsp72 levels decreased 13-35% from pre to 90 min of exercise, and 48-58% from pre to 1 hr post exercise.

**CONCLUSION:** With exercise there is an initial depletion of intracellular Hsp72 levels. This preliminary data suggests the response of intracellular Hsp72 during exercise is opposite of serum Hsp72.

**Use Of Diffusion Tensor Magnetic Resonance Imaging For Assessment Of Musculoskeletal Structure Following High-force Eccentric Exercise: A Case Study**

Naomi Cermak, Michael Noseworthy, Martin Gibala. *McMaster University, Hamilton, ON, Canada.* (Sponsor: Lawrence Spriet, FACSM)  
Email: cermaknm@mcmaster.ca  
(No relationships reported)

Typically, only dramatic muscle damage associated with edema and hemorrhage has been visible with MRI as even with MRI's superior spatial resolution, subtle muscle tear evaluation has been limited. Recently however, diffusion tensor (DT) MRI has been successful in detecting abnormalities in muscle tissue induced by disease or traumatic injury (Zaraskaya, et al. 2006). DT-MRI offers not only a way to diagnose skeletal muscle disruption, but also to quantify the abnormality within the muscle tissue. As a noninvasive technique, DT-MRI makes it possible to perform repeat imaging and evaluate the duration and severity of the muscle injury over time. Strenuous unaccustomed exercise induces ultrastructural evidence of skeletal muscle disruption; however the potential use of DT-MRI to investigate exercise-induced muscle tissue alteration has not been examined.

**PURPOSE:** To investigate acute changes in musculoskeletal structure following a high-force eccentric exercise protocol previously shown to induce skeletal muscle disruption (Beaton et al., *Med Sci Sports Exerc* 34:798-805, 2002).

**METHODS:** A healthy active 39 year old man performed 24 sets of 10 maximal eccentric actions with the leg extensors of the dominant limb on a Biodex isokinetic dynamometer (0.52 rad\*s<sup>-1</sup>), separated by 30 s rest. The contralateral leg served as a non-exercised control limb. Isometric peak torque and DT-MRI was measured before and after exercise. DT-MRI was performed using a GE 3T excite-HD MRI system using 6 diffusion encoding directions (4 NEX, FOV=20cm, TE/TR=67/6000, 64x64 matrix, 3mm thick, 0 skip, b=400s/mm<sup>2</sup>). DT-MRI fractional anisotropy (FA) analysis was performed using diffusion toolkit software; while fiber tracking for visualization of muscle tears was done using TrackVis software.

**RESULTS:** Isometric peak torque was lower immediately following exercise compared to pre-exercise (202 vs 237 N•m) and remained lower after 24 h (208 N•m) of recovery. An increase in FA (typically seen in tissues that are exhibiting loss of cell membrane integrity) as well as muscle fiber disorganization was observed in the exercised limb. These changes were not visualized in the contralateral control limb.

**CONCLUSION:** Preliminary data suggest that DT-MRI is very sensitive to muscle tissue alteration following high-force eccentric exercise.

(No relationships reported)

The leusine metabolite beta-hydroxy-beta-methylbutyrate (HMB) has been shown to increase muscle mass and strength following resistance training and has been also proposed to function as an anticatabolic agent and decrease exercise induced muscle damage.

**PURPOSE:** The aim of this study was to investigate the effects of 14 days oral supplementation of HMB on muscle damage as a result of intense and prolonged uphill and downhill running.

**METHODS:** Subjects (n=22) well trained endurance runners were randomly assigned to treatment of either HMB (3g/day) or a placebo for 2 weeks before race. They all run Olympus mountain marathon (44km) consisted of 21km uphill to 2700m altitude and 23km continuous downhill. Venous blood samples were obtained from the participants before, immediately after the race, also 3 and 7 days post race. They were analysed with standard methods for creatine phosphokinase (CPK), lactate dehydrogenase (LDH) and myoglobin (MGL).

**RESULTS:** Mean±sd (n=22) pre race CPK (149.55±21.47 U/L), MGL (32.31±4.00 mcg/l) and LDH (327.27±34.43 U/L) increased 5 (714.06±203.02U/L), 20 (662.06±260.99mcg/l) and 2 (698.06±107.84 U/L) fold (p<0.01) respectively immediately after the race. Mean CPK (256.93 U/L), MGL (61.64 mcg/l) and LDH (467.21 U/L) activities remained elevated 1.7, 1.9, and 2.1 fold (p<0.05) respectively 72 hours after the race. The placebo-supplemented group exhibited significantly greater (p<0.05) plasma concentration of CPK, LHD and MGL post race, 3 days and 7 days after the race than did the HMB supplemented group. Placebo-supplemented group presented also greater (p<0.05) mean difference (post race minus pre race values) in muscle damage biomarkers.

**CONCLUSIONS:** The results of this study indicate that 2 weeks dietary supplementation of 3.0g HMB/day in endurance runners resulted in decreased CPK, LDH and MGL, after a very prolonged run. The finding agree with the hypothesis that HMB supplemented athletes experienced less muscle damage and also recovered at a faster rate.

**Dietary Protease Supplementation Attenuates Eccentric-exercise Induced Force Production Decrements By Regulating Leukocyte Activity**

Thomas W. Buford, Matthew B. Cooke, Liz Redd, Geoffrey M. Hudson, Brian D. Shelmadine, Cecelia Curts, Darryn S. Willoughby, FACSM. *Baylor University, Waco, TX.* (Sponsor: Darryn S. Willoughby, FACSM)  
Email: thomas\_buford@baylor.edu  
(No relationships reported)

Dietary protease supplementation has been purported to reduce the damaging effects of eccentric exercise and accelerate recovery of muscle function, possibly by regulating local inflammation.

**PURPOSE:** To determine the effectiveness of prophylactic protease supplementation in attenuating eccentric-exercise induced skeletal muscle damage and inflammation.

**METHODS:** Following standard physical and hemodynamic assessment subjects donated fasting venous blood samples. Subjects then performed isokinetic extension/flexion of the quadriceps group on a Biodex isokinetic dynamometer at 60°/s, followed by VO<sub>2</sub>max testing. Subjects were randomly assigned to consume 5.83g daily of either a cellulose placebo (N= 15; 22.27±3.33 yr, 71.17±2.91 in, 179.4±24.05 lb, 50.55±5.66 ml/kg/min) or a proteolytic supplement containing fungal proteases, bromelain, and papain (N= 14; 22.85±5.9 yr, 70.0±2.67 in, 173.11±29.94 lb, 49.69±6.15 ml/kg/min) for a period of 21 days. Following the supplementation period, subjects donated blood samples prior to performing a 45 minute downhill (-17.5%) treadmill protocol at 60% of VO<sub>2</sub>max. An additional 4 blood draws and 3 muscle function tests were performed over the next 48h. Blood was analyzed using standard hematology and clinical chemistry, ELISA, and bead-array. Blood data were analyzed using MANOVA with repeated measures, while Biodex data were analyzed using MANOVA on %D values.

**RESULTS:** Significant group differences (T1-T3, p= 0.033; T1-T4, p= 0.043) and another strong trend (T1-3h, p= 0.055) were observed for flexion peak torque %D at 60°/s. No significant differences were observed for extension. Following eccentric exercise, muscle force in the protease group actually increased (T1-3h: 4.73%, T1-T3: 3.01%, T1-T4: 6.44%), while the placebo group experienced significant force decrements (T1-3h: -19.54%, T1-T3: -27.94%, T1-T4: -25.87%). Significant group x time interactions (p < 0.05) for the protease group were observed with increases in circulating eosinophils, basophils, and decreases in serum COX2, IL-6, and IL-12.

**CONCLUSION:** Protease supplementation appears to attenuate muscle strength loss following eccentric exercise by altering leukocyte activity and inflammatory responses.

**Delayed Inflammation-regeneration Response Following Eccentric Contractions In Diabetic Rat Skeletal Muscle**

Mai Shinohara, Mizuki Sudo, Yutaka Kano. *Univ. of Electro-communications, Dept. of Appl. physics & Chemistry, Tokyo, Japan.*

Email: kano@pc.uec.ac.jp

(No relationships reported)

Background: Resistance training using eccentric contractions (ECC) can induce muscle hypertrophy more effectively compared with isometric and concentric contractions but also can incur substantial muscle damage. In diabetes mellitus (DIA) skeletal muscle atrophies and there is a pressing need for therapeutic strategies for sustaining muscle mass. Unfortunately DIA is also accompanied by increased muscle fragility and ECC in DIA might cause more extreme and prolonged muscle damage.

**PURPOSE:** To test the hypothesis that DIA is associated with a delayed muscle recovery (phagocytosis and regenerative action) following ECC.

**METHODS:** Ten-week-old male Wistar rats were divided randomly into diabetic (DIA: 65 mg/kg Streptozotocin i.p.) and nondiabetic groups (NORM: saline injection). Four weeks later the right tibialis anterior (TA) muscles in both NORM and DIA were subjected to 40 electrically-induced eccentric contractions (10 volt stimulation, 100 Hz frequency, 700 msec stimulation period i.e., 70 pulses) and synchronous stretching (lengthened from 50 to 180 degrees of the ankle joint) by electromotor. The contralateral TA muscle served as control for each group. TA muscle was dissected after 1(1D), 3 (3D), 7 (7D) and 14 days (14D) following ECC (each time point, n = 5-8). Damaged fibers were defined as those with: swollen appearance, infiltration by inflammatory cells, pale staining of the cytoplasm, or central nuclei (hematoxylin-eosin (HE) stain). The inflammatory cells (neutrophils, ED1+ and ED2+ macrophages) were identified immunohistologically.

**RESULTS:** Damaged muscle fibers appeared swollen and infiltration of inflammatory cells were present on 1D to 7D in both NORM and DIA. The extent of muscle damage was lower (P<0.05) in DIA (1D: 0.9±/ 0.4%, 3D: 9.7±/ 1.7%, 7D: 3.7±/ 2.6%, 14D: 0.1±/ 0.0%) than NORM (1D: 0.9±/ 0.4%, 3D: 19.1±/ 4.5%, 7D: 1.6±/ 0.7%, 14D: 0.2±/ 0.1%). ED1+ macrophages were observed mostly at 3D in NORM but continuously expressed until 7D in DIA. The number of pale staining fibers (invasion end phase) was higher in DIA than NORM at 7D. Muscle fibers with central nuclei were persisted from 7D to 14D in NORM but detected only at 14D in DIA.

**CONCLUSION:** The ECC-induced inflammation-regeneration response is delayed in diabetes.

**Location Of Damage In Skeletal Muscle After Lengthening Contractions**

Richard M. Lovering, Alan B. McMillan, Roa Gullapalli. *University of Maryland School of Medicine, Baltimore, MD.* (Sponsor: E.G. McFarland, FACSOM)

Email: rlovering@som.umaryland.edu

(No relationships reported)

Submaximal lengthening ("eccentric") contractions are used in everyday life, but high force lengthening contractions are associated with muscle damage and pain. The muscle-tendon junction (MTJ) is commonly cited as the primary area where myofiber damage occurs.

**PURPOSE:** To study the location of myofiber damage resulting from muscle strain injury. In mammalian skeletal muscle, myofibers do not extend the length of the muscle. Thus, even if an injury extends throughout the cell, it cannot be assumed that damage observed in a cross section is similar throughout the whole muscle. We hypothesized that the most damage to the fibers after lengthening contractions occurs in the middle of the muscle.

**METHODS:** Injury to the rat (N=10) tibialis anterior muscle (TA) was induced by lengthening contractions (described previously, 2007). High resolution (250µm in-plane @ 1mm slice thickness) multi-echo proton density/T2-weighted spin-echo MR images (TE1/TE2/TR=13/48/2000ms) were acquired on a Bruker Biospec 7T/30 Avance MR system to assess muscle damage on the day of injury (D0) and days 1 and 3 (D1; D3). TAs were harvested either on D0 to quantify the number of fibers with membrane damage (using IP injections of Evans Blue Dye [EBD]), or on day 14 to quantify the number of centrally nucleated fibers (using HE stain to visualize CNFs). CNFs are an accepted a marker of myogenesis that occurs after myofibers damage, but they do not appear immediately after injury.

**RESULTS:** Injury was confirmed by a significant loss of torque (45 %). On D0, T2 values were elevated (60%) throughout the muscle belly, but limited to the MTJ by D1 after injury. The number of fibers with membrane damage was much higher in the middle of the muscle (30 ± 12% of fibers) than in the distal portion of the muscle (4 ± 1% of fibers). The occurrence of CNFs was much higher in the middle of the muscle (40 ± 8% of fibers) than in the distal muscle (5 ± 3% fibers).

**CONCLUSIONS:** If treatments are delivered to muscle tissue to foster myogenesis and facilitate muscle growth, it is important to know where the damage is occurring. Our results suggest that myofiber injury occurs primarily in the middle portion of the muscle and that the consequent edema is initially widespread, but then limited to the MTJ. Thus, findings on MRI several days after injury may not necessarily reflect damage to the myofibers.

(No relationships reported)

Although pressure, shear and ischemia have been identified in the etiology of pressure ulcer, the molecular mechanisms contributing to the development of pressure ulcer are still unclear.

**PURPOSE:** To scrutinize the mRNA expression of NOS-1 and NOS-2 in rat skeletal muscle in the molecular regulation of pressure-induced deep tissue injury.

**METHODS:** Eight adult Sprague Dawley rats were subjected to an deep tissue injury protocol as induced by moderate prolonged compression. Static pressure of 100mmHg

loading was applied to an area of 1.5cm<sup>2</sup> in the tibialis region of the right limb of the rats for 6 hours each day on two consecutive days. The loading force was continuously monitored by a 3-axial force transducer equipped in the load indenter. A laser Doppler flowmetry with a contact probe was used to monitor the blood flow of the loading site. The left unloaded limb served as intra-animal control. Tissues directly underneath the loading region were collected and quickly frozen. Upon analysis, total RNA was extracted from both the control and loading muscle samples. The gene expression level of NOS-1 and NOS-2 were determined by real time reverse transcript-polymerase chain reaction (RT-PCR). Data were expressed as the fold differences (mean  $\pm$  SEM) over controls normalized to the housekeeping GAPDH gene. Paired t-test was used to examine differences between control and compressed groups. Level of statistical significance was accepted at  $P < 0.05$ .

**RESULTS:** Blood flow of the loading area was reduced by ~50% as determined by the Doppler flowmetry. No significant difference was found in the mRNA level of NOS-1 between control and compressed rat skeletal muscle ( $p > 0.05$ ). NOS-2 transcript content was observed to be folds-upregulated ( $421.26 \pm 263.14$  fold, ranging from 8 to 2187 fold) in all the compressed muscles relative to control but this change did not reach statistical significance level probably due to the large variability in the increasing response of NOS-2 mRNA to compression.

**CONCLUSIONS:** We interpret our data that NOS-2 transcript is probably upregulated in pressure-induced deep tissue injury as induced by prolonged moderate compression. Additional study is needed to further examine the involvement of NOS in deep pressure ulcer.

**Sex Difference In Intracellular  $\text{Ca}^{2+}$  Accumulation Following Eccentric Contractions Of Rat Skeletal Muscle**

Takashi Sonobe<sup>1</sup>, Jun Nagata<sup>1</sup>, Tadakatsu Inagaki<sup>1</sup>, David C. Poole, FACSM<sup>2</sup>, Yutaka Kano<sup>1</sup>. <sup>1</sup>University of Electro-Communications, Chofu, Tokyo, Japan. <sup>2</sup>Kansas State University, Manhattan, KS.

(No relationships reported)

Skeletal muscle damage is lower in females than males following unaccustomed intense eccentric exercise (e.g., Komulainen et al. Acta Physiol. Scand. 165: 57-63, 1999). The mechanistic bases for this gender-specific phenomenon remain to be resolved. Muscle damage has been linked to loss of  $\text{Ca}^{2+}$  homeostasis and resultant intramyocyte  $\text{Ca}^{2+}$  accumulation ( $[\text{Ca}^{2+}]_i$ ) and it is possible, therefore, that males experience greater eccentric exercise-induced muscle damage because of more pronounced  $\text{Ca}^{2+}$  accumulation.

**PURPOSE:** To test the hypothesis that, following repeated bouts of unaccustomed eccentric contractions, the rise in  $[\text{Ca}^{2+}]_i$  evident in males would be either reduced or absent in females.

**METHODS:** The experiments were performed by  $\text{Ca}^{2+}$  imaging using fura2-AM in rat spinotrapezius muscle *in vivo*. Adult Wistar rats were divided into three groups: Male, Female and, to investigate the effects of estrogen specifically, ovariectomized females (OVX). For *in vivo* microscopic observation, animals were anesthetized and the spinotrapezius muscle exteriorized maintaining principal blood vessels and neural pathways intact. Tetanic eccentric contractions (100Hz, 700 ms duration, 20 contractions per minute for a total of 10 sets of 50 contractions) were elicited by electrical stimulation during synchronized muscle stretch of 10% resting muscle length evoked via a stimulator-linked stretching unit. Change of fluorescence ratio (340/380 nm) was determined from fluorescence images captured following each set of contractions, and used to estimate  $[\text{Ca}^{2+}]_i$  and changes thereof.

**RESULTS:** Following eccentric contractions  $[\text{Ca}^{2+}]_i$  increased significantly in Male ( $42.8 \pm 5.3\%$ ,  $P < 0.01$ ) but not in Female ( $9.4 \pm 3.5\%$ ) rats. OVX evidenced an intermediate response ( $17.0 \pm 1.2\%$ ) that remained significantly reduced compared with Male.

**CONCLUSIONS:** These results demonstrate that Females maintain  $[\text{Ca}^{2+}]_i$  homeostasis following novel eccentric contractions whereas Males do not which is consistent with a role for elevated  $[\text{Ca}^{2+}]_i$  in eccentric exercise-induced muscle damage. The presence of estrogen is not obligatory for this gender difference.

**Muscle Force And Indirect Markers Of Exercise-induced Muscle Damage**

Ken A. van Someren<sup>1</sup>, Glyn Howatson<sup>2</sup>. <sup>1</sup>English Institute of Sport, Marlow, United Kingdom. <sup>2</sup>St Mary's University College, Twickenham, United Kingdom. (Sponsor: Tibor Hortobágyi, FACSM)

Email: ken.vansomeren@eis2win.co.uk

(No relationships reported)

**PURPOSE:** To identify the heterogeneity of responses in muscle force production and other indirect measures of exercise-induced muscle damage following a bout of eccentric exercise; and, to determine the level of agreement between the magnitude of responses in muscle force production and indirect measures of muscle damage.

**METHODS:** 46 male participants, who were unaccustomed to eccentric exercise, performed a damaging bout of exercise comprising 3 sets of 15 maximal lengthening contractions of the elbow flexors at  $30^\circ \cdot \text{s}^{-1}$ . Elbow flexor isometric torque (MVC), CK activity in blood (CK), muscle soreness (SORE) using the Talag scale, elbow range of motion (ROM) and upper arm girth (GIRTH), were measured pre-exercise and at 48 h and 96 h post-exercise. Cluster analysis of the peak responses in dependent variables was performed to identify LOW, MEDIUM and HIGH responders to the exercise protocol; comparison between MVC and other dependent variables for LOW, MEDIUM and HIGH was made.

**RESULTS:** For MVC, 29 cases were classified as LOW (mean  $\pm$  SD =  $-15.0 \pm 6.6\%$ ), 12 cases as MEDIUM ( $-32.5 \pm 5.1\%$ ) and 5 cases as HIGH ( $-52.7 \pm 8.9\%$ ). For CK, 15 cases were classified as LOW ( $292.7 \pm 108.8$  IU/L), 18 cases as MEDIUM ( $723.7 \pm 171.0$  IU/L) and 13 cases as HIGH ( $1455.5 \pm 273.5$  IU/L). For SORE, 21 cases were classified as LOW ( $2.6 \pm 0.5$ ), 16 cases as MEDIUM ( $4.0 \pm 0.2$ ) and 9 cases as HIGH ( $5.2 \pm 0.4$ ). For ROM, 27 cases were classified as LOW ( $-7.1 \pm 2.8\%$ ), 11 cases as MEDIUM ( $-16.7 \pm 2.6\%$ ) and 8 cases as HIGH ( $-27.1 \pm 3.6\%$ ). For GIRTH, 24 cases were classified as LOW ( $0.9 \pm 0.3\%$ ), 20 cases as MEDIUM ( $2.0 \pm 0.5\%$ ) and 2 cases as HIGH ( $3.9 \pm 0.1\%$ ). Comparison of LOW, MEDIUM and HIGH group membership revealed poor agreement between MVC and the indirect measures of muscle damage.

**CONCLUSIONS:** This study supports previous literature reporting a high level of heterogeneity in the manifestation of signs and symptoms associated with exercise-induced muscle damage. In addition, there appears to be only limited agreement between the magnitude of response in muscle force production and that of indirect measures following eccentric exercise.

**Gene Expression In Human Skeletal Muscle Following An Acute Bout Of Concentric Or Eccentric Exercise In Young Women**

David N. Erceg, Nicole E. Jensky, Jennifer K. Sims, Michael J. Hitchler, Judd C. Rice, E. Todd Schroeder. University of Southern California, Los Angeles, CA. (Sponsor: Steven Hawkins, FACSM)

Email: erceg@usc.edu

(No relationships reported)

**PURPOSE:** To investigate changes in mRNA expression of muscle atrophy F-box (MAFbx), p70S6 kinase (p70<sup>S6k</sup>), forkhead box 3A (FOXO3a) and myogenic differentiation factor (MyoD) at rest and in response to a single bout of concentric or eccentric contractions in young women.

**METHODS:** Twelve recreationally active young women were divided into two groups to perform unilateral, leg extension resistance exercise: 6 ( $24 \pm 0$ yr,  $65 \pm 7$ kg) in the concentric (CON) group performed 10 sets of 10 repetitions of maximal concentric contractions, while 6 ( $25 \pm 1$ yr,  $59 \pm 7$ kg) in the eccentric (ECC) group performed 10 sets of 10 repetitions of maximal eccentric contractions. Muscle biopsies were taken from the vastus lateralis before and 8 hours after the exercise bout. mRNA from the muscle

samples were evaluated using RT PCR and normalized to 18s (house keeping gene). *t* tests were used to compare gene expression changes within and between groups with significance set at  $p < 0.05$ .

**RESULTS:** In response to exercise, MAFbx expression decreased by  $43 \pm 23\%$  ( $p = 0.007$ ) in the CON group, and by  $81 \pm 13\%$  ( $p < 0.001$ ) in the ECC group. The decrease in MAFbx was significantly different between groups ( $p = 0.007$ ). MyoD expression increased  $135 \pm 11\%$ , ( $p = 0.03$ ) in the CON group and  $61 \pm 47\%$  ( $p = 0.025$ ) in the ECC group.  $p70^{S6k}$  and FOXO3a demonstrated no significant change in gene expression.

**CONCLUSIONS:** These data indicate that a single bout of maximal CON or ECC training does not influence mRNA gene expression for  $p70^{S6k}$  and FOXO3a. Data also indicate that a single bout of maximal ECC training has greater down regulation of MAFbx, a known regulator of muscle protein breakdown. This suggests that contraction mode may be important in mediating specific myogenic regulatory genes.

**Traumatic Skeletal Muscle Injury Alters Post-translational Matrix Metalloprotease-3 Expression**

Maria L. Urso<sup>1</sup>, Eric R. Szelenyi<sup>1</sup>, Gordon L. Warren, FACSM<sup>2</sup>, Brian R. Barnes<sup>1</sup>. <sup>1</sup>USARIEM, Natick, MA. <sup>2</sup>Georgia State University, Atlanta, GA.  
Email: maria.urso@us.army.mil

(No relationships reported)

Matrix metalloproteases (MMPs) are regulatory enzymes that function in proteolytic cascades and extracellular matrix (ECM) remodeling. Since skeletal muscle injury is accompanied by major changes in the ECM (e.g., inflammation, degeneration, satellite cell activation) it is important to characterize the role of MMPs in the injury process. Stromelysin-1 (MMP-3) has particular significance in muscle injury since it degrades numerous ECM proteins and the expression and activation of MMP-3 is a critical regulatory step in the activation of other MMPs and possibly, satellite cells.

**PURPOSE:** To characterize the time course and profile of MMP-3 expression and activity post-injury in skeletal muscle.

**METHODS:** Forty-two C57BL/6J mice were anesthetized, one tibialis anterior (TA) muscle was exposed, and injury was induced by applying a steel probe (cooled to -79 C) to the belly of the TA muscle for 10s. Muscle samples were collected from both uninjured and injured legs at 3, 10, 24, 48, and 72 h post-injury. Quantitative Real Time Polymerase Chain Reaction (qRT-PCR), immunoblotting, and immunohistochemistry (IHC) were used to quantify/localize MMP-3 expression and activity. IHC for PAX-7 was used to identify satellite cell activation.

**RESULTS:** Relative to the uninjured leg, the MMP-3 mRNA level increased 2.7-, 18.7- and 12.0- fold at 3, 10, and 24 h post-injury ( $p < 0.01$ ), and returned to baseline levels 48 h post-injury. Latent (57/59 kDa) MMP-3 protein levels increased 24.8-, 24.9-, 31.1-, 29.9-, and 23.5-fold at 3, 10, 24, 48, and 72 h post-injury ( $p < 0.05$ ). In contrast, active (45 kDa) MMP-3 protein levels were decreased by 4.0-, 5.4-, 5.2-, 4.9-, and 7.2- fold at 3, 10, 24, 48, and 72 h post-injury ( $p < 0.05$ ), respectively. There was a concomitant increase in MMP-3 staining and macrophage infiltration between 3 and 24 h, with macrophage infiltration and PAX-7 staining peaking 72h post-injury. Increased skeletal muscle expression of MMP-3 mRNA appears to drive increases in the latent form of the MMP-3 protein post-injury. However, post-translational processing of the MMP-3 protein to its active form is decreased post-injury.

**CONCLUSION:** Regulation of latent and active MMP-3 protein levels at this post-translational step may be a critical therapeutic target for the control of ECM remodeling post-injury.

**Impact Of Two Different Resistive Exercise Methods In Post-exercise Creatine-kinase Plasma Levels**

Mario A. Charro<sup>1</sup>, Daniel Rodriguez<sup>2</sup>, Edimar C. Pereira<sup>3</sup>, Francisco L. Pontes<sup>4</sup>, Reury FP Bacurau<sup>4</sup>. <sup>1</sup>São Caetano do Sul University – USCS, São Paulo, Brazil. <sup>2</sup>Runner Institute of Research, São Paulo, Brazil. <sup>3</sup>São Caetano do Sul University – USCS, São Caetano, Brazil. <sup>4</sup>School of Arts Sciences and Humanity, University of São Paulo – USP, São Paulo, Brazil.

(No relationships reported)

**PURPOSE:** The aim of this investigation was to determine the effect of two different RE methods on creatine-kinase (CK) plasma levels.

**METHODS:** Young adult men ( $n = 10$ ,  $26.1 \pm 6.3$  years old;  $174.0 \pm 5.4$  cm height;  $76.4 \pm 13.3$  kg weight;  $15.48 \pm 5.42$  % body fat) with previous experience in RE were divided in to two groups and both performed an exercise sessions in two different intensities determined by one maximum repetition (1MR) tests, with one week interval between them. The training sessions consisted in three consecutive exercises for the same muscle group (bench press, incline bench press, peck deck); the variable intensity (VI) session performed 3 sets for each exercise performed at 67%, 75% and 80% of 1MR while the constant intensity (CI) group performed 3 sets for each exercise at 75% of 1MR. Blood samples were obtained from the antecubital vein at rest, immediately after, 24, 48 and 72 after the exercise sessions. CK levels were analyzed using the spectrophotometry method (Bio System). Friedman-Anova was applied to analyze blood CK. Wilcoxon test was utilized to detect differences.

**RESULTS:** The results will be presented on the table below:

**CONCLUSIONS:** Is well established on the literature that muscle contractions can provoke muscle damage specially 24-48 hours after the end of the exercise session. We observed an increase in CK levels 48-72 hours after the end of both exercise sessions, indicating that blood CK level may not be a good indicator of muscle damage.

Creatine-kinase (U/L)	Pre (x±s)	Post (x±s)	24h (x±s)	48h (x±s)	72h (x±s)
CI	220,9± 99,8	236,2± 93,5	480,1± 402,4	1.236,6± 1.686,4	2.708,9± 1.936,5*
VI	336,3± 206,7	601,2± 522,7	1.178,2± 1.109,2	1.811,0± 2.050,1*	2.199,4± 1.747,0*

**Increased Mechano-growth Factor Gene Expression Following Stretch-shortening Contraction Loading: Impact Of Glutathione And Age**

Robert G. Cutlip<sup>1</sup>, James Ensey<sup>1</sup>, Brent A. Baker<sup>1</sup>, Melinda S. Hollander<sup>2</sup>, Michael L. Kashon<sup>1</sup>. <sup>1</sup>NIOSH, Morgantown, WV. <sup>2</sup>West Virginia University, Morgantown, WV. (Sponsor: Stephen E. Alway, Ph.D., FACSM, FACSM)

Email: rgc8@CDC.GOV

(No relationships reported)

Specific genes regulating multiple pathways in the adaptive response in skeletal muscle following glutathione modulation and repetitive mechanical loading are not known.

**PURPOSE:** The purpose of this study was to characterize gene transcripts influenced by dietary supplementation with a glutathione antagonist (L-Buthionine Sulfoximine (BSO)) following chronic high-intensity mechanical loading via stretch-shortening contractions (SSCs) in young and old rats.

**METHODS:** Left dorsiflexor muscles of young (12 weeks, N= 32) and old (30 months, N = 30), vehicle- (VEH) and BSO-treated rats were exposed 3 times per week for 4.5-weeks to a protocol of 80 maximal SSCs per exposure *in vivo*, while cage, age-matched rats served as controls (CON). Messenger levels for MyoD, Bax, Bcl2, Caspase-9, IL-15, IL-1-b, MCP-1, TGF-b1, IL-10, mechano-growth factor (MGF), and 18s (control) genes were characterized by RT-PCR analysis following the SSC-exposure period.

**RESULTS:** Following 4.5 weeks of SSC loading only MGF mRNA levels were significantly altered by treatment (young BSO increased versus young VEH;  $p < 0.05$ ) and age (young BSO increased versus old BSO;  $p < 0.05$ ).

**CONCLUSIONS:** Even though MGF mRNA was the only transcript influenced by glutathione modulation and/or aging, further investigation is needed to evaluate changes in protein levels. However, the present study clearly demonstrates that MGF mRNA is influenced by both glutathione modulation and aging.

**Glutamine Supplementation Preserves Skeletal Muscle Force During Acute Inflammation**

Benjamin M. Meador, Kimberly A. Huey. *University of Illinois, Urbana, IL.* (Sponsor: Jeffrey A. Woods, FACSM)

(No relationships reported)

Acute and chronic inflammatory diseases are often associated with respiratory and skeletal muscle weakness and potential muscle wasting. Decrements in muscle function under these conditions may be mediated in part by elevated levels of catabolic cytokines such as TNF $\alpha$ , which has been shown to independently and acutely reduce contractile function. Glutamine has been shown to protect in various tissues against inflammatory insults, in part by the up-regulation of protective heat shock proteins (HSP) and/or reducing catabolic cytokine levels.

**PURPOSE:** To test the hypothesis that acute Glutamine (GLN) supplementation can counteract skeletal muscle contractile dysfunction occurring in response to an inflammatory insult by elevating muscle Hsp expression and reducing systemic and muscle cytokines.

**METHODS:** Mice received 5mg/kg Lipopolysaccharide (LPS) concurrently with 1g/kg GLN or saline (Sal) vehicle treatments. Plantarflexor isometric force-production was measured 2 hours post-injection in anesthetized mice with a lever/footplate system able to simultaneously control length and measure force. Sciatic nerve stimulation was used to elicit 10 repetitions (5-sec rest) to capture maximal force and fatigue. Immediately after the last contraction, blood and gastrocnemius muscles were collected. Serum and muscle TNF $\alpha$  and IL-6 were quantified by Elisa and muscle Hsp72 and Hsp25 by Western blot.

**RESULTS:** Sal/LPS-treatment was associated with a 33% reduction in maximal force and elevated serum TNF $\alpha$  and IL-6 compared to the Sal/Sal group ( $p < .05$ ). GLN completely prevented the force decrement with LPS, however, GLN alone did not affect force (i.e., no differences among Sal/Sal, GLN/Sal, and GLN/LPS groups). No group differences were found for muscle fatigue. Additionally, no main effect for GLN was found on muscle or serum TNF $\alpha$  or IL-6, however muscle Hsp72 was significantly reduced by 47% in the GLN/LPS group compared to the other 3 groups.

**CONCLUSIONS:** GLN supplementation provides an effective, novel, and clinically applicable means of preserving muscle force under conditions of acute inflammation. These data indicate that preservation of force is not dependent on reductions in muscle or serum cytokines or elevated Hsp levels, as these measures were not altered with GLN treatment.

**Plasma Matrix Metalloproteinase-9 Activity As A Marker Of Exercise-induced Muscle Injury In Humans**

Molly C. Madden, Nicole T. Bannister, Jacob A. Lebin, Michelle S. Janer, Matthew E. Batliner, Zachary T. Leonard, William C. Byrnes, FACSM, David L. Allen, FACSM. *University of Colorado at Boulder, Boulder, CO.*

Email: molly.madden@colorado.edu

(No relationships reported)

**PURPOSE:** The role of matrix metalloproteinases (MMPs) in skeletal muscle remodeling has received increasing scientific attention regarding its role in skeletal muscle damage and repair. The purpose of this study was to determine if eccentric exercise-induced changes in plasma MMP-9 activity were correlated with indices of muscle damage post-exercise in humans.

**METHODS:** Fifteen males unaccustomed to eccentric exercise participated in a protocol involving eccentric exercise (120% concentric maximum) of the non-dominant upper arm. The dependent measures included force/angle curves, range of motion (ROM), arm circumference, soreness perception, plasma MMP-9, & creatine kinase (CK) levels. Dependent measures were re-assessed Immediately Post (IP), 1-, 2-, 4-, and 7-days post task. Functional and biochemical variables were correlated in time and magnitude of response with Spearman's rho correlational analyses.

**RESULTS:** Plasma MMP-9 activity increased up to an average of 137% of pre-levels during follow-up time points; however, the timing and magnitude of the increase varied across subjects. There were significant increases in soreness perception (45.27/100 mm 2-days post), optimal angle of force production (+10.5 degrees IP), biceps belly and elbow joint circumference (+8.27 mm 4-days post and +10.76 mm 7-days post, respectively), and CK activity (12.3 fold increase 4-days post), and significant decreases in ROM (-18.57 degrees IP), and force production (53.9% IP, 57.7% 1-day post) during the week following the exercise task. Immediately post eccentric exercise, changes in MMP-9 activity were temporally correlated with a change in the optimal angle of force production ( $r=0.580$ ). At the timepoint of peak perceived soreness (2-days post), MMP-9 activity was significantly correlated with both CK activity ( $r=0.636$ ) and an increase in elbow joint circumference ( $r=0.554$ ).

**CONCLUSIONS:** These data demonstrate that plasma MMP-9 activity is increased following a damaging eccentric exercise task in humans and that the change in MMP-9 activity is correlated with indices of muscle damage.

**The Effect Of Different Management For Muscle Performance On Acute Stage Muscle Damage**

Chau-Chlung Chen<sup>1</sup>, Kuo-Wei Tseng<sup>2</sup>, Yu-Lin Ning<sup>1</sup>, An-Hsu Chen<sup>1</sup>, Fu-Hsiu Huang<sup>1</sup>, Tung-Wu Lu<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Taiwan University, Taipei, Taiwan.

Email: fossil@tpec.edu.tw

(No relationships reported)

**INTRODUCTION:** Muscular injury is one of the most common sports injuries. When the athletes suffer from injury, they usually need to receive emergent management to come back competition. Cold agents are used popularly as first-aid in management acute sports trauma. However, cold agents may cause joints stiffness and decreasing soft-tissue flexibility, it will influence the performance in the next round or section of the competition.

**PURPOSE:** This study was designed to find the best way for short-term performance outcomes and long-term physical recovery outcomes to manage muscle damage in the acute stage.

**Method:** 36 subjects performed one set of eccentric exercise protocol (ECC1). After the ECC1, subjects were randomly placed into cryotherapy group (n=12), electrical therapy group (n=12) or control group (n=12), and accepted treatment protocol with cryotherapy, transcutaneous electrical nerve stimulation (TENS) modality or resting without management for one hour. When treatment protocol finished, all subjects performed the second set of eccentric exercise protocol (ECC2). Active range of motion (ROM), upper arm circumference (CIR), Serum creatine kinase (CK-MM) and maximal voluntary isometric contraction (MVC) were assessed immediately before and after each eccentric exercise bout and day2, day4, day7, day10. CK-MM was collected at ECC1b and 2d, 4d, 7d, 10d.

Result: The short term performance ability showed significant changes ( $p<0.05$ ) in MVC between ECC1b and ECC2b in electrical therapy group, but not in cryotherapy group. The long term recovery outcomes showed significant changes ( $p<0.05$ ) in ECC1b CK-MM on day2 and day7 in electrical group, and on day4 in control group. In intergroup analysis, CK-MM showed significant different ( $p<0.05$ ) between electrical group and cryotherapy group on day2, day4, day7 and day10, and the same results between electrical group and control group.

**CONCLUSIONS:** The long-term recovery outcomes showed cryotherapy is the most beneficial for muscle damage management between repeated sets, the short-term outcomes showed cryotherapy and resting are beneficial to the muscle performance, such as muscle strength and active range of motion. Electrical therapy is disadvantaged to manage muscle damage between repeated sets exercise.

**Glucose Uptake And Fiber Damage In Skeletal Muscle Stimulated With Different Frequencies**

Julia M. Santos<sup>1</sup>, Sandra A. Benite-Ribeiro<sup>1</sup>, Gloria Queiroz<sup>2</sup>, Hans-Joachim Appel<sup>3</sup>, José A.R. Duarte<sup>1</sup>. <sup>1</sup>Faculty of Sport- University of Porto, Porto, Portugal. <sup>2</sup>Faculty of Pharmacy - University of Porto, Porto, Portugal. <sup>3</sup>German Sport University, Cologne, Germany. (Sponsor: FCT, FACSM)  
Email: jujumatz@yahoo.com.br  
(No relationships reported)

**PURPOSE:** Glucose uptake of skeletal muscle has widely been studied *in vitro* using electrical stimulation, being accepted that high stimulation frequencies comparing to low frequencies result in higher rates of glucose uptake. However, it can be hypothesised that slow-twitch muscles, such as *soleus*, are physiologically not capable to sustain high frequency stimuli without the development of severe homeostatic alterations. Therefore, since the enhanced glucose uptake observed under these conditions might be the result of non-physiological mechanisms, the aim of this study was to analyse the effects of low vs. high frequency stimulation on *in vitro* glucose uptake and on muscle structure in the slow rat *soleus* muscle.

**METHODS:** Eighteen Wistar rats were assigned to two groups: electro stimulation at 10Hz and at 100Hz. Muscles were isolated and incubated in an oxygenated Krebs buffer. After a stabilization period 0.2 mCi/ml of 2- [<sup>3</sup>H] -deoxy-D-glucose and 0.06  $\mu$ Ci/ml of [<sup>14</sup>C] -D mannitol were added in the buffer and muscles were electro stimulated (10V, 0.2ms pulse width, 10 sec/min) with their pre-determinate frequency. Followed, a group of muscles (n=24) were homogenised for biochemical analysis while other were processed for morphological (n=12) examination. Glucose uptake was determined by scintillation spectrophotometry and the intrafiber localization of GLUT4 was assessed by immunohistochemistry. As an estimate for potential damage were quantified the release of taurine into the buffer by HPLC, cleaved caspase-3 by immunohistochemistry and westernblot, and morphological signs of fiber damage in muscle slides stained by hematoxylin/eosin.

**RESULTS:** Stimulation at 100Hz resulted in a more pronounced glucose uptake than at 10Hz despite of the similar distribution on GLUT4 at the sarcolemma ( $P<0.05$ ). The signs of cellular and membrane damage were more apparent in muscles stimulated at 100Hz than at 10Hz evidenced by an increase of taurine release, cleaved caspase-3 and the presence of eosinophilic and swelling fibers ( $P<0.05$ ).

**CONCLUSION:** It is concluded that cellular damage might accounted for an artificial glucose influx from the buffer by muscles stimulated at 100Hz. It therefore does not seem meaningful to study glucose uptake in slow muscles with non-physiologically high stimulation frequencies.

**Time-Dependent Effects Of Prior Fatigue On Cyclical Power Output After Eccentric Muscle Damage.**

SeungJun Choi, Jeffrey J. Widrick. Oregon State University, Corvallis, OR.  
Email: choise@onid.orst.edu  
(No relationships reported)

**PURPOSE:** Power output is reduced in skeletal muscles subjected to either fatiguing contractions or to damaging eccentric activity. Because many physical activities have the potential to induce both fatigue and eccentric damage, we examined the separate and combined effects of these two treatments on the cyclical power output of the mouse soleus.

**METHODS:** Solei were subjected to work loops *in vitro* at 35°C. Pre-treatment, immediate post-treatment, and post-recovery cyclical power was assessed using 3 consecutive work loops that optimized pre-treatment power output (5 Hz cycles;  $\pm 5\%$  fiber length strain). The fatigue protocol consisted of 25 consecutive optimal cycles. Damage was induced by stimulating muscles during the lengthening phase of 10 consecutive low frequency (2 Hz), high amplitude ( $\pm 25\%$  strain) cycles. Data were analyzed using a repeated ANOVA (treatment x recovery time,  $p < 0.05$ ).

**RESULTS:** Mean ( $\pm$  SE) pre-treatment cyclical power did not differ between treatment groups ( $35.6 \pm 1.4$  W/kg). Control muscles ( $N = 7$ ) showed no change in power over the course of the experiment. Solei subjected to fatiguing contractions ( $N = 7$ ) showed an immediate  $21 \pm 2\%$  reduction in power, with complete recovery after 30 minutes of rest. Muscles subjected to damaging contractions ( $N = 7$ ) showed a significantly greater immediate reduction in power ( $33 \pm 2\%$ ) that failed to completely recover (final reduction of  $20 \pm 8\%$ ). Solei that were fatigued and then immediately subjected to lengthening cycles ( $N = 7$ ) showed an immediate reduction in power that was significantly greater than all other treatments ( $64 \pm 2\%$ ). Nevertheless, these muscles showed complete restoration of power after 30 minutes of recovery. Reassessment of optimal length (an index of muscle damage) at the conclusion of the recovery period revealed a shift towards longer lengths for the damage-only treatment ( $110 \pm 1\%$  of pre), a significantly smaller shift for the fatigue and damage trial ( $104 \pm 1\%$  of pre), and no change for the fatigue-only or the control trials.

**CONCLUSIONS:** Prior muscle fatigue, 1) exacerbates the short-term reduction in cyclical power that occurs after eccentric activity, but 2) reduces long-term muscle damage and contractile dysfunction.

**Exercise Intensity And Desmin Protein In Rodents**

Allen C. Parcell, FACSM, Nathan A. Bexfield, Gary W. Mack, FACSM, Daniel Nelson, Brett Noble. Human Performance Research Center, Brigham Young University, Provo, UT.  
(No relationships reported)

An intricate network of filament proteins in muscle fibers is responsible for force transmission, structural integrity and possibly cellular signaling. Desmin (53kD) is an intermediate filament protein that integrates myofibrils at the level of the Z disk and connects the network of myofibrils to the sarcolemma via costameric interactions. Our laboratory has reported increased desmin concentrations in human skeletal muscle following exercise training. This study was designed to assess the impact of exercise intensity on desmin content in skeletal muscle. To accomplish this 21 adult male Sprague-Dawley rats weighing between 245-350 grams were randomly assigned to one of three groups: cage control (CC); continuous exercise training, 60 min /day at 72% (LI) and high intensity, intermittent exercise training, 8 bouts of 4 min at 98% followed by 5 min at 48% (HI). Animals completed 12, equal volume, training sessions over a 2 week period. 24 hours after the last training session the rats were anesthetized and the gastrocnemius muscle was dissected and stored for later analysis. Immunoblot analysis showed no difference in desmin concentration in LI and HI when compared to CC. Previous research suggests increased muscle tension is required for desmin alterations. These data demonstrate that the muscle force and metabolic stress associated with treadmill exercise is insufficient to elicit changes in desmin content within a 12 day training period.

**2457 Board #102 May 29 9:00 AM - 10:30 AM**  
**Nandrolone Decanoate And Mouse Tibialis Anterior Muscle Regeneration: The Effect Of Fiber Type**

Shuichi Sato, *The University of South Carolina, Columbia, SC.*  
Email: satos@mailbox.sc.edu  
(No relationships reported)

Skeletal muscle has the capacity to regenerate and even hypertrophy after damaging stimuli. Bupivacaine is a local anesthetic that is widely used to induce muscle damage. Although Nandrolone Decanoate (ND) has been shown to increase fiber area, its effect on regeneration from bupivacaine-induced damage is not well understood.

**PURPOSE:** The purpose of study was to determine the effect of ND administration on the recovery of type IIa and IIb fiber cross-sectional area (CSA) in the mouse tibialis anterior (TA) muscle after muscle injury induced by bupivacaine (INJ).

**METHODS:** To induce muscle injury the TA from 8 week old castrated C57BL/6 mice was injected with PBS (n=10) or bupivacaine (n=9). Mice were then divided into sesame oil (n=10) or ND (n=9) that was administered at the time of injury and then every 7 days for 6 weeks. After 42 days of recovery from injury, the TA muscles were removed and frozen in OCT for histological and immunohistochemical analysis. Cross-sections (12  $\mu$ m) were taken from the mid-belly. Type IIa and type IIb fibers were identified by immunohistochemical staining. Fiber CSA and fiber type distribution were quantified.

**RESULTS:** Both INJ and ND treatments increased the mean CSA of type IIb fibers 13% (p=.035) and 28% (p<.001), respectively, but not type IIa fibers. No interaction between INJ and ND was observed on mean CSA. Changes in muscle growth were also examined by the distribution of large and small diameter fibers. Both INJ (p=.002) and ND (p<.001) treatments significantly decreased the percentage of small diameter type IIa and IIb fibers. INJ (p<.001) and ND (p<.001) also significantly increased the percentage of large diameter type IIa and IIb fibers. Neither INJ nor ND significantly changed the overall percentage of IIa and IIb fibers.

**CONCLUSION:** During the recovery from bupivacaine injury ND induces preferential hypertrophy of type IIb fibers without changing the overall fiber type distribution of the muscle.

### 2458 Board #103 May 29 8:00 AM - 9:30 AM Relationship Between Time To Stabilization Measures And Demographic And Self-reported Data

Kimitake Sato, Gary D. Heise, Kathy Liu. *University of Northern Colorado, Greeley, CO.*  
Email: jpnsatok@hotmail.com  
(No relationships reported)

**PURPOSE:** Determine correlations between time-to-stabilization (TTS) and body mass, height, foot size, and leg length. In addition, self-reported leg dominance, brace-use, and past injury were examined with respect to TTS.

**METHODS:** 83 collegiate football players participated in TTS test. Anthropometric data (see Table 1), leg dominance, brace-use, and past injury were gathered. In a bare-foot condition, participants performed a "step-step-hop" approach, hopped over a 15-cm hurdle which was placed 100% of leg-length from the center of the force plate, and landed on one foot. They performed randomly ordered L- and R-foot landings. GRF were sampled at 200 Hz, and smoothed with Fast Fourier Analysis. TTS was calculated by determining when the sequential average of ML or AP GRF reached  $\pm 0.25$  standard deviation of the overall mean. TTS and anthropometric data were analyzed using Pearson correlation coefficient, and independent t-tests were used to evaluate differences in TTS between self-reported data.

**RESULTS:** Anthropometric data were moderately correlated with both L- and R-foot AP force TTS but not with ML force TTS (see Table 1). Only R-foot dominant subjects showed significantly higher AP force TTS from R-foot trials (R: 4.664 vs. L: 4.578 sec,  $p < .05$ ). No differences in TTS measures were found between conditions of brace-use and past injury.

**CONCLUSIONS:** Positive correlations between AP force TTS and anthropometric data suggest that a higher center of mass location requires longer TTS. These results are consistent with those from static stability tests. Self-reported comparisons indicate that R-foot dominant individuals are more stable on their non-dominant leg, but the same cannot be said for L-dominant subjects.

Correlation between the anthropometric (mean $\pm$ SD) & TTS.				
	R-Foot AP	R-Foot ML	L-Foot AP	L-Foot ML
Height (184.35 $\pm$ 7.17cm)	.389**	-.003	.400**	-.055

### 2459 Board #104 May 29 8:00 AM - 9:30 AM Knee Function Following Perturbation Training In Potential Copers And Noncopers

David Logerstedt<sup>1</sup>, Lynn Snyder-Mackler<sup>1</sup>, Michael J. Axe<sup>2</sup>. *<sup>1</sup>University of Delaware, Newark, DE. <sup>2</sup>First State Orthopaedics, Newark, DE.*  
Email: davlog@udel.edu  
(No relationships reported)

Single leg hop tests have been used to assess knee function in athletes following an ACL injury. Side-to-side hop symmetry less than 85% represent abnormal knee function. Most noncopers (NC) can be unwilling to hop and those that do hop demonstrate different movement strategies than copers. The use of perturbation training has only been previously used to train knee function in potential copers (PC).

**PURPOSE:** To assess knee function utilizing a series of 4 hop tests in the involved (INV) and uninvolved (UNINV) limb following perturbation training (Fitzgerald et al, 2000) in NC and PC.

**METHODS:** 56 subjects with an acute ACL tear who participated regularly in level I or II activities were screened following an injury to the index limb and classified as a PC (15 women, 24 men; 25.2  $\pm$  9.9 yrs) or NC (5 women, 13 men; 31.9  $\pm$  11.6 yrs). Knee function was assessed using 4 single leg hop tests before and after perturbation training. Independent t-tests were used to study differences between PC and NC in the INV and UNINV limbs. Paired t-tests were used to study differences between limbs in PC and NC.

**RESULTS:** NC hop index was significantly less than PC in the single hop for distance (SHP), triple hop (THP), and the 6-m timed hop (TimHP) pre-training (PrTr) and

significantly less in the SHP and the THP post training (PoTr). In NC, THP index was significantly higher PoTr as compared to PrTr ( $p < .05$ ). SHP and THP scores were significantly lower in the INV as compared to the UNINV PrTr ( $p < .05$ ) and PoTr ( $p < .05$ ). SHP scores significantly higher in the INV and UNINV limbs PrTr to PoTr ( $p < .05$ ) and in the INV THP scores PrTr to PoTr ( $p < .05$ ). In PC, SHP and THP index are significantly higher PoTr as compared to PrTr ( $p < .05$ ). SHP and TimHP scores were significantly lower in the INV as compared to the UNINV PrTr ( $p < .05$ ) and PoTr ( $p < .05$ ). Cross-over hop (XHP) and THP scores were significantly lower in the INV as compared to the UNINV PrTr ( $p < .05$ ). TimHP scores significantly higher in the INV and UNINV PrTr to PoTr ( $p < .05$ ) and in the INV XHP and THP scores PrTr to PoTr ( $p < .05$ ).

**CONCLUSIONS:** Perturbation training can improve knee function in the INV in NC and PC. The differences between limbs and between groups may be due to the number of training sessions, training plateau effect, or neuromuscular differences within and between groups.

Supported by NIH Grant R01HD037985-6.

Normalization of electromyographic (EMG) activity is necessary for comparisons between subjects or across muscles. However, there is no consensus on the most reliable and efficient method for performing this normalization procedure.

**PURPOSE:** To evaluate the intrasession reliability and measurement precision of EMG activity in six lower extremity muscles during single leg stance (SLS) and maximal voluntary isometric contraction (MVC).

**METHODS:** EMG activity was recorded in 20 healthy subjects (10 male, 10 female,  $20.7 \pm 2.4$  years) during three 5-second trials of SLS and MVC for the following muscles of the dominant leg: gluteus maximus, gluteus medius, rectus femoris, vastus lateralis, adductor group, and biceps femoris. RMS EMG amplitude was calculated over the middle 3 seconds of each trial. Intraclass correlation coefficients (ICC 2,1) and standard errors of measurement (SEM) were calculated to assess reliability and precision. Kinematic analysis was used to evaluate hip and knee motion during SLS.

**RESULTS:** ICCs and SEMs for each muscle are presented in Table 1. Kinematic angles during SLS were consistent across trials (Mean  $\pm$  SD): knee flexion ( $1.3 \pm 6.0^\circ$ ), hip extension ( $7.4 \pm 6.0^\circ$ ), and hip abduction ( $0.7 \pm 4.1^\circ$ ).

**CONCLUSION:** SLS demonstrated similar reliability compared to MVC with minimal kinematic variation indicating a standardized subject position. As SLS allows for normalization of multiple muscles at one time, its use may be preferred in protocols evaluating several muscles or when pain limits use of a MVC. In addition, the SLS method measures coordinated muscle activity during a functional task compared to an isolated MVC. Future research should evaluate what influence this may have on the interpretation of EMG amplitudes.

		Gluteus Maximus	Gluteus Medius	Rectus Femoris	Vastus Lateralis	Adductor Group	Biceps Femoris
SLS	ICC (2,1)	0.85	0.93	0.94	0.90	0.94	0.80
	SEM (mV)	8.5	19.5	18.6	27.3	6.1	11.2
MVC	ICC (2,1)	0.95	0.98	0.95	0.98	0.84	0.99
	SEM(mV)	49.4	50.4	120.8	84.0	201.0	30.7

(No relationships reported)

It is noted that muscle damage was induced by intense eccentric exercise and affected not only muscle structure but also central nervous system. Recently, it was reported that electromyographic (EMG) activity and force fluctuation were increased immediately after eccentric exercise. However, it is unclear what neural mechanisms underlie these phenomena.

**PURPOSE:** We determined the effect of muscle damage induced by eccentric exercise on motor control during sustained submaximal voluntary contractions by using electroencephalogram (EEG) - EMG coherence measurement.

**METHODS:** Eleven healthy male volunteers (21-31 yrs) performed brief MVCs and submaximal voluntary contractions (5, 10, 20 and 50%MVC) with dorsiflexion before and immediately after eccentric (ECC) and concentric (CON) exercise, which consisted of 30 contractions at maximal effort. During voluntary contractions, the surface EMG of tibial anterior and EEG around Cz were recorded in order to analyze the EEG-EMG coherence. Force fluctuation was also measured during voluntary contractions. In addition, indirect markers of muscle damage, such as MVC, pressure pain threshold and range of motion, were measured before and immediately after and 1 days following these exercises.

**RESULTS:** A significant decline in MVC without any sign of muscle soreness was observed immediately after CON and ECC (72.7% vs. 65.7%). One days after the exercises, all indirect markers of muscle damage, such as the decline in MVC and ROM and the increase in muscle soreness, were significantly greater in ECC than CON ( $p < 0.05$ ), and these markers had recovered fully in CON. During submaximal voluntary contractions, EMG activity and force fluctuation were significantly higher in ECC than CON ( $p < 0.05$ ). The peak value of EEG-EMG coherence in the beta range (13-30 Hz) during 10 and 20%MVC was significantly increased in ECC ( $p < 0.05$ ), but not in CON.

**CONCLUSIONS:** It is suggested that increase in EMG activity and force fluctuation immediately after eccentric exercise, which induce acute muscle damage, were attribute in part to increase in corticomuscular coherence.

**Influence Of Fatigue-induced Muscle Afferent Stimulation On Motor Evoked Potentials**

Douglas J. Dearth, Jonathan Umbel, Richard L. Hoffman, David W. Russ, Thad Wilson, Brian C. Clark. *Ohio University, Athens, OH.*

Email: dd343805@ohio.edu

(No relationships reported)

Post-exercise muscle ischemia (PEMI)-induced stimulation of muscle afferents depresses motoneuron excitability (Martin et al., J Neurosci, 2006). However, little is known regarding the influence of muscle afferents on motor evoked potential (MEP) characteristics.

**PURPOSE:** The purpose of this study is to determine the effect of a submaximal fatiguing elbow extensor muscle contraction followed by 2-min of PEMI on MEP amplitude and the duration of corticospinal silent period (SP).

**METHODS:** Fifteen subjects (9 men and 6 women; 22.2±4.1 yrs) performed a submaximal elbow extensor fatigue task to failure at 15% of max strength. Immediately following the fatigue task, a 2-minute PEMI period was induced. Mean arterial blood pressure (MAP) and heart rate (HR) were measured on a beat-by-beat basis. Before, during, and after the exercise task, electromyographic responses were recorded from the lateral head of the triceps brachii in response to transcranial magnetic stimulation (TMS) pulses to the motor cortex and electrical stimulation of the brachial plexus to evoke a maximal muscle action potential (Mmax). MEP amplitude was normalized to the Mmax, and the SP duration was determined.

**RESULTS:** The fatigue task was performed for 482±33.4 sec. MAP increased from 93±5.8 mmHg at rest to 148±8.9 mmHg at task failure ( $p<0.05$ ), and remained elevated above resting conditions during PEMI (125±6.8 mmHg;  $p<0.05$ ). HR also increased from 71±3.5 bpm at rest to 97±3.7 bpm at task failure ( $p<0.05$ ); however, HR returned to resting levels during PEMI (75±2.3 bpm). MEP amplitude increased from 28±3.8% of Mmax at the start of exercise to 72±8.2% of Mmax at task failure ( $p<0.05$ ), and remained elevated above pre-fatigue levels during PEMI (56±5.8% of Mmax;  $p<0.05$ ). SP duration increased from 114±7.5 msec at the start of exercise to 176±14.0 msec at task failure ( $p<0.05$ ); however, SP duration returned to pre-fatigue levels during PEMI (140±11.5 msec).

**CONCLUSIONS:** These findings suggest that stimulation of muscle afferents via PEMI facilitates MEP amplitude without affecting the SP duration. Further work is required to determine the relative influence of spinal versus cortical modulation on these observations, as well as their functional implications on the mechanisms of muscle fatigue.

**Bilateral Neuromuscular Plasticity Associated With Unilateral Resistance Training Of The Ankle Dorsiflexor Muscles**

Katie Dragert, E. Paul Zehr. *University of Victoria, Victoria, BC, Canada.*

*(No relationships reported)*

In the early weeks of high-intensity resistance training (RT), strength gains are attributed to plasticity within the nervous system. Unilateral RT causes adaptation in both the trained and untrained limb, i.e. a muscular crossed effect. H-reflex amplitude has been shown to increase only in the trained plantarflexor (SOL) muscle despite comparable changes in strength bilaterally. However, it is unknown whether similar changes occur in the functional antagonist of the SOL, the tibialis anterior (TA). Also, following RT it is unknown whether reduced reflex activity in the functional antagonist muscle contributes to strength gains in the agonist muscle in either limb.

**PURPOSE:** To examine the effects of high-intensity unilateral ankle flexor (TA) RT on agonist and antagonist (SOL) muscular strength and H-reflex response in the trained and untrained limbs.

**METHODS:** Ankle flexor torque and SOL and TA H-reflex responses were observed before and after 5wks of unilateral dorsiflexion RT, and compared to controls. During data collection, bilateral H-reflexes were evoked via stimulation delivered to either the tibial (SOL) or CP nerves (TA). EMG recordings were taken from the SOL, TA, VL, PD and AD muscles. In TA and SOL H-reflex measurements were taken from recruitment curves and included modulation of 50% Hmax and Hmax.

**RESULTS:** Following RT, TA force was significantly ( $p < 0.05$ ) increased in both the trained and untrained limb by 14 and 8%, respectively, without concomitant changes in H-reflex amplitude.

**CONCLUSIONS:** These results further extend evidence of muscular crossed effects to the ankle dorsiflexor muscles. This is also the first work to quantitatively measure spinal reflex activity in a muscle functionally antagonist to a RT movement, and the relative size of any resulting reflex modulation is unknown. Thus, H-reflex may not be a sensitive enough measure to detect subtle changes in TA / SOL spinal excitability following ankle flexor RT.

**Does Strength Training The Free Limb Attenuate Strength Loss During Unilateral Immobilization?**

Jonathan P. Farthing, Joel R. Krentz, Charlene R.A. Magnus. *University of Saskatchewan, Saskatoon, SK, Canada.*

Email: jon.farthing@usask.ca

*(No relationships reported)*

**PURPOSE:** The objective was to determine if strength training the free limb during a 3-week period of unilateral immobilization attenuates strength loss in the immobilized limb, through cross-education.

**METHODS:** Thirty right-handed participants were assigned to three groups. One group ( $n=10$ ) wore a cast and trained the free arm (CAST-TRAIN). A second group ( $n=10$ ) wore a cast and did not train (CAST). A third group ( $n=10$ ) received no treatment (CONTROL). Casts were applied to the non-dominant (left) wrist and hand by a physician. Strength training was maximal isometric ulnar deviation (right hand) 5 days/week. Peak torque (dynamometer), electromyography (EMG), and muscle thickness (ultrasound) were assessed in both arms before and after the intervention.

**RESULTS:** CAST-TRAIN improved right arm strength (14.3[SD5.0] to 17.7[SD4.8] Nm;  $p<0.05$ ) with a trend for muscle hypertrophy (3.73[SD0.43] to 3.84[SD0.52] cm;  $p=0.09$ ). The immobilized arm of CAST-TRAIN did not change in strength (13.9[SD4.3] to 14.2[SD4.6] Nm) or muscle thickness (3.61[SD0.51] to 3.57[SD0.43] cm). The immobilized arm of CAST decreased in strength (12.2[SD3.8] to 10.4[SD2.5] Nm;  $p<0.05$ ) and muscle thickness (3.47[SD0.59] to 3.32[SD0.55] cm;  $p<0.05$ ). CONTROL showed no changes in the right (strength: 15.3[SD6.1] to 14.3[SD5.8] Nm; muscle thickness: 3.57[SD0.68] to 3.52[SD0.75] cm) or left arm (strength: 14.5[SD5.3] to 13.7[SD6.1] Nm; muscle thickness: 3.55[SD0.77] to 3.51[SD0.70] cm). Agonist muscle activation remained unchanged after the intervention for both arms (Right: 302[SD188] to 314[SD176]  $\mu$ V; Left: 261[SD139] to 288[SD151]  $\mu$ V) with no group differences.

**CONCLUSIONS:** Strength training of the free limb attenuated strength loss in the immobilized limb during unilateral immobilization. Strength training may have prevented muscle atrophy in the immobilized limb.

**H-reflex Modulation During Different Head Movements**

Masaaki Tsuruike<sup>1</sup>, Koichi Kitano<sup>2</sup>, David M. Koceja<sup>2</sup>. <sup>1</sup>*Osaka Univ. of Health and Sports Sciences, Osaka, Japan.* <sup>2</sup>*Indiana University, Bloomington, IN.*

Email: tsuruike@ouhs.ac.jp

*(No relationships reported)*

Head movement stimulates the vestibulospinal tract, which contributes to the balance system. Head movement increased our postural sway amplitude. The amplitude of the soleus spinal stretch reflex was decreased by contralateral side head movement. However, it has yet to be investigated if presynaptic inhibition to the soleus Ia afferents is modulated by the head movement.

**PURPOSE:** To examine the modulation of the soleus H-reflex and presynaptic inhibition (PI) to the soleus Ia afferents during standing with head movement.

**METHODS:** Seven young active subjects (mean: 23.3 yrs) were examined. The H-wave and M-responses of the right soleus were determined for each subject during a static standing position. Each subject turned the head up and contralaterally or ipsilaterally with or without hands on table for support while the H-reflexes were examined. To examine H-reflex modulation, a PI H-reflex

conditioning protocol was administered. The control H-reflex stimulus was set at 10% of M-max. PI was induced via conditioning of the soleus H-reflex with peroneal nerve stimulation at 100 msec prior to the test stimulus on the tibial nerve. The conditioning stimulus was delivered once the EMG activity of sternocleidomastoid muscle occurred as a trigger signal for lateral head movements. For the head up movement, an electrogoniometer was placed on the cervical spine and this was used as a trigger signal. Each mean of PI H-reflexes was normalized by the amplitude of control H-reflex (%). For data analyses, a 2 x 4 repeated measures ANOVA was used to determine each mean of H-reflex and PI-H reflex.

**RESULTS:** The H/M-max ratio during standing without hands on the table was 41%. The ratio of PI H-reflex to the control H-reflex was 68.5% and 85.7% during standing with and without hands on the table, respectively. The mean ratio of PI H-reflex to control H-reflexes was decreased when the head was turned contralaterally by 8.4% and 13.5% with and without hands on the table, respectively. The ratio was decreased by 27.0% when the head was turned ipsilaterally with hands on the table, whereas it was not changed without hands on the table.

**CONCLUSIONS:** The soleus H-reflex was modulated during head movements. PI to the soleus Ia afferents was decreased when the head was turned laterally, yet the modulation was dependant on the head movement and body stability.

**Differences In Obstacle Crossing Performances And The Associated Attentional Demands Between Elderly And Younger Adults**

WenLan Wu, ChiuJung Huang, ChunHao Huang, LanYuen Guo, HwaiTing Lin. *Department of sports medicine, Kaohsiung City, Taiwan.*

Email: wenlanwu@kmu.edu.tw

(No relationships reported)

The walking patterns and the performances of stepping over obstacles change with age. This has implications for the problem of falls in elderly adults.

**PURPOSE:** To investigate the differences in obstacle crossing performances and the associated attentional demands between elderly and younger adults under the single or dual task condition.

**METHODS:** In total, twelve healthy elderly adults and fifteen healthy younger adults were included in this study. The sound operating system was used to provide a stimulus tone to the subject. Two in-series force platforms were used to record ground reaction forces. A three dimensional motion analysis system was used to collect the motion data. During reaction time (RT) test, a self-assembly radio telemetry handheld trigger was used to signal a response. Single-primary task (obstacle crossing alone), single- secondary task (hand button pressing alone), and dual-task (obstacle crossing plus hand button pressing tasks) were tested for each participant.

**RESULTS:** The medial COM-COP inclination angles were significantly smaller in the elderly subjects than in younger subjects. However, no group differences were detected for peak anterior and posterior inclination angles. In addition, significant decreases in COM peak velocities in the A/P and M/L directions were detected in the elderly group when compared to the younger group during all tasks. The RT was significantly faster for all participants in the single- secondary task than for the dual-task condition. Task differences in reaction time were almost 100 ms for both the younger and elderly groups. During the dual-task test, the accuracy decreased for both the younger and elderly groups. In addition, the accuracy in the tone discrimination task was significantly higher for elderly participants in the single- secondary task condition than for the dual-task condition. However, no significant differences were detected for younger adults.

**CONCLUSIONS:** Our study has verified that aging might delay early sensory processing and cognitive functioning. In addition, aging will also influence the gait strategy to maintain stability during obstacle crossing.

**Fatigue Induced Changes In Vertical Jumping Performance Following A Simulated Team Handball Match**

Mette K. Zebis<sup>1</sup>, Peter Mortensen<sup>1</sup>, Lars L. Andersen<sup>1</sup>, Michael Kjær<sup>2</sup>, Per Aagaard<sup>3</sup>. <sup>1</sup>National Research Centre for the Working Environment, Copenhagen, Denmark. <sup>2</sup>Institute of Sport Medicine, Copenhagen, Denmark. <sup>3</sup>Institute of Sports Sciences and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark.

Email: mettezebis@hotmail.com

(No relationships reported)

**PURPOSE:** In the light of the importance of explosive strength in elite sports, we examined how neuromuscular activity and force-generating capacity was affected in response to a simulated team handball match.

**METHODS:** Eight female elite team handball players (age  $24 \pm 5$  years, height  $170 \pm 6$  cm, weight  $73 \pm 6$  kg) were tested before and after a simulated team handball match for maximal strength in knee extensors and flexors (MVC) and countermovement jumping ability (CMJ) by means of force plate analysis. Electromyography (EMG) recordings from the quadriceps (VL, VM, RF), hamstrings (BFcl, ST), gluteus medius (GT) and triceps surae (GL, GM) were obtained during the CMJ. The simulated handball match consisted of a series of intermittent exercises (side steps, cross over steps, jumps, high and low intensity running and sprinting) mimicking handball match activity (50 min).

**RESULTS:** The simulated team handball match induced reductions in MVC (knee extensors:  $-15.5\% \pm 11.1$ ,  $P = 0.046$ , knee flexors:  $-16.2\% \pm 7.9$ ,  $P = 0.028$ ) and in several of the mechanical CMJ parameters: Jump height ( $-8.2\% \pm 6.1$ ,  $P = 0.017$ ), Peak force in the eccentric phase ( $-6.1\% \pm 6.4$ ,  $P = 0.017$ ), Work in the concentric phase ( $-5.5\% \pm 5.5$ ,  $P = 0.012$ ) and mean power in concentric phase ( $-5.2\% \pm 5.3$ ,  $P = 0.036$ ). The ability to rapid force exertion in the final part of the plantar flexor phase seemed also slightly reduced (increased negative impulse in the plantar flexor phase:  $10.8\% \pm 10.0$ ,  $P = 0.025$ ). Normalized EMG was unaltered for all muscles during the CMJ, suggesting the existence of a robust muscle stimulation pattern (motor program) that can not be easily changed with fatigue.

**CONCLUSION:** Several muscle mechanical parameters were acutely affected by the simulated team handball match, potentially leading to impaired functional performance. However, no clear evidence of altered neuromuscular activity was found.

**Multiple Strategies Are Used To Maintain Fixed Head Position During Higher-frequency Anterior-posterior Oscillations**

Kevin Terry, Venkata Gade, W. Thomas Edwards. *KMRREC, W. Orange, NJ.*

Email: kterry@kmrrec.org

(No relationships reported)

Our study of postural responses to anterior-posterior (A-P) cyclic perturbations confirmed that as frequency increased, head movement decreased until it was relatively stationary.

However, multiple strategies were used to limit head movement. A lower body (LB) strategy fixed the upper body in space while allowing rotation of the lower body about the hip.

Alternately, a whole-body (WB) strategy fixed head position while allowing progressively larger linear displacements with increased distance from the head. These multiple strategies may be driven by idiosyncratic characteristics such as body geometry, reaction time, or overall stability. Identification of these drivers could lead to better balance training for athletes and more specific rehabilitation for those with diminished balance.

**PURPOSE:** Identify stereotypical muscle activation and kinematic patterns used to establish stable head position at higher-frequency A-P oscillations.

**METHODS:** Motion, force, and EMG data were collected and synchronized for 11 able-bodied subjects standing on a research platform during A-P sinusoidal translations at 0.1, 0.25, 0.5, 0.75, 1.0, and 1.25 Hz with a peak-to-peak amplitude of 12 cm. Each frequency progression was repeated twice.

**RESULTS:** Five subjects used the LB strategy, five used the WB strategy, and one subject used an atypical strategy that did not fix head position. For the third repetition at 1.25

Hz, the LB strategy had well-stereotyped kinematics, with translations <7.5 mm and rotations <1.4 deg for all joints above the hip. Joint rotation was largest at the hip (10.7±1.4 deg). Mean center-of-pressure (COP) excursion decreased from 148 to 79.5 mm with repetition and was out-of-phase with center-of-mass (COM) displacement. For the WB strategy, kinematic, EMG, and COP/COM patterns were far less consistent. However, the significantly larger mean head displacement for the WB strategy (25.9 vs. 10.6 mm ( $p = 0.045$ )) decreased with repeated exposure until head displacements for each strategy were not statistically different (9.22 vs. 7.54 mm ( $p = 0.51$ )).

**CONCLUSION:** Although people tended to fix their head in space at higher A-P cyclic frequencies, there was one strategy (LB) that was well-stereotyped and another (WB) that was a collection of unique strategies that were equally effective at fixing head position.

**The Relationship Between The Knee Joint Moment And The Control Of The Center Of Mass.**

Issei Ogasawara<sup>1</sup>, Shumpei Miyakawa<sup>2</sup>. <sup>1</sup>*Japan Institute of Sports Sciences, Tokyo, Japan.* <sup>2</sup>*University of Tsukuba, Ibaraki, Japan.*

Email: ogasawaraissei@gmail.com

(No relationships reported)

**PURPOSE:** To understand how the control of the center of mass (CoM) affects the frontal-plane knee joint moment.

**METHODS:** Based on the principle of virtual work, the joint moment  $\tau$  of the link system can be written as  $\tau = J^T F$ , where  $J$  (the Jacobian matrix of the link system) is a function of joint angle,  $F$  is a ground reaction force (GRF). On the other hand, the GRF  $F$  acting on the distal edge of the link system can be expressed using the acceleration of CoM as  $F = Mc - Mg$  ( $M$ : total mass,  $c$ : acceleration of CoM,  $g$ : acceleration of gravity). From these two equations, the joint moment  $\tau$  can be then written as  $\tau = J^T(Mc - Mg)$ . This means that the joint moment  $\tau$  depends on the acceleration of CoM. To check this equation in actual human movement, we conduct a landing experiment. 7 healthy adults jumped from 30 cm high box and landed using their dominant leg. The target on the force platform which subjects were asked to land were pointed by the PC-controlled laser pointer. The landing target randomly changed to another point after the landing action started. The purpose of this random landing task is to make various landing posture.

**RESULTS:** Fig.1 shows the frontal-plane knee joint moment as a function of the frontal-plane component of the vector of GRF with respect to leg coordinate system(A), and as a function of the frontal-plane component of the vector of estimated GRF based on the acceleration of CoM with respect to leg coordinate system. These two plots showed quite similar results.

**CONCLUSIONS:** Fig.1(B) showed that estimated GRF affects the frontal-plane knee joint moment as the real GRF does. For the prevention of ACL injury, not only the control of lower limb alignment, but also the control of CoM plays an important role in decreasing the valgus knee moment.

**Open And Closed Kinetic Chain Exercises Increase Wrist Stability During A Forward Fall**

Michelle A. Sandrey, Patricia L. Hatches. *West Virginia University, Morgantown, WV.*

Email: msandrey@mail.wvu.edu

(No relationships reported)

Limited research has been conducted on open (OKC) and closed kinetic chain (CKC) wrist exercises and the impact on controlling a fall. It is uncertain if wrist exercises have an effect on increasing wrist stability by enhancing neuromuscular pathways during a forward fall.

**PURPOSE:** To determine if wrist exercises in the OKC and CKC can enhance neuromuscular pathways, aiding in wrist stability during a forward fall.

**METHODS:** Thirty healthy college students (23.0±2.0 yrs) with no upper extremity injuries in the past 6 months volunteered for the study. Subjects were randomly assigned to an OKC, CKC exercise group or a control group (no exercise). Subjects met with the researcher for six weeks to perform exercises for the dominant (writing hand) hand and wrist. Training included five wrist-specific weight-bearing exercises for the CKC group and five wrist-specific non-weight bearing exercises for the OKC group that increased in reps, sets, or time per week. Pre-post testing was performed using the Biodex Stability System (BSS) at levels 8,6,4, and 2. Each subject performed three practice trials for body placement and how to fall on the platform. One trial was performed for each of the four randomized stability levels for a total of four trials. The randomized levels of stability were used to simulate the element of surprise associated with falling on different types of surfaces. The stability levels were averaged over a stability level continuum producing one value for each stability index (anterior/posterior, medial/lateral and overall stability).

**RESULTS:** For medial/lateral stability, a significant main effect existed for time ( $F_{1,30} = 12.986$ ,  $P = .001$ ). Post-test stability index decreased indicating greater stability than pre-test. For overall stability, a significant interaction existed for group by time ( $F_{1,30} = 5.675$ ,  $P = .006$ ), time ( $F_{1,30} = 18.70$ ,  $P = .001$ ), and group ( $F_{1,30} = 6.295$ ,  $P = .009$ ). Although post-test results decreased for the CKC group, only the OKC and control groups were different for overall stability ( $p = .001$ ). All other results were not significant.

**CONCLUSIONS:** Open and closed kinetic chain exercises can be effective in integrating new neuromuscular patterns. Future research should continue to investigate the use of OKC and CKC wrist specific exercises to aid in wrist stability during a forward fall.

**Upper Extremity Activity And Strenght Characteristics Between Thrower And Non-trower During Isokinetic Shoulder Muscle Action**

Siyoun Park, Shumpei Miyakawa, Hitoshi Shiraki, Naoki Mukai. *University of Tsukuba, Tsukuba, Japan.*

Email: park@med.taiiku.tsukuba.ac.jp

(No relationships reported)

**PURPOSE:** To examine the patterns of electromyography(EMG) activity and torque values during maximal, isokinetic muscle action with shoulder flexion (Flex<sub>Con</sub>/Flex<sub>Ecc</sub>), abduction (Abd<sub>Con</sub>/Abd<sub>Ecc</sub>) and diagonal activities (Dia<sub>Con</sub>/Dia<sub>Ecc</sub>), and to determine whether concentric or eccentric contractions or any of the obtained values were correlated with thrower and non-throwers at 60 and 180°/s on the dynamometer.

**METHODS:** The participants for this investigation were 18 males who assigned to two groups, thrower group of 9 male subjects (mean age, 21.9±1.2 years; mean height, 177.2±4.2 cm; mean body mass, 74.8±4.7 kg) that volunteered from university students who participate in overhead sports at least three days a week and non-thrower group of 9 healthy male subjects (mean age, 24.3±1.7 years; mean height, 175.9±2.5 cm; mean body mass, 65.1±6.4 kg). We assessed muscle activation of the anterior deltoid, middle deltoid, posterior deltoid, upper trapezius, middle trapezius, lower trapezius, pectoralis major, and biceps brachii muscles by surface electromyography.

**RESULTS:** The anterior deltoid and biceps brachii muscle activities were significantly greater for thrower group than non-thrower group during Abd<sub>Con</sub>/Abd<sub>Ecc</sub>, at 60 (both,  $P < 0.05$ ) and 180°/s (both,  $P < 0.001$ ). The middle and posterior deltoid muscle activities were significantly greater for thrower group than non-thrower group during Flex<sub>Con</sub>/Flex<sub>Ecc</sub> (both,  $P < 0.05$ ) and Abd<sub>Con</sub>/Abd<sub>Ecc</sub> (both,  $P < 0.001$ ) at 180°/s. The middle trapezius muscle activity was significantly greater for thrower group than non-thrower group during all tasks at 60°/s (Flex<sub>Con</sub>, Dia<sub>Con</sub>, and Abd<sub>Ecc</sub>,  $P < 0.05$ ; the other tasks,  $P < 0.001$ ). In the upper trapezius and pectoralis major muscle activities were not found to be dependent on all tasks of the velocity (60 or 180°/s) and the mode (Con or Ecc). The muscle strength value on thrower group was significantly higher for eccentric than concentric contraction in all the tasks (Abd,  $P < 0.05$ ; the other tasks,  $P < 0.001$ ).

**CONCLUSIONS:** This study has provided evidence that isokinetic eccentric muscle strength testing of the posterior upper extremity muscle is effective to develop of a proper program for overhead athlete requires forceful stability during throwing phases.

**The Effect Of Workload On Measures Of Gross Motor Performance While Cycling**

Kenneth Krings, Erin Wilfong, Mindy Frederick, Don Hoover. *Rockhurst University, Kansas City, MO.*  
Email: don.hoover@rockhurst.edu  
(No relationships reported)

**PURPOSE:** Several studies have investigated physiological and biomechanical factors which may impact cycling training and performance. However, variables such as neuromuscular efficiency or gross motor performance while cycling have received relatively little attention. Knowledge of performance from this perspective may help scientists understand factors which influence related physiological and biomechanical issues or help coaches optimally apply the principle of specificity in ways which boost performance or lower risk of injury or overtraining. This study investigated the influence of workload on measures of gross motor performance during submaximal cycling.

**METHODS:** Fourteen avid recreational cyclists (47.20 ± 11.93 yr, 181.40 ± 5.85 cm, 80.58 ± 7.67 kg) volunteered for this study. Each completed three submaximal exercise bouts during two separate sessions. Each participant completed three submaximal exercise trials at workload (Watts) to bodyweight (kg) ratios of 1.5:1, 2.0:1, and 2.5:1. The order of the two sessions and three workloads were randomized. Numerous dependent measures of gross motor performance, perceived effort, and physiologic response were collected throughout each trial.

**RESULTS:** A two-way within-subjects analysis of covariance (2 x 3) was conducted to evaluate the effect of workload on dependent variables. Significant differences ( $p < 0.05$ ) were found for measures of workload (wattage), and gross motor performance (SpinScan™ and average torque angle), and perceived effort (RPE and OMNI). Post-hoc analysis showed subjects demonstrated significantly greater pedaling efficiency as the workload level increased during steady state cycling ( $p < 0.016$ ). HR responses for the different workloads approached statistical significance ( $p < 0.05$ ).

**CONCLUSIONS:** This study showed that workload level significantly influenced measures of gross motor performance or pedaling efficiency. These findings suggest that neuromuscular coordination responses contribute greatly to cycling performance and that such responses differ slightly from, and may interact in interesting ways with, the physiological and biomechanical responses seen also during cycling. More study is needed on the relationship between gross motor performance and cycling intensity.

**The Effect Of 6weeks Intensive Core Stability On Functional Fitness And Postural Control Ability Of Stroke Patients**

Hyejung Choi<sup>1</sup>, Hyunjung Tae<sup>1</sup>, Ayoung Cho<sup>1</sup>, Sookyung Park<sup>2</sup>, Sunggon Shone<sup>1</sup>, Sungmin Park<sup>1</sup>. <sup>1</sup>*Bobath Memorial Hospital, Gyeonggi, Republic of Korea.* <sup>2</sup>*Seoul National University, Seoul, Republic of Korea.*  
Email: cho993@hanmail.net  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effects of core stability training on functional fitness and postural control ability of stroke patients.

**METHODS:** Nineteen subjects volunteered to participate and divided into two group: exercise group (EG; n=14), comparative group (CG; n=5). Muscular strength, muscular endurance, and flexibility for functional fitness were measured by PASS (Postural Assessment Scale for Stroke Patients) which was divided into two subscales: Maintaining a posture and changing posture.

**RESULTS:** Regarding the functional fitness variables, there were no significant differences in muscular strength. However, time x group interactions ( $p < 0.018$ ) and time ( $p < 0.043$ ) differences were shown significantly in upper and lower muscular endurance, respectively. In flexibility, significant difference were shown in time ( $p < 0.005$ ) and time x group interactions ( $p < 0.04$ ). Regarding to posture variables, significant time x group interaction was shown in controlling posture ( $p < 0.046$ ) and maintaining a posture ( $p < 0.008$ ).

**CONCLUSIONS:** according to the results, the effect of core stability training on stroke patients was positive. Therefore, core stability exercise should be included in the treatment for stroke patient during the post stroke rehabilitation stage.

**Decoupled Elliptical Machine Training: Withdrawal And Crossed-extensor Reactions During Bipedal Stance**

Raoul F. Reiser, II, FACSM, Brian L. Tracy, FACSM, Megan A. Endrizzi, Abbey R. Keene, Leah N. Hitchcock. *Colorado State University, Fort Collins, CO.*  
Email: rfreiser@cahs.colostate.edu  
(No relationships reported)

When rapid ankle inversion is sensed, the withdrawal and crossed-extensor reflex unloads the ipsilateral limb and extends the contralateral limb. This reflex response potentially protects against ankle sprains.

**PURPOSE:** To determine if the withdrawal and crossed-extensor reflex response could be heightened through bilateral training on a human-powered, decoupled elliptical machine.

**METHODS:** Five male subjects who had completed a challenging series of skill progressions on the machine were compared to matched controls who had never used the machine (PS = Progressed Subjects, CS = Control Subjects). A bipedal standing test with electrical stimulation to either ankle was conducted to elicit the withdrawal and crossed-extensor reflex. Once the 50 ms stimulus was felt, the subject lifted the stimulated foot completely off the ground as quickly as possible. Ten noxious stimulus trials were followed by ten sub-noxious trials (five to each ankle randomly). Ground reaction forces under each foot and surface EMG of vastus lateralis and biceps femoris muscles were recorded bilaterally. Differences in time to react were assessed at  $p < 0.10$  for the five stimuli trials to the dominant ankle in each condition.

**RESULTS:** Age, height, body mass, reported athletic participation/accomplishment, and current physical activity were similar in PS and CS. In general, the PS reacted faster for both noxious and sub-noxious stimuli. PS withdrew the ipsilateral foot more rapidly in both noxious ( $308 \pm 33$  vs  $389 \pm 85$  ms,  $p = 0.083$ ) and sub-noxious trials ( $320 \pm 44$  vs  $437 \pm 69$  ms,  $p = 0.013$ ). Also, during sub-noxious trials the PS activated the ipsilateral ( $114 \pm 8$  vs  $133 \pm 15$  ms,  $p = 0.035$ ) and contralateral biceps femoris more rapidly ( $101 \pm 15$  vs  $175 \pm 087$  ms,  $p = 0.094$ ) and produced the first detectable change in contralateral force more rapidly ( $136 \pm 19$  vs  $165 \pm 20$  ms,  $p = 0.047$ ). Reactions by both groups were generally faster in the noxious condition, as expected.

**CONCLUSIONS:** These preliminary findings indicate that decoupled elliptical training may enhance the withdrawal and crossed-extension response during both reflex and non-reflexive conditions; potentially reducing the likelihood of ankle sprain.

**The Effect Of Retro Locomotion On Flexibility Of The Low Back And Hamstrings**

Chet R. Whitley, Janet S. Dufek, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.*  
Email: chetley04@embarqmail.com  
(No relationships reported)

Low back pain (LBP) is a serious health problem in America affecting over 80% of the population (NIH, 2006) and is often characterized by a lack of flexibility of the low back and hamstrings.

**PURPOSE:** To explore whether retro locomotion can be an effective means to increase flexibility of the low back and hamstrings, ultimately decreasing LBP.

**METHODS:** Ten healthy female adults (29.9±10.0 yrs; 165.1±8.2 cm; 68.53±18.4 kg) presenting without LBP within the past four months volunteered to participate. The pre-test consisted of participants first warming up with a 2-5 minute forward walk at a personally comfortable velocity followed by three trials of the YMCA Sit-and-Reach test to measure low back and hamstrings flexibility. A biaxial electrogoniometer (Biometrics, model SG 150) was secured externally to the low back vertically spanning T12-S2. Participants then walked backward on a treadmill at their preferred velocity for 10-15 minutes. Low back motion data from the electrogoniometer (1000 Hz) was obtained for 20 sec during the sixth minute of the walk capturing 10 complete walking strides. Following the pre-test, participants completed four weeks of backward walking on a treadmill or over ground for 10-15 minutes/day, four days/week, at the participant's chosen velocity. After completing the intervention, a post-test session which duplicated pre-test procedures was conducted. Four dependent variables were identified including maximum sit-and-reach score (SR), walking velocity (Vel) and average sagittal (sROM) and coronal (cROM) range of motion (cROM) of the low back averaged across 10 walking strides. Pre-post differences were evaluated with correlated t-tests ( $\alpha = 0.05$ ).

**RESULTS:** Statistically greater post-test SR ( $p < 0.001$ ) and Vel ( $p < 0.001$ ) values were observed with no differences for sROM ( $p = 0.289$ ) or cROM ( $p = 0.320$ ).

**CONCLUSION:** Retro locomotion may be a practical means to improve flexibility of the low back and hamstrings as evidenced by improved SR scores. Low back range of motion may not be similarly influenced; however individual responses in low back motion were evidenced.

**Prophylactic Ankle Stabilizers Affect Ankle and Knee Joint Kinematics During Landing**

Lindsay N. Barlow, Jacob K. Gardner, Steven T. McCaw, FACSM. *Illinois State University, Normal, IL.*

Email: lnbarlo@ilstu.edu

(No relationships reported)

**PURPOSE:** Ankle joint dorsiflexion contributes to energy absorption when landing, but wearing ankle stabilizers has been shown to restrict passive and active measures of dorsiflexion. Recent changes in stabilizer design and materials have been intended to improve support to the lateral ankle joint without restricting sagittal plane motion. This study compared the effects of various ankle stabilizers on ankle and knee joint kinematics during soft and stiff landings.

**METHODS:** Subjects ( $N=11$ ) performed two-legged landings off a 0.32-m platform onto a force platform while recorded with an optotrak system (200 Hz). Five soft and five stiff landings were performed in five bilateral ankle stabilizer conditions (no stabilizer; standard taping; neoprene shell with support; reinforced lace up boot; hinged lace up boot), a total of fifty trials per subject. Stabilizer and style conditions were randomized across subjects. Each subject's five-trial mean value of selected ankle and knee kinematic variables for each landing style/stabilizer condition was entered into a two-way repeated measures ANOVA ( $\alpha=0.05$ ).

**RESULTS:** As previously reported in the literature, joint ROMs were less in stiff landings than soft landings. Compared with the no stabilizer condition, the ROM at the ankle and knee were reduced in most stabilizer conditions, reflecting a more extended landing position at both ground contact and maximum joint flexion when using an ankle stabilizer. Stabilizer effects at the ankle joint were of similar magnitude to soft vs stiff differences, but of a smaller magnitude at the knee joint.

**CONCLUSIONS:** In spite of design and material changes to the stabilizers, the results indicate that some ankle stabilizers still adversely affect ankle joint kinematics during landing, possibly inducing changes in the knee joint kinematics.

**ACKNOWLEDGEMENTS:** Ankle stabilizers were supplied at no-cost by the manufacturers. The financial support of IAHPERD through a *Jump Rope for Heart* grant is gratefully appreciated.

**Effect Of Mandibular Orthopedic Repositioning Device On Neuropsychological Measures**

Scott G. Piland<sup>1</sup>, Trenton E. Gould<sup>1</sup>, David Morris<sup>2</sup>, Tyler D. Martin<sup>3</sup>. <sup>1</sup>The University of Southern Mississippi, Hattiesburg, MS. <sup>2</sup>Appalachian State University, Boone, NC. <sup>3</sup>Troy University, Troy, AL (Sponsor: Michael J. Webster, FACSM)

Email: scott.piland@usm.edu

(S.G. Piland, Shock Doctor, Inc., Salary; Shock Doctor, Inc., Contracted Research.)

Mandibular orthopedic repositioning appliances (MORA) have been purported to enhance human performance related to muscular strength, balance, concentration, attention and coordination. However, limited scientific evidence is available for review, thus claims are mostly supported anecdotally.

**PURPOSE:** To determine the effect of treatment condition (Control or MORA) on measures of attention, concentration, dexterity, visual sequencing, coordination and reaction time of physically active college-aged individuals.

**METHODS:** Twenty-seven physically active male subjects (age = 21.33 ± 2.22 yr; ht = 177.0 ± 7.26 cm; wt = 85.85 kg) were group matched on age, height and weight then placed into a prospective randomized, doubly multivariate, crossover design over a period of 4 weeks. The aforementioned constructs were measured using a battery of neuropsychological tests to include: Comprehensive Trail-Making Test (CTMT), the ImPACT computerized neurocognitive program and the Grooved Peg Board Test (GPBT). Pre-crossover data were used to determine the effect of the IV (treatment: control, MORA) on the DV's (mean composite CTMT score, mean ImPACT composite reaction time and visual composite scores, and mean GPBT score) using four separate Univariate analysis with age, height, weight, and grade level as covariates.

**RESULTS:** With no significant covariates noted, no statistically significant differences were found between the MORA and Control group for composite CTMT score, ImPACT composite reaction time and visual composite scores,  $p = .454$ ,  $p = .711$  and  $p = .630$  respectively. No statistically significant differences were found between the MORA and Control group for dominant and non-dominant hand GPBT,  $p = .257$  and  $p = .136$  respectively.

**CONCLUSIONS:** Contrary to anecdotal claims, the use of a MORA device does not increase attention, coordination, reaction time, visual sequencing demands, reaction time and dexterity as measured by the utilized neuropsychological assessment battery.

**Motor Variability In A Hand Muscle: Greater Visuomotor Contribution To Force Fluctuations For Older Adults**

Brian L. Tracy, FACSM, Jyoti S. Jennewein, Halden J. Clark, Caitlin E. Feldman, Leah N. Hitchcock. *Colorado State University, Fort Collins, CO.*

Email: tracybl@cacs.colostate.edu

(No relationships reported)

Muscle force fluctuations depend primarily on the neural signal to the motor unit pool. For older adults, the neural signal can be more variable and contribute to the amplitude of force fluctuations when visual feedback is important to task performance - for large proximal muscles. For distal hand muscles however, the afferent sensory feedback, neural inputs to motor neurons, and typical use is very different.

**PURPOSE:** The purpose was to determine age-related differences in the contribution of visuomotor correction to force fluctuations during contractions of the first dorsal interosseus (FDI).

**METHODS:** Young ( $N = 21$ , 22 ± 7 yrs) and elderly adults ( $N = 12$ , 72 ± 9 yrs) underwent assessment of maximum voluntary contraction (MVC) and force fluctuations during constant-force (CF) isometric contractions of the left FDI muscle. Subjects were seated with the elbow at a right angle, palm down, and wrist, thumb, and fingers 3-5 restrained. They produced steady abduction forces of the index finger at each target force (2.5, 30, and 65% MVC) in random order. For each trial, visual feedback of the force was provided for 8-10 s (VIS) and removed for 8-10 s (NOVIS). Mean force, standard deviation (SD), and coefficient of variation (SD/mean force, CV) of force was calculated for VIS and NOVIS data segments. Drift of the force signal away from the target (< 0.5 Hz) was removed from all data before fluctuation analysis.

**RESULTS:** MVC force tended to be lower for elderly adults ( $32 \pm 11$  N vs.  $38 \pm 9$  N,  $P = 0.12$ ). For young adults the CV of force was similar between VIS and NOVIS for the 2.5% ( $4.9 \pm 1.8\%$ ), 30% ( $3.4 \pm 1.4$ ) and 65% ( $4.2 \pm 1.5\%$ ) target forces. In contrast, for elderly adults the CV of force was greater for VIS than NOVIS for 2.5% MVC ( $7.1 \pm 2.9\%$  vs.  $4.5 \pm 1.8\%$ ), but not for the 30% ( $2.6 \pm 1.6\%$ ) and 65% ( $3.4 \pm 2.1\%$ ) target forces. The effect of visual feedback was greater for elderly than young subjects (vision x age group interaction,  $P = 0.004$ ).

**CONCLUSION:** As with large proximal muscles, visuomotor correction contributed substantially to the amplitude of force fluctuations in a small hand muscle. The fluctuations increased by 58% for older adults when vision was used as a source of feedback, suggesting a reduced ability to process visuomotor information and execute ongoing corrections during simple motor tasks.

**A Novel Ankle-supinating Device**

Gregory M. Gutierrez<sup>1</sup>, Thomas W. Kaminski, FACSM<sup>2</sup>. <sup>1</sup>New York University, New York, NY. <sup>2</sup>University of Delaware, Newark, DE.

Email: gmgutierrez@nyu.edu

(No relationships reported)

Lateral ankle sprains (LAS) are common injuries and while many are resolved with treatment, others develop Ankle Instability (AI). It follows that considerable attention has been directed towards understanding the underlying causes of this pathology, however little is known to date concerning the neuromuscular mechanisms behind the development of AI, possibly due to a dearth of analyses of individuals with AI in dynamic conditions.

**PURPOSE:** To perform a pilot kinematic and EMG analysis of the landing phase of a drop jump onto a device which simulates the mechanism of a LAS in persons with AI (AI group), persons who've suffered a LAS, but did not develop AI (NO group), and uninjured controls (CO group).

**METHODS:** Six subjects with bilaterally equivalent ankle status were divided equally into the 3 groups. A pneumatic rotary actuator powered the rotation of a landing plate via a linkage system, aiming to safely mimic a LAS event. The protocol included subjects dropping off a take-off platform (test leg first) and landing with both feet simultaneously onto the device and surrounding landing platform; followed by an immediate jump "as high and fast as possible". Subjects were familiarized with the protocol, then 10 experimental trials were performed with 3 supinating and 7 non-supinating trials in a random order, unknown to the subject. Markers were placed according to a modified Helen Hayes marker set and EMG was performed on the Tibialis Anterior (TA) and Peroneus Longus (PL). Due to the pilot nature and low power, only descriptive statistics were calculated.

**RESULTS:** Kinematics indicated that the platform created a perturbation causing increased ankle plantar flexion ( $\sim 8^\circ$ ), adduction ( $\sim 9^\circ$ ), and inversion ( $\sim 13^\circ$ ). The EMG data suggests NO subjects demonstrate an increased activation of the PL prior to landing and in response to a perturbation, relative to the other groups.

**CONCLUSION:** The device adequately simulates the mechanism of a LAS in a safe, controlled environment, even in individuals with AI. The preliminary EMG data suggests the work evaluating subjects who have a previous history of at least one LAS and don't experienced recurrent symptoms may help elucidate some compensatory mechanisms or more appropriate neuromuscular control strategies following a LAS, so more appropriate treatment paradigms can be developed.

**Steadiness During Plantar Flexion Is Associated With Postural Sway In Young But Not Elderly Adults**

Motoki Kouzaki<sup>1</sup>, Minoru Shinohara, FACSM<sup>2</sup>. <sup>1</sup>Kyoto University, Kyoto, Japan. <sup>2</sup>Georgia Institute of Technology, Atlanta, GA.

Email: m.kouzaki@kt8.ecs.kyoto-u.ac.jp

(No relationships reported)

Fluctuations in motor output during steady isometric contractions with a muscle or muscle group are often greater in elderly than young adults, but the functional significance of force fluctuations during isolated muscle contractions is not determined.

**PURPOSE:** The present study examined the association between force fluctuations during isolated contractions with plantar flexor muscles and postural sway during quiet standing in young and elderly adults.

**METHODS:** Twenty young ( $28.1 \pm 4.0$  yrs) and 20 elderly ( $69.7 \pm 2.8$  yrs) subjects performed a force-matching task with unilateral isometric plantar flexion (PF) at 2.5%, 5%, 10%, 15%, and 20% of subjects' maximal voluntary contraction (MVC) for 30 s. The knee joint was fully extended and the ankle joint was in the neutral position during PF. They also maintained quiet standing (QS) on a force platform for 30 s as a separate task. To quantify the variability of motor output, the coefficient of variation (CV) of force during PF and the CV of center of pressure displacement during QS were calculated. Surface electromyogram (EMG) was recorded from the soleus, medial gastrocnemius and lateral gastrocnemius muscles during PF and QS. Power spectrum density of the rectified EMG was calculated to characterize the muscle activation strategies.

**RESULTS:** In young subjects, a significant ( $P < 0.05$ ) positive correlation was found in the CV between QS and PF at lower contraction intensities (2.5% and 5% of MVC). There was no correlation between QS and PF at any contraction intensity in elderly adults. During PF, the EMG power around 10 Hz was significantly ( $P < 0.05$ ) greater in the medial gastrocnemius in elderly than young adults at low contraction intensities (2.5% and 5% of MVC). There was no difference in the EMG power distribution in other muscles between young and elderly adults during PF. During QS, the EMG power around 10 Hz was significantly ( $P < 0.05$ ) greater in all the muscles in elderly than young adults.

**CONCLUSION:** The variability in postural sway during quiet standing was correlated to the force fluctuations during isolated plantar flexion at low contraction intensities in young but not elderly adults. The presence or absence of association between postural sway and force fluctuations may be influenced by the muscle activation strategy around 10 Hz.

**Exploration Of Muscle Activity Patterns During Deep Water Running**

John A. Mercer, FACSM<sup>1</sup>, Kenji Masumoto<sup>2</sup>. <sup>1</sup>UNLV, Las Vegas, NV. <sup>2</sup>Kyushu University, Fukuoka, Japan.

Email: john.mercer@unlv.edu

(No relationships reported)

Deep water running (DWR) simulates running while submerged in the water up to neck level and unable to touch the bottom of the pool. It is not known which aspects of DWR are critical to provide a cross-training stimulus for on land running. We sought to understand the coordination between select lower extremity muscles.

**PURPOSE:** To compare the magnitude of co-contraction between select muscles during DWR and treadmill running (TMR).

**METHODS:** Subjects ( $n=7$ ,  $26.3 \pm 4.3$  yrs,  $158 \pm 9.9$  cm,  $61 \pm 6.6$  kg) were instrumented to record electromyography (EMG) of the Rectus Femoris (RF), Biceps Femoris (BF), Gastrocnemius (GA), and Tibialis Anterior (TA). Subjects first completed three exercise conditions during DWR at Rating of Perceived Exertion (RPE) levels of 11 (fairly light), 13 (somewhat hard), and 15 (hard). Subjects then completed the same RPE levels during TMR. EMG data were recorded (1500 Hz) and a 25-s data set extracted for analysis. EMG data were smoothed (500 Hz), zero-offset removed, rectified and normalized to maximal voluntary contraction. A co-contraction index (CCI) was calculated for RF-BF and GA-TA muscle combinations using the formula:  $CCI(i) = (M1(i)/M2(i) \times (M1(i) + M2(i)))/2$  for  $i=0-25$ s, M1 is the lower and M2 the higher EMG at each time. Average CCI for RF-TF and GA-TA was calculated across the 25-s data set and compared across Mode (DWR, TMR) and RPE (11, 13, 15) using a 2 x 3 repeated measures ANOVA. Planned comparisons were conducted using paired t-tests to compare CCI between DWR and TMR at each RPE level.

**RESULTS:** RF-BF CCI was influenced by the interaction of Mode and RPE ( $p=0.036$ ) whereas GA-TA CCI only tended to be different between modes ( $p=0.069$ ). It was determined that RF-BF CCI was lower ( $p<0.05$ ) during DWR then TMR at RPE 11 (DWR  $1.94\pm0.64\%$ , TMR  $7.65\pm6.1\%$ ) and RPE 13 (DWR  $2.76\pm1.4\%$ , TMR  $7.49\pm5.2\%$ ) but not at RPE 15 (DWR  $4.46\pm2.34\%$ , TMR  $9.59\pm7.4\%$ ,  $p>0.05$ ). GA-TA CCI was lower ( $p<0.05$ ) during DWR than TMR at RPE 11 (DWR  $1.65\pm1.2\%$ , TMR  $8.89\pm3.7\%$ ) and RPE 13 (DWR  $1.99\pm2.2\%$ , TMR  $8.61\pm3.7\%$ ) and tended to be lower at RPE 15 (DWR  $3.20\pm3.8\%$ , TMR  $8.07\pm6.43\%$ ,  $p=0.08$ ).

**CONCLUSION:** There was less co-contraction for flexor/extensor pairs of muscles during DWR then TMR at lower intensities. It appears that higher intensity DWR is needed to achieve similar co-contraction magnitudes of lower intensity TMR.

**2482 Board #127 May 29 8:00 AM - 9:30 AM**  
**A Lack Of Peripheral Fatigue Effects On Force Sense At The Knee**

Timothy C. Sell, Anne Benjaminse, Anthony J. House, Hung-Chun Huang, John P. Abt, Scott M. Lephart, FACSM. *University of Pittsburgh, Pittsburgh, PA.*

Email: tcs15@pitt.edu

(No relationships reported)

Peripheral fatigue impacts neuromuscular control of knee joint stability as evidenced by reports of injuries occurring during the latter stages of competition. Previous research has demonstrated that fatigue can affect proprioception, as measured by threshold to detect passive motion (TTDPM). The effects of peripheral fatigue on proprioception measured actively by force sense (FS) have not been investigated. FS measures an individual's ability to produce a measured amount of force and may provide insight into feedback from musculotendinous mechanoreceptors.

**PURPOSE:** To determine the effects of peripheral fatigue on quadriceps and hamstrings FS.

**METHODS:** A total of twenty healthy and physically active females and males (age:  $23.4\pm2.7$  years, mass:  $69.5\pm10.9$ kg, height:  $169.7\pm9.4$ cm) participated. FS of the hamstrings and quadriceps was tested on separate days before and after three sets of isokinetic knee flexion and extension to fatigue. Prior to the fatigue protocol, each individual performed a maximum isokinetic test to determine peak torque production. The first two sets were 40 repetitions, with the last set truncated at 90 repetitions or stopped if torque production dropped below 25% of peak torque. Electromyographic data of the tested musculature were collected in order to calculate and determine median frequency shift. FS was measured by examining the ability to produce a target isometric torque (25% MVIC) with and without visual feedback (FS Error). Separate dependent t-tests were conducted to examine pre-fatigue and post-fatigue FS Error for flexion and extension.

**RESULTS:** Despite verification of fatigue via torque production decrement and shift in median frequency, no significant differences were observed in FS Error for either knee flexion (pre= $0.54\pm2.28$  N-m; post= $0.47\pm1.62$  N-m ( $p=.45$ )) or extension (pre= $0.28\pm2.69$  N-m; post= $0.21\pm1.78$  N-m ( $p=.44$ )) pre-fatigue compared to the post-fatigue condition.

**CONCLUSION:** Although previous research has demonstrated that peripheral fatigue negatively affects TTDPM, it did not affect FS as measured in this study. The peripheral fatigue protocol may have a greater effect on the mechanoreceptors responsible for TTDPM than those responsible for FS. Further investigation into the effects of fatigue across various aspects of proprioception is warranted.

**The Effect Of High Velocity Resistance Training In Older Men And Women**

Shanelle D. Carolan, Stephen P. Sayers. *University of Missouri, Columbia, MO.*

(No relationships reported)

Traditional resistance training (RT) with a strengthening component improves muscle strength and power in older adults; however, the strenuous nature of traditional RT can make adherence to this regimen difficult. Alternative RT protocols are needed in this population to ensure continued participation.

**PURPOSE:** To evaluate the effects of traditional RT (high load, slow velocity) compared to high velocity RT (low load, high velocity) on muscle strength (MVC), peak power (PP), functional performance, work, and rating of perceived exertion (RPE) in older adults.

**METHODS:** 38 men and women (Age:  $72.4\pm5.9$  years) were randomly assigned to one of three groups for a 12-week study: Strength (STR:  $n=13$ ), Velocity (VEL:  $n=13$ ), or Control (CON:  $n=12$ ). STR performed 3 sets of 8-10 reps at 80% 1RM slowly (concentric portion: 2-s) 3x/wk; VEL performed 3 sets of 12-14 reps at 40% 1RM as quickly as possible concentrically 3x/wk. STR, VEL, and CON all performed stretching exercises 3x/wk. Lower extremity MVC and PP were obtained using computer-interfaced Keiser a420 knee extension machines. Functional measures included timed up and go, tandem walk, habitual and maximal gait speed, timed stair climb and descent, and 400 meter walk. Statistical analyses included repeated measures (group x time) ANOVA and independent samples t-tests. Statistical significance was accepted at  $p<0.05$ .

**RESULTS:** With training, MVC increased by 26% and 25% in STR and VEL, respectively, compared with CON (ANOVA;  $p=0.002$ ). With training, PP increased similarly in STR and VEL by 12% and 24%, respectively, compared with CON ( $p<0.001$ ). There was no improvement in any functional measure between STR and VEL (all  $p>0.05$ ). There was no difference in work performed between STR (3673 J) and VEL (4070 J) ( $p=0.47$ ), but RPE during resistance training was lower in VEL (RPE=14.6) compared with STR (RPE=16.7) ( $p=0.002$ ).

**CONCLUSIONS:** Traditional RT with a strengthening component and high-velocity, low load RT both showed increases in strength and power, but had no effect on function. Despite similar effects on muscle performance and similar amounts of work performed, high-velocity RT was perceived to be less strenuous than traditional RT. Employing high velocity RT could have a beneficial impact on exercise adherence in this population.

**Development Of A Metabolic Equation For Nustep® Recumbent Stepper Exercise In Older Adults**

Lance C. Dalleck, Erica C. Borresen, Amanda L. Parker, Kelly M. Abel, Jessica S. Tischendorf. *University of Wisconsin - Eau Claire, Eau Claire, WI.*

Email: dalleck@uwec.edu

(No relationships reported)

Exercise professionals frequently rely upon metabolic equations to prescribe exercise intensity and to estimate the energy expenditure of different exercise modalities (Franklin, 2000). To date there has been no research performed to develop accurate prediction equations for the NuStep® (NS) recumbent stepper.

**PURPOSE:** The purpose of this study was to develop an accurate metabolic equation for estimating steady-state  $\text{VO}_2$  during submaximal NS exercise.

**METHODS:** Forty male and female participants (mean  $\pm$  SD, age:  $64.0 \pm 6.5$  yr.; height:  $170.1 \pm 9.1$  cm; weight:  $85.7 \pm 19.9$  kg) performed two randomized testing sessions. Each session consisted of six stages with combinations of four workloads (1, 3, 5, and 7) at 3 cadences (60, 80, and 100 steps/min). Steady-state  $\text{VO}_2$  measurements from the last 2 min of each workload were used to develop a metabolic prediction equation for NS exercise.

**RESULTS:** Multiple regression analysis to predict steady-state  $\text{VO}_2$  from NS workload (W), NS steps/min (s/min), and subject body mass resulted in the following model ( $R^2 = .733$ ): Steady-state  $\text{VO}_2 = 3.5 - 0.53(W \cdot \text{s/min}) + 0.92(\text{s/min}) + 0.16(\text{wt})$ . The standard error of the estimate (SEE) and total error (TE) for the prediction of steady-state  $\text{VO}_2$  under all NS workload conditions were 2.3 mL/kg/min and 2.4 mL/kg/min respectively (see Figure). The correlation coefficient between predicted  $\text{VO}_2$  and measured  $\text{VO}_2$  values was significant ( $p < .05$ ),  $r = 0.86$ .

**CONCLUSION:** SEE and TE values for the developed NS metabolic equation are similar to those reported in previous studies investigating the accuracy of metabolic equations for other exercise modalities. These findings support the use of the equation developed in the present study to predict steady-state  $\text{VO}_2$  for NS exercise.

**Falls Prediction By Physical Function And Health Status In Elderly Men And Women.**

Catarina LN Pereira, FACSM<sup>1</sup>, Fátima Baptista, FACSM<sup>2</sup>. <sup>1</sup>University of Évora, Évora, Portugal. <sup>2</sup>Faculty of Human Movement, Technical University of Lisbon, Lisbon, Portugal.

Email: clnp@uevora.pt

(No relationships reported)

Fullerton batteries have been used by exercise professionals to assess physical function and balance in elderly, however there is no sufficient knowledge about its capacity to discriminate fallers from nonfallers.

**PURPOSE:** To analyse falls prediction by physical function attributes (evaluated by field tests), age and health status in elderly men and women.

**METHODS:** Participants were 549 community-dwelling persons, aged 50-87 yrs ( $68.1 \pm 6.8$  yrs): 317 fallers vs. 154 nonfallers females and 100 fallers vs. 18 nonfallers males. Body weight, height, body mass index, lower and upper body strength and flexibility, agility, aerobic endurance (AE), and multidimensional balance (MB) were evaluated by Fullerton batteries. Body fat mass percentage (BFM%) was evaluated by bioimpedance using a HBF-306C, and waist circumference (WC) was measured at navel level. Age, sum of the number of diseases and incapacities (DI-number) and the occurrence of falls in the last year were evaluated through questionnaire by interview. Fallers were those who had fallen at least once within the last 12 months.

**RESULTS:** Chi-Square revealed that women fell more than men (33 vs 23%,  $p=0.020$ ). T-Student showed that women presented a lower body weight, height, WC, strength, agility, AE, and MB, but higher flexibility, BFM%, and DI-number than men ( $p \leq .01$ ). T-Student also showed that fallers were older and had lower muscle strength, flexibility, AE, and MB, and higher BFM%, DI-number than nonfallers ( $p \leq .05$ ). Logistic regression with backward stepwise selection, showed that predictor variables to falls occurrence were gender OR=2.1, 95% CI (1.003-4.529), weight OR=0.974, 95% CI (0.954-0.994), BFM% OR=1.063, 95% CI (1.023-1.105), DI-number OR=1.212, 95% CI (1.108-1.327) and MB OR=0.934, CI 95% (0.908-0.961). The analysis of the area under the receiver operating characteristics (ROC) curve was 0.70, 95% CI (0.65-0.75), with a specificity of 0.64 and sensitivity of 0.65 for a cut point  $p=0.3$ .

**CONCLUSION:** Men fall less than women, perhaps due to a better physical function, body composition and health status. However, for a similar MB, body weight, BFM%, and DI-number, men is more prone to falling than women. Regarding overall accuracy of ROC curve, these predictor variables may discriminate fallers from nonfallers.

**Self-selected Walking Intensity Of Healthy Older Women (65-74yr) During Treadmill And Over-ground Walking**

Mathew Haycock<sup>1</sup>, Surendran Sabapathy<sup>1</sup>, Norman Morris<sup>1</sup>, Gregory Gass<sup>2</sup>, Clare Minahan<sup>1</sup>. <sup>1</sup>Griffith University, QLD, Australia. <sup>2</sup>Bond University, QLD, Australia.

Email: m.haycock@griffith.edu.au

(No relationships reported)

**BACKGROUND:** Current exercise guidelines for older adults recommend at least 30 min of physical activity (PA) on most days of the week ( $\geq 4/\text{wk}$ ) performed at 55-90% of maximum heart rate (HRmax). While the recommended frequency and duration of PA can be easily self-selected, it is unclear if older adults are able to select the recommended exercise intensity.

**PURPOSE:** To determine if healthy women (65 - 74 yr) are able to self-select a walking intensity that is within the current recommendations for daily PA during treadmill (TM) and over-ground (OG) walking.

**METHODS:** Nine healthy older women (age =  $68.5 \pm 3.2$  yr, BMI =  $26.2 \pm 5.7$  kg/m<sup>2</sup>, peak O<sub>2</sub> uptake ( $\text{VO}_{2\text{peak}}$ ) =  $22.7 \pm 4.7$  mL/kg/min) performed four, 30-min walking trials (two TM and two OG) in a counterbalanced, randomized order. For the initial TM and OG trials, subjects self-selected their walking speed. Walking speed, heart rate (HR) and ratings of perceived exertion (RPE) were recorded during these trials. For the second TM and OG trials, walking speed was controlled to match the speeds selected during the initial TM and OG trials. During the second TM and OG trials, pulmonary gas exchange was measured using a COSMED K4b2, in addition to HR and RPE.

**RESULTS:** Exercise intensity during self-selected TM and OG walking were within the current guidelines for daily PA (TM = 70% HRmax, 95%CI = 66 - 75%; OG = 73% HRmax, 95%CI = 67 - 79%). Differences in the HR and  $\text{VO}_2$  responses for TM and OG walking were not significant (%HRmax,  $p = .06$ ; % $\text{VO}_{2\text{peak}}$ ,  $p = .08$ ), while walking speed during OG was significantly greater than TM walking ( $p = .01$ ).

**CONCLUSION:** Healthy older women are able to self-select a walking intensity that is suitable for meeting the current recommendations for daily PA during both TM and OG walking.

**"Tailored" Step Test For Rapid, Accurate And Safe  $\text{VO}_{2\text{max}}$  Determination In Healthy Elderly.**

Cecilia Bellotti, Lorenzo Casiello, Silvia Pogliaghi. Università di Verona, Verona, Italy.

Email: silvia.pogliaghi@univr.it

(No relationships reported)

**PURPOSE:** The study aimed at developing and validating a "tailored" version of the Åstrand step test, suitable for  $\text{VO}_{2\text{max}}$  determination in healthy elderly. Furthermore, we tested the hypothesis that a direct measure (compared to estimation) of the step test  $\text{VO}_2$ , adds accuracy to  $\text{VO}_{2\text{max}}$  determination in this population, characterized by low fitness and muscle strength and reduced coordinative ability.

**METHODS:** In 27 healthy elderly (age 68±5, 14 M, 13 F) a target  $\dot{V}O_2$  ( $\dot{V}O_{2t}$ ) for the step test was calculated as 60% of the  $\dot{V}O_{2max}$  (predicted based on their referred activity pattern). Thereafter, subjects performed a 5-min test, on a 30 cm step, with a stepping rate (10-25 steps\*min<sup>-1</sup>) “tailored” based on  $\dot{V}O_{2t}$  and the predicted cost of stepping. Heart rate (HR) and  $\dot{V}O_2$  were measured using a portable, hand-held, metabolic analyzer.  $\dot{V}O_{2max}$  was estimated based on Åstrand equation and age correction using either  $\dot{V}O_{2t}$  ( $\dot{V}O_{2max, t-est}$ ) or measured  $\dot{V}O_2$  ( $\dot{V}O_{2max, m-est}$ ). Finally,  $\dot{V}O_{2max}$  was measured directly ( $\dot{V}O_{2max, d}$ ) during an incremental cycling test to exhaustion with breath by breath determination of cardiorespiratory variables, with a traditional metabolic chart. Agreement among  $\dot{V}O_{2max, t-est}$ ,  $\dot{V}O_{2max, m-est}$ ,  $\dot{V}O_{2max, d}$  was evaluated by Bland Altman analysis.

**RESULTS:** All the subjects completed the incremental exercise to exhaustion (maximal HR 98±7% of age-predicted value, maximal respiratory quotient 1.1±0.04). Mean ± standard deviation  $\dot{V}O_{2max}$  was 27±5 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>. All the subjects were also able to complete the “tailored” step test with no difficulty.  $\dot{V}O_{2max, m-est}$  was not significantly different from  $\dot{V}O_{2max, d}$  (bias -0.3, not different from 0; precision 4.1 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>). On the contrary,  $\dot{V}O_{2max, t-est}$  was significantly underestimated compared to  $\dot{V}O_{2max, d}$  (bias -2.3, ≠ 0; precision 4.6 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>).

**CONCLUSION:** The study developed and validated a “tailored” version of the Åstrand step test, suitable for a rapid (5 min duration), safe (submaximal test) and accurate (unbiased)  $\dot{V}O_{2max}$  determination in healthy elderly individuals. In this population, estimation of the step test  $\dot{V}O_2$  leads to a small (9%) yet significant error in  $\dot{V}O_{2max}$  estimation. Therefore, our data suggest that a direct measure of the step test  $\dot{V}O_2$  should be performed to assure accuracy to  $\dot{V}O_{2max}$ -estimation.

**Changes In Health-related Quality Of Life And Functional Ability With Exercise Training In Senior Center Members**

Brian Hand<sup>1</sup>, Arnold Eppel<sup>2</sup>, William Forbes<sup>1</sup>. <sup>1</sup>Towson University, Towson, MD. <sup>2</sup>Baltimore County Department of Aging, Baltimore, MD.

Email: BHand@towson.edu

(No relationships reported)

Successful aging encompasses physical, functional, social, and psychological health, which are all important aspects in maintaining quality of life.

**PURPOSE:** To determine the effect of exercise on health-related quality of life (HRQL) and functional ability, as assessed by ability to carry out activities of daily living (ADL), in older adults who attend senior centers.

**METHODS:** Changes in HRQL and ability to carry out ADLs were assessed after 12 weeks of endurance training (ET), following ACSM guidelines, in 16 previously inactive older (72±6 yrs) men (n=3) and women (n=13) and compared with changes in HRQL and ability to carry out ADLs in 16 aged-matched (76±7 yrs) inactive controls (men (n=1), women (n=15)). All research participants were members of the Baltimore County Department of Aging Senior Centers. Changes in HRQL for several domains including: physical functioning, physical health-related role limitations, bodily pain, general health, vitality, social functioning, mental health-related role limitations, and mental health were assessed by the Medical Outcomes Survey Short Form-36 (MOS SF-36) questionnaire. Changes in ability to carry out ADLs were assessed using the Senior Fitness Tests (SFT), which included: chair stand, arm curl, 2-minute step, chair sit-and-reach, back scratch, and 8-foot up-and-go tests. ANCOVA was used to test for significant differences in changes in HRQL and ability to carry out ADLs between the ET and control groups.

**RESULTS:** There was a significantly greater increase in the physical health-related role limitations domain in the ET group compared with controls (12±19 vs. -8±20, P=0.01). Also, there was a significantly greater increase in the number of steps completed in the 2-minute step test in the ET group compared with controls (15±10 vs. 4±8, P=0.01). There were no other significant differences between the ET and control groups for changes in the other HRQL domains or the other SFTs.

**CONCLUSIONS:** These preliminary results suggest that in older adults who attend senior centers, ET may improve aerobic fitness and the ability to carry out work and other physical daily activities.

**The Effect Of High-Speed Power Training On Muscle Performance In Older Men And Women.**

Stephen P. Sayers. University of Missouri - Columbia, Columbia, MO.

Email: sayerss@missouri.edu

(No relationships reported)

Peak power is a key outcome measure of muscle performance in older adults. Peak power is typically obtained by choosing the highest power output measured across a range of external resistances (40%-90% 1RM). Although resistance training (RT) improves peak power in older adults, few studies have examined how different RT protocols impact muscle power and its individual components (force and velocity) across a range of external resistances.

**PURPOSE:** To compare the effects of high-load, slow-speed RT and low-load, high-speed RT on muscle power and the components of force and velocity across a range of external resistances in older adults.

**METHODS:** 38 men and women (Age: 72.4 ± 5.9 years) were randomly assigned to one of three groups for a 12 wk training study: strength training (STR: n=13), high-speed power training (HSPT: n=13), or control (CON: n=12). STR performed 3 sets of knee extension (KE) exercise (8-10 reps; 80% 1RM slowly [concentric: 2 s]; 3x/wk); HSPT performed 3 sets of KE exercise (12-14 reps; 40% 1RM [concentric: as fast as possible]; 3x/wk). All groups performed stretching exercises 3x/wk. Knee extension peak power (PP), peak power force (PPV), peak power velocity (PPV), and peak velocity (PV) across 6 different external resistances (40%-90% 1RM) were obtained at baseline and after 12 weeks using Keiser a420 equipment. Change scores were calculated from baseline to 12 weeks and analyzed using a 3 x 6 repeated measures (group x time) ANOVA. Statistical significance was accepted at p<0.05.

**RESULTS:** PP and PPF increased across a range of external resistances in both STR and HSPT compared to CON (p<0.001), but there was no difference between active treatments (all p>0.05). Although PPV was not different among groups at any external resistance (p=0.08), change in PV was higher in HSPT compared to STR (at 40%, 50%, 60% 1RM) and CON (at 50% and 60% 1RM) (all p<0.05).

**CONCLUSIONS:** Both high-load, slow-speed RT and low-load, high-speed RT increased peak power and the force component of power across a range of external resistances. HSPT increased contraction speed at lower external resistances while STR reduced contraction speed across all external resistances. If contraction speed is critical to muscle performance in older adults, HSPT may be a preferred RT format in this population.

**Functional Fitness Differences Among Males And Females Greater Than 70 Years Of Age**

Linda D. Wilkin, Bryan L. Haddock. California State University, San Bernardino, San Bernardino, CA.

Email: lwilkin@csusb.edu

(No relationships reported)

By 2030, it is projected that there will be 71 million older adults in the U.S. It is imperative that we understand the aging process.

**PURPOSE:** To assess the functional fitness of older adults to analyze the differences among males and females.

**METHODS:** 108 older adults (>70 years of age) were recruited. All participants were apparently healthy and lived independently. Participants were assessed on physical activity, cognitive status, depression, activities of daily living, and nutrition. Functional fitness was assessed using the following: 1) 30-sec chair stand; 2) 30-sec arm curl; 3) 2-min step-n-place;

4) chair sit-n-reach; 5) back scratch; and 6) 8-ft up-n-go. Participants were placed into four categories based on the SFT scores: 1) at risk for loss of mobility (AR); 2) below average (BA); 3) average (A); and 4) above average (AA).

**RESULTS:** 73 females and 35 males completed all assessments. Males had higher incomes, physical activity, strength and faster times on the 8-ft up-n-go than females. Females had greater flexibility than males. Males and females were compared separately by category on each of the six SFT. Females: 1) on chair stand those BA were older than the other three categories and those AR were on more meds than BA and AA; 2) on arm curl age was not different; 3) on step-n-place those BA were less active than the other three categories; 4) on sit-n-reach there were no differences; 5) on back scratch AA had lower BMI than AR; AA had fewer meds than AR & A; 6) on 8-ft up-n-go AR were older than BA & A; AA had lower BMI than the other three groups; AR had lower activities of daily living than the other three groups; AA had fewer meds than the other three groups. Males: 1) on chair stand AA had lower BMI than AR & BA; AR had higher scores on depression than the other three groups; 2) on arm curl BA had higher depression scores than the other three groups; 3) on step-n-place AR were older than BA & A; 4) on sit-n-reach there were no differences; 5) on back scratch there were no differences; 6) on 8-ft up-n-go AR had higher depression scores than A & AA; BA had lower scores on nutrition than the other three groups.

**CONCLUSION:** For females, the most common difference between categories was age followed by meds and BMI. For males, depression scores were higher for those at risk for loss of mobility and below average on three of the six functional tests.

**2491 Board #136 May 29 9:00 AM - 10:30 AM**  
**A Targeted Balance And Mobility Program Is Effective For Treatment Of Arthritis In Older Adults**

Debra J. Rose, Danielle Hernandez. *California State University, Fullerton, Fullerton, CA.*  
(No relationships reported)

**PURPOSE:** The primary objective was to investigate the short-term effectiveness of a targeted balance and mobility training program on balance, strength, and flexibility in a group of older adult women with osteoarthritis and/or rheumatoid arthritis. The secondary objective was to evaluate the responsiveness of the Berg Balance Scale in detecting meaningful change in the intervention group.

**METHODS:** Thirty-five independently residing women (Mean = 79 years) with a primary diagnosis of osteoarthritis and/or rheumatoid arthritis participated in this study. The intervention group (N=20) attended two, one-hour balance and mobility classes per week for eight weeks. The program incorporated exercises designed to improve the multiple dimensions of balance, mobility, upper and lower body strength, and flexibility. All participants were also included in the responsiveness analyses. Responsiveness was calculated using two

**METHODS:** (1) Standardized Response Mean (SRM) which is the mean change in scores divided by the standard deviation of the change in scores; (2) Responsiveness-Retrospective (RR) Coefficient which is the mean change of intervention subjects divided by the standard deviation of change of the control (stable) subjects.

**RESULTS:** The intervention group demonstrated significant improvements in balance, upper and lower body strength, and flexibility. The SRM results indicated that the intervention group exhibited a medium to large effect size (SRM = 0.74) compared to the small effect size demonstrated by the control group (SRM = 0.09). The RR coefficient indicated that mean change for the intervention group demonstrated a large effect size (RR = 1.85) when adjusted for the spurious change reflected in the variability in score changes among the control group.

**CONCLUSION:** Older adult females with arthritis can derive significant benefits from an intervention that focuses on improving balance and mobility in a full weight-bearing environment.

**Age Scale For Assessing Functional Fitness In Korean Older Adults**

Misook Lee<sup>1</sup>, Jaehyeon Park<sup>1</sup>, Miji Kim<sup>2</sup>, Junghwan Cho<sup>3</sup>, Kiyoji Tanaka, FACSM<sup>2</sup>. <sup>1</sup>*Korea National Sport University, Seoul, Republic of Korea.*  
<sup>2</sup>*Tsukuba University, Tsukuba, Japan.* <sup>3</sup>*Seoul Women's University, Seoul, Republic of Korea.* (Sponsor: Kiyoji Tanaka, FACSM)  
Email: misook@knsu.ac.kr  
(No relationships reported)

**PURPOSE:** Considerable variability exists in physical health status including functional fitness among older adults. Previous research has examined to help individuals age "actively", "healthfully", "successfully" and has shown that individuals who maintain a physically active life-style in middle and old age are significantly less likely to experience age-related decrements in their ability to perform activities of daily living compared with less active individuals of the same chronological age (CA). With this in mind, the purpose of present study was to develop an age scale for the assessment of functional fitness in Korean older women.

**METHODS:** This study was a cross-sectional analysis and the subject inclusion criteria were age of 60 years or older, living in the community. Korean older women volunteered and they were divided into three groups: a) less active (n=138), b) sedentary (n=25), and c) active (n=25). The less active group was used for the development of the functional fitness age (FFA), while data from sedentary and active groups were utilized for the assessment of the criterion-related validity. Six functional fitness variables were selected as test items related to ADL.

**RESULTS:** After applying the principal component analysis to the correlation matrix among 6 items, functional fitness score (FFS)=0.065X<sub>1</sub>+0.868X<sub>2</sub>+0.035X<sub>3</sub>+0.163X<sub>4</sub>+0.066X<sub>5</sub>+0.236X<sub>6</sub>-9.806, where X<sub>1</sub>=grip strength (kg), X<sub>2</sub>=waist hip ratio, X<sub>3</sub>=functional reach (cm), X<sub>4</sub>=walking around two cones (s), X<sub>5</sub>=tandem balance (s), X<sub>6</sub>=chair-sit-to stands (s). FFA=-5.0FFS+70.9. The mean CA of the 3 groups were not significantly different from one another. The mean FFA of less active group (70.9±5.0years) obtained from this equation was matched with their mean CA (70.4±7.2years). The mean FFA of the sedentary group (76.7±5.4years) was significantly higher than their mean CA, and the mean FFA of the active group (65.7±4.7years) was significantly lower than their mean CA.

**CONCLUSIONS:** The criterion-related validity of the FFA equation was clearly demonstrated as a means to assess the functional fitness in Korean older women. FFA will provide a simple way for this subjects to become aware of their current functional status, and motivate them to maintain a active life-style.

**Effects Of A Physician-Based Exercise Counseling Program For Improving Aerobic Fitness In Older Adults**

Chasitity N. Lattanzio, Robert J. Petrella, FACSM, Sheree Shapiro, Tom Overend. *The University of Western Ontario, London, ON, Canada.*  
Email: petrella@uwo.ca  
(No relationships reported)

Unequivocal evidence supports healthy lifestyles for cardiovascular disease prevention. Family physicians are ideally positioned to address this care gap.

**PURPOSE:** To determine the impact of an exercise prescription for older sedentary adults in family practice.

**METHODS:** The Step Test Exercise Prescription (STEP) was a 12 month trial with 360 older adults (50-85 years) from 40 family practices in four regions of Canada. Intervention physicians were trained to deliver a tailored exercise prescription and transtheoretical behavior change counseling program. Control physicians were trained to deliver the exercise prescription alone. Primary outcome measures were cardiorespiratory fitness (VO<sub>2</sub>max) and energy expenditure (7-day PAR).

**RESULTS:** Participants (intervention, n=193; control, n=167) were healthy community men (48%) and women (52%) with a mean age of 64.9 ±7.1 years. In both groups, VO<sub>2</sub>max significantly increased (p<0.001) for the intervention (+2.88 ±4.22 ml·kg<sup>-1</sup>·min<sup>-1</sup>) and control (+2.56 ±5.20 ml·kg<sup>-1</sup>·min<sup>-1</sup>) at 12 months, however there was no difference between groups. Women in the intervention improved their fitness significantly higher than control (+2.99 ±4.38 ml·kg<sup>-1</sup>·min<sup>-1</sup>). The intervention group had a 4mmHg reduction in systolic blood pressure (0.4 mmHg in the control (p<0.001)). The mean energy expended (EE) significantly increased but was higher in the intervention vs

control (69.06 ±169.87 vs -6.96 ±157.06 Kcal-d-1). There were no significant practice setting differences among the primary outcomes.

**CONCLUSIONS:** STEP exercise and behavioral intervention improved fitness, activity and lowered systolic blood pressure across a range of Canadian practices. Women showed higher levels of fitness than control while men showed similar improvement in both groups.

**Assessment Of Leg Muscle Power Using A Stair-climbing Power Test In Community-dwelling Elderly People**

Yutaka Yoshitake<sup>1</sup>, Akiyo Higashionna<sup>1</sup>, Hiroshi Nagayama<sup>1</sup>, Koji Zushi<sup>1</sup>, Misaki Sumino<sup>1</sup>, Tomohito Wada<sup>1</sup>, Masayoshi Yamamoto<sup>1</sup>, Mieko Shimada<sup>2</sup>, Kazuto Saito<sup>1</sup>, Akira Maeda<sup>1</sup>, Takafumi Hamaoka, FACSM<sup>1</sup>, Naotake Inoue<sup>1</sup>. <sup>1</sup>National Institute of Fitness and Sports in Kanoya, Kanoya, Japan. <sup>2</sup>Chiba College of Health Science, Chiba, Japan.

Email: yositake@nifs-k.ac.jp

(No relationships reported)

A stair-climbing power test (SCPT) is an inexpensive, practical test that is simple to perform. An individual's lower extremity power is a critical element regarding both mobility and the activities of daily living, while it is also a key determinant of independence for elderly people.

**PURPOSE:** To determine the usefulness of the SCPT, a modification of the Margaria stair-climbing power test, by comparing the results obtained from the SCPT with those from a leg power test in community-dwelling elderly people.

**METHODS:** The subjects of this study consisted of physically-independent elderly men (N=19, aged 75+/-6 yrs) and women (N=18, aged 77+/-6 yrs). The stair-climbing power was measured using ordinary stairs (17.5cm step height, 6-stair flights, 105 cm total height). The time spent in stair climbing was measured by a stopwatch. The subjects were instructed to ascend the stairs as fast as they could. The stair-climbing power was then calculated with the body mass, the time spent in stair climbing, the vertical height travelled, and the gravitational acceleration. The bilateral leg extensor power (LEP) was measured using an isotonic leg power system (Combi, Anaero Press 3500, Japan) in a sitting position. The isometric knee extension strength was measured on each side of the knee using a specially designed dynamometer (Yagami, Japan).

**RESULTS:** The stair-climbing power was 297.6+/-60.3 watts (mean +/- SD) for men and 199.1 +/-60.6 watts for women. LEP was 768.2+/-324.6 watts for men and 361.6+/-152.8 watts for women. The knee extension strength was 39.4 +/-9.2 kg for men and 24.0 +/-6.8 kg for women. The stair-climbing power correlated closely with both the leg extensor power (r=0.557, p<0.05 in men and r=0.541, p<0.05 in women) and with the knee extension strength (r=0.566, p<0.05 in men and r=0.657, p<0.05 in women).

**CONCLUSIONS:** From a practical viewpoint as a field test, the SCPT was found to be useful for assessing the functional leg power levels in physically-independent, ambulatory elderly people.

**Water-based Exercise: Balance Benefits To Land For Older Women In The USA And Japan**

Mary E. Sanders, FACSM. *University of Nevada, Reno, Reno, NV.*

Email: marysanders@prodigy.net

(No relationships reported)

Both land- and water-based exercise (WEX) programs have been shown to improve the fitness levels of older adults. However, the extent to which WEX improves balance on land is not well understood.

**PURPOSE:** The purpose of this study was to determine the impact of a WEX program on balance performed on land by older women.

**METHODS:** A USA pilot study was conducted and then replicated in Japan. Data were analyzed by the same investigators. The 16-week USA pilot study included women (60-89 yr of age) who self-selected to a training (TR) group (n=44) or control (n=17). The USA training consisted of a 16-wk (45 min.day-1, 3 d-wk-1) supervised WEX program that included 10 min warm-up (water walking), 30 min skill learning and practice of progressions designed to target land-based balance using navel to nipple depth water exercises (feet grounded), using resistance and buoyancy for challenge and support, and 5 min warm-down exercise. In Japan, women (50-80 yr of age) volunteered to participate in an ongoing replicated community-based program that was conducted in chest to shoulder depth water (feet somewhat off-loaded), self-selecting to attend 1, 2 or 3 d-wk-1. USA Participants performed static and dynamic balance tests at baseline and 16 weeks. Japanese participants were assessed at baseline and 36 weeks for dynamic balance (n=47).

**RESULTS:** In the USA, TR improved (p<.05) static balance on right and left legs (42%, 40% respectively) and (p<.001) dynamic balance (10.2%) while controls did not change significantly. In Japan, dynamic balance did not change significantly among participants. No injuries were reported by the USA or Japanese groups.

**CONCLUSIONS:** These results reveal that this WEX program, when conducted in navel to shoulder depth is a safe and effective training mode that results in improved balance skills, suggesting that the benefits of WEX do transfer to land-based activities under certain training conditions.

**Resistance Training And Activities Of Daily Living Training Improves Functional Performance In Elderly Women**

Mariane M. Fahlman, FACSM<sup>1</sup>, Heather L. Hall<sup>2</sup>. <sup>1</sup>Wayne State University, Detroit, MI. <sup>2</sup>Elmhurst College, Elmhurst, IL.

Email: m.fahlman@wayne.edu

(No relationships reported)

Functional ability has been inversely correlated with short-term morbidity and the need for assisted living among older adults. As the aging population increases in number, it is imperative to devise measures which enable them to maintain high levels of physical function.

**PURPOSE:** To evaluate the effect of two different training methods on functional performance in elderly women.

**METHODS:** Sixty women over the age of 70 were randomly assigned to either a resistance training group (RT; n = 20); an activities of daily living group (ADL; n = 20); or a non-intervention control group (C; n = 20). The C group was instructed to maintain normal levels of activity; the exercise groups completed 3 sessions of exercise per week for 24 weeks. The RT group completed 3 sets of 15, bilateral repetitions, of 13 different strength training exercises using Thera Band® resistance bands and hand weights while the ADL group completed a battery of ADL's and flexibility exercises. Physical outcome measures were taken from the Senior Fitness test: 30-second chair stand, 30 second arm curl, chair sit-and-reach, back-scratch, get-up-and-go and the 6-minute walk. Other self-reported measures included Self-perceived Function (SF36) and Instrumental Activities of Daily Living (IADL). Each test was analyzed separately using a 3 (Groups: C v. RT v. ADL) X 2 (Time: baseline v. post) Analysis of Variance (ANOVA) with repeated measures on the second factor. Simple effects and the modified Bonferroni post-hoc procedure were used to respectively assess significant interactions and main effects. The statistical package used to run all analysis was SPSS (Ver. 16.0), Chicago, IL.

**RESULTS:** There was a significant main effect of group or time and a significant interaction on every measure except back-scratch. Post-hoc analysis revealed that both training groups increased in measures from the Senior Fitness Test, SF36 and IADL, compared to the controls. The ADL group was significantly higher than the RT group at post in sit-and-reach and back-scratch, while the RT group was significantly higher than ADL in arm curl and 30-second chair stand.

**CONCLUSIONS:** This data suggests that both methods of training are effective for increasing select measures of functional performance in elderly women.

**Functional Fitness And Health-Related Quality Of Life Differences In Older Adults With And Without Extended Care In Japan**  
Tomomi Yamada<sup>1</sup>, Daisuke Koizumi<sup>1</sup>, Sung Chul Lee<sup>1</sup>, Nicole Rogers<sup>2</sup>, Michael Rogers, FACSM<sup>2</sup>, Nobuo Takeshima<sup>1</sup>. <sup>1</sup>Nagoya City University, Nagoya, Japan. <sup>2</sup>Wichita State University, Wichita, KS.  
Email: tomomi.yamada@nsc.nagoya-cu.ac.jp  
(No relationships reported)

Several assessments of functional fitness in older adults have shown consistent declines with advancing age. These declines in functional fitness often lead to physical dependence and poor health-related quality of life (HRQOL). However, few studies have focused on differences in functional fitness and HRQOL between those who live in the community and require extended care (dependent older adults) and those not requiring such care (independent-living older adults).

**PURPOSE:** The purpose of this study was to compare functional fitness and HRQOL in older Japanese community-dwelling adults who use extended care to those who do not.

**METHODS:** Participants included 16 older adults (age  $82.8 \pm 3.3$ ) with extended care (group1) and 20 older adults (age  $81.3 \pm 2.3$ ) without extended care (group2) who lived in the community. Seven performance tests, including 30-sec arm curl (AC), 30-sec chair stand (CS), sit and reach (SR), back scratch (BS), up & go (UPGO), functional reach (FR), and 12-min distance walk (12W), were conducted to assess four components (endurance, flexibility, muscle strength, balance) of functional fitness and the MOS 36-Item Short-Form Health Survey (SF-36) was used to assess HRQOL. T-tests were employed to analyze differences ( $p < 0.05$ ).

**RESULTS:** There were significant differences in functional fitness: AC ( $10 \pm 4$  vs.  $18 \pm 3$ ), CS ( $8 \pm 4$  vs.  $16 \pm 3$ ), UPGO ( $10.1 \pm 3.4$  vs.  $5.9 \pm 1.0$ ), SR ( $3.6 \pm 10.1$  vs.  $5.9 \pm 1.0$ ), BS ( $-20.1 \pm 12.8$  vs.  $-9.35 \pm 13.7$ ), FR ( $16.8 \pm 6.1$  vs.  $22.2 \pm 4.3$ ), 12W ( $342 \pm 240$  vs.  $849 \pm 06$ ), and physical health factors of HRQOL: physical functioning ( $22.8 \pm 21.2$  vs.  $40.3 \pm 16.4$ ), role-physical ( $23.1 \pm 18.1$  vs.  $46.2 \pm 8.9$ ), and general health ( $40.0 \pm 12.5$  vs.  $49.0 \pm 12.5$ ) between group1 vs. group2, respectively.

**CONCLUSIONS:** These results suggest that functional fitness (endurance, flexibility, muscle strength, and balance) and physical health factors of HRQOL are lower but mental health factors of HRQOL are not different in community-dwelling older adults who need extended care compared to those who do not. Further research is needed to develop and evaluate well-rounded exercise programs that improve functional fitness and physical health factors in this population.

(Supported by the Grants-in-for Scientific Research of MEXT Japan.)

**2498 Board #143 May 29 9:00 AM - 10:30 AM**  
**Response Of Perceived And Performance Based Function In Older Adults With Exercise Intervention**  
Anne E. O'Brien, Trudy Moore-Harrison, M. Elaine Cress, FACSM. University of Georgia, Athens, GA.  
Email: aobrien@uga.edu  
(No relationships reported)

Exercise interventions have been used to increase physical function in older adults. However, with some older adults, measures of perceived and performance-based physical function are not aligned. Individuals who express little or no perceived functional limitation may have low performance based function putting them at risk of future dependency (Cress & Meyer, 2003).

**PURPOSE:** This study evaluates the influence of exercise on both perceived and performance-based physical function with the hypothesis that after the exercise intervention, more individuals would have alignment between perceived and performance-based function.

**METHODS:** Using a cross-sectional and longitudinal designs, older adults, 74.5 years  $\pm$  6.21 ( $n=73$ ), from the community at large or retirement dwellings responded to the SF36 physical function (SF36PF) questionnaire and performed the Continuous Scale Physical Functional Performance (CS-PFP) test. SF36PF  $\leq$  65 (0-100) and CS-PFP  $<$  57 (0-100) are associated with increased dependence, "at risk" (Cress & Meyers, 2003). Participants were randomly assigned to either a control or an aerobic/strength combined or walking exercise group. The predictive value of the SF36 PF using a cutoff of  $\leq 65$  was determined based on the CS-PFP (gold standard) using a cutoff of  $< 57$ . For analysis, participant's baseline results were stratified into four groups (CS-PFP  $<$  57 and SF36 scores  $\leq 65$ , CS-PFP  $\geq 57$  and SF36  $\leq 65$ , CS-PFP  $<$  57 and SF36  $\geq 65$ , and CS-PFP  $\geq 57$  and SF36  $>$  65 scores).

**RESULTS:** The predictive value of the SF36PF, using a cutoff of  $\leq 65$ , was determined based on the CS-PFP (gold standard) using a cutoff of  $< 57$ . The SF36PF specificity was 100% and the sensitivity was 23.9%. At baseline testing, the prevalence of those "at risk" was approximately equal in the exercise (48.6%) and control (47.3%) groups. Following the intervention, the control group showed a slight decrease (7.89%) in the prevalence of "at risk" participants, however, the decrease in the (25.72%) exercise (25.7%) was dramatic. The bulk of the responders were those with high perceived and low performance based function.

**CONCLUSION:** The non-alignment of perceived and performance-based function can be an effective tool for targeting individuals at greatest risk of dependency, while exercise interventions can reduce the prevalence of that risk.

---

**2499 Board #144 May 29 9:00 AM - 10:30 AM**  
**A Simple Training Program For Reducing Fall Risk In The Elderly In Group And Independent Settings**  
Jessica Schroeder, Erin Schroeder, Michele LeBlanc, Steven Hawkins, FACSM. California Lutheran University, Thousand Oaks, CA.  
Email: shawkins@callutheran.edu  
(No relationships reported)

Previous research has demonstrated that a simple exercise training program delivered individually in-home increased balance, mobility and lower extremity strength in older adults. It is unlikely that this delivery method is either realistic or affordable on a large scale.

**PURPOSE:** To determine if a simple training program delivered in group or independent settings is effective in reducing fall risk in older adults.

**METHODS:** Twenty-nine sedentary subjects, 65 years or older (mean =  $82.4 \pm 4.8$  yrs), were recruited. Nineteen senior-residence dwellers participated in the group program (GP) while 10 in-home dwelling subjects were in the independent program (IP). Postural sway, mobility and isotonic lower extremity strength were measured in the laboratory. Both groups participated in the training program two times a week for a period of six weeks. The GP was led by two of the investigators, while the IP group trained independently using standardized instructions. IP subjects were contacted weekly by phone to encourage adherence. Training consisted of eight lower extremity exercises focusing on balance and strength development using elastic bands. Data were analyzed by dependent t-tests, with  $p < 0.05$  for significance.

**RESULTS:** The training program was completed by 80% and 40% of the GP and IP subjects, respectively. The GP subjects improved mobility time ( $12.7 \pm 8.6$  to  $11.2 \pm 7.8$  s,  $p < 0.05$ ) and increased lower extremity strength values ( $195 \pm 48$  to  $240 \pm 62$  lbs,  $p < 0.05$ ). The GP subjects decreased their mediolateral sway distance ( $90.4 \pm 23.7$  to  $80.2 \pm 18.5$  cm,  $p < 0.05$ ), but had no changes in the anteroposterior direction. Apparent changes in mobility, strength and postural sway in the IP group were not statistically significant, likely due to the small sample who completed the study.

**CONCLUSIONS:** A simple exercise training program proved to be effective in increasing mobility, lower extremity strength and balance in the group setting, and appeared effective in individual settings. Greater adherence was seen with the GP, possibly due to the more formal structure, group encouragement and leader expectations. We can conclude that this training program is effective in improving variables associated with fall risk in the elderly.

## Effect Of Machine And Stability Strength Training On The Walking Speed Of Postmenopausal Women

Anne M. Tester. *Seattle Pacific University, Seattle, WA.* (Sponsor: Dr Mark Blegen, FACSM, FACSM)

Email: testea@spu.edu

(No relationships reported)

The increased risk of bone mineral density loss and sarcopenia makes postmenopausal women a target for intervention to reduce the risk of fractures and falls. Though exercise brings benefits, it is yet to be determined which methods of strength training would be most beneficial in regards to decreased fall risk and increased walking function.

**HYPOTHESIS:** Performing resistance training using a rubber domed device (D.D.) may be more beneficial than using a leg press (L.P.) machine to increase walking speed in postmenopausal women.

**METHODS:** Women (N=18; mean age=61 yrs) were randomly assigned to one of three groups: D.D. squats, L.P. machine, or control group. The L.P. group performed 2 sets of 12 repetitions seated leg press exercises on a Life Fitness machine. The D.D. group performed 2 sets of 12 repetition rubber dome device squats (with weight). Exercises were performed 2 nonconsecutive days a week for 4 weeks. The control group maintained their current workout status (walking). All groups completed a six-minute walk test at self-selected speeds on a treadmill prior to and following the four week trial. At both baseline and completion, a questionnaire that assessed the likeability and perceived future adherence was completed by the participants to determine the practicality of the exercise.

**RESULTS:** There was no significant difference in the starting walking speed for all groups. The D.D. group increased walking speed 6.6%, the L.P. group increased 15.3%, and the control group increased walking speed 1.0%. The D.D. group ( $p=0.013$ ) and L.P. group ( $p=0.007$ ) showed significant difference between their starting and ending walking speeds. The control group ( $p=0.791$ ) did not show significant difference. The L.P. group showed the greatest increase in preferred walking speed of all three groups and is significantly different from the controls ( $p=0.037$ ).

**CONCLUSION:** Both activity groups improved self-selected walking speed with the L.P. group showing the greatest increase therefore the hypothesis is rejected. In further research sample size and study length will be increased, a measure of force distribution will be collected to account for changes in accessory muscle group strength, and measures of stability changes in order to better account for the possibility that a D.D. might decrease the risk of falling.

#### The Impact Of A University-based Exercise Program On Functional Abilities In Elderly Population

Keisuke Ida, Jacob E. Barkley, Edward J. Ryan, Chul-Ho Kim, Judith A. Juvancic-Heltzel, Ellen L. Glickman, FACSM. *Kent State University, Kent, OH.*

Email: kida@kent.edu

(No relationships reported)

Functional capacity typically begins to decline after approximately 30 yrs of age. This is believed to be a normal response to the aging process. However, it has been demonstrated that regular participation in exercise may attenuate this age-related decline in functional capacity in the older adult. **PURPOSE:** The purpose of the present investigation was to determine if participation in an exercise program designed for the older adult slows or prevents the expected functional decline in this age group.

**METHODS:** Eight male (76.6  $\pm$  3.1 yrs of age) and 7 female adults (72.3  $\pm$  9.8 yrs of age) volunteered to participate in an exercise program for a period of two years. The program consisted of three, 60-minute sessions per week. Functional fitness parameters that were evaluated at the start and end of the program included: upper body strength (arm curl test), lower body strength (chair stand test), upper body flexibility (back-scratch test), lower body flexibility (chair sit and reach test), agility/dynamic balance (8-foot and go) and aerobic endurance (6-minute walk test).

**RESULTS:** Gender (male, female) by time (pre, post) ANCOVAs, co-varying for total attendance, demonstrated no significant decreases in functional fitness parameters over time ( $P = 0.10$ ), nor were there any main or interaction effects of gender ( $P = 0.12$ ). While not statistically significant participants exhibited improvements in the majority of functional fitness tests when examining pre and post intervention data: Chair Stand Test (15.9  $\pm$  3.4 vs 17.3  $\pm$  5.8), Arm Curl Test (21.6  $\pm$  5.7 vs 22.4  $\pm$  7.1), Chair Sit and Reach Test (-0.6  $\pm$  4.6 vs -1.7  $\pm$  4.4), Back Scratch Test (-3.7  $\pm$  3.9 vs -3.0  $\pm$  3.5), 8-Foot Up and Go Test (4.9  $\pm$  1.1 vs 4.8  $\pm$  1.1) and 6-Minute Walk test (553.4  $\pm$  64.8 vs 559.0  $\pm$  97.5).

**CONCLUSIONS:** Participation in an exercise program for the older adult may attenuate the normal age-related declines in functional capacity and maintain or possibly improve the ability of older adults to perform activities of daily living.

#### Impact Of The First Step To Active Aging Exercise Program On Older Adults Functional Fitness, Balance, And Daily Activity

Nicole L. Rogers<sup>1</sup>, Eun Young Park<sup>1</sup>, Mindy L. Slimmer<sup>1</sup>, Nobuo Takeshima<sup>2</sup>, Phil Page<sup>3</sup>. <sup>1</sup>Wichita State University, Wichita, KS. <sup>2</sup>Nagoya City University, Nagoya, Japan. <sup>3</sup>Louisiana State University, Baton Rouge, LA. (Sponsor: Michael E. Rogers, FACSM)

Email: nicole.rogers@wichita.edu

(No relationships reported)

Advancing age is often accompanied by declines in strength, postural stability, flexibility, and cardiovascular fitness. Such declines negatively impact the functional ability and independence of older adults.

**PURPOSE:** To determine how the First Step to Active Aging (FSAH) program impacts functional fitness (FF), balance, and daily physical activity (DPA) in older adults.

**METHODS:** Eighteen women (X=73 $\pm$ 7 yrs) completed FSAH and all assessments. The FSAH group met at a senior center and completed a 12 wk, 50 min, 2d/wk training program (flexibility training; strength training, using elastic resistance bands; balance training using firm and pliable foam pads; and cardio-respiratory activity using pedometers and goal setting. A control group of 15 women (X=75 $\pm$ 6 yrs) was drawn from a waiting list for a similar program at a second area senior center. Subjects (Ss) were screened using the Exercise Screening for You to determine if they needed a healthcare provider visit before starting the program. Program effectiveness was assessed using the Senior Fitness Test to assess functional fitness (chair stand, arm curl, sit and reach, up & go, scratch test, and 12-min walk), balance (NeuroCom Balance Master Limits of Stability (LOS)): movement velocity (MVL), endpoint excursion (EPE), maximum EPE (MXE), and directional control (DCL) for forward (F), right (R), left (L) and back (B) movements), pedometer (Omron HJ-112) measured DPA, and weight.

**RESULTS:** No baseline difference existed between groups. Repeated measures ANOVAs revealed group x time interactions ( $p<0.05$ ) on all measures except the flexibility measures. After 12 weeks, significant FF improvements were noted in the FSAH group: Chair Stand 35%, Arm Curl 26%; Up-&-Go 8%; 12-min Walk 14%. With respect to LOS, MXE improved in all 4 directions (F 18%, R 14%, B 23%, L 10%) and DCL improved in the F direction 9%. DPA also increased the equivalent of 1 mile, from 3,108 to 5,077 steps (38%) and Ss lost 2.3lbs (2%). The control group did not demonstrate change in any variable. **DISCUSSION:** Participating in a FSAH program improves FF. Improving an older adult's FF, a concept reflecting the ability to perform normal everyday activities safely, independently, and without undue fatigue, may allow individuals to function at a higher level and live independently for a longer period of time.

#### Differences In Functional Fitness And Fear Of Falling Among Older Japanese Women

Aiko Hikosaka<sup>1</sup>, Daisuke Koizumi<sup>1</sup>, Tomomi Yamada<sup>1</sup>, Michael E. Rogers, FACSM<sup>2</sup>, Nicole L. Rogers<sup>2</sup>, Nobuo Takeshima<sup>1</sup>. <sup>1</sup>Nagoya city university,

Nagoya, Japan. <sup>2</sup>Wichita State University, Wichita, KS.  
Email: a.hikosaka@nsc.nagoya-cu.ac.jp  
(No relationships reported)

**PURPOSE:** Declines in functional ability and the prevalence of falling are problems in older adults. In the elderly, the fear of falling (FOF) may be as limiting as falling itself in terms of restricting daily physical activity. Therefore, measures of functional fitness may be related to FOF.

**METHODS:** A total of 537 women (68.9±5.7 y; range=60-94 y) were recruited from the community and divided into three groups: no fear of falling (NF, n=163), low fear of falling (LF, n=311), and high fear of falling (HF, n=63). FOF was assessed using a single question survey. Functional fitness was assessed by seven measures: 1) Chair Stand (CS); 2) Arm Curl (AC), 3) 8-foot up & go (UPGO); 4) Sit & Reach (SR); 5) Back Scratch (BS), 6) Functional reach, and 7) 12min-walk (12W). Balance was assessed using static postural sway (CTSIB) and limits of stability. Group comparisons were made using analysis of variance.

**RESULTS:** All parameters of functional fitness except BS (upper body flexibility) were significantly lower in HF compared to other groups. Differences in CTSIB with foam-open-eyes were observed between all three groups with HF having lower balance than NF and LF groups.

	NF	LF	HF	Post hoc
AC(times/30sec)	23.2±4.3	22.2±4.2	20.8±4.9	NFvsHF*
CS(times/30sec)	21.9±4.9	20.8±4.9	19.6±5.6	NFvsHF*
UG(sec)	4.6±0.5	4.7±0.8	5.0±0.9	NFvsHF*
SR(cm)	16.0±9.2	15.4±8.8	12.1±7.1	NFvsHF*
BS(cm)	-1.5±9.5	-2.0±10.1	-1.7±9.2	N.S.
FR(cm)	29.4±5.1	28.0±5.1	26.9±6.0	NFvsHF*, LFvsHF*
12W(m)	1061±123	1035±146	1019±119	NFvsHF^

\*p<0.05, ^p<0.10

**CONCLUSIONS:** Results suggest that fear of falling may have negative consequences with respect to older adults' functional fitness and balance. Further study is needed to determine if cause and effect relationships exist. It would also be interesting to examine if an exercise program for persons with FOF would increase functional fitness and balance while reducing FOF.

Supported by the Grants-in-for Scientific Research of MEXT Japan.

**2504 Board #149 May 29 9:00 AM - 10:30 AM**  
**Differences Between Two Exercise Programs On Measuring Fall Risk In Older Adults**

Timothy J. Leszczak, Ro Di Brezzo, Kirk W. Evanson, A. Page Glave. *University of Arkansas, Fayetteville, AR.* (Sponsor: Dr. Barry Brown, FACSMT)  
Email: tleszcz@uark.edu  
(No relationships reported)

The loss of balance and strength are two physiological components of aging that can be detrimental to the functional capacity in older adults. Research shows that increasing leg strength can be a major contributor to the reduction of fall related injuries in older adults. Moderate to high intensity exercise interventions have been successful in strengthening the muscles of the lower extremity, therefore possibly reducing the incidence of falls. Balance training, as well, has been shown to improve dynamic balance in this same age group. However, finding an appropriate exercise intervention that is both stimulating and beneficial for older adults to continue on a regular basis seems to be limited.

**PURPOSE:** To determine whether differences existed between a four week balance training intervention and a four week strength training intervention on measures of postural sway, agility, and dynamic balance in older adults.

**METHODS:** Twelve older adults aged 56-91 participated in the study with mean (± SD) age and body weight at 79 ± 10.84 yr. and 167.17 ± 39.97 pounds. Each participant was randomly assigned to one of three groups (strength, balance, and control). Participants were tested (Week 0) on weight, postural sway, agility, and dynamic balance. Each group participated in their specified training intervention for four weeks (Week 1 to 4) and were then tested again on Week 5.

**RESULTS:** An a-priori multivariate analysis of variance was used to determine if differences existed between the three groups. Three contrast statements were used in the analysis: strength trained and balance trained vs. control, strength trained vs. control, and balance trained vs. control. There were no significant differences between the strength and balance vs. control groups, Wilk's lambda = .54; F (6,17) = 2.01, p = .20; strength vs. control groups, Wilk's lambda = .49; F (6,17) = 2.35, p = .16; and for balance vs. control groups, Wilk's lambda = .71; F (6,17) = .96, p = .46. Based on this information, no further analysis was needed due to the non significant differences between the groups.

**CONCLUSION:** These results indicate that no significant differences existed between the three groups on measures of postural sway, agility, or dynamic balance. This is primarily due to the small sample size in the study and the lack of variability between the groups.

**2505 Board #150 May 29 9:00 AM - 10:30 AM**  
**Psoas Major Muscle In Elderly Female Rowers**

Meiko Asaka, Chiyoko Usui, Yohei Takai, Tetsuo Fukunaga, Mitsuru Higuchi, FACSMT. *Waseda University, Saitama, Japan.*  
(No relationships reported)

The psoas major muscle (PM), which is recruited for hip/lumbar stabilization and during hip joint flexion, plays an important role in maintenance of upright posture and walking. The age-related wasting of PM size is more remarkable than quadriceps femoris muscle. Rowing exercise, which includes hip joint flexion, may be categorized as one of the exercise mode for maintaining PM size and functions. We showed that elderly rowing trained men had larger PM than age-matched untrained men (MSSE, 40(5)suppl.:371, 2008). However, little is known whether rowing exercise can prevent the wasting and weakness of PM in elderly women.

**PURPOSE:** The purpose of this study was to evaluate the effects of regularly performed-rowing exercise on the morphology and function of PM in elderly women.

**METHODS:** Participants were 8 elderly female rowers (ER: age 64.1±4.6 yrs, BMI 20.7±0.8 kg/m<sup>2</sup>, mean±SD), 14 age-matched female walkers as active control group (EC: 62.8±3.8 yrs, 21.6±2.3 kg/m<sup>2</sup>) and 6 young untrained women (YC: 21.5±1.0 yrs, 20.2±0.9 kg/m<sup>2</sup>). Elderly rowers and walkers performed rowing or walking exercise regularly twice a week and each session 60-120 min. Muscle cross-sectional area (CSA) of PM scanned by magnetic resonance imaging and bilateral leg extension power were measured.

**RESULTS:** The CSA of PM in EC was 33% lower than that in YC (p<0.001). ER had 74% higher CSA of PM than EC (p<0.001), which was comparable to that of YC (YC: 9.4±1.3 cm<sup>2</sup>, EC: 6.2±1.0 cm<sup>2</sup>, ER: 8.7±1.7 cm<sup>2</sup>, mean±SD). The leg extension power in EC was 28% lower than that in YC (YC: 853±221 W vs EC: 616±148 W, p<0.05), whereas there was no significant difference between ER and YC (ER: 704±154 W). The CSAs of PM was strongly associated with leg extension power (r=0.914, p<0.001). Furthermore, partial correlation analysis revealed that PM is strong independent predictor of leg extension power (r=0.585, p<0.001).

**CONCLUSIONS:** These results provide the possibility that PM plays an important role in the muscle function of leg extension, and that rowing exercise can prevent age-

**Effect Of Inspiratory Muscle Training On Exercise Capacity And Quality Of Life In Older Adults**

Kathleen M. Knutzen, FACSM, Morgan A. Jackson, Lorraine R. Brilla, FACSM, Brandi S. Row. *Western Washington University, Bellingham, WA.*  
(No relationships reported)

Older adults (>65 yrs) undergo numerous age-related changes in pulmonary function, resulting in weakened respiratory muscles that promote dyspnea and decrease exercise capacity. Inspiratory muscle training (IMT) strengthens respiratory muscles by creating resistance during inspiration. IMT may enhance respiratory system functioning, diminishing respiratory muscle fatigue. IMT devices create a negative pressure which must be overcome for inspiration, resulting in improved inspiratory muscle strength and endurance.

**PURPOSE:** To examine the effects of IMT on respiratory muscle function, exercise capacity, and quality of life in community dwelling older adults.

**METHODS:** Twelve individuals ( $72 \pm 6$  yrs) participated in a 6-week IMT program. The training group ( $n=6$ ) trained at 85% MIP, known to elicit changes in respiratory muscle function. The placebo group ( $n=6$ ) trained at an ineffective intensity of 15% MIP. Training was 3 sets of 12 breaths, 3 days per week. Measurements of respiratory muscle function, exercise capacity, and quality of life (QOL) was assessed pre and post. A 2-way mixed ANOVA was used.

**RESULTS:** IMT did result in significant differences pre post in both groups (15%MIP group: pre  $0.57 \pm 0.39$  post  $0.90 \pm 0.26$  cmH<sub>2</sub>O; 85%MIP group:  $0.72 \pm 0.30$  post  $1.20 \pm 0.33$ ;  $p < 0.05$ ). MIP between placebo and training groups was not significantly affected (post:  $0.90 \pm 0.26$  vs.  $1.20 \pm 0.33$  cmH<sub>2</sub>O,  $p=0.408$ ). A significant improvement in walking distance (6MWD) was seen pre to post IMT. The interaction between training and placebo groups was not significant (post:  $539 \pm 88$  vs.  $370 \pm 59$  m,  $p=0.175$ ), while the main effect of test was seen ( $p = 0.001$ ). IMT did not significantly affect QOL, measured by the EQ-5D and EQ-VAS ( $p=0.679$ ,  $p=0.509$ ).

**CONCLUSIONS:** Six weeks of IMT did not significantly improve quality of life in community dwelling older adults although improvements in MIP and 6MWD were observed.

**Effects Of Different Intensities And Frequencies Of Resistance Training On Muscle Mass, Strength, And Sarcopenia Classification In Older Men And Women**

Michael Bembien, FACSM, Debra Bembien, FACSM. *University of Oklahoma, Norman, OK.*  
Email: mgbembien@ou.edu  
(No relationships reported)

The loss of muscle mass is a normal occurrence of aging. Decreased muscle mass, or sarcopenia, can be determined by calculating the relative skeletal muscle mass index (RSMI) using appendicular skeletal muscle mass divided by height squared. RSMI scores  $< 5.45$  kg/m<sup>2</sup> and  $7.26$  kg/m<sup>2</sup> are classified as sarcopenia for women and men, respectively. Traditional high intensity resistance training is effective for increasing muscle mass and strength in older adults, but it is unknown if varying the intensity or frequency of training would result in similar findings.

**PURPOSE:** The purpose of this study was to investigate the effects of four different resistance training programs on muscle mass, strength, and sarcopenia classification in older men and women.

**METHODS:** Forty-four men ( $65 \pm 0.5$  years) and 77 women ( $63 \pm 0.4$  years) were assigned to one of four training groups for 40 weeks (80% 1RM, 3 sets, 8 reps, either 2X or 3X/week or 40% 1RM, 3 sets, 16 reps, either 2X or 3X/week). Upper body exercises included lat pulls, military press, bicep curls, tricep extension, and low row and lower body exercises included knee extension, knee flexion, leg press, hip flexion, hip extension, hip abduction, and hip adduction. Appendicular skeletal muscle mass was estimated from total body DXA scans (Lunar DPX-IQ).

**RESULTS:** At baseline, 10 men (23%) and 16 women (21%) met the criteria for sarcopenia. Following the intervention, 5 of the men and 6 of the women were no longer considered to be sarcopenic. There were significant ( $p < 0.01$ ) time x gender effects for skeletal muscle mass and upper and lower body strength. Men significantly ( $p < 0.01$ ) increased RSMI while women did not, and training groups exhibited similar improvements in skeletal muscle mass. Average upper and lower body strengths significantly ( $p \leq 0.01$ ) increased for both genders, with men having significantly greater improvements. A significant ( $p < 0.01$ ) time x training group effect was found for lower body strength with the low intensity 2 days/week group showing smaller increases than both high intensity groups.

**CONCLUSION:** Differential effects of training intensity were evident only for average lower body strength and the training programs had minimal effects on sarcopenia re-classification. Although both men and women increased strength, only men demonstrated muscle hypertrophy.

**Differential Anti-aging Effects Of Tai Chi Chuan On Aging Process Of Balance**

Wei Hung Su<sup>1</sup>, Yi-Liang Chen<sup>1</sup>, Cheng-Hsiu Lai<sup>1</sup>, Chia-Hua Kuo<sup>1</sup>, Shih-Wei Chou<sup>2</sup>. <sup>1</sup>Taipei physical education college, taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, taipei, Taiwan. (Sponsor: Dr. John L. Ivy, FACSM)  
Email: a306865a@yahoo.com.tw  
(No relationships reported)

Tai-Chi Chuan (TCC) is a traditional Chinese martial art. Debates had been made about the anti-aging effects of TCC in many researches. However, no previous research studies about the interaction effect of age and TCC in aging process of balance. We conduct a two-factor designed study to evaluate the antiaging effect of TCC on balance.

**PURPOSE:** To determine anti-aging effects and the interaction effects of aging and TCC on balance.

**METHODS:** Four groups (old TCC group,  $n=26$ , age= $68.3 \pm 6.2$ , duration of practice=  $13.3 \pm 9.6$ ; young TCC group,  $n=13$ , age= $21.8 \pm 2.5$ , duration of practice=  $3.0 \pm 1.7$ ; old control group,  $n=14$ , age= $69.1 \pm 3.1$ ; young control group,  $n=19$ , age= $24.8 \pm 3.8$ ) of subjects were tested with The Smart Balance Master (Neuro Com Inc., Clackamas, Oregon, USA) to acquire postural stability measurement. The sensory organization test (SOT) will be conducted to assess the balance control of subjects. During the SOT, subjects will be exposed to 6 combinations of visual and support surface conditions as follows: (1) eyes open and fixed support (EO), (2) eyes closed and fixed support (EC), (3) sway-referenced vision and fixed support (SV), (4) eyes open and sway-referenced support (SS), (5) eyes closed and sway-referenced support (ECSS), and (6) sway-referenced vision and support (SVSS). **RESULT:** TCC effects are significant in all the counter-active conditions (SV,SS, ECSS, SVSS). Age effects are significant in all conditions. Interaction effects are significant in ECSS and SVSS. Main effects of TCC and age are both significant in visual, vestibular and preferential ratios. Interaction effects are not significant in all ratios.

**CONCLUSION:** TCC can improve postural stability and prevent balance deterioration during aging process.

**Influence Of Ankle Strength On Lower-extremity Physical Function In Older Adults**

Rudy J. Valentine<sup>1</sup>, Abby M. Blankenberger<sup>1</sup>, Kyle T. Ebersole<sup>2</sup>, Ellen M. Evans, FACSM<sup>1</sup>. <sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>University of Wisconsin-Milwaukee, Milwaukee, WI.  
Email: rvalenti@illinois.edu

(No relationships reported)

Prevention of age-related reductions in physical function is a primary public health concern. Leg muscle strength is related to improved lower-extremity physical function (LEPF); however, the influence of ankle strength in particular is not well known.

**PURPOSE:** To evaluate the association between physical activity, regional leg strength and LEPF in healthy elderly.

**METHODS:** LEPF was assessed in 42 older adults ( $70.1 \pm 6.6$  y, 28 females, 15 males) using a 7-m walk (WALK) and a 7-m walk with an obstacle (OBWALK) at normal walking speed, a timed up-and-go task performed as quickly as possible (UPGO), and a chair stand test with 5 repetitions completed as quickly as possible (CHAIR). Knee extension (K-Ext) and flexion (K-Flex) strength were assessed using an isokinetic dynamometer at 180 deg/sec, whereas ankle plantarflexion (A-PFlex) and dorsiflexion (A-DFlex) strength was assessed at 120 deg/sec. Physical activity was assessed for 7 days step counts via pedometer.

**RESULTS:** Absolute K-Flex and A-PFlex strength were related to performance on all walking tasks ( $r$  range = 0.35 to 0.60, all  $p < 0.05$ ) as were K-Ext and A-DFlex with UPGO ( $r = 0.33$ ,  $p < 0.05$ ). When normalized to body mass correlations improved ( $r$  range = 0.34 to 0.70) and all strength measures were related to all gait function tasks ( $p < 0.05$ ). CHAIR time was inversely related to relative A-PFlex strength ( $r = -0.31$ ). Using stepwise linear regression analysis, A-PFlex strength normalized to body mass was the only independent predictor of WALK and OBWALK, explaining 44% and 47% of the variance, respectively, and was the most significant predictor of UPGO, explaining 41% of the variance. Weekend step count was a significant correlate of UPGO, and total step count was the only independent predictor of CHAIR, explaining 6% and 14% of the variance, respectively.

**CONCLUSIONS:** Leg strength at the knee and ankle joints is related to gait and LEPF in healthy older adults. Ankle plantarflexion appears to have a substantial influence on function in this population. Physical activity, particularly on weekends, appears to impact physical function as well. These findings support the importance of physical activity and maintenance of ankle strength for the preservation of physical function in older adults.

**Using Measures Of Fatigue To Discriminate Between Levels Of Self-reported Functional Ability.**

Olga Theou<sup>1</sup>, Gareth R. Jones<sup>2</sup>, Jennifer M. Jakobi<sup>2</sup>, Anthony A. Vandervoort, FACSM<sup>1</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>University of British Columbia-Okanagan, Kelowna, BC, Canada.

Email: otheou@uwo.ca

(No relationships reported)

The role of lower limb strength in functional ability is well known. Whether fatigue can be used to dissociate between levels of functional ability remains to be established.

**PURPOSE:** Determine if measures of muscle fatigue and subjective fatigue can discriminate between different levels of functional ability in older women.

**METHODS:** Twenty-eight Caucasian older women were divided into two groups (high and moderate/low functioning) based on self-reported functional ability. Functional ability was assessed with the Composite Physical Function scale. Fourteen women were high functioning ( $72 \pm 5$  yrs) and 14 were of moderate to low functioning ( $75 \pm 3$  yrs). Isometric hand grip strength and fatigue, as well as isometric and isotonic leg extension strength and fatigue were compared between groups. Field-based tests of walking speed, 8ft up-and-go, 30-seconds arm curl, 30-seconds chair stands, and subjective fatigue (mobility-tiredness scale and two items from the WHO Quality of Life Questionnaire) were also compared. Hand grip and leg extension isometric fatigue was defined as the time when force decreased to 50% of maximum. Isotonic leg extension fatigue was a percentage decline in maximum isometric strength following 3 sets of 10 isotonic leg extensions with ankle weights at 70% of 1RM maximum.

**RESULTS:** Leg extension strength ( $p < 0.05$ ), walking speed ( $p < 0.01$ ), and performance for 8ft up-and-go and 30-second chair stands test ( $p < 0.001$ ), were greater in high functioning women compared to the moderate/low functioning women. Subjective fatigue was greater ( $p < 0.05$ ) in the moderate/low functioning women compared to the high functioning group. No significant differences were found between the two groups for hand grip strength ( $p = 0.23$ ), hand grip fatigue ( $p = 0.18$ ), leg extension fatigue ( $p = 0.31$ ), and performance for the 30-seconds arm curl test ( $p = 0.15$ ).

**CONCLUSIONS:** Lower limb tests of muscle strength and mobility were better able to discriminate between functional ability levels compared with upper limb tests. Objective measurements of muscle fatigue, in both upper and lower limbs, did not influence self-reported functional ability scores in these older women, however, measurements of subjective fatigue were related to functional ability.

**Increased Perceived Quality Of Life Burden With Age-associated Decline In Vascular And Physical Function**

Tracie R. Parish<sup>1</sup>, Daniel P. Credeur<sup>2</sup>, Katie Cherry<sup>2</sup>, Michael A. Welsch, FACSM<sup>2</sup>. <sup>1</sup>South Eastern Louisiana University, Hammond, LA. <sup>2</sup>Louisiana State University, Baton Rouge, LA.

Email: Tracie.Parish@selu.edu

(No relationships reported)

Impaired vascular function is typically associated with a marked reduction in functional ability and a decline in health-related quality of life (HRQOL) in patients with cardiovascular and metabolic disease. However, the literature is not clear on the quality of life burden associated with age-dependent changes in vascular and physical function, and the potential modifying effects of daily physical activity.

**PURPOSE:** (1) to examine the age-associated changes in vascular and physical function and its relation to HRQOL in older adults; and (2) to determine the possible modifying role of physical activity status, in nonagenarians.

**METHODS:** Participants from the Louisiana Healthy Aging Study ( $n = 168$ ; Age:  $87 \pm 7$ , Range: 61 to 99yrs) were used for these analyses. Physical activity status was assessed using a self-reported physical activity survey (YALE activity index), and the doubly-labeled water technique (physical activity level: PAL=TDEE/RMR). Brachial artery reactivity (BAR) was determined from high-resolution ultrasonography. Physical function (CS-PFP10) was determined from a previously validated instrument used to assess activities of daily living. HRQOL was assessed using the SF-36.

**RESULTS:** From the 7<sup>th</sup> through the 10<sup>th</sup> decade, the average decline in BAR and the total CS-PFP10 score was  $\sim 0.8\%/decade$  ( $BAR = -0.07 \times (Age) + 9.30$ ,  $r = -0.22$ ), and  $\sim 15U/decade$  ( $CS-PFP10 = -1.50 \times (Age) + 169.89$ ,  $r = -0.61$ ). BAR ( $r = 0.43$ ) was strongly associated with the CS-PFP10 scores, and both measures were significantly related to several of the SF-36 scores including the physical component score, vitality, and physical functioning. Prediction models (using BAR and CS-PFP10) accounted for  $\sim 30$  to  $60\%$  of the variance in the physical component score, vitality, and physical functioning of the SF-36. Importantly, in nonagenarian men, a MANOVA revealed those in the highest tertile of the Yale activity index and PAL had greater BAR, and higher scores on the CS-PFP10, and several of the SF-36 component scores ( $p < 0.05$ ).

**CONCLUSION:** These data confirm an age-dependent decline in vascular and physical function. This decline appears to contribute to a greater quality of life burden, particular in men. However, the magnitude of the quality of life burden may be diminished by a high daily physical activity status, in nonagenarians.

**Optimal Loading For Power In Older Men**

Sara Mow<sup>1</sup>, Bernard A. Roos<sup>1</sup>, Daniel H. Serravite<sup>2</sup>, Joseph F. Signorile<sup>1</sup>. <sup>1</sup>VA Medical Center, Miami, FL. <sup>2</sup>University of Miami, Coral Gables, FL. (Sponsor: Arlette Perry, FACSM)

Email: s.mow@umiami.edu

(No relationships reported)

Power is the most important physical attribute affecting independence and falls in older veterans. Due in part to our published data comparing the knee and ankle, we hypothesized that different loads would be required to maximize power development for different movements/muscle groups.

**PURPOSE:** The purpose of the study was to examine if different resistance training exercises would generate maximal power at different optimal loads due to differences in physiological and/or biomechanical properties.

**METHODS:** Sixteen men, aged  $80.5 \pm 4.4$  yrs, participated in a five-day protocol. There were two days each of maximal strength-testing and power-testing, using six pneumatic machines. Power tests were performed at 20-80% of the patients' maximal load for each machine. This allowed us to determine if particular exercises required different optimal loads to maximize power due to the biomechanical and physiological differences among the joints and muscle groups targeted.

**RESULTS:** Our results showed the optimal loads that elicited peak power varied in specific patterns that were determined by the number of joints involved, the nature of those joints, and the volume of the associated musculature. The lowest loading patterns were for the triceps pushdown (30-50% 1RM) and biceps curls (40% 1RM). Both exercises use joints designed for velocity, rather than strength, due to their longer lever systems and smaller musculature. The long lever system at the knee with its larger muscle groups, developed power at the next highest load of 50% 1RM. This was similar to the optimal loads for the chest press and row, both multi-joint movements, which produced their highest power at 50% 1RM. Finally, heel raise produced it highest power at 60% 1RM, as we expected, given the fact that the ankle joint is a short lever designed for force production rather than speed of movement.

**CONCLUSION:** These results indicate that the "one-size-fits-all" pattern of loading, currently used by most physical therapy and fitness facilities, does not provide optimal loading for power development. When power training is not maximized, its efficiency and effectiveness are reduced and the physical benefits to the patient are proportionally decreased.

#### **Dose-response Relationship For Controlled Aerobic Training On $\text{VO}_{2\text{max}}$ Improvement In Older Adults**

Guoyuan Huang<sup>1</sup>, Pei-zhen Zhang<sup>2</sup>, Cheryl A. Gibson<sup>3</sup>, Xiangrong Shi, FACSM<sup>4</sup>. <sup>1</sup>University of Southern Indiana, Evansville, IN. <sup>2</sup>Beijing Sports University, Beijing, China. <sup>3</sup>University of Kansas Medical Center, Kansas City, KS. <sup>4</sup>University of North Texas Health Science Center, Fort Worth, TX.  
Email: ghuang@usi.edu

(No relationships reported)

**PURPOSE:** Although much research has been conducted examining cardiorespiratory fitness ( $\text{VO}_{2\text{max}}$ ) increases with endurance training, little insight and insufficient information is individually provided regarding a quantifiable dose-response relationship for older adults. The purpose of this investigation was to identify a quantitative dose-response relationship for improvement of  $\text{VO}_{2\text{max}}$  in sedentary older adults, resulted from controlled aerobic exercise training.

**METHODS:** We used a systematic meta-analysis approach to synthesize the existing scientific studies regarding the effect of controlled endurance training on aerobic fitness development in older adults. Fifty-one studies were qualified for the final analysis. A total of 2522 older subjects (mean age  $67.45 \pm 5.25$  yrs) were included with 1511 in the exercise group and 1012 in the control. Effect sizes were calculated for training-induced improvements in  $\text{VO}_{2\text{max}}$ .

**RESULTS:** The pooled standardized effect size showed an average effect of  $0.64 \pm 0.05$  (mean  $\pm$  SEM, 95% CI = 0.56 to 0.73;  $p < 0.001$ ) for  $\text{VO}_{2\text{max}}$ . Effect sizes indicated different responses in improvements of  $\text{VO}_{2\text{max}}$  based on the aerobic training regimens. Training with mean intensities of 60%-65% of heart rate reserve (HRR) produced a similar effect as intensities of 75%-80% of HRR in affecting  $\text{VO}_{2\text{max}}$ . A mean exercise duration of approximately 45 minutes per session elicited maximal gains of  $\text{VO}_{2\text{max}}$ . Trained individuals experienced a greater  $\text{VO}_{2\text{max}}$  increase with a mean exercise frequency of 3 to 4 d.wk<sup>-1</sup>. Greater improvement in aerobic fitness was found to be associated with a mean training length of 30 to 40 weeks with the greatest gains in those who trained for approximately 36 weeks.

**CONCLUSIONS:** This study presented a quantifiable dose-response relationship and trends related to controlled endurance training and aerobic fitness changes in older adults. The results provide insight into the magnitude of  $\text{VO}_{2\text{max}}$  alterations as affected by exercise dose, a function of its intensity, duration, frequency, and training length. This information can be useful in the development and prescription of effective and safe exercise programs to benefit cardiovascular healthy aging for older adults.

---

**2514 Board #159 May 29 9:00 AM - 10:30 AM**

#### **$\text{VO}_2$ Kinetics Are Slowed In The Upper Compared To Lower Range Of Moderate Exercise In Older Men**

Matthew D. Spencer<sup>1</sup>, Harry B. Rossiter, FACSM<sup>2</sup>, John M. Kowalchuk<sup>1</sup>, Donald H. Paterson, FACSM<sup>1</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>University of Leeds, Leeds, United Kingdom.  
Email: mspenc25@uwo.ca

(No relationships reported)

The adaptation of pulmonary  $\text{O}_2$  uptake ( $\text{VO}_2$  kinetics) is slower and the gain (G,  $\text{DVO}_2/\text{DWR}$ ) greater when exercise is initiated in the upper compared to the lower range of the moderate-intensity exercise domain in younger adults. It remains unclear, however, whether this response persists in older adults who have consistently been shown to have slowed  $\text{VO}_2$  on-kinetics compared to younger adults.

**PURPOSE:** To determine the phase 2  $\text{VO}_2$  kinetics (time constant ( $t\text{VO}_2$ ) and G) in older adults during exercise performed in the upper compared to the lower ranges of the moderate-intensity domain.

**METHODS:** Six males (70 ( $\pm$ SD) (4) yr; 89 (12) kg; 174 (4) cm) each completed 6 repetitions of leg cycling exercise consisting of baseline cycling at 20 W, followed by 2 equal step-transitions (lower step, S1; upper step, S2) to a S2 work rate corresponding to 90% estimated lactate threshold. Expired gases were analyzed breath-by-breath using a volume turbine and mass spectrometer, and the phase 2  $\text{VO}_2$  response was modeled with a mono-exponential function using non-linear regression. The  $t\text{VO}_2$  and G for S1 and S2 were compared using paired sample t-tests.

**RESULTS:** The  $t\text{VO}_2$  was greater ( $p < 0.05$ ) in S2 (52 (15) s) than in S1 (37 (10) s). The  $\text{VO}_2$  gain was not different ( $p = 0.11$ ) between S1 (9.2 (1.2) ml·min<sup>-1</sup>·W<sup>-1</sup>) and S2 (9.9 (0.5) ml·min<sup>-1</sup>·W<sup>-1</sup>).

**CONCLUSION:** Despite already having 'slowed'  $\text{VO}_2$  kinetics in S1 as compared to values reported for younger adults (i.e., ~ 25 s),  $\text{VO}_2$  kinetics were slowed even further in the upper compared to the lower range of the moderate-intensity exercise domain in older men, thereby conferring an even greater  $\text{O}_2$  deficit in this region of the moderate-intensity domain.

#### **The Seated Medicine Ball Throw As A Test Of Upper Body Power In Older Adults**

Chad Harris, FACSM<sup>1</sup>, Andrew P. Wattles<sup>2</sup>, Mark DeBeliso<sup>3</sup>, Kent J. Adams, FACSM<sup>3</sup>, Joseph M. Bering<sup>4</sup>. <sup>1</sup>Western New Mexico University, Silver City, NM. <sup>2</sup>Boise State University, Boise, ID. <sup>3</sup>California State University, Monterey Bay, Monterey, CA. <sup>4</sup>New Mexico State University, Las Cruces, NM.

Email: harrisc@wnmu.edu

(No relationships reported)

While muscle strength is an important fitness component for older adults, muscle power production may be a better indicator of functional ability. Unfortunately, few studies have evaluated the validity and reliability of field tests for upper body power in the older adult population.

**PURPOSE:** This study's aim was to evaluate the validity and reliability of the seated medicine ball throw as a measure of upper body power in older adults.

**METHODS:** Older adults (n=42; Age 72.4±5.2 years) completed 12 trials of a medicine ball (MB) throw over 2 testing days using two weights of MBs (1.5 Kg and 3.0 Kg). For each day and each MB, 3 trials were performed. From a seated position, subjects threw the MB as far as possible using a motion similar to a chest pass in basketball. Additionally, subjects completed 6 trials of an explosive modified push-up on a force plate (Kistler, 9281C) over 2 testing days. Push-up force data were collected at 1250 Hz and maximal vertical force output (Zmax) was recorded. Validity was assessed via a Pearson Product-Moment correlation coefficient (PPM) between MB throws and Zmax. Reliability of the MB throw was determined using PPMs, Intra-class Correlation Coefficients (ICC) and Bland-Altman Plots (BAP).

**RESULTS:** The association between the medicine ball throws and the push-up test revealed a PPM of  $r=0.641$  and  $r=0.614$  for the 1.5 kg and 3.0 kg medicine balls respectively. PPM values for test-retest reliability of the 1.5kg and 3.0kg MB toss was  $r=0.967$  and  $r=0.958$ , respectively. ICC values for test-retest reliability of the 1.5kg and 3.0kg MB toss was,  $R=0.994$  and  $0.989$  for the 1.5 kg and 3.0 kg MB throws, respectively. BAPs revealed >95% of the differences were within  $\pm 2$  standard deviations of the mean difference for both weights of MB throws. The ICC for the push-up test was  $R=0.969$ . For the modified push-up, reliability of Zmax was  $r=0.944$  using PPM and  $R=0.969$  using ICC. BAP showed 90% of the differences were within  $\pm 2$  standard deviations of the mean difference.

**CONCLUSION:** As a field test for upper body power for the older adult, the seated medicine ball throw appears to be highly reliable test. Its validity relative to the maximal force exerted during modified push-up is modest. However, for assessing and tracking upper body power in the older adult the medicine ball throw test is an inexpensive, repeatable measure.

**2516 Board #161 May 29 9:00 AM - 10:30 AM**  
**Effects Of 12week Aerobic Exercise On Leptin, Tnf-a And Ghrelin On Postmenopausal Women**

Hyun-Lyung Jung<sup>1</sup>, Eun-Mi Kim<sup>1</sup>, Seung-Kyun Noh<sup>1</sup>, Ho-youll Kang<sup>1</sup>, Young-Su Kang<sup>2</sup>, Jong-Do Lee<sup>3</sup>, Sang-Wan Hong<sup>2</sup>. <sup>1</sup>Kyungpook National University, Daegu, Republic of Korea. <sup>2</sup>Daegu National University of Education, Daegu, Republic of Korea. <sup>3</sup>Arizona State University, Mesa AZ, AZ.  
Email: hykang62@hotmail.com  
(No relationships reported)

**PURPOSE:** This study determined the effects of 12-week walking/running exercise on plasma leptin, TNF- $\alpha$  and ghrelin on postmenopausal women.

**METHODS:** The 17 postmenopausal women were volunteered for this study (Age; 56.8±1.8 yr, Height; 154.3±2.0 cm, Body Weight; 64.9±3.0 kg). The training protocol was treadmill walking and running for 30-60 min/5-days/12-weeks. The running distance was progressively increased for whole training. Maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ) was determined by the method of expired gas analysis and body composition (%fat) was measured by method of skinfold thickness. Plasma insulin, and leptin, ghrelin were measured by radioimmunoassay methods. TNF- $\alpha$  was determined by using ELISA kit.

**RESULTS:** After 12-week walking/running exercise, the changes of all variables in the current study are follows;

	PRE	POST	p
$\text{VO}_{2\text{max}}$ (ml/kg/min)	22.7 ± 0.6	25.3 ± 0.7 *	.005
%fat (%)	31.3 ± 1.6	27.6 ± 1.1 *	.006
Insulin ( $\mu\text{IU/mL}$ )	4.3 ± 0.3	3.7 ± 0.2 *	.029
Glucose (mg/dl)	96.9 ± 3.5	95.6 ± 3.1	.312
Leptin (ng/ml)	12.0 ± 1.2	9.1 ± 0.9 *	.004
TNF- $\alpha$ (pg/ml)	45.4 ± 0.1	45.4 ± 0.1	.593
Ghrelin (pg/ml)	26.8 ± 2.2	29.4 ± 2.3 *	.009

Values are Mean ± SE.

\*: Significantly different from PRE,  $p < .05$

**CONCLUSIONS:** The results of this study indicate that 12-week aerobic training significantly reduced % body fat and attenuated insulin resistance with no significant change of TNF- $\alpha$ . In addition, plasma leptin levels were significantly reduced but ghrelin levels were reversely elevated.

**Effect Of 12 Weeks Of Step Aerobics Training On  $\text{VO}_{2\text{max}}$  Of Older Adult Women**

Tatiane Hallage<sup>1</sup>, Maressa Priscila Krause<sup>2</sup>, Cristiane Petra Miculis<sup>1</sup>, Sergio Gregorio da Silva<sup>1</sup>. <sup>1</sup>Universidade Federal do Parana, Curitiba, Brazil. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.  
Email: thallage@hotmail.com  
(No relationships reported)

Step aerobics (SA) is one of the most popular fitness activities and has been practiced for almost three decades. Several studies have recognized SA as an effective training to improve cardiovascular capacity, determined by maximal aerobic capacity ( $\text{VO}_{2\text{max}}$ ), in young adult population. However, only a few studies were conducted with older adults.

**PURPOSE:** To evaluate the effect of step aerobics training on maximal aerobic capacity of older adult women.

**METHODS:** Fifteen previously sedentary, apparently healthy older women [(mean, SD) age 62.5±1.82yrs; and body mass index 29.1±5.0 kg/m<sup>2</sup>], participated in 36 step aerobics sessions during a 3-month period. Each session was 45-60 min in length. The Bruce treadmill maximal exercise test was used to assess maximal aerobic capacity one week before and after the training period.

**RESULTS:** Mean rate of attendance to the SA sessions was 85%. The  $\text{VO}_{2\text{max}}$  (mL·kg<sup>-1</sup>·min<sup>-1</sup>) increased significantly after SA training [(mean, SD) pre-test 24.5±2.85 and post-test 28.1±4.41;  $p < 0.001$ ], which represent an average increase of 15%. Similarly, maximal heart rate ( $\text{HR}_{\text{max}}$ ) achieved during the maximal test increased after SA training, [(mean, SD) pre-test 145.0bpm±7.46 and post test 157.6bpm±6.42;  $p < 0.001$ ].

**CONCLUSIONS:** Twelve weeks of step aerobics training were effective to improve maximal aerobic capacity in previously sedentary, apparently healthy older women, assessed by the  $\text{VO}_{2\text{max}}$  and  $\text{HR}_{\text{max}}$ . These results are an indicative that older women, as well as young adults, can have fitness benefits when performing bench stepping exercises. Further studies should examine these effects on fitness components as well as adherence after longer periods of training.

(No relationships reported)

**PURPOSE:** To explore the effect of either (i) a 6-month resistance training (EX1), or (ii) a 6-month bench-step aerobic training program (EX2), on bone mineral density (BMD) and sex hormone in postmenopausal women (PMW).

**METHODS:** 66 PMW (mean age were  $55.03 \pm 3.86$  year-old) who were sedentary and with no history of hormone replacement therapy were randomly divided into two exercise groups and a sedentary control group (C). EX1 consisted of (13 muscle groups, 1-3 sets, 8-25 repetitions,  $49.82 \pm 2.52$ – $56.10 \pm 8.85\%$  maximal heart rate reserve, MHRr), and EX2 included ( $58.87 \pm 11.15$ – $80.43 \pm 13.46\%$  MHRr), with exercise training 3 times per week, 60 minutes per session for 6 months. BMD was determined using dual-energy x-ray absorptiometry (DEXA) at the lumbar spine and femur neck at baseline, 3-, 6-month, and 3-month follow-up. Estradiol (E2) and testosterone (T) were assessed using chemiluminescence by the ADVIA Centaur® system (BAYER) at baseline, 3-month, and 3-month follow-up. All data were analyzed using Pearson correlations and a two-way ANCOVA. The significance level was  $\alpha=0.05$ .

**RESULTS:** (1) Compared to baseline, there were no sig. difference in BMD of femur neck and lumbar at 3-, 6-month, and 3-month follow-up. (2) Compared to baseline, EX1 were sig. decreased in T at 3-month follow-up; but there were no sig. difference in E2. (3) Compared to baseline, EX2 were significantly increased in T at 3-month. (4) Compared to baseline, E2 were significantly increased in T at 3-month and 3-month follow-up; (5) Compared to 3-month, EX2 showed significant declines in T at 3-month follow-up; (6) EX1 were sig. different from EX2 in T at 3-month follow-up; (7) There were no differences between EX1, EX2, and C in E2 at 3-month and 3-month follow-up; (8) Sex-hormone was not related to BMD.

**CONCLUSION:** 6-month of EX1 and EX2 can maintain BMD in lumbar and femur neck in PMW; 3-month bench-step aerobics increase T in PMW.

**Indicators Of Physical Activity, Disability, And Quality Of Life: Differences Among Assisted And Independent Living Residents**

Katherine S. Morris Hall, Edward McAuley. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Eric E. Hall, FACSM)  
Email: ksmorri1@gmail.com  
(No relationships reported)

As the population of older adults grows so too does the need and number of residential care facilities such as assisted living (ALF) and independent living (ILF). The degree to which residents in these distinct facility types differ in important aspects of health such as physical activity and functional health is unclear.

**PURPOSE:** To determine whether residents in ALF and ILF significantly differ on assessments of physical and functional health and associated indicators.

**METHODS:** 106 older adults were recruited from ALF ( $n = 68$ ) and ILF ( $n = 38$ ) to complete self-report assessments of physical activity, self-efficacy, functional limitations and disability, and quality of life. Participants also wore an Actigraph accelerometer which provided activity counts and step counts. The Short Physical Performance Battery (SPPB) was used to assess functional performance through tests of balance, gait, and lower body strength. Facility comparisons were made using one-way ANOVA.

**RESULTS:** Self-report physical activity ( $38.5$  vs.  $56.4$ ,  $p < 0.05$ ), self-efficacy ( $48.5$  vs.  $61.8$ ,  $p < 0.05$ ), and quality of life ( $21.8$  vs.  $24.8$ ,  $p < 0.05$ ) were significantly lower in the ALF residents. ALF residents reported greater functional limitations ( $16.0$  vs.  $18.7$ ,  $p < 0.05$ ) and disability ( $26.5$  vs.  $30.6$ ,  $p < 0.05$ ) than ILF residents. However, no significant group differences were observed for activity counts or step counts. Standing balance, gait speed, and lower body strength also did not significantly differ between ALF and ILF residents.

**CONCLUSION:** Although residents in assisted living facilities are understood to have greater difficulty with activities of daily living than residents in independent living, these results suggest that there is in fact no difference in individual capabilities as evidenced by the SPPB and accelerometer. Instead, the individual differences appear to be manifest in individual perceptions of functional limitations and capabilities, ultimately influencing the quality of life of these individuals. This research was

Supported by an ACSM Foundation Research Grant from the American College of Sports Medicine Foundation.

**Shopping Habits And Physical Activity In Older Adults: The Older People And Active Living Project.**

Afroditi Stathi<sup>1</sup>, Mark G. Davis<sup>2</sup>, Georgina Bentley<sup>2</sup>, Janice L. Thompson, FACSM<sup>2</sup>, Jo Coulson<sup>2</sup>, Kenneth R. Fox<sup>2</sup>. <sup>1</sup>University of Bath, Bath, United Kingdom. <sup>2</sup>University of Bristol, Bristol, United Kingdom.  
Email: A.Stathi@bath.ac.uk  
(No relationships reported)

**PURPOSE:** To use a mixed-methods approach to explore the shopping habits of UK older adults (70+ years) and their association with levels of physical activity (PA) and body mass index (BMI).

**METHODS:** 240 participants (mean age  $\pm$  SD =  $78.1 \pm 5.7$  yrs, 47.9% female) in the Older People and Active Living (OPAL) project provided quantitative data on physical activity (PA by accelerometry), BMI, and shopping habits (using self-report questionnaires); semi-structured interviews were also conducted with 46 participants (mean age  $\pm$  SD =  $79.7 \pm 6.3$  yrs, 41.3% female) to provide qualitative data on patterns of shopping during a typical week, reasons for shops preferences and perceived importance of shopping to activity levels.

**RESULTS:** BMI data (mean  $\pm$  SD =  $27.2 \pm 4.9$  kg/m<sup>2</sup>) indicated that the majority of participants were overweight (38.8%) or obese (27.9%). More than 79.8% reported doing their own shopping alone or with someone; 68.6% drove or were driven to shops. Participants who drove/were driven to their main food shop had significantly higher BMI values ( $27.8 \pm 4.3$  vs.  $25.9 \pm 4.8$  kg/m<sup>2</sup>,  $p = .021$ ). Those who made most of their journeys by car were significantly less active than those who made most journeys by other forms of transport (walking, cycling, bus;  $3672.4 \pm 2245.0$  vs.  $4935 \pm 2823.7$  steps/day,  $p = .004$ ); and ( $14.5 \pm 13.9$  vs.  $22.8 \pm 22.19$  min/day moderate-to-vigorous PA,  $p = .004$ ). Shopping was reported as the main structured activity for these participants. Participants preferred shopping in supermarkets; they offered variety of choices and competitive prices compared to the limited provision and high prices of local amenities. Shopping malls were an accessible and attractive destination for these older adults, helping them to overcome barriers such as safety concerns and weather conditions and offering opportunities for socialising.

**CONCLUSION:** Shopping and running errands contributed significantly to older adults' PA levels. Opportunities for active trips to shops required the provision of better local amenities. Shopping malls have potential as important health promotion venues for older people but consideration of proximity and attractiveness of local shops and amenities is critical for increasing daily activity.

**Older Adults' Perceived Physical Activity Enablers And Barriers: A Multicultural Perspective**

Anna E. Mathews<sup>1</sup>, Sarah B. Laditka<sup>2</sup>, James N. Laditka<sup>2</sup>, Sara Wilcox<sup>1</sup>, Sara J. Corwin<sup>1</sup>, Rui Liu<sup>1</sup>, Daniela B. Friedman<sup>1</sup>, Rebecca Hunter<sup>3</sup>, Winston Tseng<sup>4</sup>, Rebecca Logsdon<sup>5</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of North Carolina at Charlotte, Charlotte, NC. <sup>3</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC. <sup>4</sup>University of California, Berkeley, CA. <sup>5</sup>University of Washington, Seattle, WA.  
Email: priceae@mailbox.sc.edu

(No relationships reported)

Almost all population groups in the United States need more physical activity (PA). PA programs are particularly needed for groups affected by health disparities; lack of PA contributes to disparities. Identifying perceived PA barriers and enablers among various racial/ethnic groups may help develop effective PA programs.

**PURPOSE:** To identify perceived PA enablers and barriers among a racially/ethnically diverse group of older adults.

**METHODS:** Data were from 42 focus groups (n=396) with United States residents ages 50 and older, including: African Americans, American Indians, Hispanics, Chinese, Vietnamese, and non-Hispanic Whites (hereafter Whites). Grounded theory identified themes. Thematic analysis organized content. Constant comparison methods examined themes by race/ethnicity.

**RESULTS:** Barriers perceived in common among the groups were health problems, fear of falling, and lack of exercise facilities. Enablers perceived in common were positive health outcome expectations, social support, and PA program access, including senior centers. American Indians mentioned the built environment (e.g., lack of suitable areas for walking) and lack of knowledge about PA as barriers; they also described health benefits as an enabler more often than other groups. Whites and American Indians emphasized the importance of PA programs specifically designed for older adults, stressing the need for activities that are easy on joints, such as water aerobics. African Americans mentioned financial cost as a barrier more often than others. There were no differences between barriers and enablers offered in common among the groups and those offered by Chinese and Vietnamese participants, although Vietnamese participants offered fewer barriers and enablers.

**CONCLUSION:** Results suggest several ways to promote PA among older adults, including developing exercise programs for them and health messages promoting existing PA places and programs. Racial/ethnic differences should be considered when designing such programs, and when developing messages and communication campaigns to promote them. Results also suggest that certain groups, such as American Indians, may be particularly affected by barriers in the built environment. Concerted action by communities and governments may be needed to overcome such barriers.

Email: bandaj@mailbox.sc.edu

(No relationships reported)

**PURPOSE:** To examine the validity of the Behavioral Risk Factor Surveillance System (BRFSS) physical activity (PA) questions, and the Aerobics Center Longitudinal Study (ACLS) PA short and long surveys in middle-aged and older adults.

**METHODS:** 71 adults > 45 years of age (68% female, 32% male; 74% White [W], 26% African American [AA]) participated in the study. Telephone interviews were used to administer the BRFSS PA questions, and to obtain self-reported height and weight. Each participant was then mailed and asked to wear an Actical accelerometer for 7 consecutive days, to complete a daily PA log, and to complete the ACLS short and long surveys. Two-tailed Spearman correlation coefficients were used to compare moderate, vigorous, and moderate and greater intensity PA (MVPA; min/day) to accelerometer determined PA. We also examined gender and race differences in the validity of the surveys.

**RESULTS:** The participant's were older ( $M$  age =  $57.4 \pm 9.9$  yrs) and overweight ( $M$  BMI =  $27.9 \pm 4.9$  kg/m<sup>2</sup>), but otherwise healthy adults. The Spearman correlations revealed moderate agreement between self-reported PA and accelerometer determined PA. There was moderate agreement between accelerometer determined moderate intensity PA and the ACLS long ( $r = .306, p < .05$ ) determined moderate intensity PA. There was moderate agreement between accelerometer determined vigorous intensity PA and BRFSS ( $r = .330, p < .05$ ), ACLS short ( $r = .455, p < .001$ ), and ACLS long ( $r = .451, p < .001$ ) determined vigorous intensity PA. There was also moderate agreement between accelerometer determined MVPA and BRFSS ( $r = .302, p < .05$ ), ACLS short ( $r = .315, p < .05$ ), and ACLS long ( $r = .472, p < .001$ ) determined MVPA. The mean MVPA for the BRFSS was 66.2 min, 75.6 min for the ACLS short, 39.7 min for the ACLS long, and 27.2 min for accelerometry. The strength of the associations were greater among women than in men, and among Ws than in AAs.

**CONCLUSION:** Few studies have assessed the validity of these PA surveys among diverse middle-aged and older adults. We found moderate correlations with accelerometer data, with results also varying by gender and race. Researchers need to be aware of the limitations associated with self-report PA surveys for this age group, especially among certain subpopulations, and obtain objectively-measured PA data whenever possible.

---

**2523 Board #168 May 29 9:00 AM - 10:30 AM**  
**Metabolic Equivalent Intensity Levels Of Household Activities In Elderly Women**

Timo Hinrichs, Sebastian Wendel, Paola Hensel, Claudio Bucchi, Ulrike Trampisch, Petra Platen, FACSM. *University of Bochum, Bochum, Germany.*  
Email: timo.hinrichs@rub.de

(No relationships reported)

Metabolic equivalent (MET) intensity levels are used to estimate energy cost of physical activities in individuals and to compare results across epidemiological studies using self-reports of physical activity. There are concerns that there may be differences in MET intensity levels of specific activities between individuals who differ in age, cardiorespiratory fitness levels or mechanical efficiency. Therefore MET intensity levels derived from studies in young healthy adults may not be used to estimate energy cost in surveys assessing self-reported physical activity in elderly people.

**PURPOSE:** To investigate the intensity levels of four different self-paced household activities in older women ( $\geq 70$  years) in comparison to younger women (20-40 years).

**METHODS:** Oxygen uptake was assessed by mobile spirometry in 18 older women (aged  $74.5 \pm 5.0$  (70-89) years; body mass index (BMI)  $25.8 \pm 3.6$  kg•m<sup>-2</sup>; percentage body fat measured by bioimpedance analysis  $32.3 \pm 3.4\%$ ) and in 19 younger women (aged  $27.5 \pm 5.4$  (20-39) years; BMI  $24.6 \pm 5.2$  kg•m<sup>-2</sup>; percentage body fat  $31.0 \pm 5.8\%$ ) during the following self-paced household tasks in the subjects' homes: cleaning the bathroom, preparing a meal, ironing, and vacuuming. The household tasks were conducted in randomized order. MET intensity levels were calculated by dividing oxygen uptake during activity (mL•kg<sup>-1</sup>•min<sup>-1</sup>) by a resting oxygen uptake constant of  $3.5$  mL•kg<sup>-1</sup>•min<sup>-1</sup>. Statistical analysis for differences between the age groups was done with Student's t-test. Level of significance was set at  $p < 0.05$ .

**RESULTS:** The two age groups did not differ significantly in BMI or percentage body fat ( $p > 0.05$ ). MET intensity levels were:  $2.8 \pm 0.8/2.6 \pm 0.5$  for cleaning the bathroom,  $1.9 \pm 0.5/2.0 \pm 0.4$  for preparing a meal,  $1.9 \pm 0.5/2.0 \pm 0.3$  for ironing,  $2.8 \pm 0.7/2.9 \pm 0.4$  for vacuuming (older/younger women respectively). MET intensity levels of the four household tasks did not differ significantly between the two age groups ( $p > 0.05$ ).

**CONCLUSIONS:** These data suggest that MET intensity levels of household tasks that have been derived from studies in younger women may also be used in epidemiological studies on self-reported physical activity in elderly women. Due to high standard deviations, estimation of energy cost in individuals by using predefined MET intensity levels is imprecise.

**Objectively Measured Patterns Of Physical Activity: The Older People And Active Living (opal) Project.**

Mark G. Davis, Jane E. Shill, Janice L. Thompson, FACSM, Jo C. Coulson, Melvyn Hillsdon, Debbie J. Sharp, Kenneth R. Fox. *University of Bristol, Bristol, United Kingdom.*

Email: Mark.Davis@bris.ac.uk

(No relationships reported)

**PURPOSE:** Firstly, to describe objectively measured physical activity patterns of a sample of older adults (70+ years), stratified by index of multiple deprivation and proximity to retail outlets; secondly, to determine the association of journeys away from their residence with physical activity.

**METHODS:** 240 participants (mean age  $\pm$  SD = 78.1 $\pm$ 5.7 yrs, 47.9% female) wore an Actigraph GT1M accelerometer for 7 days. Accelerometers were programmed to record activity counts and steps in 10s epochs. Participants kept a log of when the Actigraph was worn and recorded details of any journeys made from home including purpose and transport mode used. Actigraph data were reduced using MAH/UFFE v.1.9.0.3 software.

**RESULTS:** Males were significantly more active than females (minutes of at least moderate physical activity [MVPA]  $\cdot$  d<sup>-1</sup>: 22.3  $\pm$  20.6 [M] vs. 13.9  $\pm$  12.8 [F], p<.001; steps  $\cdot$  d<sup>-1</sup>: 4584.4  $\pm$  2736.7 [M] vs. 3882.1  $\pm$  2251.6 [F], p=.042) and made more daily journeys (journeys [Jy]  $\cdot$  d<sup>-1</sup>: 1.51  $\pm$  0.79 [M] vs. 1.25  $\pm$  0.56 [F], p=.005). Young participants (70-75y) were significantly more active than older participants (MVPA  $\cdot$  d<sup>-1</sup>: 25.0  $\pm$  20.0 [70-75y] vs. 13.3  $\pm$  14.9, p<.001 [80-85y], 8.2  $\pm$  8.2, p<.001 [85-90y], 1.6  $\pm$  0.4 p<.001 [90+y]; steps  $\cdot$  d<sup>-1</sup>: 5178.7  $\pm$  2681.5 [70-75y] vs. 3749.4  $\pm$  2273.0, p=.006 [80-85y], 2498.4  $\pm$  1730.5, p<.001 [85-90y], 942.5  $\pm$  609.2, p<.001 [90+y]) and made significantly more journeys (Jy  $\cdot$  d<sup>-1</sup>: 1.64  $\pm$  0.76 [70-75y] vs. 1.19  $\pm$  0.50, p=.001 [80-85y], 1.10  $\pm$  0.58, p=.013 [85-90y], 0.44  $\pm$  0.31, p<.001 [90+y]). Those who did most Jy  $\cdot$  d<sup>-1</sup> (>1.67 Jy  $\cdot$  d<sup>-1</sup>) were significantly more active (28.6  $\pm$  21.9 MVPA  $\cdot$  d<sup>-1</sup>, 5689.6  $\pm$  2529.5 steps  $\cdot$  d<sup>-1</sup>) than those who did fewer Jy  $\cdot$  d<sup>-1</sup> (MVPA  $\cdot$  d<sup>-1</sup>: 16.7  $\pm$  13.2, p<.001 [1.00-1.67 Jy  $\cdot$  d<sup>-1</sup>], 8.4  $\pm$  11.0, p<.001 [ $<$ 1.00 Jy  $\cdot$  d<sup>-1</sup>]; steps  $\cdot$  d<sup>-1</sup>: 4334.6  $\pm$  1995.6, p=.001 [1.00-1.67 Jy  $\cdot$  d<sup>-1</sup>], 2538.5  $\pm$  1676.9, p<.001 [ $<$ 1.00 Jy  $\cdot$  d<sup>-1</sup>]). Participants were significantly more active on weekdays (W) than weekend days (WE) (steps  $\cdot$  d<sup>-1</sup>: 4444.7  $\pm$  2650.9 [W] vs. 3741.3  $\pm$  2638.8 [WE], p<.001). Diurnal peaks in activity occurred late morning and mid afternoon.

**CONCLUSIONS:** Getting out of the house makes a significant contribution to PA in older adults. Encouraging older adults to get out more may help reduce age related declines in physical activity.

---

**2525 Board #170 May 29 9:00 AM - 10:30 AM**  
**Mobility Performance Tests For Discriminating Frailty In Community-dwelling Older Women**

Mi-Ji Kim, Noriko Yabushita, Miyuki Nemoto, Satoshi Seino, Maeng-Kyu Kim, Junko Okuno, Kiyoji Tanaka, FACSM. *University of Tsukuba, Tsukuba, Ibaraki, Japan.*  
Email: mijiak@stat.taiiku.tsukuba.ac.jp  
(No relationships reported)

Along with the increase in frail older persons, concern about screening for frailty has been increasing as well. Mobility performance measures could be objectively used to identify frailty in older people who are at an increased risk for loss of functional independence. However, little is known about the identification of frailty using mobility performance tests.

**PURPOSE:** To identify frailty using optimal cutoff values with four mobility performance tests in community-dwelling older women.

**METHODS:** A cross-sectional sample of 377 community-dwelling older women, aged 65 years and over, participated in this study. Participants were classified into a frail group (n = 166, 75.0  $\pm$  5.8 years) and a non-frail group (n = 171, 74.1  $\pm$  4.7 years) based on original criteria using questionnaires from the Japanese Ministry of Health Labour and Welfare. The four mobility performance tests were alternate step, timed up-and-go (TUG), timed rapid gait (TRG), and usual gait speed. Receiver operating characteristic curves were obtained for all the scales to assess the optimal cutoff values, and logistic regression analysis was performed.

**RESULTS:** All mobility performance tests showed the largest areas under the curve (AUC) discriminated between non-frail and frail (AUC > 0.80, p < 0.000). The optimal cutoff value of alternate step (4.8 s), TUG (7.1 s), TRG (6.0 s), and usual gait speed (1.24 m/s) were indicated by maximum sensitivity and specificity in the discrimination between non-frail and frail. In the logistic model, adjusted for body mass index and number of diseases, alternate step (odds ratio [OR], 1.72; 95% confidence interval [CI], 1.17-2.53) and usual gait speed (OR, 0.10; 95% CI, 0.22-0.51) were significantly associated with the frail.

**CONCLUSION:** The optimal cutoff values derived from these results can be used as criterion reference points for identifying deterioration or loss of mobility in community-dwelling older women.

**2526 Board #171 May 29 9:00 AM - 10:30 AM**  
**Lessons Learned Recruiting Senior Masters Athletes As Research Participants**

Dutch M. Plante, Christina A. Porucznik, Stuart E. Willick, Jerilin Nunu, Susanne M. Cusick, Brock Niceler, Elizabeth A. Joy, FACSM. *University of Utah, Salt Lake City, UT.*  
(No relationships reported)

**BACKGROUND:** Physical activity throughout the lifespan is essential for promoting and maintaining health. Older athletes have different risk factors for injury and a longer recovery time than younger athletes. Seniors are at higher risk for acute injury during athletic pursuits and such injuries are a frequent cause for emergency room visits. We administered injury surveys to athletes at the Huntsman World Senior Games in 2006, 2007, and 2008 using a variety of recruitment techniques. Each year there are approximately 8,000 athletes participating in the Games, which occurs in early October for a 2-week, and 3-weekend period. The Games are open to athletes older than 50 and include 24 individual and/or team activities ranging from archery to volleyball.

**PURPOSE:** To describe and evaluate effectiveness of methods used to recruit senior athletes into an injury survey study.

**METHODS:** Paper-based surveys were administered to Games athletes in 2006, 2007, and 2008. In 2008, an option for completing an electronic version of the survey online was added. Utah Sports Research Network faculty and staff traveled to the Games each year to distribute surveys and encourage athlete participation. In 2008, surveys were included in the registration packets, and staff distributed postage-paid return envelopes for surveys in addition to collection at the Games.

**RESULTS:** In 2006 and 2007, we collected 124 and 169 completed surveys, respectively, primarily from athletes that completed and returned the surveys during the Games. Each year a few committed participants returned surveys by mail at their own expense. Responses from 2008 are still arriving by mail and online but have already surpassed the previous two years combined. We have received more than 250 paper surveys, approximately half returned by mail, and over 60 online surveys.

**CONCLUSIONS:** Providing multiple means of response achieved a better response rate. Including the survey in the registration packet increased the number distributed and the profile of the study among athletes and possibly encouraged participation. Next year we plan to include the postage-paid return envelopes in the registration packet as well as the survey and encourage more online survey completion.

**ACKNOWLEDGMENTS:** Athletes and staff of the Huntsman World Senior Games; Utah Sports Research Network.

**Walking Behavior And Maximum Walking Speed In An Elderly Community Population: A Cross-sectional Analysis**

Masamitsu Kamada<sup>1</sup>, Jun Kitayuguchi<sup>1</sup>, Shinpei Okada<sup>2</sup>, Kuninori Shiwaku<sup>3</sup>, Shigeru Inoue<sup>4</sup>, Yoshiteru Mutoh<sup>5</sup>. <sup>1</sup>Physical Education and Medicine Research Center UNNAN, Unnan, Shimane, Japan. <sup>2</sup>Physical Education and Medicine Research Center, Tomi, Nagano, Japan. <sup>3</sup>Shimane University, Izumo, Shimane, Japan. <sup>4</sup>Tokyo Medical University, Tokyo, Japan. <sup>5</sup>The University of Tokyo, Tokyo, Japan.  
(No relationships reported)

Previous studies have shown that physical activity plays a role in maintaining functional ability later in life. Walking is the most common physical activity behavior of the elderly. The determinants of walking behavior have been reported to vary with the purposes (e.g., recreation or transport) of walking. However, specific relationships between walking for particular purposes and functional ability have not been clear.

**PURPOSE:** To clarify specific relationships between walking for particular purposes and maximum walking speed (MWS) in the elderly.

**METHODS:** A cross-sectional survey was conducted in 2007 using a sample of community-dwelling elderly people aged 60 and over in Mitoya, Unnan City, Shimane Prefecture, rural Japan. 372 men ( $n=132$ ) and women ( $n=240$ ) responded to questionnaires and face-to-face interviews. MWS was measured by a 10m walking test. Associations with MWS were examined separately for self-reported weekly time of walking for recreation, walking for transport, and total walking time using multiple linear regression analyses. All regression models were adjusted for age, body mass index, a number of chronic conditions, musculoskeletal pain in the hip and lower limb, and depression.

**RESULTS:** The mean MWS were  $2.2\pm0.4$  m/s in men and  $2.0\pm0.4$  m/s in women. The mean walking time for recreation and for transport were  $66\pm101$  min./w. and  $26\pm51$  min./w. in men and  $47\pm87$  min./w. and  $35\pm70$  min./w. in women. Both in men and women, walking for recreation was significantly associated with MWS after controlling for potential confounding factors (men:  $b=0.188$ ;  $p<0.05$ , women:  $b=0.185$ ;  $p<0.01$ ). However, walking for transport was not significantly associated with MWS. Total walking time was significantly associated with MWS only in women ( $b=0.126$ ;  $p<0.05$ ).

**CONCLUSIONS:** Elderly people with longer walking times for recreation had faster MWS. Walking for recreation may contribute to maintaining functional ability in the elderly.

**The Relation Between Health And Physical Activity In Adults 65 And Older**

Alex B. Shafer, BS, Constance Mols Bayles, Ph.D, FACSM, Joseph Robare, MS, RD, Erin Gammill, Ph.D, Robert Robertson, Ph.D, FACSM.  
*University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

**PURPOSE:** To examine physical activity as it relates to health in a sub group of "The Environmental Correlates of Physical Activity in Older Adults: A Healthy Aging Research Network Collaboration Study". This is a Centers for Disease Control, Prevention Research Center national investigation.

**METHODS:** A sub-sample of 201 individuals aged 65 years and older, were recruited from Allegheny County, Pennsylvania senior centers. During an interview, data were gathered using a questionnaire, physical performance assessments, and cognitive functioning tests.

**RESULTS:** Mean age, 75.24 (SD  $\pm 6.25$  years); 78.6% female; 75.6% White. 51.24% reporting 150 minutes or more of Physical Activity (PA) per week. Differences were observed in groups reporting >150 mins PA vs less than 150 mins: self reported health status, 84.5% reported good-excellent vs 68.4%; mean BMI,  $29.382$  kg/m<sup>2</sup> vs  $29.521$  kg/m<sup>2</sup>; performance in jug lift 74.8% lifting jug over eye level vs 30.3%; and chair stand test, 11.84 seconds for 5 repetitions vs 13.13 seconds.

**CONCLUSIONS:** Older individuals who engage in regular physical activity generally feel healthier and are more physically fit than those who are not physically active.

**Objective Measurement Of Sedentary And Active Behavior In Older Adults**

Elizabeth Grimm, Scott J. Strath, Ann M. Swartz, Nora E. Miller, Keith P. Gennuso, Aubri E. Rote, Chris J. Dondzila, Karlee M. Sweere. *University of Wisconsin-Milwaukee, Milwaukee, WI.*  
Email: ekgrimm@uwm.edu  
(No relationships reported)

**PURPOSE:** To describe the physical activity (PA) behavior of community dwelling older adults, aged 50 to 87 years.

**METHODS:** Two hundred and eighteen older adults (62 men,  $66.0 \pm 8.5$  y; 156 women,  $63.8 \pm 7.4$ ) participated in this study. Each participant wore a belt-mounted accelerometer (ACC; Actigraph 7164, Fort Walton Beach, FL) for 7 consecutive days. ACC derived PA was categorized into accumulated time spent in sedentary ( $\leq 260$  cts/min), moderate (1952-5725 cts/min), vigorous ( $\geq 5725$  cts/min), moderate + vigorous activity (MVPA;  $>1952$  cts/min), and time spent in  $\geq 10$  min bouts of MVPA. Means  $\pm$  SD are presented for all PA classifications. Overall age and gender comparisons were made using independent t-tests. A multivariate ANOVA was performed to explore gender and age category differences (50-59 y, 60-69 y, and 70+ y).

**RESULTS:** On average participants wore the ACC  $6.92\pm0.32$  days for  $967.29\pm85.8$  min/d. Overall, older adults spent 75.2% of their day in sedentary behavior and 2.9% in MVPA. There were no gender differences in time spent in sedentary or MVPA, but significant differences were noted across age groups. Sedentary behaviors increased significantly with age from 50-59 y to 70+ y ( $719.2\pm86.5$  to  $762.6\pm75.7$  min/d;  $p=0.044$ ) and 60-69 y to 70+ y ( $713.1\pm110.1$  to  $762.6\pm75.7$  min/d;  $p=0.011$ ). MVPA decreased significantly with increasing age, 50-59 y to 60-69 y ( $37.5\pm25.3$  to  $28.0\pm21.9$  min/d;  $p=0.026$ ), 50-59 y to 70+ y ( $37.5\pm25.3$  to  $18.4\pm16.1$  min/d;  $p=0.000$ ), and 60-69 y to 70+ y ( $28.0\pm21.9$  to  $18.4\pm16.1$  min/d;  $p=0.035$ ). Bouts of MVPA also decreased with increasing age, 50-59 y to 70+ y ( $15.6\pm19.0$  to  $7.0\pm10.7$  min/d;  $p=0.010$ ).

**CONCLUSIONS:** These findings present an objective measure of an older adult's daily pattern of sedentary and active behavior. Results indicate that older adults are spending a large portion of their day participating in primarily sedentary behavior, with little time spent in accumulated MVPA. MVPA is further reduced when expressed in bouts lasting  $\geq 10$  min in duration. Collectively, results worsen with advancement in age. Given that time spent in activities requiring low levels of energy expenditure have been associated with increased risk for chronic disease, efforts to reduce the amount of time older adults spend in sedentary activities are warranted.

**2530 Board #175 May 29 9:00 AM - 10:30 AM**  
**Effectiveness Of Water-based Exercise For Managing Pain Among Frail Elderly Women With Knee Pain**

Koichiro Oka, Ai Shibata, Yoshio Nakamura, Isao Muraoka. *Waseda University, Tokorozawa, Saitama, Japan.* (Sponsor: Mitsuru Higuchi, FACSM)  
Email: koka@waseda.jp  
(No relationships reported)

Osteoarthritis is one of the most prevalent musculoskeletal disorders in the elderly. Pain and impairment on knee frequently leads to moderate to severe limitations of participation in daily life and decreased quality of life. Water-based exercise (WE) provides several water-specific benefits to reduce pain and improve functional decline.

**PURPOSE:** To evaluate the effectiveness of WE and its sustainability for managing pain among frail elderly women with knee pain at the community-based setting.

**METHODS:** Fifty one elderly women with knee and/or back pain (age=72.1 $\pm$ 4.6 years) were randomly assigned to either a WE group (WEG) or a waiting-list control group (CG). Only participants with knee pain were included for the data analysis (WEG:  $n=19$ ; CG:  $n=16$ ). WEG first participated in a 12-week WE program. CG was provided the same program immediately after the intervention as a cross-over design. The Japanese Knee Osteoarthritis Measure (JKOM) and Japanese short-version of Coping Strategy Questionnaire (CSQ) were assessed at baseline and post-intervention. Both groups completed the same assessments at 3 months after their own WE programs. Mixed factorial and repeated measures ANOVA were utilized for analyses. Effect sizes were calculated.

**RESULTS:** No significant differences at baseline were found between WEG and CG in all variables. WEG significantly improved activity restriction (AR; pre= $29.4\pm20.7$ ; post= $17.9\pm9.4$ ) and reduced pain (PA; pre= $12.2\pm7.4$ ; post= $6.6\pm3.9$ ) on JKOM, and reduced reinterpreting pain sensation (RPS; pre= $2.3\pm1.4$ ; post= $1.7\pm1.8$ ) and enhanced self-efficacy for self-management (SE; pre= $3.0\pm1.2$ ; post= $3.9\pm1.1$ ) on CSQ at post-intervention ( $p<0.05$ ) whereas did not change in CG ( $p>0.05$ ). Improvement of AR, PA, and RPS significantly maintained for 3 months after WE programs ( $p<0.05$ ). Effect sizes of each item for the effectiveness of WE and its sustainability were moderate to large on JKOM and small to moderate on CSQ.

**CONCLUSIONS:** WE would be effectively and safely provided with the frail elderly as a community-based preventive program for knee pain, and could maintain its effectiveness for short-term period. To enhance the effectiveness of exercise program for managing knee pain, it would be important to incorporate the psychological approaches into existing therapeutic exercise intervention.

**Predictors Of Self-reported And Directly Measured Physical Activity Among Healthy Older Adults Living In Rural Communities.**

E. Laurette Taylor, Mary K. Dinger, FACSM. *University of Oklahoma, Norman, OK.*

Email: eltaylor@ou.edu

(No relationships reported)

**PURPOSE:** The importance of a physically active lifestyle in chronic disease prevention is well established. Still, inactivity is common among older adults. Identification of factors associated with physical activity would be useful in developing programs to increase physical activity. The purpose of this study was to assess the strength of several variables in predicting self-reported and directly measured physical activity (PA) levels in healthy, independent rural dwelling older adults.

**METHODS:** Subjects were recruited from two rural nutrition program meal sites (42 women and 14 men). Potential predictor variables included BMI, a crude measure of chronic disease status, age, and the 5 subscales of the MOS - Short Form [SF-36] that are related to physical health & function. These include: Physical Functioning (PF), Role-Physical (RP), Bodily Pain (BP), Vitality (VT), and General Health (GH). MOS scores were transformed to a 0-100 scale with high scores indicating minimal to no perceived limitation. The self-reported PA variable was total PASE score (TOT PASE). The accelerometer (CSA) measures were total counts/day (TC/day) and mean counts/ minute (CTS/min).

**RESULTS:** PF was the only significant correlate of TC/day and CTS/min and was a poor predictor of both TC/day ( $r^2=.062$ ,  $p=.038$ ) and CTS/min ( $r^2=.067$ ,  $p=.032$ ). There were no significant predictors for TOT PASE.

**CONCLUSIONS:** PA level was poorly predicted by variables measured in this study. Even though the PF measure was a statistically significant predictor for both direct measures, the total variance accounted for was < 20% in both cases, indicating no practical value as a predictor.

**"Strictly-ballroom": Can Dance Raise The Amount And Intensity Of Physical Activity In Senior Adults?**

Stephen P. Cobley, Nicholas Wattie, Duncan Radley, Andy J.W. Smith, Jim McKenna. *Leeds Metropolitan University, Leeds, United Kingdom.*

Email: s.cobley@leedsmet.ac.uk

(No relationships reported)

**PURPOSE:** In the present pilot study, we examined the impact of a 12-week community based ballroom dancing intervention on objectively measured total minutes of physical activity and assessments of intensity within lessons.

**METHODS:** Sedentary senior adults ( $N=27$ , 22 female; aged  $53 \pm 6$  y) with a self-assessed status of being physically inactive, volunteered to participate in a 12-week (1 x 2 hrs per week) instructor-led dance class, which introduced novices to ballroom dancing (e.g., tango). Participants generally lived near ( $3.8 \pm 3.2$  miles) to the community venue situated in North of the UK. Physical activity was assessed using an Actigraph GT1M accelerometer, set at 2-second epochs, with measures taken in weeks 1 or 2 compared to weeks 11 or 12. To identify intervention impact we calculated total lesson step counts and minutes spent in sedentary, light and moderate physical activity based on published cut points.

**RESULTS:** Repeated measures MANOVA, identified that the amount and intensity of activity increased across the 12 week intervention (time  $F(3, 23) = 24.59$ ,  $p<.001$ ,  $L = .238$ ,  $h^2 = .76$ ). No main or interaction effect was identified for any participant characteristics (e.g., gender). Specifically, from initial to latter weeks, the number of total steps per lesson increased by over 500 ( $1321 \pm 296 - 1884 \pm 411$ ;  $F(1, 25) = 52.96$ ,  $p<.001$ ,  $h^2 = .67$ ). Activity intensity also changed, with the time spent in low ( $F(1, 25) = 20.83$ ,  $p<.001$ ,  $h^2 = .45$ ) and moderate intensity increasing ( $F(1, 25) = 4.37$ ,  $p<.005$ ,  $h^2 = .14$ ). Lesson time spent in these intensities increased from 31.4-36.2% (37.5 - 43.25 mins) and 3.1-7% (3.75 - 8.5 mins) respectively, with concomitant reductions in sedentary lesson time.

**CONCLUSIONS:** Among senior adults, beginner dance lessons replaced previously sedentary time, helping them achieve close to 20% (i.e., 2000 steps) of recommended daily steps within a 2-hour period by the end of the intervention. Likewise, activity intensity increased over time, but intensity did not meet recommended moderate daily levels (i.e., 30 mins per day). Nonetheless, considering participant characteristics (e.g., age), replicated at a population level such incremental changes are still beneficial.

**Dose Response Walking Activity And Physical Function In Older Adults**

Scott J. Strath<sup>1</sup>, Ann M. Swartz<sup>1</sup>, Sergey S. Tarima<sup>2</sup>, Keith P. Gennuso<sup>1</sup>, Nora E. Miller<sup>1</sup>, Elizabeth K. Grimm<sup>1</sup>, Linda J. Cieslik<sup>3</sup>. <sup>1</sup>University of Wisconsin-Milwaukee, Milwaukee, WI. <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI. <sup>3</sup>Milwaukee County Department on Aging, Milwaukee, WI.

Email:sstrath@uwm.edu

(No relationships reported)

**PURPOSE:** To examine the dose-response relationship between walking activity and physical function in community-dwelling older adults.

**METHODS:** The Wellness Works Program is an ongoing community-academic partnership providing free access to exercise facilities for Milwaukee County seniors. The present study evaluated 836 older adults who underwent an intake assessment including measures for general demographics and anthropometrics, physical activity (PA) and function assessments, prior to joining the program. PA was assessed by pedometer (Yamax SW-200) worn on the mid-thigh line of the right hip for 7 consecutive days. Function was evaluated by the Physical Functioning (PF) scale of the Medical Short-Form Outcomes questionnaire, and from the completion of a 6 minute walk test (6MWT). PA was averaged for the week and categorized into 4 groups (1= $\leq 2500$  [ $n=281$ ], 2=2501-5000 [ $n=326$ ], 3=5001-7500 [ $n=141$ ], and 4= $\geq 7501$  steps/d [ $n=88$ ]). PF and 6MWT distributions among PA groups were summarized with sample means and SD. ANOVA and general linear models were used for unadjusted and adjusted (for age and gender) group comparisons.

**RESULTS:** The average age and body mass index for men was  $68 \pm 9$  yrs ( $n=334$ ) and  $30 \pm 6$  kg/m<sup>2</sup> ( $n=334$ ) and for women was  $67 \pm 8$  yrs ( $n=491$ ) and  $31 \pm 7$  kg/m<sup>2</sup> ( $n=500$ ). Overall, participants walked an average of 4022 step/d, reported a PF score of 71.7 % and walked 1097.5 ft on the 6MWT. Across PA groups, PF mean scores increased from  $66.9 \pm 1.4\%$  to  $73.5 \pm 1.3\%$  to  $78.8 \pm 1.9\%$  to  $81.3 \pm 2.5\%$  and 6MWT distance increased from  $941.7 \pm 15.2$  ft to  $1154.1 \pm 14.0$  ft to  $1260.1 \pm 21.3$  ft to  $1294.0 \pm 26.8$  ft. Both PF and 6MWT scores were statistically different across all PA groups, apart from groups 3 and 4. PA and ranks of PA groups were highly significant predictors ( $p<.0001$ ) for both PF and 6MWT in unadjusted and adjusted for age and gender analyses.

**CONCLUSIONS:** There was a dose-response relationship evident for both PF and 6MWT with increasing levels of PA, with the greatest benefit being seen between PA group 1 ( $\leq 2500$  steps/d) and PA group 2 (2501-5000 step/d). Low levels of PA appear to be an important determinant of physical function in older adults. Efforts to increase walking behavior in this population are warranted to improve function.

**Everyday Physical Activity Patterns In Elderly Men And Women**

Anna Moschny, Timo Hinrichs, Ulrike Trampisch, Claudio Bucchi, Katja Dierichs, Petra Platen, FACSM. *University of Bochum, Bochum, Germany.*

Email: anna.moschny@rub.de

(No relationships reported)

**PURPOSE:** To evaluate gender differences in everyday physical activity patterns and in activity related energy expenditure in elderly people (>70 years).

**METHODS:** The sample was made of 136 community-dwelling older people: 67 men (median age 76; 71-88 years; 49.3%) and 69 women (median age 77; 71-89 years). Subjects were interviewed by telephone on their physical activities of the previous week. Activities were summarized to the following categories: homework, gardening, sporting activities and walking. Hours spent on specific activities were multiplied by predefined metabolic equivalent (MET) levels to estimate activity related energy expenditure (in MET-hours per week=MET-h/w). Statistical analysis for differences between sexes was done with Student's t-test.

**RESULTS:** Total time per day (hh:mm) subjects spent on being active did not differ significantly between sexes (men/women: 10:36±1:51/10:53±2:28; p=0.468). However, women (58.1±21.9 MET-h/w) had a higher (p<0.001) total activity related energy expenditure than men (40.3±19.4 MET-h/w). Energy expenditure (MET-h/w) of men/women within the four categories was: homework 19.9±14.3/48.1±19.3 (p<0.001), gardening 2.3±3.6/1.1±1.5 (p=0.024), sporting activities 11.3±16.3/8.6±11.4 (p=0.272), walking 3.5±2.4/2.7±2.1 (p=0.036). Relating energy expenditure within the respective category to the subjects' total energy expenditure revealed that homework made up 80.9±13.6% of women's and 51.0±27.7% of men's total energy expenditure (p<0.001). Sporting activities accounted for 24.7±27.8/11.1±13.5% (p=0.002), gardening for 6.4±12.2/1.6±2.4% (p=0.007) and walking for 11.7±11.1/4.5±4.1% (p<0.001) of elderly men's/women's total energy expenditure.

**CONCLUSION:** Homework accounted for the greatest portion of total energy expenditure in elderly men and women. A higher amount of homework led to a much higher total energy expenditure in women compared to men. The effects of everyday physical activity on health and functioning should be subject of further studies as they are poorly understood yet.

*The study has been conducted within the research cooperation PRISCUS ("Prerequisites for a new health care model for elderly people with multimorbidity"), which is funded by the German Federal Ministry of Education and Research (01ET0720).*

**2535 Board #180 May 29 9:00 AM - 10:30 AM**

**Functional Fitness Differences In Japanese Older Women Who Walk 10,000 At Different Intensities.**

Daisuke Koizumi<sup>1</sup>, Sungchul Lee<sup>1</sup>, Tomomi Yamada<sup>1</sup>, Nobuo Takeshima<sup>1</sup>, Nicole L. Rogers<sup>2</sup>, Michael E. Rogers, FACSM<sup>2</sup>. <sup>1</sup>Nagoya City University, Nagoya, Japan. <sup>2</sup>Wichita State University, Wichita, KS.

Email: d.koizumi@nsc.nagoya-cu.ac.jp

(No relationships reported)

Regular physical activity (PA) plays an important role in maintaining and promoting health, physical fitness, and functional independence in older adults. However, research is less clear when examining the impact of recommended levels of PA accumulation versus PA intensity on health, fitness and functional independence.

**PURPOSE:** To determine if functional fitness (FF) differences exist between community-dwelling older women who accumulate 10,000 steps/day and engage in 30 minutes/day or more of MI versus those who accumulate 10,000 steps/day and engage in less than 30 minutes/day of MI.

**METHOD:** Subjects (Ss) underwent a FF test and received a Lifecorder (Suzuken Co, Japan) accelerometer (LC) to record 2 consecutive weeks of steps and PA intensity (0=low intensity to 9=high intensity). PA intensity was defined as MI corresponding to LC levels 4-6 (3-6 METS). FF was assessed using Arm Curl, Chair Stand, Up & Go, Sit and Reach, Back Scratch, Functional Reach, and 12-min Walk. 603 Ss completed PA and FF assessments; of those 132 Ss (age: 68 ± 5, daily average step: 12370 ± 2087) accumulated 10,000+ steps/day and were selected for analysis. Ss were assigned to one of two groups: 30 or more minutes/day of MI PA (30MMI) or less than 30 minutes (30LMI).

**RESULTS:** in table.

	30LMI (n= 43)	30MMI (n=89)	t-test
Age	68 ± 5	67 ± 5	N.S.
Arm Curl (times/30sec)	22 ± 4	24 ± 4	N.S.
Chair Stand (times/30sec)	20 ± 4	23 ± 5	*p< 0.05
Up&Go (sec)	4.8 ± 0.5	4.5 ± 0.6	*p< 0.05
Sit&Reach (cm)	16.8 ± 9.7	16.2 ± 8.8	N.S.
Back Scratch (cm)	-2.4 ± 11.1	-2.2 ± 11.9	N.S.
Functional Reach (cm)	28 ± 5	30 ± 5	N.S.
12-min Walk (m)	1055 ± 140	1107 ± 97	*p< 0.05

**CONCLUSION:** There appears to be a relationship between MI and FF even for individuals *accumulating* the recommended PA levels. Individuals who accumulate 10,000 steps/day and engage in 30 minutes/day or more of MI appear to have greater lower body strength, mobility, and cardio-respiratory fitness compared to those who accumulate 10,000 steps/day and engage in less than 30 minutes/day of MI. Future research should examine the impact of increasing MI to recommended levels on FF.

**The Effects Of Home Based Nutrition And Exercise Interventions In Improving Functional Capacity And Reducing Falls Among The Elderly**

Shanthi Johnson, FACSM. University of Regina, Regina, SK, Canada.

Email: shanthi.johnson@uregina.ca

(No relationships reported)

Unintentional falls are one of the leading causes of mortality and morbidity among frail older adults. The higher incidence of falls coupled with a higher number of individuals at risk for poor nutrition and physical function among this group make it critical to explore this issue within the proposed context.

**PURPOSE:** The purpose of the study was to examine the synergistic role of functional capacity and nutrition on falls as well as the impact of combined, home-based nutrition and exercise interventions.

**MEASURES:** For the purpose of the study, 80 individuals over 65 years of age were recruited through Continuing Care and other community-based organizations. The participants were placed in one of four groups: exercise only, nutrition only, exercise and nutrition group, and no intervention comparison group. The exercise and nutrition interventions were the Home Support Exercise Program and consumptions of liquid adult nutritional supplement (Ensure ®) daily for six months. The participants' demographic information, status on health, function, nutrition, and falls were assessed at baseline and again at 6 months.

**RESULTS:** The participants' age ranged from 61-98 (ave=81). Of the participants, 83% were female, 50% lived alone, and 65% required personal assistance to leave their home. The 6 months follow-up showed improvement in improvement in functional capacity in the intervention groups.

**CONCLUSION:** Working with frail elderly providers unique opportunities and challenges.

*Supported by Nova Scotia Health Research Foundation and the Canadian Institutes of Health Research*

#### Dynamics Of Muscle Deoxygenation And Hemoglobin Supply In Active And Non-active Muscles During Heavy Exercise

Tadashi Saitoh<sup>1</sup>, Shunsaku Koga<sup>2</sup>, Kyuichi Niizeki<sup>1</sup>. <sup>1</sup>Yamagata University, Yonezawa, Japan. <sup>2</sup>Kobe Design University, Kobe, Japan.

Email: saitoh-t@yz.yamagata-u.ac.jp

(No relationships reported)

As compared to rest, during exercise, blood flow is redistributed and considerable amount of blood is supplied to active muscles. However, the dynamics of respiration and circulation at the muscle tissue level during exercise remains unclear.

**PORPOSE:** We evaluated the dynamics of muscle deoxygenation and hemoglobin supply to active and inactive muscles during repeated bouts of heavy cycling exercise by using near-infrared spectroscopy (NIRS).

**METHODS:** Six healthy subjects (25.1 ± 5.2 yrs) performed 2 bouts (6 min each) of cycling exercise at 80% peak of the pulmonary oxygen uptake; the 2 bouts were separated by 6 min of exercise at 10 W. The rate of gas exchange and heart rate were measured throughout the experiment. Further, oxyhemoglobin and deoxyhemoglobin concentrations ([O<sub>2</sub>Hb] and [HHb], respectively) in the vastus lateralis muscles (VLMs) or the flexor digitorum superficialis muscles (FDSMs) were measured using NIRS.

**RESULTS:** The total hemoglobin concentration (total-[Hb]) in the VLMs increased exponentially after heavy exercise, while it decreased in the FDSMs and was not restored to the baseline. The baseline total-[Hb] in the second bout of heavy exercise increased as compared to that in the first bout. [HHb] showed a rapid exponential increase in the VLMs, while it showed a gradual increase in the FDSMs after starting the heavy exercise. As compared to the baseline [HHb] in the first bout, it increased in the FDSMs and dropped in the VLMs in the second bout of heavy exercise.

**CONCLUSION:** More hemoglobin was supplied to the active muscles, while its supply was reduced to the inactive muscles after heavy exercise. However, deoxyhemoglobin level increased in both the active and inactive muscles, although the dynamics were different between the 2 types of muscles. This suggested the presence of oxidative activity in the inactive muscles during heavy exercise, although there flow no increase in the blood supply.

#### Changes In VO<sub>2</sub> And Muscle Deoxygenation Kinetics With Training In Old And Young Adults

Juan M. Murias, John M. Kowalchuk, Donald H. Paterson, FACSM. *The University of Western Ontario, London, ON, Canada.*

Email: jmurias@uwo.ca

(No relationships reported)

Phase II pulmonary VO<sub>2</sub> (VO<sub>2p</sub>) kinetics are slower in older (O) than in younger (Y) adults. Training results in a faster VO<sub>2p</sub> kinetics in both O and Y, however, the time-course and mechanisms underlying this faster adaptation are unknown.

**PURPOSE:** To determine the time-course and mechanisms of adaptation for phase II VO<sub>2p</sub> time constant (tVO<sub>2p</sub>) in O and Y men in response to a 12-week endurance training program.

**METHODS:** VO<sub>2p</sub> and muscle deoxygenation kinetics were examined during step transitions from 20 W to moderate-intensity cycling (90% of estimated lactate threshold) in 8 O (68 (7) yr; mean (±SD)) and 8 Y (23 (5) yr) men pre-training, and at 3, 6, 9, and 12 weeks of training. VO<sub>2p</sub> was measured breath-by-breath using a volume turbine and a mass spectrometer. Changes in deoxygenated-hemoglobin concentration ([HHb]) of the vastus lateralis muscle were measured by near-infrared spectroscopy. VO<sub>2p</sub> and [HHb] were modeled with a mono-exponential using non-linear regression. Training was performed on a cycle-ergometer three times per week for 45 min at ~70% of VO<sub>2peak</sub>; training intensity was adjusted at 3 week intervals to reflect changes in fitness level.

**RESULTS:** Pre-training tVO<sub>2p</sub> was greater (p<0.05) in O (43 (11) s) than Y (34 (8) s). The tVO<sub>2p</sub> decreased (p<0.05) by 3 weeks training in both O (35 (9) s) and Y (22 (8) s) with no further changes seen with continued training: tVO<sub>2p</sub> at 12 weeks was 32 (7) s (O) and 20 (7) s (Y). Pre-training, [HHb] adaptation (MRT=TD+t) was faster than tVO<sub>2p</sub> in both O and Y, which resulted in the [HHb]/VO<sub>2</sub> displaying a transient "overshoot" relative to the subsequent steady state level. After 3 weeks training the [HHb]/VO<sub>2</sub> "overshoot" was attenuated in both O and Y. With further training, the "overshoot" persisted in O but was eliminated in Y.

**CONCLUSION:** The training-induced speeding of VO<sub>2p</sub> kinetics in O and Y at 3 weeks of training (i.e., reduced tVO<sub>2p</sub>) appeared to be the result of an improved (microvascular) blood flow distribution (as represented by a lower [HHb]/VO<sub>2</sub>). The continued "overshoot" in the [HHb]/VO<sub>2</sub> in O, but not Y, may reflect a reduced vasodilatory responsiveness that may limit muscle blood flow distribution (and O<sub>2</sub> delivery) at exercise onset and thus limit further speeding of VO<sub>2</sub> in O.

#### Severity Of Expiratory Muscle Fatigue Is Greater After Whole-body Exercise Versus Maximal Voluntary Hyperpnea

Bryan J. Taylor<sup>1</sup>, Stephen C. How<sup>2</sup>, Lee M. Romer<sup>1</sup>. <sup>1</sup>Brunel University, London, United Kingdom. <sup>2</sup>University of Gloucestershire, Gloucester, United Kingdom. (Sponsor: Prof Alison McConnell, FACSM)

Email: bryan\_taylor\_82@hotmail.com

(No relationships reported)

The severity of diaphragm fatigue is greater after exhaustive whole-body exercise compared to maximal voluntary isocapnic hyperpnea (VIH) during which diaphragm pressure is in excess of that generated during exercise; whether this occurs in the expiratory muscles is unknown.

**PURPOSE:** To compare the severity of expiratory muscle fatigue in response to high-intensity whole-body exercise and VIH.

**METHODS:** Five healthy male subjects participated in the study [mean ± SD peak oxygen uptake (V<sub>O2peak</sub>) = 47.6 ± 2.3 ml·kg<sup>-1</sup>·min<sup>-1</sup>]. On separate occasions, the subjects cycled at >90% V<sub>O2peak</sub> to the limit of tolerance (11.4 ± 2.1 min) and performed 2 min of VIH. Expiratory muscle fatigue was assessed following both conditions by measuring the reduction from baseline of the magnetically evoked gastric pressure (P<sub>ga</sub>) response to stimuli at 1, 5, 10, 15, 20 and 25 Hz.

**RESULTS:** At all frequencies of stimulation, P<sub>ga</sub> was lower than baseline immediately after whole-body exercise and VIH [-25 ± 6% and -17 ± 4%, respectively (mean for all frequencies); P < 0.01]. The severity of expiratory muscle fatigue was greater after exercise versus VIH (P = 0.041). Maximum ventilation during exercise (153 ± 23 l·min<sup>-1</sup>) was lower (P < 0.05) than ventilation during the first and the last 10 s of VIH (198 ± 22 and 156 ± 15 l·min<sup>-1</sup>, respectively). The product of the tidal integral of gastric pressure and breathing frequency (P<sub>ga</sub> × f<sub>R</sub>) was lower (P < 0.01) during the first and last 10 breaths of exercise (452 ± 104 and 525 ± 96 cmH<sub>2</sub>O·s·min<sup>-1</sup>) compared to the first and last 10 breaths of VIH (1724 ± 719 and 822 ± 337 cmH<sub>2</sub>O·s·min<sup>-1</sup>). The cumulative ∫P<sub>ga</sub>, however, was not different for exercise vs. VIH (6505 ± 982 vs. 8124 ± 1051 cmH<sub>2</sub>O·s<sup>-1</sup>, P = 0.14).

**CONCLUSION:** Although the cumulative pressure output of the expiratory muscles was similar between trials, high-intensity whole-body exercise elicited a greater degree of

expiratory muscle fatigue compared with 2 min of VIH. We postulate that a greater competition for blood flow between different vascular beds during exercise compared to VIH may have accounted for the additional expiratory muscle fatigue after exercise.

**Inspiratory Muscle Function In Elite Male Field Hockey Players**

Martin R. Lindley PhD, Rebecca M. Smith BSc (hons). *Loughborough University, Loughborough, United Kingdom.* (Sponsor: T.D. Mickleborough, FACSM)

Email: m.r.lindley@lboro.ac.uk

(No relationships reported)

Inspiratory Muscle Function has been studied in many sports however there are few studies that investigate the phenomenon in team based game such as Field Hockey.

**PURPOSE:** To determine whether inspiratory muscle fatigue is induced via a regulation field hockey match and what affect a 5 week inspiratory muscle training programme will have on inspiratory muscle function in elite male field hockey players.

**METHOD:** Baseline pulmonary function (FVC, FEV<sub>1.0</sub>) and maximal inspiratory pressure (MIP) were measured for all players (n=16). MIP was then measured at three separate time points (pre-game[Pre], at half-time [HT] and post-game [Post]) relating to a standard regulation league match (English National Hockey League Premier Division). The sixteen players were then split randomly into training (n=8) and placebo groups (n=8). Each group underwent a 5 week training programme, the intervention group (IMT) training consisted of 30 inspiratory efforts, twice a day at approximately 50% of MIP while the placebo group (PG) performed 60 inspiratory efforts one day at approximately 15% of MIP. The players were informed that each protocol was measuring Inspiratory Muscle function and that the two protocols were going to be compared. All players took part with full informed consent and all procedures were as accepted by the institutional ethics committee.

**RESULTS:** There was a significant drop in inspiratory muscle function, as shown by a reduce MIP when comparing the Pre results to the Post results (p<0.05) which indicates a level of fatigue occurs throughout a match. With training a 25% increase in MIP occurred for the IMT group while a there was no change in the PG. However upon re-testing there was no significant difference between the two training groups when inspiratory muscle fatigue was looked at throughout a second competitive match. **CONCLUSIONS:** An elite level male field hockey match can induce inspiratory muscle fatigue and these same players can increase their MIP with training. Many studies have looked at various forms of inspiratory muscle training in different sports however this is one of the very few studies to show that games based sports also induce inspiratory muscle fatigue.

**The Influence Of Two Weeks Use Of A Respiratory Protective Device Upon Airway Function In London Cycle Couriers**

Alison K. McConnell, FACSM, John Eagle. *Brunel University, Uxbridge, United Kingdom.*

Email: alison.mcconnell@brunel.ac.uk

(No relationships reported)

Exposure to the particulate matter (PM) emitted by vehicle exhausts has been linked to a range of negative health effects, including acute inflammation and decrements in lung function in people with asthma (McCreanor et al, 2007). By virtue of their proximity to traffic, the duration of exposure, and the elevated breathing demands of exercise, cycle couriers are subjected to the highest levels of exposure of any city dweller. We wished to examine whether this group exhibited any evidence of impaired of lung function due to PM by assessing the influence of 2-wk use of a respiratory protective device (RPD) that removed PM.

**PURPOSE:** To determine whether protection from PM improved lung function in cycle couriers.

**METHODS:** 7 healthy male cycle couriers with no history of asthma were assessed prior to, immediately after, and two weeks after using a RPD for 2-wk. Outcome variables included peak expiratory flow rate (PEFR), forced expiratory volume in 1 sec (FEV<sub>1</sub>), forced vital capacity (FVC), and instantaneous flow rates 1, 2 and 3 litres below total lung capacity (IFR<sub>1, 2 or 3</sub>). Individual exposure indices (amount of PM inhaled) were calculated for each participant using local PM monitoring stations, work logs, and an assumed minute ventilation of 30 l.min<sup>-1</sup>. Measurements were made on a Friday evening, immediately following the working day. Statistical comparisons were made using repeated measures ANOVA.

**RESULTS:** Average PM concentration did not exceed the WHO threshold of 50 µg.m<sup>-3</sup> at any point in the study, but did fluctuate, as did individual exposures to PM. Relative to baseline, PEFR increased significantly immediately following the intervention and decreased 2-wk later (9.27±1.92 vs. 9.72±1.93 vs. 9.14±2.16 l.sec<sup>-1</sup>, respectively; P<0.05). A similar pattern was observed for IFR<sub>1</sub> (P<0.05), and FVC (P<0.05), but there were no changes in IFR<sub>2</sub>, IFR<sub>3</sub>, or FEV<sub>1</sub>.

**CONCLUSION:** Healthy cycle couriers exhibit signs of large airway inflammation, which is diminished following a 2-wk period during which PM exposure is reduced by using a RPD.

**Exhaled Nitric Oxide Is Correlated With Changes In Small And Large Airway Obstruction**

Louise A. Turner, Sandra Tecklenburg-Lund, Joel M. Stager, FACSM, Timothy D. Mickleborough, FACSM. *Indiana University, Bloomington, IN.*

Email: loturner@indiana.edu

(No relationships reported)

**PURPOSE:** Previous research has shown that pre-exercise fraction of exhaled nitric oxide (FENO) levels, a marker of airway inflammation, are elevated in people who exhibit exercise-induced bronchoconstriction (EIB). It has previously been shown that a positive relationship exists between pre-exercise FENO levels and post-exercise large airway closure as documented by changes in FEV<sub>1</sub>. Therefore, the purpose of this study was to determine if pre-exercise FENO levels demonstrated the same positive relationship with changes in FEF<sub>25-75%</sub> (indicative of small airway closure).

**METHODS:** Twelve EIB subjects, as determined by a post-EVH drop of ≥ 10% in FEV<sub>1</sub>, and 6 control (non-EIB) subjects completed 3 expiratory maneuvers in order to measure the FENO using an online measurement restricted exhaled breath protocol (NOA 280i, Sievers Instruments Boulder, CO). Subsequently subjects underwent a eucapnic voluntary hyperventilation (EVH) challenge. The EVH challenge required each subject to hyperventilate for 6 min at a ventilation calculated as 30 x the volume of baseline FEV<sub>1</sub>, while breathing a gas mixture containing 5% CO<sub>2</sub>, 21% O<sub>2</sub>, and balance N<sub>2</sub>. Pulmonary function was measured pre- and post-EVH at 5, 10, 15, and 20 min.

**RESULTS:** Significant (P<0.05) positive correlations were observed between pre-EVH FENO and post-EVH drops in FEV<sub>1</sub> (r=0.730, P=0.007) and FEF<sub>25-75%</sub> (r=0.798, P=0.002). Pre-EVH FENO levels were also significantly (P<0.05) higher in subjects who exhibited EIB (41.0±25.4ppb) as compared to control subjects (17.8±10.3ppb).

**CONCLUSION:** This study has demonstrated that FENO is associated with drops in post-EVH FEV<sub>1</sub> and FEF<sub>25-75%</sub>, indicating that FENO is correlated with both changes in the large and small airways. Since FENO is a marker of airway inflammation, these data indicate that subjects who exhibit EIB have underlying inflammation at rest. The data also indicate that subjects with higher levels of inflammation at rest may have a greater degree of airway hyperresponsiveness when challenged. Furthermore, these data indicate that exhaled nitric oxide may be a useful tool in the prediction of EIB and of the magnitude of both large and small airway changes as a result of exercise or other bronchial hyperresponsiveness challenges.

**Exhaled Breath Condensate Ph Is Correlated With Post-exercise Small Airway Obstruction**

Sandra Tecklenburg-Lund, Louise A. Turner, Joel M. Stager, FACSM, Timothy D. Mickleborough, FACSM. *Indiana University, Bloomington, IN.*  
Email: stecklen@indiana.edu  
(No relationships reported)

**PURPOSE:** It has been shown that individuals with asthma and exercise-induced bronchoconstriction (EIB) exhibit lower exhaled breath condensate (EBC) pH values than healthy individuals. The purpose of this study was to determine if EBC pH was correlated with the degree of airway obstruction following a bronchial hyperresponsiveness challenge.

**METHODS:** Twenty three subjects [15 asthmatics subjects with EIB, as determined by a post-EVH drop of  $\geq 10\%$  in  $FEV_1$ ; 8 control subjects (no-asthma/no EIB)] were asked to breathe normally at rest for 10 min wearing a nose clip while their exhaled breath was collected (EcoScreen, Jager, Hoechberg, Germany). The pH of the condensate was measured immediately following collection. Subsequently subjects underwent a eucapnic voluntary hyperventilation (EVH) challenge. The EVH challenge required each subject to hyperventilate for 6 min at a ventilation calculated as  $30 \times$  the volume of baseline  $FEV_1$ , while breathing a gas mixture containing 5%  $CO_2$ , 21%  $O_2$ , and balance  $N_2$ . Pulmonary function was measured pre-EVH and post-EVH at 5, 10, 15, and 20 min.

**RESULTS:** The EBC pH was significantly ( $p < 0.05$ ) lower in the subjects that exhibited EIB ( $6.83 \pm 0.43$ ) as compared to those who did not ( $7.37 \pm 0.32$ ). The EBC pH was not significantly correlated to the post-EVH drop in  $FEV_1$  ( $r = 0.048$ ,  $p = 0.827$ ). However, EBC pH was found to be significantly inversely correlated to post challenge drop in  $FEF_{25-75}$  ( $r = 0.579$ ,  $p = 0.004$ ).

**CONCLUSION:** Exhaled breath condensate pH was significantly lower in subjects who exhibit EIB than in healthy control individuals, which may indicate acidification of the airways in individuals with airway hyperresponsiveness. The pH was also inversely related with the post-EVH drop in  $FEF_{25-75}$  indicating that the lower EBC pH in the airways may be indicative of heightened reactivity in the small airways.

**2544 Board #189 May 29 8:00 AM - 9:30 AM**  
**Comparative And Synergistic Effects Of Caffeine And Albuterol On The Severity Of Exercise-induced Bronchoconstriction.**

Timothy A. VanHaitsma<sup>1</sup>, Timothy D. Mickleborough, FACSM<sup>2</sup>, Martin R. Lindley<sup>3</sup>, David Kocaja<sup>2</sup>, Joel M. Stager, FACSM<sup>2</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Indiana University, Bloomington, IN. <sup>3</sup>Loughborough University, Leicestershire, United Kingdom.  
Email: tim.vanhaitsma@utah.edu  
(No relationships reported)

**PURPOSE:** Previous research has demonstrated a beneficial effect of caffeine on preventing exercise-induced bronchoconstriction (EIB). Therefore, the main aim of this study was to extend previous published findings that have demonstrated a beneficial effect of caffeine on EIB by evaluating the comparative and synergistic effects of caffeine and albuterol ( $\beta_2$ -agonist) on the severity of EIB.

**METHODS:** Ten asthmatic subjects with EIB participated in a randomized, double-blind double-dummy crossover study. One hour before an exercise challenge, each subject was given 0, 3, 6, or 9mg/kg of caffeine or placebo mixed in a flavored sugar drink. Fifteen minutes before the exercise bout, an inhaler containing either albuterol (180 $\mu$ g) or placebo was administered to each subject. Pulmonary function tests were conducted pre- and post-exercise (1, 5, 10, 15 and 30 min). The exercise challenge comprised of each subject running on a motorized treadmill to volitional exhaustion while breathing dry air from a gas tank.

**RESULTS:** Caffeine significantly reduced ( $P < 0.05$ ) the mean maximum % fall in post-exercise  $FEV_1$  at 6 and 9mg/kg ( $-9.0 \pm 9.2\%$  and  $-6.8 \pm 6.5\%$ ) as compared to the double-dummy (placebo;  $-14.3 \pm 11.1\%$ ) and baseline ( $-18.4 \pm 7.2\%$ ). There was no significant difference ( $P > 0.05$ ) in the post-exercise % fall in  $FEV_1$  between albuterol (without caffeine) ( $-4.0 \pm 5.2\%$ ) and the 9mg/kg dose of caffeine ( $-6.8 \pm 6.5\%$ ). Interestingly, there was no significant difference ( $P > 0.05$ ) in the post-exercise % fall in  $FEV_1$  between albuterol (without caffeine) ( $-4.0 \pm 5.2\%$ ) and albuterol with 3, 6 or 9mg/kg of caffeine ( $-4.4 \pm 3.8$ ,  $-6.8 \pm 5.6$ ,  $-4.4 \pm 6.0\%$  respectively). Similar changes noted for the post-exercise % fall in  $FEV_1$  were also observed for FVC,  $FEF_{25-75}$  and PEF. In addition, it was determined that a dose-response relationship existed between the %fall in post-exercise  $FEV_1$  and caffeine dose administered (0, 3, 6 and 9 mg/kg) for all dependent variables.

**DISCUSSION:** These data indicate that moderate (6 mg/kg) to high doses (9 mg/kg) of caffeine can reduce the severity of EIB in a dose-response manner. These data also indicate that no significant difference exists between high doses of caffeine and albuterol which suggests that caffeine may represent an alternative to albuterol reducing the severity of EIB.

**2545 Board #190 May 29 8:00 AM - 9:30 AM**  
**Concordance Of Two Methods For Airway Hyperresponsiveness In Obese Adolescents**

Fabrcio Cieslak, Suelen Meira Góes, Wendell Artur Lopes, Thiago Krzesinski Dos Santos, André Luiz Félix Rodacki, Paulo César Kussek, Nelson Rosário Filho, Neiva Leite. *Federal University of Parana, Curitiba, Brazil.*  
Email: facieslak@gmail.com  
(No relationships reported)

**PURPOSE:** To evaluate the concordance of two methods airway hyperresponsiveness of the saline hypertonic solution and exercise in obese adolescents.

**METHODS:** This study was realized with 16 obese individuals (mean age  $12.93 \pm 2.04$ ), 10 female (mean age  $13.30 \pm 2.11$ ) and 6 male (mean age  $12.33 \pm 1.96$ ). The pulmonary function was measured for spirometer (Spirosift 3000) and were evaluated the forced expiratory volume ( $FEV_1$ ) in baseline and during the tests. Inhalation of 4.5% hypertonic saline was obtained by large volume ultrasonic nebulizer (DeVilbiss), continuously through 0.5, 1, 2, 4, 8 minutes until a  $FEV_1$  fall of  $> 15\%$  in relation to baseline. The physical exercise test was realized as American Thoracic Society protocol and the  $FEV_1$  was measured in 3, 5, 10, 15 and 30 minutes after the exercise, considered the bronchial o exercise the reduction of  $> 15\%$  in relation to baseline. The statistical analysis used was Shapiro-Wilk's test for the normality of data, index of concordance of kappa, Bland-Altman plots and intraclass correlation ( $P < 0.05$ ).

**RESULTS:** Normality of data was confirmed ( $P = 0.606$ ). The provocation test with hypertonic saline was positive in 12.5% of subjects and the exercise test was positive in 6.25% of the group, with a high concordance between the methods ( $k = 0.87$ ;  $P = 0.007$ ). The intraclass correlation coefficient was strong ( $r = 0.883$ ;  $P < 0.001$ ). Bland-Altman graphs confirmed the absence of bias in the intermethod comparison.

**CONCLUSION:** Our data supported that the two methods for the detection of airway hyperresponsiveness probably have the same trigger point, that is to say, both promoted the bronchial hyperosmolarity and therefore possess a degree of agreement.

**Breathe Right® External Nasal Dilator Strips As An Ergogenic Aid To Exercise**

Chadd Allen<sup>1</sup>, Kelly Brooks<sup>2</sup>, William Brooks<sup>2</sup>. <sup>1</sup>University of Louisiana at Monroe, Monroe, LA. <sup>2</sup>Louisiana Tech University, Ruston, LA. (Sponsor: Jeff Chandler, FACSM)  
Email: kbrooks@latech.edu  
(No relationships reported)

**PURPOSE:** Having the ability to breathe easily through the nose is an important part of exercising. The nose effectively warms and humidifies incoming air to better suit the bodies needs. It is known that having difficulty breathing through the nose can negatively affect exercise performance.

**METHODS:** The purpose of this study is to investigate the effects of the Breathe Right® external nasal dilator strip on exercise performance at 80% of an individual's  $VO_2$

max. Eighteen people participated in the study. Subjects signed an informed consent, PAR-Q, additional questionnaire, and rated their ease of breathing through their nose on a 1 to 10 scale prior to testing. Testing was performed in the Human Performance Laboratory at the University of Louisiana at Monroe. Subjects VO<sub>2</sub> max was measured using open spirometry on a treadmill ergometer. On two separate occasions participants returned to the laboratory for a treadmill run at 80% of the subjects predetermined VO<sub>2</sub> max; once with the nasal dilator strip and once with a placebo. Heart rate (HR), Borg's Rate of Perceived Exertion (RPE), and time to exhaustion were measured. Statistical analysis was conducted using SPSS 14.0. Significance level was preset at p<.05.

**RESULTS:** A significant difference was found in the time to exhaustion between runs with the Breathe Right® strip vs. runs with the placebo strip. No significant difference in HR or RPE was found between runs with the Breathe Right® strip vs. runs with the placebo strip.

**CONCLUSIONS:** Prior data shows mixed results when testing at a high percentage of VO<sub>2</sub> max. This study provides further support that Breath Right® strips may have an ergogenic effect on aerobic exercise performance.

**2547 Board #192 May 29 8:00 AM - 9:30 AM**  
**Increased Ventilatory Response To Submaximal Exercise After 5 Weeks Of Head-down Bed Rest**

Chelsie J. Rowell<sup>1</sup>, Helen E. Wood<sup>1</sup>, M. Dean Palmer<sup>1</sup>, Jeff Hastings<sup>1</sup>, Felix Krainski<sup>1</sup>, Eric Pacini<sup>1</sup>, Benjamin D. Levine, FACSM<sup>2</sup>, Tony G. Babb, FACSM<sup>2</sup>. <sup>1</sup>Institute for Exercise and Environmental Medicine, Dallas, TX. <sup>2</sup>UT Southwestern Medical Center, Dallas, TX.  
(No relationships reported)

Previously, ventilation (V<sup>E</sup>) during incremental exercise was found to be elevated after 7 days of horizontal bed rest (FASEB J 1991, 5:A1477). We investigated the effects of 5 weeks of head-down bed rest (HDBR) on the exercise ventilatory response (EVR), defined as the slope of the relationship between V<sup>E</sup> and CO<sub>2</sub> production (VCO<sub>2</sub>), to submaximal constant load exercise. To further explore the effects of HDBR, we examined short-term modulation (STM) of the EVR before and after HDBR. STM is defined as a neural mechanism where EVR is augmented in the presence of increased respiratory dead space (DS; J Appl Physiol 2008, 104: 244-252).

**PURPOSE:** To examine the effects of 5 weeks of HDBR on EVR and the capacity for STM.

**METHODS:** 25 subjects (3 female) spent 5 weeks in HDBR. As part of a larger study, subjects were assigned to 3 groups, 2 of which undertook exercise training during HDBR (semi-recumbent rowing 3 days/wk and horizontal strength training 2 days/wk) while the third remained inactive. The EVR was measured at rest and during upright cycle exercise (30W) without (Control) and with 400ml added external DS, before and after HDBR. The main effects of group and HDBR were analyzed with a two-way repeated measures ANOVA.

**RESULTS:** The main effect of group was not significant for any of the variables tested. The physical characteristics for the 25 subjects were: age 33±11 yr, height 175±10 cm, weight 74±12 kg and BMI 24±2 kg/m<sup>2</sup>. EVR both with and without added DS was elevated post HDBR (Control: 27.9±4.5 and 30.3±5.6; DS: 31.4±7.2 and 36.0±8.1; pre and post HDBR, respectively; p<0.05). EVR was significantly augmented with DS vs. Control both pre and post (p<0.05), indicating STM of the EVR, and this capacity to augment the EVR was unaffected by HDBR. The increase in EVR was due to a significant decrease in VCO<sub>2</sub> (Control: 0.79±0.15 and 0.73±0.11; DS: 0.75±0.11 and 0.70±0.10 l/min; at 30W pre and post HDBR, respectively; p<0.05), with no affect of HDBR on V<sup>E</sup> during exercise.

**CONCLUSION:** HDBR appears to alter the EVR mainly by a reduction in VCO<sub>2</sub>, which we speculate might be associated with a change in substrate metabolism. However, HDBR does not appear to affect the capacity for STM to augment the EVR with added DS.

Supported by NASA grant CA00701, the King Charitable Foundation Trust, Cain Foundation.

**Pulmonary Ventilation During Incremental Ramp Exercise Under Acute Acetazolamide Administration**

Kellie A. Ehlen, Michael J. Buono, FACSM, Fred W. Kolkhorst, FACSM, Paul W. Miller, Daniel T. Cannon. *San Diego State University, San Diego, CA.*  
Email: d.t.cannon08@leeds.ac.uk  
(No relationships reported)

The relative contribution of the chemoreflex drive to the exercise hyperpnoea is largely uncertain. Carbon dioxide rebreathing protocols clearly demonstrate chemoreflex driven respiration resulting from alterations in P<sub>a</sub>CO<sub>2</sub>, however, the stimuli for exercise ventilation remain controversial, particularly as arterial CO<sub>2</sub> content is well constrained during exercise.

**PURPOSE:** This study aimed to examine ventilation during incremental ramp exercise under acute acetazolamide (Acz) administration, which is known to result in impaired CO<sub>2</sub> elimination via inhibition of carbonic anhydrase.

**METHODS:** Nine healthy volunteers (mean ± SD age = 28 ± 7 yr; height = 183 ± 13 cm; mass = 83.6 ± 19.1 kg; VO<sub>2peak</sub> 4.48 ± 0.74 l min<sup>-1</sup>) completed two incremental ramp exercise tests (8 W min<sup>-1</sup>) at sea level (~755 mmHg) on an electromagnetically-braked cycle ergometer after either placebo or Acz administration (500 mg orally, 2.5 hr prior to exercise). Arterialized capillary blood samples (P<sub>a</sub>O<sub>2</sub> > 70 mmHg) were taken at rest and every 4 min during the incremental ramp protocol for blood gas, [La<sup>-</sup>], and pH measurements. Pulmonary ventilation (V<sub>E</sub>, V<sub>T</sub>, f<sub>R</sub>) was measured breath-by-breath via hot-wire anemometer.

**RESULTS:** Peak work rate was lower (291 vs. 300 W; CI<sub>Diff</sub> 3, 16; P < 0.05) in the Acz trial as compared to placebo, however, no differences were observed for VO<sub>2peak</sub> (CI<sub>Diff</sub> -0.17, 0.43 l min<sup>-1</sup>; P > 0.340). At exhaustion, P<sub>a</sub>CO<sub>2</sub> was higher during the Acz trial, as compared with placebo (33.2 vs. 27.4 mmHg; CI<sub>Diff</sub> 2.8, 8.8; P < 0.05). Blood pH was similar at exhaustion, but lower in the Acz trial at baseline and all other work rates (n=7; F[1, 12] = 37.662; P < 0.05; h<sup>2</sup> = 0.758). No interactions (work rate x trial) were observed for any of the ventilatory variables (V<sub>E</sub>: F[5, 80] = 1.113; P > 0.360; h<sup>2</sup> = 0.065; V<sub>T</sub>: F[2.591, 41.463] = 0.597; P > 0.597; h<sup>2</sup> = 0.036; f<sub>R</sub>: F[2.823, 45.168] = 0.536; P > 0.649; h<sup>2</sup> = 0.032). Despite the substantially smaller reduction in P<sub>a</sub>CO<sub>2</sub> and lower pH during the Acz trial, ventilation was similar at all work rates between the Acz and placebo trial (P > 0.05).

**CONCLUSION:** These data indicated that the modulation in P<sub>a</sub>CO<sub>2</sub> and pH from an acute dose of Acz did not affect ventilation during maximal graded exercise at sea level.

This investigation was Supported by the Frederick W. Kasch Endowment for Graduate Study.

**Cerebral Oxygenation During Incremental Ramp Exercise Under Acute Acetazolamide Administration**

Daniel T. Cannon, Kellie A. Ehlen, Fred W. Kolkhorst, FACSM, Paul W. Miller, Michael J. Buono, FACSM. *San Diego State University, San Diego, CA.*  
Email: d.t.cannon08@leeds.ac.uk  
(No relationships reported)

Recently, near-infrared spectroscopy (NIRS) has been employed for monitoring cerebral oxygenation during exhaustive and maximal exercise. While the implications of cortex oxygenation/perfusion for exercise tolerance are unclear, it is likely that the changes seen in the NIRS signal represent the balance of oxygen consumption and availability, the latter modulated by local vascular tone and perfusion pressure. It has been suggested that hypocapnic hyperventilation and cerebrovascular reactivity are probable mechanisms for cerebral deoxygenation during maximal exercise.

**PURPOSE:** The aim of this study was to examine cerebral oxygenation and perfusion under acute acetazolamide (Acz) administration. Acute Acz therapy has been shown to impair CO<sub>2</sub> elimination via inhibition of carbonic anhydrase and to reduce the severity of hypocapnia during graded exercise.

**METHODS:** Nine healthy volunteers (28 ± 7 yr; VO<sub>2peak</sub> 4.48 ± 0.74 l min<sup>-1</sup>) completed two incremental ramp exercise tests (8 W min<sup>-1</sup>) at sea level (~755 mmHg) on an electromagnetically-braked cycle ergometer after either placebo or Acz administration (500 mg orally, 2.5 hr prior to exercise). Arterialized capillary blood samples (P<sub>a</sub>O<sub>2</sub> > 70 mm Hg) were taken at rest and every 4 min during exercise for blood gas measurements. Cerebral oxygenation was measured using NIRS with the emission/detection optodes

placed over the left prefrontal cortex.

**RESULTS:** At exhaustion,  $P_aCO_2$  was elevated during the Acz trial, resulting in relative isocapnia throughout exercise, as compared with placebo (33.2 vs. 27.4 mmHg;  $CI_{diff}$  2.8, 8.8;  $P < 0.05$ ). No interactions (work rate  $\times$  trial) were present for the NIRS signals ( $DO_2Hb$ :  $F[1.383, 22.126] = 0.062$ ;  $P > 0.878$ ;  $h^2 = 0.004$ ;  $DHHb$ :  $F[1.296, 20.736] = 0.476$ ;  $P > 0.546$ ;  $h^2 = 0.029$ ;  $DTHb$ :  $F[1.632, 26.110] = 0.100$ ;  $P > 0.866$ ;  $h^2 = 0.006$ ). Despite the elevated  $P_aCO_2$  in the Acz trial, no differences were observed for  $DO_2Hb$ ,  $DHHb$ , or  $DTHb$  between trials ( $P > 0.05$ ).

**CONCLUSION:** These data indicated that cerebrovascular reactivity resulting from a reduction in  $P_aCO_2$  did not, alone, account for the increase in cerebral deoxygenation or the blunted perfusion response occurring near exhaustion during incremental exercise.

*This investigation was Supported by the Frederick W. Kasch Endowment for Graduate Study.*

**Exercise Characteristics Of Patients With Exercise-induced Arteriovenous Fistula In Pulmonary Circulation And Unexplained Exertional Dyspnea.**

Stephanie Kelly<sup>1</sup>, Shalabh Singhal<sup>2</sup>, Tehmina Naz<sup>2</sup>, Jean Elwing<sup>2</sup>, Mian Yousuf<sup>2</sup>, Yukitaka Shizukuda<sup>2</sup>. <sup>1</sup>Health Alliance, Cincinnati, OH. <sup>2</sup>University of Cincinnati, Cincinnati, OH. (Sponsor: Mitchell Whaley, PhD, FACSM)

Email: kellysj@healthall.com

(No relationships reported)

Dynamic appearance of arteriovenous fistula in pulmonary circulation (AVF) during exercise can be diagnosed with an agitated saline microbubble injection study of supine bicycle exercise echocardiography. Using this technique, we have reported that AVF can be observed in one in five outpatients who presented with unexplained exertional dyspnea (UED). However, an effect of AVF on exercise performance in patients with UED has been poorly understood.

**PURPOSE:** To determine exercise characteristics to patients with AVF who presented with UED.

**METHODS:** Forty-one outpatients (age;  $53 \pm 13$ , 35 females) who underwent supine bicycle exercise echocardiography to evaluate a cause of UED were analyzed to compare exercise characteristics in the presence or absence of AVF in this population. Symptom-limited 15 watts 3-minute incremental protocol was used. The delayed microbubble appearance in the left atrium at more than 5 beats after the right atrial opacification was defined as AVF. All exercise data were collected non-invasively.

**RESULTS:** Ten patients (24%) were diagnosed to have exercise-induced AVF. Both patients with AVF and without AVF showed similar peak exercise heart rate, systolic blood pressure, and rate-pressure product ( $136 \pm 16$  vs.  $134 \pm 25$  bpm,  $167 \pm 36$  vs.  $170 \pm 30$  mmHg,  $22.4 \pm 4.2$  vs.  $22.9 \pm 6.3$  bpm-mmHg  $\cdot 10^3$  respectively,  $P = N.S.$  for all, data are mean  $\pm$  SD). Estimated peak systolic pulmonary artery pressure measured with echocardiography at peak exercise was also comparable between two groups ( $54 \pm 15$  vs.  $57 \pm 13$  mmHg). However, peak exercise oxygen saturation tended to be lower in patients with AVF compared with those without AVF ( $95.6 \pm 2.8$  vs.  $97.2 \pm 2.8\%$ ,  $P = 0.12$ ) and only patients with AVF showed a significant drop of oxygen saturation from baseline ( $97.2 \pm 2.5\%$ ,  $P < 0.05$ ).

**CONCLUSION:** Exercise-induced AVF may have a physiological significance in patients with UED by lowering oxygen saturation at exercise. Further investigation to characterize exercise-induced AVF is warranted.

**Altered GABAergic Modulation Of Ventilatory Response To Hypoxia In Diabetic Rats**

Yen-Wen Lin<sup>1</sup>, Bor-tsang Wu<sup>1</sup>, Yueh-Ling Hsieh<sup>1</sup>, Chia-Hua Kuo<sup>2</sup>, Shin-Da Lee<sup>1</sup>. <sup>1</sup>China Medical University, Taichung, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: jin73822@hotmail.com

(No relationships reported)

**PURPOSE:** Diabetes mellitus (DM) patients exhibit blunted ventilatory responses to acute hypoxia whereas the underlying mechanism is unknown. The purpose of the study is to determine whether altered gamma-aminobutyric acid (GABA)ergic mechanisms acting in GABAA receptors contribute to the abnormal ventilatory response to hypoxia in diabetes mellitus.

**METHODS:** Sixteen male Wistar rats at 8 weeks of age were randomly divided into control group (non-DM), streptozotocin-induced DM (65 mg/kg i.v., DM). Eight non-DM Wistar rats and 8 Type 1-like diabetic rats were studied at 12 weeks of age. Respiratory function in conscious rats was assessed using a whole body plethysmograph (Buxco System) where the rat body was not restricted. Ventilation (VE), tidal volume (VT), and breathing frequency (f) during room air breathing and in response to acute hypoxic (10%  $O_2$ ), sustained (30 min) hypoxic (10%  $O_2$ ) challenges were measured on two separate occasions following the randomized blinded administration of equal volumes of DMSO (vehicle), bicuculline (0.5 mg/kg, GABAA receptor antagonist).

**RESULTS:** Ventilatory response to acute (not sustained) hypoxia in DM group was significantly ( $P < 0.05$ ) blunted compared to non-DM group. Bicuculline administration in non-DM Wistar rats had no effect on ventilation either during room air breathing, or acute and sustained exposure to hypoxia. In contrast, bicuculline administration in DM group significantly increased ventilatory response to acute hypoxia. However, bicuculline administration in DM Wistar rats had no effect on ventilation either during room air breathing or sustained hypoxia.

**CONCLUSIONS:** Blunted ventilatory responses to acute hypoxia in diabetes mellitus appeared to be suppressed by endogenous GABA by acting specifically on GABAA receptors. Altered GABAergic modulation in diabetes might potentially impact acute hypoxia related ventilatory compensation.

**The Correlation Between Triaxial Accelerometer And Indirect Calorimetry Measurements During Forehand Table-tennis Trial**

Pei-Fan Wang, Li-Lan Fu. National Taiwan Sport University, Taoyuan, Taiwan.

Email: peifan0919@hotmail.com

(No relationships reported)

Triaxial accelerometer was often used to measure energy expenditure in whole body and lower limbs activities, including running, walking and stepping exercise. However, the application of triaxial accelerometer in high percentage upper limbs exercise, such as table tennis, badminton, and volleyball was not so clear.

**PURPOSE:** The purpose of this study was to examine the validity of RT3 triaxial accelerometer in assessing energy expenditure (EE) during table-tennis exercise in recreational athletes.

**METHODS:** Ten recreational athletes healthy male (mean age  $23.19 \pm 3.11$  years, height  $173.85 \pm 3.51$  cm, weight  $69.65 \pm 4.84$  kg) participated in this study. The triaxial accelerometer (RT3, Stayhealthy, Inc.) and indirect calorimetry (SensorMedics, Vmax 29) were used simultaneously to measure the energy expenditure and oxygen consumption during exercise. Four accelerometers were attached at lower back (L3), dominant side of wrist, elbow, and shoulder. All accelerometers were attached without limiting the movement process. Each subject was required to strike forehand successively for 5 minutes at 75 balls per minutes, determined by table tennis robot (SMARTPONG). The average data of RT3 and oxygen consumption was calculated between the second to fourth minutes of each trial. Pearson correlation coefficient was used to examine the correlation between the RT3 and indirect calorimetry measurements.

**RESULTS:** The lower back RT3 energy consumption and vector magnitude were both highly correlated with indirect calorimetry ( $r = .843$ ,  $p < 0.01$ ;  $r = .832$ ,  $p < 0.01$ ).

Vector magnitude of RT3 at elbow and wrist was significantly correlated with indirect calorimetry ( $r = .413$ ;  $r = .412$ ,  $p < 0.05$ ). No significant correlation was found between RT3 at shoulder (energy consumption, vector magnitude) and oxygen consumption.

**CONCLUSIONS:** RT3 triaxial accelerometer attached at lower back is a valid way to measure the energy expenditure during continuous table-tennis forehand trial. The RT3 attached at upper limb may over estimate the energy consumption during upper limb exercise without any correction of the internal formula.

**Cross Validation And Reliability Of The 20mst For Predicting Of Cardiorespiratory Fitness In Korean**

Sung-Yeon Kim<sup>1</sup>, Hyun-Chul Cho<sup>1</sup>, Seoung-Ki Kang<sup>1</sup>, Eui-Young Kim<sup>2</sup>, Jong-Dae Yoon<sup>3</sup>, Jong-Kyu Kim<sup>1</sup>. <sup>1</sup>*Yongin University, Kyungki, Republic of Korea.* <sup>2</sup>*Hoseo University, Chun An, Republic Of Korea.* <sup>3</sup>*Kyungwoon University, Gumi, Republic Of Korea.*

Email: sharing1225@hanmail.net

(No relationships reported)

**PURPOSE:** Cardiorespiratory fitness is related to an individual's ability to use the large muscles for prolonged periods of dynamic, moderate-to-high intensity exercise. Level of cardiorespiratory fitness is dependent on the condition of the respiratory, cardiovascular and skeletal muscle systems. Analysis of cardiorespiratory fitness is important because of its relationship to health and wellness. Poor cardiorespiratory fitness is related to a marked increase in risk of premature death from all causes. There are many kinds of method to measure cardiorespiratory fitness.

The purpose of this study is to develop an equation to predict a cardiorespiratory fitness of Korean and to evaluate cross validation and reliability of 20MST.

**METHODS:** One hundred-sixteen male volunteers participated in this study (develop equation group,  $n=71$ : Age= $22.04 \pm 2.91$  year, Height= $174.6 \pm 5.25$  cm, Weight= $73.71 \pm 10.73$  kg; cross validation group,  $n=45$ : Age= $22.2 \pm 2.79$  year, Height= $174.34 \pm 5.25$  cm, Weight= $73.08 \pm 11.83$  kg; retest group,  $n=90$ : Age= $22.11 \pm 2.18$  year, Height= $174.54 \pm 5.16$  cm, Weight= $72.06 \pm 9.56$  kg). The peak oxygen uptake (VO<sub>2</sub>peak) was measured by graded exercise test (Bruce protocol) and 20M-Shuttle Run Test was administered on a nonslip surface indoor track in accordance with the procedures described by leger et al (1988), in which running velocity was increased by 0.5 km/hr after every 1-minute stage.

**RESULTS:** An equation was developed through 20M-shuttle run test influenced by running speed and BMI. It was  $Y = -32.046 + (7.086 \times \text{speed}) + (-.490 \times \text{BMI})$  that its R-square was .652. Cross validity using forty-five targets was R-square .618. There was no significant difference between measured and predicted values ( $t = -1.353$   $r = .794$ ,  $p = .179$ ). The relationship between measured and predicted VO<sub>2</sub>peak was  $r = .87$  with an SEE of 1.77 counts.

**CONCLUSIONS:** In conclusion for this research a validation and reliability, 20MST was developed and can be used to evaluate cardiorespiratory fitness for Korean.

**Effect Of Breath Retention On The Development Of Swimming Skills In Preschool Children**

Amanda M. J. King, Darren Kruisselbrink. *Acadia University, Wolfville, NS, Canada.*

Email: 050133k@acadiau.ca

(No relationships reported)

Little research has examined breathing strategies for preschool aged swimmers. The standard Canadian learn-to-swim program focuses on exhaling while performing swimming skills. In pre-school aged children, the attention demands of exhalation combined with the attention demands of coordinating the arms, legs and body position to execute a swimming skill may exceed a preschooler's attentional capacity. Alternate private programs teach children to hold their breath for the first number of skill levels guided by the belief that breath retention makes children more buoyant and feel safer in the water atmosphere.

**PURPOSE:** To examine the effect of exhalation and breath retention breathing strategies on the development of swimming skills and perceived comfort in the water in preschool aged children.

**METHODS:** Skill development and overall comfort in the water were examined in four level 2 swim classes ( $N = 16$ ,  $M = 4.8$  years,  $SD = 1.52$  years); two classes were randomly assigned to be taught to exhale while performing front glides, back glides, front floats, and back floats, and two classes were taught to hold their breath. Each skill was rated by three swim instructors on the first and last week of an eight week program; the Modified Erbaugh Rating Scale was used to rate the front glide, rating scales were developed for the front float, back float and back glide. Inter-rater reliability for all but the pretest back glide (0.68) ranged between 0.89 and 1.00. Change scores from pretest to posttest were compared across groups by independent t-tests.

**RESULTS:** The classes utilizing the breath retention strategy showed significantly greater improvement for the front ( $p < .01$ ) and back ( $p = .03$ ) glides and back float ( $p = .05$ ), and a trend towards greater improvement for the front float ( $p = .07$ ). The groups did not differ substantially on overall comfort in the water.

**CONCLUSIONS:** The results show that there is an overall increase in skill development when preschool children were taught to hold their breath rather than exhaling while performing front floats, back floats, front glides and back glides. Thus, the coordination components of the skills should be learned before the skills are made more complex by adding the breathing components.

**Little League Elbow Related Factors In Throwing Pattern And Physical Characteristics**

Yung-Shen Tsai<sup>1</sup>, Ting-Yu Wu<sup>2</sup>, Yung-Ting Chen<sup>2</sup>. <sup>1</sup>*Taipei Physical Education College, Taipei, Taiwan.* <sup>2</sup>*National Cheng Kung University, Tainan, Taiwan.*

Email: ystsai@tppec.edu.tw

(No relationships reported)

Little league elbow related factors have not been thoroughly explored.

**PURPOSE:** To compare the differences in throwing kinematics and physical characteristics between youth baseball players with and without medial elbow pain (MEP).

**METHODS:** Fifteen players with previous MEP and 15 healthy players were matched by age, height, and weight. Practice hours per week and years of playing organized baseball games were similar between the two groups. Throwing kinematics were recorded by an electromagnetic motion analysis system. Ball speed was recorded with a sports radar gun. Isometric strength of trunk, hip, and shoulder was measured using a torque sensor attached to a custom device. Elbow, shoulder, and hip flexibility were measured with a goniometer and a tape measure. Single leg standing balance was assessed with a force plate. Paired-t tests were performed to compare the differences between the two groups.

**RESULTS:** MEP group demonstrated less elbow flexion angle at maximum shoulder external rotation ( $91.2 \pm 17.0^\circ$  vs.  $101.3 \pm 10.4^\circ$ ,  $p=0.004$ ), more trunk lateral tilt to the non-dominant side at ball release ( $29.3 \pm 9.9^\circ$  vs.  $23.4 \pm 9.0^\circ$ ,  $p=0.035$ ), greater maximum upper torso rotational velocity ( $1065.8 \pm 66.8$  vs.  $931.1 \pm 104.2^\circ/s$ ,  $p=0.0002$ ), greater maximum pelvic rotational velocity ( $727.7 \pm 88.2$  vs.  $622.1 \pm 84.2^\circ/s$ ,  $p=0.001$ ), and greater ball speed ( $89.2 \pm 9.7$  vs.  $82.7 \pm 9.7$  km/hr,  $p=0.006$ ) compared to the healthy group. MEP group had less PROM in shoulder external rotation of the throwing arm compared to the healthy group ( $109.3 \pm 6.9^\circ$  vs.  $115.9 \pm 9.8^\circ$ ,  $p=0.01$ ). In the MEP group, total elbow ROM ( $146.7 \pm 6.7^\circ$  vs.  $150.4 \pm 6.4^\circ$ ,  $p=0.047$ ) and hip flexibility measured from the lateral epicondyle of knee to the table during Patrick test ( $11.2 \pm 2.2$  vs.  $10.3 \pm 1.3$  cm,  $p=0.048$ ) were less in the non-dominant side when compared to their dominant side. No significant differences were found in isometric muscle strength and single leg standing balance between the two groups.

**CONCLUSION:** Differences in throwing kinematics and flexibility were found between youth baseball players with and without previous MEP. Clinicians and baseball coaches should pay attention to these factors in addition to age, height, weight, and overuse that were mentioned to be related to youth players' injury rate for protecting them.

**2556 Board #201 May 29 9:00 AM - 10:30 AM**  
**Comparison Of Swim Starts Using Side Handle And Front Handle Grip Techniques**

Richard N. Hinrichs<sup>1</sup>, Peter F. Vint<sup>2</sup>, Scott P. McLean<sup>3</sup>, Scott A. Riewald<sup>2</sup>, Robyn K. Mason<sup>2</sup>. <sup>1</sup>Arizona State University, Tempe, AZ. <sup>2</sup>United States Olympic Committee, Colorado Springs, CO. <sup>3</sup>Southwestern University, Georgetown, TX.  
 Email: hinrichs@asu.edu  
 (No relationships reported)

FINA rule FR 2.7 provides for, but does not require, the inclusion of starting blocks equipped with side grip handles for the hands. These side handles were available at the 2003, 2005, and 2007 World Championships but not at the 2004 and 2008 Olympic Games. While a number of studies have documented effects of various starting techniques, none has examined the efficacy of a side handle grip technique.

**PURPOSE:** To quantify differences in swim start performances using side handle and front handle grip techniques.

**METHODS:** A custom-built, instrumented starting block system was designed using two force plates and two 3D force transducers attached to handles which were configurable to allow front grip and side grip starting techniques. Thirty male and 18 female swimmers participating in USA Swimming junior elite and national select camps completed three maximum effort starts each using front and side handle grip techniques. Force data were collected at 600 Hz and used to quantify parameters related to starting performance.

**RESULTS:** Two-way MANOVA with repeated measures on grip revealed a number of significant differences between gender and starting technique.

	Sig.	Front Handle Grip		Side Handle Grip	
		Males	Females	Males	Females
Propulsion time (s)	*†	0.60 ± 0.04	0.65 ± 0.08	0.64 ± 0.07	0.69 ± 0.09
H. takeoff velocity (m/s)	*†‡	4.01 ± 0.36	3.77 ± 0.17	4.85 ± 0.52	4.29 ± 0.24
Takeoff angle (deg)	*†	-1.44 ± 6.64	-6.93 ± 6.80	2.66 ± 5.48	-3.95 ± 6.40
H. peak power (watts/kg)	*†‡	31.08 ± 6.47	27.75 ± 3.92	41.28 ± 7.94	33.54 ± 4.61
Hand/Total impulse (%)	* ‡	11.14 ± 8.18	14.58 ± 9.91	24.74 ± 10.28	22.75 ± 11.77
*Side handle significantly different than front handle ( $p < .001$ ). †Male significantly different than female ( $p < .05$ ). ‡Significant two-way interaction ( $p < .05$ ).					

Males had significantly shorter propulsion times but produced faster and more horizontal takeoffs than females. They also produced more power per unit of body mass. Across all swimmers, starts performed with a side handle grip technique were characterized by significantly longer propulsion times with faster and more horizontal velocities, and greater power.

**CONCLUSION:** Improved starting performance when using the side grip handles was likely attributable to longer propulsion times and significantly greater relative force contribution from the arms.

**2557 Board #202 May 29 9:00 AM - 10:30 AM**  
**Efficacy Of Digital Video Techniques To Estimate Knee Alignment Of Females During A Drop Jump**

John J. Toepke<sup>1</sup>, Terese L. Chmielewski<sup>2</sup>, Ryan L. Mizner<sup>1</sup>. <sup>1</sup>Eastern Washington University, Spokane, WA. <sup>2</sup>University of Florida, Gainesville, FL.  
 (No relationships reported)

Female athletes in cutting, jumping and pivoting sports have increased risk for ACL injury compared to their male counterparts. One injury risk factor is landing from a jump with a large knee abduction (ABD) angle and moment. While 3D motion analysis is the gold standard for determining joint kinematics and kinetics, there is a need for affordable and clinically efficacious alternatives. The frontal plane projection angle (FPPA) of the thigh in relation to the shank and the ratio of knee-to-ankle separation are 2D measurements proposed to estimate knee ABD angle. There is little data on the reliability of these 2D measures and their comparison with 3D frontal plane knee kinematics and kinetics.

**PURPOSE:** To determine: 1) inter- and intra-rater reliability of FPPA and knee-to-ankle separation ratio measures; and 2) the correlation of both 2D measures with 3D frontal plane knee angle and moment from the landing phase of a drop vertical jump (DVJ).

**METHODS:** Female collegiate athletes ( $n = 36$ , age =  $20 \pm 1$  yrs) competing in IKDC level I and II sports performed a DVJ while data were collected with a 7 camera motion capture system (250 Hz) and 2 force plates (1500 Hz). Simultaneous digital video was captured with a digital video camera (30 Hz) positioned 3 m away at a height of 0.6 m. Intra and inter-rater reliability of the 2D measures were assessed with ICC's with two blinded evaluators of digital images at peak knee flexion during the land. Pearson Correlation Coefficients were calculated between 2D and 3D measures.

**RESULTS:** Both 2D analysis methods showed excellent reliability (FPPA: intra-rater ICC = 0.95, inter-rater = 0.89; knee-to-ankle separation ratio: intra-rater = 0.97, inter-rater = 0.92). Poor to moderate correlations were found between the FPPA and knee ABD angle ( $r = 0.381$ ;  $p = 0.022$ ) and abduction moment ( $r = 0.504$ ;  $p = 0.002$ ). Moderate to strong correlations were found between the knee-to-ankle separation ratio and knee ABD angle ( $r = 0.592$ ;  $p < 0.001$ ) and ABD moment ( $r = 0.628$ ;  $p < 0.001$ ).

**CONCLUSIONS:** The 2D analysis methods had good consistency and moderate validity with known 3D measures of ACL injury risk. The knee-to-ankle ratio showed better validity compared to the FPPA. 2D analysis has potential to be an inexpensive, reliable and effective means of estimating frontal plane knee position and moment as part of ACL injury screening.

## Contribution Of Form Drag And Skin Friction Drag During The Swimming Gliding

Luísa Novais<sup>1</sup>, Daniel A. Marinho<sup>2</sup>, Victor M. Reis<sup>1</sup>, Mário C. Marques<sup>2</sup>, Aldo M. Costa<sup>2</sup>, Luciano S. Sousa<sup>1</sup>, Francisco B. Alves<sup>3</sup>, João P. Vilas-Boas<sup>4</sup>, Leandro Machado<sup>4</sup>, Abel I. Rouboa<sup>1</sup>, António J. Silva<sup>1</sup>. <sup>1</sup>CIDESD / UTAD, Vila Real, Portugal. <sup>2</sup>CIDESD / UBI, Covilhã, Portugal. <sup>3</sup>FMH-UTL, Lisbon, Portugal. <sup>4</sup>FADEUP, Porto, Portugal.

(No relationships reported)

In human swimming, the total drag comprises the skin friction drag, form drag and wave drag. The relative contribution of each component to the overall hydrodynamic drag is controversy issue.

**PURPOSE:** To analyse the relative contribution of the skin friction drag and the form drag for the total drag during the gliding, using computational fluid dynamics.

**METHODS:** A 3-D domain was created to simulate the fluid flow around a swimmer model. The numerical simulation analysis consisted of the use of a three-dimensional mesh of cells that simulates the flow around the human body. Computational fluid dynamics methodology uses the finite volume approach, where the equations are integrated over each control volume. The k-epsilon turbulent model was applied to the flow around a three-dimensional model of a male adult swimmer in two gliding positions: in ventral position with the arms extended at the front and in ventral position with the arms aside the trunk. The swimmer model middle line was placed at a water depth of 0.90 m, equidistant from the top and bottom surfaces of the 3-D domain. The coefficient of drag (CD) was computed using a steady flow velocity of 2 m/s for both gliding situations. The CD was decomposed into form and skin friction drag.

**RESULTS:** The position with the arms extended at the front presented a CD value of 0.43 whereas the position with the arms aside the trunk presented a CD value of 0.74. In the position with the arms extended at the front, form drag and skin friction drag represented, approximately, 87% (CD = 0.37) and 13% (CD = 0.06) of the total drag, respectively. In the position with the arms aside the trunk, form drag and skin friction drag represented, approximately, 92% (CD = 0.68) and 8% (CD = 0.06) of the total drag, respectively.

**CONCLUSIONS:** The gliding position with the arms extended at the front produced lower drag coefficients than with the arms placed aside the trunk. Although form drag was dominant, skin friction drag was by no means negligible during the swimming gliding.

Supported by FCT (SFRH/BD/25241/2005; POCTI/DES/58872/2004).

**PURPOSE:** To investigate the relationship between unilateral hip abductor muscle fatigue and frontal plane pelvic drop while running.

**METHODS:** Five healthy, female subjects (mean age  $24.2 \pm 3.6$ ) were obtained from a sample of convenience. Subjects were recreational runners who ran  $\geq 10$  miles per week (mean 18.0 miles  $\pm 4.5$ ) and had no known cardiopulmonary or neuromuscular impairments. After a 5-minute warm-up, subjects were asked to run 3 minutes on a treadmill at a speed 10% greater than their self-selected speed ( $6.94 \text{ mph} \pm 0.31$ ) prior to and after an imposed fatiguing protocol. Fatigue was induced by asking subjects to perform a paced (72Hz) standing hip abduction activity using a black TheraBand® for resistance. The activity was halted when the subject could not continue with good form. A kinetic measure of hip abduction torque was used to verify a minimum decrease of 10% between the baseline run and the fatigued run. During each run, kinematic measurements of pelvic position were taken using a 6DOF electromagnetic tracking system (Polhemus Fastrak®). Data were sampled at 60Hz with sensors secured over the posterior superior iliac spines (PSIS) bilaterally. Pelvic drop was calculated as the angle between left and right PSIS relative to a horizontal plane using custom software (MATLAB). A nonparametric t-test was calculated using JMP v 7.0; statistical significance was defined as  $p < 0.05$ .

**RESULTS:** Mean differences between pre to post fatigue pelvic drop were  $0.59 \pm 3.05^\circ$ ,  $1.66 \pm 2.94^\circ$ , and  $1.15 \pm 3.90^\circ$ , for minutes 1, 2, and 3, respectively. These differences were not significant. Pelvic drop tended to increase pre to post fatigue, with the greatest increase seen at minute 2. Torque production showed a mean decrease of  $23.77 \pm 12.35\%$ .

**CONCLUSION:** While these findings were not statistically significant, there appears to be a relationship between fatigue and pelvic drop. From an injury prevention or clinical perspective, kinematics following fatigue may provide useful information in addition to baseline data. The small sample size is a limitation of this study. Data collection is ongoing.

---

## 2560 Board #205 May 29 9:00 AM - 10:30 AM Influence Of The Rear Arm On The Biomechanics Of The Lunge In Classically-trained Fencers

V Rene Nevola<sup>1</sup>, Mark A. Nevola<sup>2</sup>. <sup>1</sup>Defence Science and Technology Laboratory (Dstl), Hampshire, United Kingdom. <sup>2</sup>Perins School, Hampshire, United Kingdom.

(No relationships reported)

**BACKGROUND:** A fast lunge and rapid return to *en garde* (*EnG*) is critical for success in competitive fencing (Cronin *et al* 2003). Full extension of the rear leg from  $45^\circ$  flexion (typical of the classical *EnG* position) has been shown to achieve a faster lunge in trained fencers (Adrian M and Klinger A 1976) when compared with the modern upright *EnG* posture (where both legs are flexed  $<30^\circ$  from full extension). Unlike the modern technique, classically trained fencers demonstrate rapid extension of the rear arm when performing the lunge and rapid flexion of the rear arm during recovery to *EnG*.

**PURPOSE:** To compare performance of the fencing lunge and recovery to *EnG* with v without the use of the rear arm.

**METHOD:** Six classically trained, male fencers (mean [1SD]) age  $25.3$  [ $4.4$ ] years; body mass  $70.8$  [ $2.9$ ] kg; lunge distance  $0.76$  [ $0.01$ ] m) participated in this ethics approved study. Having practiced the lunge and recovery to *EnG* (the trial) for both conditions (C1: Rear arm tethered to the torso; C2: Classical rear arm technique) participants (in competitive fencing attire) conducted 5 best-effort time trials for each condition. Randomised order of trials (standardised for *EnG* posture, foot position, lunge distance and recovery) were conducted on a level, non-slip indoor surface. Ground reaction forces at the rear and lead legs in the horizontal ( $F_y$ ) and vertical ( $F_z$ ) axes were recorded during each trial using two force platforms. Video analysis of each trial identified correct completion of the lunge (lead foot's toe-lift at *EnG* to initial contact of the same foot) and recovery (loading response of the lead foot at the lunge to initial contact on return to the original *EnG* position). Data were analysed by repeated measures ANOVA ( $\alpha = 0.05$ ).

**RESULTS:** C2 produced a faster lunge (C2  $0.90$  [ $0.05$ ]  $\text{m.s}^{-1}$  v C1  $0.75$  [ $0.04$ ]  $\text{m.s}^{-1}$ ,  $p < 0.05$ ) and faster recovery to *EnG* (C2  $0.46$  [ $0.03$ ]  $\text{m.s}^{-1}$  v C1  $0.39$  [ $0.03$ ]  $\text{m.s}^{-1}$ ,  $p < 0.05$ ) than C1. Differences ( $p < 0.05$ ) in rear leg kinetics were evident between conditions during the lunge ( $F_y$ : C2  $5.12$  [ $0.07$ ]  $\text{N.kg}^{-1}$  v C1  $4.83$  [ $0.14$ ]  $\text{N.kg}^{-1}$ ; *peak horizontal power*: C2  $5.58$  [ $0.33$ ]  $\text{W.kg}^{-1}$  v C1  $4.50$  [ $0.35$ ]  $\text{W.kg}^{-1}$ ) and recovery to *EnG* ( $F_y$ : C2  $3.39$  [ $0.08$ ]  $\text{N.kg}^{-1}$  v C1  $3.15$  [ $0.09$ ]  $\text{N.kg}^{-1}$ ). No differences were observed in lead leg kinetics.

**CONCLUSION:** The fastest lunge and recovery to *EnG* was achieved when classically trained fencers used the rear arm.

---

## 2561 Board #206 May 29 9:00 AM - 10:30 AM Added Mass Of Human Swimmers: A Comparison Of Computational And Experimental Results

Per-Ludvik Kjendlie<sup>1</sup>, Fransisco Alves<sup>2</sup>, Andreas Berthelsen<sup>3</sup>, Cecilie Caspersen<sup>1</sup>, Mari Eik<sup>1</sup>, Daniel Marinho<sup>4</sup>, Csaba Pákozdi<sup>3</sup>, Abel Rouboa<sup>4</sup>, Antonio Jose Silva<sup>4</sup>, João-Paulo Vilas-Boas<sup>5</sup>. <sup>1</sup>Norwegian School of Sport Sciences, OSLO, Norway. <sup>2</sup>Technical University of Lisbon, Lisbon, Portugal. <sup>3</sup>Norwegian Marine Technology Research Institute, Trondheim, Norway. <sup>4</sup>University of Tras-os-Montes and Alto Douro, Vila Real, Portugal.

<sup>5</sup>University of Porto, Porto, Portugal.  
Email: per-ludvik.kjendlie@nih.no  
(No relationships reported)

Added mass is the amount of water a swimmer has to accelerate in addition to his body during changes in velocity. It is an important concept in determining the total body drag of swimmers during unsteady motion, as well as propulsive forces acting from accelerating hands and feet.

**PURPOSE:** The aim of this study was to find added mass of a human body using experimental and computational methods, and to compare the two methods.

**METHODS:** For one male adult subject, added mass was found experimentally using vertical oscillations. The subject were connected to a 2.8m long bar with handles, attached with springs (stiffness  $k=318\text{N/m}$ ) and a force cell. By oscillating this system vertically and registering the time period of oscillations it is possible to find the added mass of the swimmer, given the known masses of the bar and swimmer. Additionally the added mass was found using computational fluid dynamics (CFD) calculations. The body surface and volumes of the subject was determined using a computer tomography scan technique. The 3D body- and water model was created using the Gambit software (Fluent®, Inc. Hannover, USA) producing a hybrid mesh of 900 million cells for use in the CFD calculations. A finite volume model including a standard k-epsilon turbulence model was used to solve the Navier-Stokes equations of fluid flow using the Fluent Software (Fluent®, Inc. Hannover, USA). The acceleration of the water flow was set to  $a=0.4\text{ m}\cdot\text{s}^{-2}$ , and the inlet velocities were 0.1, 0.5, 1.0, 1.5, 2.0, 2.5  $\text{m}\cdot\text{s}^{-2}$ .

**RESULTS:** For the male swimmer, with a body mass (BM) of 81.6 kg, and a characteristic length of 2.39m (reaching height) the added mass was found experimentally to be 21.6kg, and using CFD to be 26.6 $\pm$ 4.3 kg.

**CONCLUSIONS:** The added mass of male humans seems to be in the proximity of 26.5 or 32.5% of BM using oscillation or CFD measurements respectively. There is a relatively close agreement between AM found using experimental and CFD methods. The different AM values found using these two methods is most probably due to the subject's experimental conditions during oscillations involve small body posture movements, whereas with the CFD model the body are completely stiff. The results indicate that CFD can be used to estimate the added mass of human swimmers. For the future, unsteady effects of human swimming hydrodynamics should be investigated.

---

**2562 Board #207 May 29 9:00 AM - 10:30 AM**  
**Front Crawl Intracyclic Velocity Variation Of The Hip In Swimmers With Down Syndrome**

Pedro Figueiredo, Inês Aleixo, António Castro, João Brito, Rui Corredeira, Maria A. Silva, Ricardo J. Fernandes. *Faculty of Sport, University of Porto, Portugal, Porto, Portugal.*  
Email: spafg@vodafone.pt  
(No relationships reported)

Intracyclic velocity variations (IVV) are considered an inverse indicator of swimming efficiency and have been widely used to evaluate high swimming performances. However, there is a lack of kinematical studies with disable competitive swimmers, which do not allow coaches to have more objective data to help their training process.

**PURPOSE:** To determine the front crawl IVV of the hip in swimmers with Down syndrome, comparing their IVV when breathing to their preferred and non preferred side.

**METHODS:** 6 swimmers (20 $\pm$ 5 yrs, 58 $\pm$ 14 kg, 154 $\pm$ 12 cm and 16 $\pm$ 12 %fat mass) from the Down Syndrome National Portuguese Team performed 2 repetitions of 20 m all-out in front crawl, one time using their preferred side breathing and other time breathing to their non preferred side. Swimmers were monitored while passing through a pre-calibrated space. Two stationary and synchronized below and above the water cameras recorded the tests at 50 Hz, being analyzed one complete stroke cycle. After digitizing and 2D reconstruction of the hip, IVV of horizontal velocity (v) was assessed through the calculation of the variation coefficient and was also expressed as a percentage of the horizontal v (%IVV). Mann-Whitney test was used to compare the different types of breathing for stroke length (SL), stroke rate (SR), v, IVV and %IVV.

**RESULTS:** Table 1 presents the values of the referred parameters during one complete stroke cycle when breathing to the subject's preferred and non preferred sides, being observed no differences.

**CONCLUSIONS:** As expected the IVV were higher than in swimmers without disability. Additionally, it seems that swimmers need to adapt their SR to maintain IVV. So, the obtained %IVV values allow to state that if the sample was higher differences may occurred.

Table 1. Mean  $\pm$  SD values of v, SL, SR, IVV and %IVV when breathing to non and preferred sides

	Preferred side	Non preferred side
v (m/s)	0.89 $\pm$ 0.13	0.85 $\pm$ 0.18
SL (m/cycle)	1.35 $\pm$ 0.10	1.37 $\pm$ 0.13
SR (cycles/min)	39.37 $\pm$ 3.98	36.98 $\pm$ 5.59
IVV	0.23 $\pm$ 0.05	0.25 $\pm$ 0.06
%IVV	26.89 $\pm$ 6.79	33.22 $\pm$ 1.29

**2563 Board #208 May 29 9:00 AM - 10:30 AM**  
**Influence Of Foot Posture On Ground Reaction Forces**

Bryan Jackson<sup>1</sup>, James A. Yaggie<sup>2</sup>, Brian Campbell<sup>3</sup>. <sup>1</sup>Wofford College, Spartanburg, SC. <sup>2</sup>University of Findlay, Findlay, OH. <sup>3</sup>Bowling Green State University, Bowling Green, OH.  
Email: jacksonbg@wofford.edu  
(No relationships reported)

Most running injuries are related to compounded stresses that occur at the lower extremities (LE). Previous literature has indicated runners with extremes in arch height (pes planus or pes cavus) are more susceptible to injuries than those with average arch structure. Although the relationship of LE stress and injury is well documented, little research describing attenuation of vertical ground reaction forces (vGRF) related to arch height exists in the current literature.

**PURPOSE:** To examine the relationship between vGRF and the change in arch height in load bearing conditions, during running bouts.

**METHODS:** Eighteen healthy female college aged Division I cross country runners (mean age = 20  $\pm$  1.7 yrs; ht = 164.4 cm  $\pm$  6.7 wt = 54.4 kg  $\pm$  5.4) participated in 5 - 7 running trials on a force plate (AMTI, OR-6, Watertown, MA) instrumented runway sampling vGRF data in body weights (BW) at 960 Hz. Measurement of navicular height and truncated foot length were taken in non-weight bearing (NWB) and weight bearing (WB) conditions prior to the running bouts to determine the calculated arch index (CAI). CAI was compared to vGRF using pearson's correlation (SPSS, IL;  $\alpha=.05$ ). Linear regression was constructed to predict peak vGRF based on CAI ( $\alpha=.05$ ). Participants were also surveyed regarding history of LE pain and injury.

**RESULTS:** A significant negative correlation ( $r=-.567$ ,  $p=.012$ ) was reported when comparing CAI to vGRF. Linear regression indicated 33.2% of the variance observed in vGRF was explained by the decrease in CAI in the NWB and WB conditions.

**CONCLUSIONS:** The comparative negative correlation between CAI and vGRF indicates that individuals with a greater residual arch height in the NWB and WB conditions (greater

CAI) tend to exhibit lower vGRF during self paced running bouts. Anecdotally, those with low CAI, with less than 10% change in NWB to WB arch height, tended to have history of knee pain. These individuals also exhibited the highest amount of vGRF during running bouts. These data indicate that the calculation of CAI may predict a runner's ability to attenuate vGRF and lend insight into causation of LE injury.

**Comparison Of EMG Activity In Trunk Training Exercises And Baseball Pitching And Hitting**

Brian M. Campbell<sup>1</sup>, David Stodden<sup>2</sup>, Colton Omler<sup>1</sup>, Bruce Garba<sup>1</sup>. <sup>1</sup>Bowling Green State University, Bowling Green, OH. <sup>2</sup>Texas Tech University, Lubbock, TX.

Email: campbeb@bgsu.edu

(No relationships reported)

Trunk training exercises are foundational for baseball strength and conditioning programs. While previous EMG research has documented the role of trunk musculature in various trunk exercises, no research has examined the relationship between EMG levels in trunk training exercises and baseball pitching and batting performance.

**PURPOSE:** To examine EMG activity of select trunk musculature during specific trunk training exercises and compare it to the EMG activity during baseball batting and pitching.

**METHODS:** Ten male subjects from a mid-western University Club baseball team participated in this study. Bilateral EMG data was sampled from four superficial trunk muscles (upper rectus abdominus and external obliques) during four trunk exercises and five to seven pitching and or batting trials. The pitching motion was divided into four phases (Phase 1 - initiation of pitch to maximum stride knee kick height, Phase 2 - maximum stride leg knee height to stride foot contact (SFC), Phase 3 - SFC to ball release, and Phase 4 - ball release to .5 seconds after ball release). The batting motion was divided into two phases. Phase 1 was defined as the loading phase (initiation of backwards movement of the bat to initiation of forward movement of the bat). Phase 2 was defined from the initiation of forward movement until .5 seconds after forward movement. Mean EMG data from each muscle during each trunk exercise were presented as percentage EMG during each pitching and batting phases. Percentages less than 100 indicated the mean EMG elicited during the trunk exercises was less than what was elicited during pitching and batting phases.

**RESULTS:** Mean EMG levels during trunk exercises were lower than the mean EMG levels in phases 3 and 4 of the pitching motion and phase 2 of batting. Mean EMG of the trunk exercises was substantially higher than mean EMG in phases 1 and 2 of pitching and phase 1 of batting.

**CONCLUSIONS:** Phases 3 and 4 of the pitching motion and phase 2 of batting are the most explosive phases of each motion respectively. Thus, the trunk training exercises did not elicit EMG levels that would be sufficient to provide an appropriate training effect for strength and/or explosiveness in pitching and batting.

**2565 Board #210 May 29 9:00 AM - 10:30 AM**

**Comparison Of Peak Forces Associated With Six Common Martial Arts Striking Techniques**

Kristen Croxford, Shawn O. Henry. *Pacific University Oregon, Forest Grove, OR.*

(No relationships reported)

One of the primary purposes of strikes in martial arts is to impart maximal force to a target, thus harming the target or recipient of the strike. Although various strikes, such as the standard forefist punch, have been investigated from a force-producing perspective, no studies have directly compared the six upper-limb strikes included in this study.

**PURPOSE:** To compare peak forces associated with six common martial arts striking techniques - knife-hand, reverse knife-hand, elbow, reverse elbow, back-fist and fore-fist.

**METHODS:** Nineteen healthy adult participants (12 men and 7 women; age  $32.9 \pm 11.9$  yrs; body mass  $77.1 \pm 19.8$  kg) with current expertise and competence in martial arts were recruited. In random and repeated design, each participant executed fifteen strikes per arm per technique (90 strikes total each arm, rest periods allowed). The peak force (N) of each style of strike was assessed utilizing a pad-covered force transducer interfaced with a computerized data acquisition system.

**RESULTS:** One-way repeated measures ANOVA revealed significant differences amongst the six strikes ( $F_{5,18} = 34.56$ ,  $p < 0.01$ ). The ranking of strikes from the greatest peak force to least is; reverse elbow ( $1490.0 \pm 537.7$  N), elbow ( $1401.0 \pm 462.6$  N), fore-fist ( $1087.6 \pm 371.5$  N), back-fist ( $969.7 \pm 335.3$  N), knife-hand ( $906.4 \pm 324.6$  N), and reverse knife-hand ( $904.0 \pm 312.7$  N). Post-hoc tests showed no differences between the two elbow striking techniques; however, both elbow techniques had higher peak forces than any of the other four striking techniques. There were no differences between the other four strikes (back-fist, fore-fist, knife-hand, or reverse knife-hand).

**CONCLUSION:** With regard to peak force, elbow strikes are superior to the hand strikes compared in this study (back-fist, fore-fist, knife-hand, reverse knife-hand). However, peak force is only one variable to be considered when comparing strikes. Additional factors dictating the effectiveness of a particular strike technique include range, accuracy, applicable targets, and timing considerations.

**2566 Board #211 May 29 9:00 AM - 10:30 AM**

**Timing Of Upper Body Segmental And Joint Velocities In Skilled Male And Female Golfers**

Sean A. Horan, Justin J. Kavanagh, Kerrie Evans, Norman R. Morris. *Griffith University, Gold Coast, Australia.*

Email: s.horan@griffith.edu.au

(No relationships reported)

It is generally accepted that a precisely timed pattern of proximal-to-distal upper body motion facilitates large clubhead speeds. Furthermore, males and females exhibit different amplitudes of segmental motion during the golf swing. However, it is unknown if gender differences exist in the timing of upper body movements during the swing.

**PURPOSE:** To examine the timing of upper body segmental and joint velocities during the swing of skilled male and female golfers.

**METHODS:** Driver data for 19 M ( $26 \pm 7$  yr) and 19 F ( $25 \pm 7$  yr) golfers with handicaps under 4 were collected using a motion analysis system. 3D peak angular velocities were calculated for the pelvis and thorax segments, and the elbow and wrist joints. From this data, the angular velocity which was greatest (i.e. flex-extension, abd-adduction, or axial rotation angular velocity) was determined and then the timing of this peak velocity was calculated. The maximum differential and timing of the maximum differential, between pelvis and thorax axial rotation angles projected onto the transverse plane (i.e. X-Factor) was also calculated. For all data, the timing of kinematic events was determined as a percentage of the downswing cycle (top of backswing to ball contact).

**RESULTS:** Clubhead speed was significantly greater for males,  $48 \pm 2$  m.s<sup>-1</sup>, compared to females,  $40 \pm 2$  m.s<sup>-1</sup> ( $p < .01$ ). No gender differences were identified for the timing of upper body segmental and joint velocities (Table 1), peak X-factor (M  $54 \pm 10^\circ$ , F  $55 \pm 9^\circ$ ) or the period in the downswing cycle where peak X-factor occurred (M  $51 \pm 6\%$ , F  $54 \pm 7\%$ ).

**CONCLUSIONS:** There was no gender difference in timing. Furthermore, the sequencing of events for males and females was not in an explicit proximal-to-distal pattern.

Table 1. Timing of upper body and clubhead peak velocities (% of downswing)

	Male	Female	Movement
Pelvis	71 $\pm$ 5	70 $\pm$ 8	Axial rot
Thorax	85 $\pm$ 18	81 $\pm$ 15	Axial rot
Right elbow	95 $\pm$ 4	97 $\pm$ 4	Ext
Left elbow	72 $\pm$ 20	78 $\pm$ 21	Ext

Right wrist	84 ± 7	83 ± 10	Flex
Left wrist	89 ± 2	86 ± 5	Ext
Clubhead	98 ± 3	97 ± 3	-

**2567 Board #212 May 29 9:00 AM - 10:30 AM**  
**Kinematic And Kinetic Comparison Of Overhand And Underhand Pitching: Implications To Proximal-to-distal Sequencing**

John C. Garner, III<sup>1</sup>, Wendi H. Weimar<sup>2</sup>, Nels Madsen<sup>2</sup>. <sup>1</sup>University of Mississippi, University, MS. <sup>2</sup>Auburn University, Auburn, AL.

Email: jcgarnar@olemiss.edu

(No relationships reported)

Currently there is a wealth of information on the kinetics and kinematics of the overhand baseball pitch, but surprisingly little on the underhand softball pitch. Even more surprising is that these two pitching motions have received no direct study to analyze and compare the proximal-to-distal sequencing of both pitches.

**PURPOSE:** The purpose of this study was to investigate the interaction between adjacent segments in relation of the competing theories of proximal-to-distal sequencing as they function in an overhand baseball and underhand softball pitch.

**METHODS:** 5 Collegiate Varsity Softball Pitchers (ht: 1.73 + .06 m, mass: 69.99 + 13.95 kg) and 5 Collegiate Varsity Baseball Pitchers (ht: 1.83 + .07 m, mass: 87.27 + 6.09 kg) who signed an institutionally approved consent document were asked to throw 5 pitches at game speed from a simulated mound. The motions were captured using an integrated Motion Reality Inc. (Marietta, GA) motion capture and Noraxon (Scottsdale, AZ) EMG system. EMG sensors were placed on the area of greatest bulk of the proximal biceps brachii and proximal triceps brachii in order to analyze the activity of the musculature during each pitch. All pitches were captured, and the pitch with the highest ball velocity was used for analysis.

**RESULTS:** Velocity and acceleration (both linear and angular) followed the expected pattern of a proximal-to-distal sequence where the distal segment's (upper arm) maximum velocity is achieved at a point near the proximal segment's (lower arm and wrist) minimum velocity with concurrent appropriate changes in acceleration. The electromyographic results revealed analogous muscle activation, suggesting that both throwing techniques use the same mechanical system to maximize the velocity of the more distal segment: an external stopping force on the proximal segment causing an inertial acceleration of the distal segment.

**CONCLUSIONS:** The results of this study confirmed the existence of proximal-to-distal sequencing in both throwing types and illustrated that both types can be theoretically categorized as an inertial acceleration of the distal segment. Additionally, the biceps activation in the underhand pitch is analogous to the triceps activation during the overhand pitch further supporting the inertial acceleration mechanism for both pitches.

**2568 Board #213 May 29 9:00 AM - 10:30 AM**  
**A Portable Instrumentation System To Evaluate Lower Extremity Athletic Performance And Injury Risk**

Eric C. Whittaker, David A. Hawkins. University of California, Davis, Davis, CA.

Email: whittaker.eric@gmail.com

(No relationships reported)

There is considerable interest in identifying the physical performance potential and injury susceptibility of athletes. However, performance screening and injury prevention guidelines are lacking due to a limited understanding of the interaction between biomechanical quantities, performance, and injury risk. Quantitative biomechanical assessments of athletes in-the-field is needed to test various theories regarding factors affecting performance and injury mechanisms.

**PURPOSE:** To develop a portable instrumentation system that can be used in-the-field to record biomechanical quantities believed to affect lower extremity athletic performance and injury risk.

**METHODS:** Biomechanical quantities of interest were selected from careful inspection of clinical and research literature and discussion with athletic trainers and coaches. The system to collect these quantities was developed using commercial and custom components. The design criteria for the system were that it: (1) sample the quantities of interest with sufficient speed and accuracy to allow useful biomechanical evaluation, (2) is portable, (3) have minimal learning curve for new researchers, and (4) allow an athlete to be tested within one hour. Bench and in-the-field tests were conducted to evaluate the system components and overall system performance.

**RESULTS:** Quantities of interest include: anthropometric measures, flexibility, absolute strengths and strength ratio of knee and ankle flexor/extensor muscles, movement kinematics, ground reaction forces, muscle activation, and reaction timing. The system consists of: a laptop computer, an analog to digital converter, a custom isometric strength testing fixture, a 60 Hz digital video camera, a force plate with portable ramp, a telemetered EMG system, and a cart. The accuracy of locating contrast markers was 1±1.8 mm for the camera positioned 3 m from the plane of motion. Ground reaction forces were accurate to within 1.1% of dynamic forces. System performance in the field included a ½ hour setup time and 2 testing stations, requiring 1 hour of testing per subject.

**CONCLUSIONS:** The portable system increases athlete accessibility and provides a unique tool for accurately collecting data relevant to athletic performance and injury risk.

**2569 Board #214 May 29 9:00 AM - 10:30 AM**  
**Relationship Between Crossbar Height Cleared And Approach Run Velocity For Non-elite And Elite Pole Vaulters**

B. Christina Kippenhan, Keith Knoke. Bemidji State University, Bemidji, MN.

(No relationships reported)

Research has shown a positive correlation between approach velocity ( $v_a$ ) and crossbar height cleared ( $h_c$ ) for elite (E) pole vaulters; and that the relationship between  $v_a$  and  $h_c$  for female (F) vaulters has shifted over the years - decreasing the contribution of  $v_a$  to  $h_c$  - approaching the relationship for males (M) (McGinnis, 2004). Little is known about this relationship for non-elite (NE) vaulters.

**PURPOSE:** To determine the relationship between  $v_a$  on  $h_c$  for NCAA Division II (Northern Sun Intercollegiate Conference - NSIC) vaulters; to determine if M-NE and F-NE vaulters show similar relationships; to compare the findings of this study to data of M-E and F-E vaulters by McGinnis (2004).

**METHODS:** The last 5 m of the approach run was recorded for vaulters in the 2005 NSIC Championships (9 F, 8 M). The best legal trial per subject was analyzed. Correlation and linear regression analysis determined the relationship between  $v_a$  and  $h_c$ . Stepwise multiple linear regression compared the relationships for the different groups.

**RESULTS:** The table summarizes the results. They show that a positive correlation between  $v_a$  and  $h_c$  also exists for NE vaulters. The regression lines for all groups but the F-NE were parallel to each other but not coincident. The F-NE line was not parallel to the F-E 1997-2003 and M-E lines but was not shown to differ from the lines of the other two groups.

**CONCLUSIONS:** For E and NE,  $h_c$  is significantly related to  $v_a$ . As the vaulters become technically more refined, the contribution of  $v_a$  to  $h_c$  decreases -same  $v_a$  leads to higher  $h_c$ . In contrast, for F-NE,  $v_a$  seems to play overall a lesser role -same increases in  $v_a$  lead to smaller increases in  $h_c$ .

## 2570 Board #215 May 29 9:00 AM - 10:30 AM Effect of Segmental Velocity Increments On Maximum Wheelchair Racing Speed

LI-SHAN CHANG<sup>1</sup>, Weerawat Limroongreungrat<sup>1</sup>, Yaping Zhong<sup>2</sup>, Yong Tai Wang, FACSM<sup>1</sup>. <sup>1</sup>GEORGIA STATE UNIVERSITY, ATLANTA, GA. <sup>2</sup>Shandong Sport University, Shandong, China.  
(No relationships reported)

**PURPOSE:** Biomechanical characteristics in wheelchair propulsion such as range of motions, segment velocities and accelerations, and pushrim forces and moments have been broadly documented; however, the effect of segmental velocities on wheelchair racing have not been investigated. This study was to determine the effect of linear segmental velocity increments of the upper extremity on the maximum wheel speed (MWS) in wheelchair racing.

**METHODS:** Seventeen elite international wheelchair racers with the mean age of  $30.3 \pm 7.0$  yrs, body mass  $57.5 \pm 10.2$  kg and wheelchair racing training  $8.9 \pm 6.6$  yrs served as participants. Reflective markers were placed on right 5th metacarpal head (hand), lateral styloid process (wrist), lateral epicondyle of the humerus (elbow) and acromion (shoulder), as well as the right wheel. Participants were filmed at 100Hz by a three-dimensional motion system while propelling their own racing wheelchairs on a training roller at their maximum speeds. After shoulder, elbow, wrist and hand linear velocities in the drive phase were calculated, linear segmental velocity increments were derived based on the difference of peak linear velocities between two adjacent joints, including shoulder-to-elbow (SE), elbow-to-wrist (EW) and wrist-to-hand (WH) velocity increments. A multiple linear regression was employed to determine the effect of each increment on the MWS.

**RESULTS:** Mean peak linear velocities were  $2.04 \pm 0.38$  m/s for the shoulder,  $5.14 \pm 0.83$  m/s for the elbow,  $6.26 \pm 1.15$  m/s for the wrist and  $7.53 \pm 1.03$  m/s for the hand. The mean MWS was  $9.14 \pm 1.72$  m/s. Peak linear velocities increased from proximal to distal joints, specifically from shoulder to the elbow (from 2.04 to 5.14 m/s). It was shown 87% of the variance of the MWS was accounted for by segmental velocity increments ( $P < 0.01$ ) with the greatest contribution from WH and the least contribution from EW ( $MWS = -21.92 + 1.67SE + 1.42EW + 2.02WH$ ).

**CONCLUSIONS:** It is speculated that increasing wrist linear velocity by performing more abduction/addition in the drive phase may improve the wheelchair racing speed.

Supported by the Roosevelt Warm Springs Institute for Rehabilitation, Warm Springs, GA

## 2571 Board #216 May 29 9:00 AM - 10:30 AM Intra-cyclic Stroke Parameter Changes Associated With Increased Speed In Competitive Front-crawl Swimming

John M. Barden<sup>1</sup>, Robert T. Kell<sup>2</sup>, Dylan Kobsar<sup>1</sup>. <sup>1</sup>University of Regina, Regina, SK, Canada. <sup>2</sup>University of Alberta, Camrose, AB, Canada. (Sponsor: Shanthi Johnson, FACSM)  
Email: john.barden@uregina.ca  
(No relationships reported)

Studies of stroke parameter relationships in swimming have shown that the basic strategy used by elite swimmers to increase speed is to increase stroke rate (SR) while attempting to maintain stroke length (SL). Recently, it has been shown that non-linear changes in SR and SL occur immediately after a swimmer reaches critical speed. The specific intra-cyclic mechanisms responsible for producing these changes, namely the duration of the propulsive and recovery phases of the stroke cycle, have not been investigated.

**PURPOSE:** To determine temporal changes in the propulsion and recovery time associated with increased SR in front-crawl swimming.

**METHODS:** Eight elite competitive swimmers (6 female, 2 male;  $17.9 \pm 0.86$  yrs) performed a 4 x 200 m interval training set (60 s rest) in a 25 m pool according to target times that were based on a critical speed test (1 = submax. intensity, 2 = max. lactate steady state, 3 = critical speed, 4 = VO2 max.). Velocity, SR, SL, propulsion time and recovery time were recorded for each 25 m length of each 200 m repetition. The data were normalized (1st length %) to compare the relative stroke parameter changes between the 4 x 200s using repeated measures ANOVA.

**RESULTS:** As speed increased, SR increased significantly ( $p < 0.05$ ) for each repetition ( $+26.5 \pm 7.8\%$  from 1st to last repetition), whereas SL decreased significantly ( $p < 0.05$ ) for the 3rd and 4th repetitions ( $-2.6 \pm 1.6\%$  &  $-4.8 \pm 2.8\%$ , respectively). In addition, SR increased markedly during the 3rd (critical speed) 200 ( $+12.0\%$  vs. the previous increase of  $+3.4\%$ ). Changes in SR were associated with significant decreases ( $p < 0.01$ ) in the propulsion time for each repetition ( $-25.6 \pm 8.1\%$  from the 1st to 4th repetition) as well as the recovery time ( $p < 0.05$ ) for the 3rd and 4th repetitions ( $-6.9 \pm 4.9\%$  &  $-13.2 \pm 5.7\%$ , respectively). An asymmetric change in the stroke cycle was shown by a significant drop ( $p < 0.05$ ) in the propulsion/recovery ratio from the 1st to 4th repetition ( $-9.3 \pm 11.2\%$ ).

**CONCLUSION:** Progressive speed related increases in SR are associated with simultaneous decreases in the duration of the propulsion and recovery phases of the stroke cycle, such that propulsion time decreases more than recovery time. This suggests that pulling/pushing the arm through the water faster contributes more to the elevation of SR than increasing the tempo of the recovery.

## 2572 Board #217 May 29 9:00 AM - 10:30 AM Kinematic And Kinetic Comparison Of Running In A Neutral Cushioned Shoe And A Minimal Shoe

Richard W. Willy, Irene S. Davis, FACSM. University of Delaware, Newark, DE.  
Email: rwilly@udel.edu  
(No relationships reported)

Minimal shoes have been promoted as a means to reduce injury risk by mimicking barefoot running. Barefoot treadmill running has been associated with a reduced rearfoot strike pattern and decreased associated impact forces. Therefore, running in minimal shoes should result in a reduction in these variables compared to a standard running shoe.

**PURPOSE:** The purpose of this study was to determine if a minimal shoe reduces ground reaction forces and strike pattern compared to a standard running shoe.

**METHODS:** This is an ongoing study with 5 subjects examined so far. Subjects were male recreational runners, 24.4 years old  $\pm 2.7$ , running at least 7 miles per week ( $18.4 \pm 10.6$ ). Minimal shoe running was novel for these subjects. Nike Pegasus shoes (Beaverton, Ore) served as the neutral cushioned shoe (NS). Nike Free 3.0 shoes were utilized for the minimal shoe condition (MS). A triaxial accelerometer (PCB Piezotronics, Depew, NY) measured tibial shock. Subjects were tested while running 3.35 m/s on an instrumented treadmill (AMTI, Watertown, Mass). Data were collected after 10 minutes for each shoe condition. Forceplate and accelerometry data were sampled at 1000 Hz. Kinematic data (Vicon, Oxford, UK) were collected at 200 Hz. Variables of interest were average vertical load rate (AVLR), tibial shock (TS), leg stiffness, ankle dorsiflexion at heel strike (DF), and horizontal angle of the foot at

heelstrike in the lab coordinate system (FLAB).

**RESULTS:** All variables of interest were surprisingly greater in the MS condition.

Variable	NS	MS	Difference	Percent Difference (%)
TS (g's)	4.5 (0.6)	5.8(1.5)	+1.3	+28.9%
AVLR(BW/S)	53.7(14.9)	85.6(24.0)	+31.9	+59.4%
Stiffness(kN/m)	11.3(1.3)	11.9(1.4)	+0.6	+5.3%
DF(deg)	2.2(4.3)	6.4(3.3)	+4.2	+190.9%
FLAB(deg)	9.6(6.6)	12.0(3.8)	+2.4	+25.0%

**CONCLUSIONS:** Novel minimal shoe running appeared to have a detrimental effect on the loading variables. Adaptation to minimal shoe running may occur with time. A study of runners who habitually run in minimal shoes is underway.

**2573 Board #218 May 29 9:00 AM - 10:30 AM**  
**Influence Of Ankle Taping On The Kinetics Of A Lateral Jump**

Adam C. Knight<sup>1</sup>, Justin F. Shroyer<sup>2</sup>, Andrea M. Sumner<sup>2</sup>, Joanna E. Booker<sup>2</sup>, Wendi H. Weimar<sup>2</sup>. <sup>1</sup>Mississippi State University, Mississippi State, MS. <sup>2</sup>Auburn University, Auburn, AL. (Sponsor: David Pascoe, FACSM)  
(No relationships reported)

The lateral ankle sprain is the most frequently occurring injury in athletics and often occurs during foot placement when landing from a jump. Ankle taping is frequently used to prevent ankle sprains but limited research has been conducted to determine the difference between different brands of tape.

**PURPOSE:** The purpose of this study was to investigate the influence of four different types of athletic tape on the medial/lateral component of the ground reaction force during a lateral jump. The tapes tested included two new types of adhesive tape developed by Cramer (Cramer Tape A and B), Coach Tape by Johnson and Johnson, and PowerTape by Andover.

**METHODS:** Thirty Three (19 F, 14 M) healthy participants (age=21.45, +1.57 years; mass 72.94 + 13.94 kg) were tested on four separate days. The peak medial/lateral component of the ground reaction force was recorded during the lateral jump using an AMTI force platform. The participants were randomly assigned to one of the 4 tape conditions each day until receiving each taping condition. A Certified Athletic Trainer (lead author) applied a closed basketweave tape procedure to both ankles. Foam prewrap was used as the underwrap, except when using the PowerTape, in which PowerFlex was used. The participants performed a lateral jump (to replicate a cutting maneuver) of 40 cm onto and off of the force platform, initiating the jump with the left leg, landing on the force platform on the right foot, and then jumping off the force platform with the right leg. The test was performed before ankle taping (pre-test), immediately after ankle taping (acute test), and after 30 minutes of walking (post-test). The data was analyzed with a 4 (ankle tape) x 3 (test number) ANOVA.

**RESULTS:** There was no significant interaction ( $p=.258$ ), and no significant main effects for the type of tape ( $p=.546$ ) or the test number ( $p=.643$ ).

**CONCLUSION:** Ankle taping should prevent ranges of motion that may lead to an ankle sprain without changing the kinetics of the activity. These results revealed that all four types of tape produced a similar medial/lateral force during the lateral jump. There was no change in this force after 30 minutes of physical activity for all four tape types. Future research should continue to measure the effects of these tapes on the kinetics and kinematics of other athletic maneuvers.

**2574 Board #219 May 29 9:00 AM - 10:30 AM**  
**Relationship Between Eccentric Knee Strength And Impact Force Attenuation In Drop Landing**

Jeremy A. Steeves, Songning Zhang, FACSM, John Dean, Michael Wortley, Julia Freedman, Clare E. Milner. *The University of Tennessee, Knoxville, TN.*  
Email: jsteeves@utk.edu  
(No relationships reported)

Skeletal muscle is a major active mechanism of impact force attenuation in human movement. During the landing phase impact attenuation is achieved through eccentric contraction of the muscles of the lower extremity. However, few studies have investigated the effects of knee strength, especially eccentric strength, on impact attenuation during landing.

**PURPOSE:** To examine effects of knee eccentric strength on impact force attenuation during drop landing.

**METHODS:** Seven NCAA DI football athletes (TRAINED) and 7 recreationally active students (REC) with limited sports training participated in this study. Isokinetic testing of the knee extensor and flexor torques was performed concentrically at 60 and 180°·sec<sup>-1</sup> and eccentrically at 60°·sec<sup>-1</sup>. Each subject performed 5 drop landings from each of 3 heights of 40, 60cm and 100% of each individual's maximum jump height (100%MJH) with simultaneous recording of 3D kinematics and ground reaction force (GRF) sampled at 240 Hz and 1200 Hz, respectively. The peak torque variables were evaluated using a mixed-design 2 x 2 (group x speed). Selected peak GRF and kinematic variables were examined using a 2 x 2 (group x height) ANOVA for 40 and 60 cm height conditions and an independent samples t-test for 100%MJH ( $p < 0.05$ ).

**RESULTS:** The TRAINED had greater concentric strength, vertical jump height, but no significant differences existed in the eccentric strength (336 vs 340 N.m/kg) between the groups. The TRAINED had marginally greater peak GRFs (2.7 & 3.5 BW vs 2.0 & 2.7 BW for 40 and 60 cm,  $p=0.051$ ) and significantly less time to the peak (0.048 & 0.043 s vs 0.060 & 0.053 compared to the REC in drop landing. The TRAINED used less but non-significant knee flexion range of motion (-60.7 & -54.1 ° vs -62.7 & -69.6 °) during drop landing than the REC. There were high, positive and significant correlations between the peak eccentric knee extensor torque and time to the first and second peak GRF.

**CONCLUSION:** Despite training the results did not find any significant differences in eccentric strength of the TRAINED subjects in comparison to their REC counterparts. They adopted a stiffer landing strategy to effectively deal with high impact loading during landing. Future research is warranted in investigating impact attenuation in landing of participants with significantly different eccentric strength.

**Kinematics Differences Among Elite, Subelite And Amateur Sprinters**

Giorgos Paradis<sup>1</sup>, Carlton Cooke<sup>2</sup>, Athanasios Bissas<sup>2</sup>, Elias Zacharogiannis<sup>1</sup>, Athanasia Smirniotou<sup>1</sup>. <sup>1</sup>University of Athens, Athens, Greece. <sup>2</sup>Leeds Metropolitan University, Leeds, United Kingdom.  
Email: gparadi@phed.uoa.gr  
(No relationships reported)

Sprinting ability is an important parameter affecting primarily the outcome in many different sports. However, there are different views in the literature regarding the main factor which affect the maximum running velocity. In order to understand the kinematics of sprint running, a comparison of different levels of sprinting performance is required.

**PURPOSE:** Aim of this study was to compare the kinematic characteristics among elite, subelite and amateur sprinters.

**METHODS:** Thirty males participated in this study (age  $24.5 \pm 3.55$  years, mass  $74.8 \pm 6.20$  kg, height  $1.78 \pm 0.02$  m), where all subjects were active sprinters and their mean maximum running speed was  $8.82 \pm 0.64$  m·s<sup>-1</sup>. Testing was employed to evaluate the differences among the three levels of sprinters on the kinematic characteristics of 35 m maximal sprint running. A Kodak EktaPro 1000 high speed video camera was used to collect video recordings of the sagittal plane of a full stride (two consecutive steps) of all three maximal sprint runs, sampling at 250 Hz. Filming was performed with the camera placed at the 35 m distance and 10 m from the performance plane such that its optical axis was approximately horizontal, forming an angle of 90° with the horizontal plane of running. Contact time, flight time, and maximal running speed were calculated according to methods reported previously (Paradisi & Cooke, 2006).

**RESULTS:** The maximum running velocity the step length and step rate for elite sprinters were  $9.67 \pm 0.25$  m s<sup>-1</sup>,  $2.19 \pm 0.06$  m and  $4.42 \pm 0.04$  Hz respectively, for subelite sprinters were  $9.07 \pm 0.10$  m s<sup>-1</sup>,  $2.08 \pm 0.10$  m and  $4.39 \pm 0.20$  Hz respectively and for amateur sprinters were  $8.52 \pm 0.42$  m s<sup>-1</sup>,  $2.08 \pm 0.10$  m and  $4.11 \pm 0.33$  Hz respectively. The maximum running velocity for elite sprinters was significantly different ( $F = 21.765$ ,  $P < 0.05$ ) from that of subelite (6.2%) and amateur (11.6%) sprinters, the step length for elite sprinters was significantly different ( $F = 6.538$ ,  $P < 0.05$ ) from that of subelite (5.3%) sprinters and the step rate for elite sprinters was significantly different ( $F = 8.620$ ,  $P < 0.05$ ) from that of amateur (6.9%) sprinters.

**DISCUSSION:** These data indicate that the step rate distinguishes the elite from the subelite sprinters where as the main difference between the elite and the amateur sprinters was the step length.

#### **Effect Of Stress On Salivary Cortisol Levels Of Top Ranking Brazilian Wrestlers.**

Birgit Keller, Ricardo W. Coelho, Flávia B. Justus, Rubens Tempiski. *Federal University of Paraná State, Curitiba, Brazil.*

Email: birgit@indailyfitness.com.br

(No relationships reported)

**PURPOSE:** The aim of this study was two fold, first to investigate the effect of basal, pre competitive and post competitive stress on salivary cortisol levels of top ranking adult Brazilian wrestlers. Second, investigate the correlations power among three different stress measures (Perceived Stress, salivary cortisol and Physiological Stress Reaction).

**METHODS:** The investigation followed the quasi-experimental design with repetitive measures. The subjects (n=16) were top ranked male wrestlers, age ranging from 18 to 30 years old (M= 23.58, SD=3.20). All of them represent the Brazilian team in international competitions. Salivary cortisol was collected in three different situations (basal, pre and post-competition). The physiological stress reaction and perceived stress scores were collected prior competition just before warm up. The data was analyzed by ANOVA with repetitive measures by Pearson and Spearman's Rho correlation at a significant level of  $p < .05$ .

**RESULTS:** The ANOVA for salivary cortisol concentration demonstrated significant main effect on basal, pre and pos competition  $F(1, 16) = 160.46$ ,  $p < .001$  and the Post Hoc results indicated that the salivary cortisol concentration was much greater in the post-competitive than pre-competitive and basal measures. The findings of Spearman's Rho and Pearson correlation demonstrated that there was no significant correlation at  $p < .05$  level among all measure.

**CONCLUSIONS:** Salivary cortisol concentration increase according to exercise intensity because the higher is the mental and physiological effort higher would be the glucogenesis. The validity of using Perceived Stress Inventory and Physiological Stress Reaction Inventory in a competitive setting is questionable. They probably are measuring different constructs but not competitive stress. This suggests that they were stressed but did not perceive as it is. The wrestlers possess a great deal of cortisol concentration resistance in stress situation. This means that even when they are in a situation of stress they don't perceived or feel the physiological effects of it or they can control very well even in high stressful situation.

### **2577 Board #222 May 29 8:00 AM - 9:30 AM**

#### **Effect Of Multi-modal Imagery Intervention On Pre-competitive Anxiety And Stress Levels In Elite Tennis Players**

Ricardo W. Coelho, Birgit Keller, Flávia B. Justus, Rubens Tempiski. *Federal University of Parana State, Curitiba, Brazil.*

Email: coelhohorcardo@ufpr.br

(No relationships reported)

**PURPOSE:** Effect of multi-modal imagery on anxiety and perceived stress levels in tennis players.

**METHODS:** The quasi-experimental design included pre- and post-treatment test subjects and a control group. Male tennis players (n=49) ranging in age from 16 to 18 years old (M=16.96, SD= 0.82) were divided into two groups: (1) a treatment multi-modal imagery group and (2) a placebo imagery group used as the control group. The 27-item Competitive State Anxiety Inventory (CSAI-2) was used to assess anxiety and the Perceived Stress Scale (PSS10) to assess stress. The treatment involved a multi-modal (relaxation, imagery and behavior modeling video) intervention conducted three times per week for 25 minutes after ordinary technical and physical practice for a period of 9 weeks between tournaments. A 2x2 multifactor analysis of variance (MANOVA; pre- and post-treatment, control and experimental groups) was used to analyze the main effect among variables at a significance level of  $p < .05$ .

**RESULTS:** Multifactor analysis of variance testing of perceived stress and anxiety subscales showed a main effect for control vs. experimental, Wilks'  $\lambda = 1.63$ ,  $F(4, 91) = 37.051$ ,  $p < .01$ , pre- vs. post-treatment, Wilks'  $\lambda = 1.26$ ,  $F(4, 91) = 28.65$ ,  $p < .01$ , and interaction between control vs. experimental and pre- vs. post-treatment groups Wilks'  $\lambda = 1.44$ ,  $F(4, 91) = 32.68$ ,  $p < .01$ . Univariate analysis revealed a significant main effect for perceived stress, cognitive anxiety and self-confidence at  $p < .05$ . There was no significant effect for somatic. ANOVA also revealed significant interaction effects for perceived stress  $F(1, 94) = 6.87$ ,  $p < .05$ , cognitive anxiety  $F(1, 94) = 4.42$ ,  $p < .05$ , and self-confidence  $F(1, 94) = 5.07$ ,  $p < .05$ . However, the interaction was not significant for somatic anxiety  $F(1, 94) = 0.78$ ,  $p > .05$ .

**CONCLUSIONS:** The results for stress and two anxiety subscales (cognitive anxiety and self-confidence) indicate that multi-modal imagery intervention represents a useful tool to build self-confidence and to lower cognitive anxiety and perceived stress levels in tennis players. These findings are in accordance with previous studies in the area of physiotherapy and medicine that concluded that imagery is an efficient psychological intervention to control anxiety and stress in many disturbing situations.

### **2578 Board #223 May 29 8:00 AM - 9:30 AM**

#### **Link Between Psychological Resilience And Dehydroepiandrosterone Sulfate Against Competition Outcome In Golfers**

Shu-Man Chen<sup>1</sup>, Mei-Chih Chen<sup>2</sup>, Kun-Ning Chen<sup>2</sup>, Chia-Hua Kuo<sup>2</sup>, John L. Ivy, FACSM<sup>3</sup>. <sup>1</sup>Committee for General Studies, Shih Hsin University, Taipei, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>3</sup>Univeristy of Texas at Austin, Austin, TX. (Sponsor: John L Ivy, FACSM)

Email: chenshuman@hotmail.com

(No relationships reported)

The neurosteroid dehydroepiandrosterone sulfate (DHEA-S) has been implicated to play a role in stress coping and recovery. The role of DHEA-S in the mood adjustment against

negative outcome for athletic competition has not previously been investigated in athletes.

**PURPOSE:** To determine the link between mood adjustment and circulating DHEA-S level following a competition for elite golfers.

**METHODS:** 14 elite golfers participated in a major national golf tournament, were subsequently divided into two groups according to their competition outcomes: made the cut (N= 8) and failed (N=6) groups. Profile of Mood States (POMS) inventory and plasma concentrations of DHEA-S and cortisol were measured 1 day before beginning of competition (baseline) and 1, 3, 5 days after their final competitions, in the morning (0800-0830) under fasted condition.

**RESULTS:** Total mood disturbance scores and DHEA-S were not changed for the made the cut group throughout the entire observation period. DHEA-S for the failed group was significantly dropped below baseline on day 1 and remained lower for 5 days. Depression subscale of POMS for the failed group was increased only on day 1 post-competition, reflecting a situational reaction on the event. Cortisol for the made the cut group was significantly dropped only on day 1 after competition and no change was observed for the failed group.

**CONCLUSIONS:** Although the post-competition overall mood state was well-maintained for those golfers who received negative competition outcome, plasma DHEA-S concentration was declined for 5 days, suggesting its role in the coping mechanism against psychological challenge.

**The Effect Of A Competitive Collegiate Basketball Season On Recovery-stress Scores**

James McMillan, Jonathan Metzler, Matthew Lee, Katie Forehand, Stephen Rossi. *Georgia Southern University, Statesboro, GA.* (Sponsor: Jeff Chandler, FACSM)

Email: jmcmillan@georgiasouthern.edu

(No relationships reported)

Heavy training and competition requires adequate rest and recovery to ensure optimal performance and training. Recovery-stress scores have been suggested as a possible tool to assess recovery from training and competition.

**PURPOSE:** The aim of the present study was to observe the influence of a competitive season on Recovery-Stress for Athletics (RESTQ-Sport 76) scores in college women basketball players.

**METHODS:** RESTQ-Sport 76 scores were collected approximately monthly (T1 - T3) during the competitive season from twelve NCAA Division I women varsity basketball players. Subjects were instructed on the proper technique for answering the questionnaire at each collection time point. Additionally athletes were asked to give a RPE score (1-10 scale) at the conclusion of each conditioning session, practice, and game. This RPE score was multiplied times the number of minutes each athlete participated to yield an estimate of accumulative physical exertion (RPE-minutes). RPE-minutes were averaged for all athletes for the three days prior to each data point (to support the directions for taking the RestQ, i.e. in the past three days).

**RESULTS:** Repeated measures ANOVA failed to reveal significant differences ( $p > 0.05$ ) in mean scores of five scales: physical recovery, general stress, general well-being, emotional exhaustion, and being in shape.

**CONCLUSIONS:** Analysis of RestQ-Sport 76 scores failed to reveal any significant differences among the five scales examined. The scores were relatively stable for each scale with no more than a 0.5 unit change across the three time periods. The average RPE-minutes for the three days prior to each data collection point supported the changes in the scales examined. The results of this study support the use of the RESTQ-Sport 76 to monitor athletes during a competitive season.

**Psychomotor Speed As Marker For Overreaching In Young Elite Soccer Players**

Michel S. Brink<sup>1</sup>, Chris Visscher<sup>1</sup>, Sandor L. Schmikli<sup>2</sup>, Romain Meeusen, FACSM<sup>3</sup>, Koen A.P.M. Lemmink<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, University of Groningen, Groningen, Netherlands. <sup>2</sup>Rudolf Magnus Institute of Neuroscience, University Medical Center Utrecht, Utrecht, Netherlands. <sup>3</sup>Vrije Universiteit Brussel, Brussel, Belgium.

Email: m.s.brink@med.umcg.nl

(No relationships reported)

Psychomotor slowness has recently been introduced as marker for functional and nonfunctional overreaching in sport. Since overreaching is characterized by sport-specific performance decrement (PD), research is needed that relates psychomotor speed to PD. Furthermore, the effect of exercise should be known to verify if such a tool would be suitable for sport practice. Up to now, research has focused on individual sports. However, it can be argued that ball team sport athletes differ in terms of information processing and motor action.

**PURPOSE:** To investigate if psychomotor speed before and after maximal exercise is a useful tool to classify young elite soccer players with and without PD.

**METHODS:** Eleven soccer players with PD of four up to eight weeks and eight controls (mean  $\pm$  SD: Age (years)  $16 \pm 1$ , Height (cm)  $177.3 \pm 5.64$ , Weight (kg)  $69.9 \pm 5.96$ ) were invited to the laboratory. These players were selected out of 94 players who performed monthly submaximal Interval Shuttle Run Tests. Subjects with a heart rate increase  $> 4 \text{ b} \cdot \text{min}^{-1}$  were classified as players with PD. Prior to participation, a sports physician screened all subjects to exclude well-known causes of PD. Subsequently, all players executed the Finger Precuing Task before and after a maximal exercise test on a treadmill.

**RESULTS:** No significant differences were found in mean time to exhaustion and maximal heart rate during the maximal exercise test in the PD group ( $18:01 \pm 2:22 \text{ (min)}$ ),  $190 \pm 11 \text{ b} \cdot \text{min}^{-1}$ ) and the control group ( $17:31 \pm 2:22 \text{ (min)}$ ,  $198 \pm 6 \text{ b} \cdot \text{min}^{-1}$ ). An ANOVA for repeated measures revealed shorter reaction time post compared to pre exercise (Reaction time (ms)  $444.18 \pm 13.27$  vs.  $406.68 \pm 12.32$ ,  $p < .05$ ). No between-subject effect was found (PD group:  $424.91 \pm 15.32$  vs. control:  $421.39 \pm 17.97$ ).

**CONCLUSIONS:** The results demonstrate no differences in reaction time before and after maximal exercise between soccer players with and without PD. This makes psychomotor speed as marker for overreaching in soccer players questionable. It might be that a more sport-specific reaction time task is required. Since in this study soccer players had relatively short-term PD, further research is needed that relates psychomotor speed to long-term PD.

(No relationships reported)

Each year high school athletes experience 2 million injuries, associated with half a million doctor visits and 30,000 hospitalizations. In general female athletes experience more injuries than males, when balanced for playing time and conditions. Reducing injuries primarily relies on pre-participation screening and avoiding harmful training and playing practices. Other existing strategies to reduce injuries involve specific neuromuscular training. Injury reduction efforts fail to incorporate upstream lifestyle habits and psychological dimensions that might impact injury rate. Previously, we found a high school sport team-based curriculum that deterred disordered eating among female athletes also reduced self-reported injuries ( $p < 0.05$ ) (Arch Pediatr Adolesc Med 2004;158:1043-9). That curriculum focused on lifestyle, psychological and social influences, which suggested relationships among those factors and injury rates.

**PURPOSE:** Examine correlates of self-reported injuries to establish lifestyle and psychological dimensions of a comprehensive model of sport injuries among female high

school athletes.

**METHODS:** 1668 female high school athletes began the described intervention study (mean age 15 years primarily [90.5%] White), and reported data are from the baseline survey assessment of intervention and control participants. At baseline 70% reported no injuries preventing training in the preceding 2 months, 29% 1 or 2 injuries and 1% 3 or more injuries. Self-reported injuries were related to lifestyle and psychological survey constructs.

**RESULTS:** Those reporting injuries had stronger intentions to engage in unhealthy weight loss behaviors ( $p < 0.05$ ), had greater alcohol use in the last 3-months ( $p < 0.05$ ), were more likely to be risk takers ( $p < 0.05$ ) and had greater desire to do things perfectly ( $p < 0.001$ ).

**CONCLUSIONS:** When assessed as single factors, other investigators have reported that psychological and lifestyle dimensions are correlates of sport injury. Our findings support a broader injury model and suggest that a sport team-based health promotion program to impact lifestyle and psychological constructs could reduce sport-related injuries among young female athletes.

**Athletes' Adherence To Injury Rehabilitation: A Test Of Self-determination Theory**

Shauna M. Hoff, James R. Whitehead, FACSM, Ronald H. Brinkert, Sandra E. Short. *University of ND, Grand Forks, ND.*  
(No relationships reported)

Athletes' recovery from injury largely depends on their adherence to the rehabilitation programs provided by athletic trainers.

**PURPOSE:** This study examined adherence versus non-adherence of collegiate athletes to musculoskeletal injury rehabilitation based on their motivational orientation and social motivational climate. Specifically, Self-Determination Theory (SDT) was used as a Meta-theory to guide an investigation of how athletes' perceptions of autonomy support and needs satisfaction predict their completion of rehabilitation following an injury.

**METHODS:** A total of 89 inter-collegiate NCAA Div. I/II athletes representing 15 teams provided data. The participants were classified *a priori* as adherent or non-adherent in completing rehabilitation (based on an operational definition) by the Certified Athletic Trainers working with their individual sports. Those identified as adherers or non-adherers were then invited to complete questionnaires designed to examine their perceptions of trainer competence, autonomy support, and basic needs satisfaction (autonomy, relatedness, and competence), as they relate to motivation to complete rehabilitation for injuries.

**RESULTS:** Discriminant analysis failed to distinguish between adherers and non-adherers on the basis of the motivational variables. However, hierarchical regression showed that when their athletic trainer satisfied their basic psychological needs, and when their perception of autonomy was Supported by their coaches and team peers, they felt more willing to complete rehabilitation ( $R^2 = .41$ ).

**CONCLUSIONS:** While the profile of SDT variables did not statistically discriminate between adherers vs. non-adherers, the findings partially supported SDT in that participants were more willing to seek treatment when their basic psychological needs were satisfied, and when they received autonomy support from coaches and team mates.

**Illness Perceptions Of Injured Athletes: Useful In Therapy?**

Cornelis P. van Wilgen<sup>1</sup>, Ad A. Kaptein<sup>2</sup>, Michel S. Brink<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, University of Groningen, Groningen, Netherlands.  
<sup>2</sup>Leiden University Medical Center, Leiden, Netherlands. (Sponsor: W van Mechelen, FACSM)  
Email: c.p.van.wilgen@sport.umcg.nl  
(No relationships reported)

The prevalence of injuries in sports is high. The duration of the injury and their impact is not only determined by the injury itself, but also by cognitive and behavioral influences. In this study Leventhal's Common Sense Model was used as theoretical framework.

**PURPOSE:** To examine illness perceptions in athletes with sports injuries, and their relationship with mood states.

**METHODS:** Respondents were selected from a University outpatient Center for Sports Medicine, and several physiotherapy practices. From the recruited athletes socio-demographic characteristics, history of injury, and sports characteristics were assessed, together with the Illness Perception Questionnaire-Revised-Sports (IPQ-R-S), the Profile Of Mood States (POMS), and social support.

**RESULTS:** 151 questionnaires were distributed, 101 (67%) were returned by injured athletes of which 95 were included in the study. All Athletes were under medical care. Internal consistency of the IPQ-R-S was good (10 of 12 domains Cronbach's alpha  $> .75$ ). Injured athletes appeared to have a weak illness identity, associated with a high controllability; they perceived their injury as not chronic, with minor consequences. They reported understanding the nature of their injury according to the high illness coherence score and did not have a very emotional representation. Athletes, however, whose injury lasted for at least 6 months experienced their injury to be more chronic, expected less from treatments and experienced significantly less psychological attributions. Athletes with strong emotional representations had a worse psychological mood state. The experienced social support was high, and negatively related to an emotional representation.

**CONCLUSIONS:** The findings of this study suggest that the Common Sense Model is a useful framework to understand the beliefs and emotions regarding injured athletes. The model has to be adapted for sport-specific use to contribute to clinical consequences; clinicians can incorporate patients' views into their medical management in order to increase the concordance between patient's and clinician's perceptions of the injuries, thereby increasing chances of quick and uneventful recovery.

**2584 Board #229 May 29 8:00 AM - 9:30 AM**  
**Emotional Affects Following Sport Injury**

Alioune B. TOURE, Elisabeth SPITZ, Pr. *University of Metz, Metz, France.*  
Email: toure@pt.lu  
(No relationships reported)

It's now recognised fully that the contribution of physical activity to health and well-being is potentially significant.<sup>1</sup> In high level sports the health of an athlete is occasionally at threat. Physical injury can lead struggling athletes to a high level of anxiety or depression.

**PURPOSE:** To determine after a one year follow up the emotional state of an athlete during the injury and during the year following the injury.

**METHOD:** The athletes of Luxembourg elite divisions' teams were invited to participate in a research project concerning psychological adjustment to physical injuries. Data were gathered using self-report questionnaires. Of the questionnaires distributed ( $n = 750$ ) a total of 310 were returned, of which 262 contain sufficient data for analysis. Inclusion criteria is the athlete missing more than a week of practice;<sup>2</sup> were moderate or major injuries

**MEASURES:** The symptoms of anxiety and depression were assessed by using Hospital Anxiety and Depression Scale, HADS<sup>3</sup>. This 14 items scale is intended as a brief screening instrument for both anxiety and depression in non-psychiatric population.<sup>4</sup> Data analysis: A total of 262 athletes answered our questionnaire. Male,  $N = 198$ ; age  $24.2 \pm 6.5$ ; female  $N = 64$  age  $19.79 \pm 2.2$  From those athletes: 40.8% are uninjured; 42.4% had an injury last year, 16.5% are actually injured

**RESULTS:** More generally, uninjured athletes face a depressive episodes  $t = 1.82$ ;  $p < 0.05$ . Uninjured athlete show depressive affect, comparatively to those with recent injuries ( $t = 1.71$ ;  $p < 0.05$ ). The anxiety level is not significant whatever the time of the injury or gender of the athlete

**CONCLUSION:** In the early stage of rehabilitation, injured athletes may be cut-off from day-to-day coaching activities. Rehabilitation will often be repetitive separated from normal training. In the literature authors says that this isolation from other athletes could lead to depressive affects<sup>5</sup>. Competitive athletes are under the stress of a result, the stress of a potential

#### **Lipolytic Agent Increases Plasma Norepinephrine And Metabolic Rate With Minimal Increase In Hemodynamics**

Kelsey H. Fisher-Wellman, Kelley G. Hammond, Adrianna A. Weber, Bradford J. Cole, Brian K. Schilling, Richard J. Bloomer. *University of Memphis, Memphis, TN.* (Sponsor: Larry Weiss, FACSM, FACSM)

Email: kfshrwl@memphis.edu

( K.H. Fisher-Wellman, Vital Pharmaceuticals, Contracted Research.)

**PURPOSE:** Dietary supplements targeting fat loss and increased thermogenesis are prevalent within the sport nutrition market, often with little or no objective evidence for the claims being purported. Moreover, many such products act as stimulants, leading to increased hemodynamic responses. The purpose of this investigation was to determine the effects of a novel yohimbine containing dietary supplement on plasma catecholamine concentration, metabolic rate, and hemodynamics.

**METHODS:** Ten resistance trained men (age =  $27 \pm 4$  yrs; BMI =  $25 \pm 3$  kg  $\cdot$  m $^{-2}$ ; body fat =  $9 \pm 3\%$ ; mean  $\pm$  SD) were provided a lipolytic agent and a placebo, in a random order, double blind cross-over design, with one week separating conditions. Heart rate and blood pressure were recorded, and fasting blood samples were collected before, and at 30, 60, and 90 minutes post ingestion. Blood samples were assayed for epinephrine (EPI) and norepinephrine (NE) concentration following extraction using an ELISA procedure. For a measurement of metabolic rate using indirect calorimetry, gas samples were collected from subjects from 30-60 minutes post ingestion.

**RESULTS:** A condition main effect was noted for systolic blood pressure ( $p=0.04$ ), with values increasing from  $117 \pm 2$  mmHg to  $123 \pm 2$  mmHg with the lipolytic agent, while remaining unchanged for placebo. No other hemodynamic changes were noted ( $p>0.05$ ). Area under the curve for NE was 32.8% greater ( $p=0.03$ ) for the lipolytic agent ( $1332 \pm 128$  pg  $\cdot$  mL $^{-1}$   $\cdot$  90min $^{-1}$ ) compared to placebo ( $1003 \pm 133$  pg  $\cdot$  mL $^{-1}$   $\cdot$  90min $^{-1}$ ), and values peaked at 90 minutes post ingestion. No difference between conditions was noted for EPI ( $p>0.05$ ). Total kilocalorie expenditure during the 30 minute collection period was 29.6% greater ( $p=0.02$ ) for the lipolytic agent ( $35 \pm 3$  kcal) compared to placebo ( $27 \pm 2$  kcal).

**CONCLUSION:** The lipolytic agent can increase plasma NE and metabolic rate, without altering hemodynamic variables in a clinically relevant manner within a sample of resistance trained men.

---

### **2586 Board #231 May 29 8:00 AM - 9:30 AM**

#### **The Effect Of Energy Patches On Substrate Utilization In College Female Cross Country Runners**

Lee Everett, Doug Smith, Ryan Fiddler, Bert Jacobson, FACSM, Joanna Fedick, Creshel Kline, Mandy Andrews, Aric Warren, Matt O'Brien, Ali Boolani. *Oklahoma State University, Stillwater, OK.*

(No relationships reported)

Energy patches have been recently developed to give users significant improvements in performance by utilizing bioelectric stimulation produced by electrical frequencies in the body's magnetic field. These energy patches incorporate organic nanoscale biomolecular antennas into two separate patches that resonate at frequencies in unison with biomolecules in the cells and signal specific metabolic pathways to beta oxidation, using fat as a primary fuel source. Substrate utilization is an important factor for endurance athletes. Utilizing lipids for longer periods of time can improve performance by sparing carbohydrate during endurance activities.

**PURPOSE:** The purpose of the study was to examine the effects of energy patches on substrate utilization during graded exercise testing.

**METHODS:** Twelve Division I female collegiate cross country runners participated in this study. Age, height, body weight and respiratory exchange ratio (RER) were recorded during a pre-test (without patch) and then in a post-test (with patch). The post-test included a placebo patch group consisting of 5 subjects and an active patch group consisting of 7 subjects. The Bruce Protocol was used to achieve maximal exertion, while RER was recorded using a TrueMax 2400 Metabolic Measurement System. Statistical analysis was conducted using dependent t-tests with an alpha level of 0.05 denoting significant mean differences.

**RESULTS:** The results of the present study indicated no significant ( $p>0.05$ ) change in RER between the baseline RER measures and the placebo patch RER measures at any stage (1-5) and at max. There was a significant ( $p<0.05$ ) increase in RER at stage 1 vs. the baseline data for the active patch group; however, there were no other differences in RER at any of the remaining stages (2-5) and at max.

**CONCLUSION:** The results indicated no increase ( $p>0.05$ ) in lipid metabolism when wearing the active patch vs. wearing the placebo patch. In fact, the one stage that exhibited any significant difference in RER while wearing the active patch indicated a decrease in lipid metabolism. It is possible that the energy patch may increase beta oxidation with a larger sample size or by using a different testing protocol; however, in the present study the runners had no significant ( $p>0.05$ ) shift toward fat utilization in subjects wearing the active patch.

### **2587 Board #232 May 29 8:00 AM - 9:30 AM**

#### **The Ergogenic And Clinical Effects Of Nutritional Supplement, Mass Fx<sup>TM</sup> In Resistance Trained Adult Males**

Patrick S. Dib, M.S., Corey J. Ellis, M.D., Roberta L. Pohlman, Ph.D.. *Wright State University, Dayton, OH.*

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effects of a nutritional supplement, Mass FX<sup>TM</sup>, on muscular strength, body composition, and blood chemistries in resistance-trained adult males.

**METHODS:** Eight subjects, mean age  $25 \pm 3.02$  years, were randomly assigned to two groups ( $n=4$ ). Each group was given either Mass FX or a Placebo in a double-blind manner to be taken orally for six weeks (4 caps/day regardless of body weight). For the duration of the study, both groups followed the same training program and a diet customized to each subject's body weight in conjunction to the supplementation. Data were analyzed using Analysis of Covariance (ANCOVA) with a Bonferroni correction resulting in a family-wise level of significance of  $\alpha=0.05$ , to avoid inflation of the Type I error. To confirm results, an independent samples t-test using a Bonferroni correction with a family-wise level of significance of  $\alpha=0.05$  was performed.

**RESULTS:** Using ANCOVA, the groups were significantly different for the Bench Press outcome; whereas using the independent samples t-test, the two groups were significantly different for Bench Press and Free Testosterone ( $p=0.001$ ). The strength improvements for Mass FX compared to the placebo were the following: Bench Press ( $+14.28 \pm 7.36$  vs.  $+1.70 \pm 2.16$  kg;  $p=0.019$ ), Leg Press ( $+48.08 \pm 28.10$  vs.  $+13.58 \pm 16.11$  kg;  $p>0.05$ ), and Dead Lift ( $+15.84 \pm 5.84$  vs.  $+7.92 \pm 9.32$  kg;  $p>0.05$ ). Body composition changes were not statistically significant ( $p>0.05$ ). Group and pretreatment measures were insufficient to explain the variance for total ( $p=0.619$ ) and free testosterone ( $p=0.076$ ). No adverse effects on selected clinical health markers for complete blood count with differential, hepatic (AST, ALP, ALT), lipids (TC, TGs, LDL, VLDL), and renal (creatinine, BUN) were observed from Mass FX supplementation (Group significance  $p>0.05$ ).

**CONCLUSIONS:** The results of this study suggest that short term supplementation with Mass FX may exert ergogenic benefits without adverse clinical effects using a

controlled training program and diet. Due to limitations in terms of sample representation and size, this study should be considered a pilot study. Future studies need to investigate these parameters using larger sample sizes and longer supplementation duration.

**Acute Effect Of Lact-away Supplementation On High-intensity Kayak Performance**

Darrell L. Bonetti, Andrew E. Kilding, Will G. Hopkins, FACSM. *AUT University, Auckland, New Zealand.*

Email: [dbonetti@aut.ac.nz](mailto:dbonetti@aut.ac.nz)

*(No relationships reported)*

Lact-Away is a new orally administered sports supplement claimed by the manufacturer to attenuate blood lactate concentration during exercise and improve performance, but there is limited research on its efficacy.

**PURPOSE:** To determine the acute effect of Lact-Away supplementation on kayak performance and related physiological measures.

**METHODS:** Twelve highly-trained kayakers were randomized in a single-blind, crossover fashion to consume either a Lact-Away or a placebo drink prior to performing a maximal incremental exercise test on a wind-braked kayak ergometer, followed 20 min later by a maximal 60-s test. The trials were performed twice in balanced order to improve precision of estimation. Performance measures were peak incremental power, lactate threshold power, heart rate threshold power and mean 60-s power. A 5-point Likert scale was used to obtain measures of gut comfort, wellness and perceived ratings of central and peripheral fatigue. Data were analyzed with mixed modeling. Clinical inferences were based on a smallest important change in performance of 1%; an effect was deemed indecisive if benefit was possible (>25% chance) but risk of harm was unacceptable (odds ratio for harm/benefit >1/66).

**RESULTS:** Effects of Lact-Away vs placebo were indecisive for measures of peak incremental power (-0.3%; 90% confidence limits,  $\pm 1.8\%$ ), mean 60-s power (0.8%;  $\pm 2.4\%$ ), heart-rate profile power (1.0%;  $\pm 1.5\%$ ) and for ratings of central and peripheral fatigue. Peak lactate concentration was substantially higher after consumption of Lact-Away following the incremental test (5.3%;  $\pm 9.4\%$ ) and the 60-s test (5.3%;  $\pm 9.7\%$ ), while lactate-profile power (-1.5%;  $\pm 1.9\%$ ) and ratings of gut comfort and wellness were decisively lower after consumption of Lact-Away.

**CONCLUSION:** The blood lactate response to exercise did not support the manufacturer's claim of a reduction following consumption of Lact-Away. Although some performance outcomes were indecisive, our findings are consistent with no worthwhile enhancement in performance. We do not recommend use of this supplement.

**Effects Of Short-term Albuterol Administration On Oral Glucose Tolerance In The Elderly**

Charles P. Lambert<sup>1</sup>, Dennis Villareal<sup>2</sup>, Selma Mohammed<sup>2</sup>, Stacie Metzger<sup>2</sup>, Gordon Smith<sup>2</sup>. <sup>1</sup>University of Louisville, Louisville, KY. <sup>2</sup>Washington University School of Medicine, St. Louis, MO. (Sponsor: Ann Swank, FACSM)

Email: [cplamb02@louisville.edu](mailto:cplamb02@louisville.edu)

*(No relationships reported)*

We have previously shown that albuterol administered at a dose of 16mg/24 h over 12 weeks increased muscle mass by ~5% without the addition of exercise (Uc et al. Clin. Neuropharmacol. 26(4):207-212, 2003).  $\beta_2$  adrenergic agonists such as albuterol act to increase calpastatin activity which inhibits the calpains. Calpain inhibition has previously been shown to impair insulin stimulated glucose disposal (Sreenan et al. Diabetes 50:2013-2020, 2001). Albuterol administration could lead to impaired insulin sensitivity. Therefore, the present study was undertaken to determine the effects of 7 days of albuterol administration (16mg/24h) on the glucose and the insulin responses to a 75 g oral glucose tolerance test (OGTT). Six elderly individuals (4 men and 2 women) age: 69.3 $\pm$ 4.3 yrs, ht: 172.5 $\pm$ 10.7 cm, wt: 79.1 $\pm$ 20.6 kg, and BMI: 26.2 $\pm$ 4.3 kg/m<sup>2</sup> participated in this investigation. OGTTs were performed before and after albuterol administration with blood sampled immediately prior to and at 30,60,90, and 120 min post-ingestion of the glucose load. Glucose and insulin responses were compared utilizing a 2 way repeated measures ANOVA. Pre and post glucose and insulin areas under the curve were calculated and compared utilizing a paired t-test. No significant visit by time interaction was observed for the glucose response to the OGTT (p=0.540) or the insulin response to the OGTT (p=0.216). No significant difference between pre and post values was observed for the glucose area under the curve (12966 $\pm$ 2413 and 15124 $\pm$ 781(mg/dL) X min mean $\pm$ SE for pre and post albuterol administration, respectively; p=0.427) or the insulin area under the curve (7871 $\pm$ 1951 and 7470 $\pm$ 1603 ( $\mu$ U/ml) X min for pre and post albuterol administration, respectively; p=0.672). In conclusion, short term albuterol administration at a dose of 16 mg/24 h did not significantly alter glucose tolerance or insulin concentrations. Therefore, the administration of albuterol, at least in the short term, would not appear to have the negative effect of impairing glucose tolerance. As a result, albuterol administration should not be contraindicated for this reason.

---

**2590 Board #235 May 29 8:00 AM - 9:30 AM**  
**Dietary Supplement Use Among Endurance Athletes**

Shawn M. Talbott, FACSM, Julie A. Talbott. *SupplementWatch, Draper, UT.*

Email: [smtalbott@supplementwatch.com](mailto:smtalbott@supplementwatch.com)

*(No relationships reported)*

Existing surveys of dietary supplement use among the general population suggest that 50-75% of adult Americans are "regular users" of dietary supplements, primarily multivitamin/mineral supplements. Supplement usage among athletes is less clear, with some reports indicating 100% usage of dietary supplement among bodybuilders, and other estimates indicating 30-50% usage among elite and non-elite endurance athletes.

**PURPOSE:** The objective of the present study was to gain a greater understanding of the awareness, perceptions, and extent of usage of dietary supplements among endurance athletes.

**METHODS:** We examined dietary supplement usage among a sample of 326 triathletes - 176 "Ironman" distance (IM, 71 females and 103 male) and 152 "Olympic" distance (OD, 63 females and 89 male) from events in 3 states. Athletes were asked 50 questions about dietary supplement usage.

**RESULTS:** Results showed that triathletes at both OD and IM distances are avid users of dietary supplements (d/wk usage = 6.1d IM / 4.5 OD), with IM tending to take more supplements for "recovery" (+20%) and "endurance" (+22%) and also tending to report greater supplement usage "after" exercise (+35%), as compared to OD. Primary sources of information about supplements comes from Friends and Training partners (89% IM/83% OD), the Internet (92% IM/95% OD), and Coaches/Trainers (65% IM/53% OD). A very high percentage of triathletes indicated difficulty finding accurate information (88-90%) and wanting more information (89-90%) about dietary supplements.

**CONCLUSION:** These data clearly show a high usage of dietary supplements among competitive triathletes, as well as a clear desire on the part of those users for additional information regarding the proper use of these products. Future research is warranted to elucidate how to best educate endurance athletes about the pros and cons of dietary supplements usage.

**2591 Board #236 May 29 8:00 AM - 9:30 AM**  
**Further Considerations For The Diagnostic Evaluation Of Anabolic Androgenic Steroid (AAS) Associated Hepatotoxicity.**

Fergal M. Grace<sup>1</sup>, Michael T. Graham<sup>2</sup>, Julien S. Baker<sup>2</sup>, Nick Sculthorpe<sup>3</sup>, Adrian Haggett<sup>1</sup>, James Brouner<sup>1</sup>, Lisa Cole<sup>1</sup>, Bruce Davies, FACSM<sup>2</sup>.

<sup>1</sup>Kingston University, London, United Kingdom. <sup>2</sup>University of Glamorgan, Cardiff, United Kingdom. <sup>3</sup>University of Bedford, Bedford, United Kingdom.

Email: f.grace@kingston.ac.uk

(No relationships reported)

**PURPOSE:** The present experiment examined the potential hepatotoxic effects resulting from long term (>20years) of AAS use. This study also examined the potential link between creatine kinase (CK) and the liver aminotransferases; alanine aminotransferase (ALT), aspartate aminotransferase (AST), which were also be markedly elevated as a result of bodybuilding exercises.

**METHODS:** Subjects were divided into four distinct groups; AAS users (n=10) who were still using AAS at time of testing results: AAS users (n=10) who had been abstinent for a period greater than three months [mean + Standard Deviation (S.D): 5 + 2.3 months] (SA), bodybuilding controls (n=10) who did not use any pharmacological ergogenic aids (BC), and (n=9) sedentary male controls. Creatine kinase (CK), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma glutamyltransferase (γGT), albumin (ALB), bilirubin (BIL) and total protein (TOT-P) were analysed by dry slide technology on an Ortho Vitros 950 analyser (Ortho Clinical Diagnostics, Amersham, Bucks, UK). Data were analysed using the SPSS 10.0 for Windows statistical package. Data are presented as means + standard deviations (S.D.) Group differences were analysed using a one way ANOVA followed by a post-hoc Tukey test. Pearson product bivariate procedure was used to examine correlations between variables. Statistical significance was accepted at the P<0.05 level.

**RESULTS:** Bilirubin (BIL) was significantly higher in both AAS using groups (P<0.05) compared with the BC and SC groups. CK, AST and ALT concentrations were not significantly different between SU, SA or BC, but were significantly lower (P<0.05) in the SC group. Furthermore, there were no differences between groups for gamma glutamyl transpeptidase (γGT). Linear regression indicated relationships between CK and AST (r = 0.821; P<0.01), and with CK and ALT (r = 0.557; P<0.01), suggesting aminotransferase alterations as a consequence of muscle damage, rather than hepatotoxicity.

**CONCLUSION:** This study supports the contention that physicians should diagnostically evaluate both CK and gamma glutamyl transpeptidase (γGT) levels in the diagnosis of AAS induced hepatotoxicity.

**Gene Expression And Autologous Blood Transfusion - A New Advance Towards Blood Doping Detection?**

Torben Pottgiesser<sup>1</sup>, Yorck O. Schumacher<sup>1</sup>, Harald Funke<sup>2</sup>, Knut Rennert<sup>2</sup>, Manfred Baumstark<sup>1</sup>, Sandy Mosig<sup>2</sup>. <sup>1</sup>Medizinische Universitätsklinik, Sportmedizin, Freiburg, Germany. <sup>2</sup>Universitätsklinikum Jena, Jena, Germany.

Email: torben.pottgiesser@uniklinik-freiburg.de

(No relationships reported)

At present, there is no detection method of autologous blood doping. It is well documented that several molecular changes occur in stored red blood cells (RBCs), commonly referred to as the "storage lesion". We therefore hypothesize that autologous transfusion will lead to a sudden exposure of cell detritus to the immune system causing a cellular and molecular immune response including gene expression alterations of white blood cells.

**PURPOSE:** To investigate the transcriptional response of T-lymphocytes after autologous blood transfusion in order to deduce a theoretical model for the detection of autologous blood doping.

**METHODS:** RBCs were stored at 4°C and reinfused after a mean interval of 35±3 days. Total RNA gene expression profiles of isolated T-lymphocytes from peripheral whole blood were measured using whole human genome microarrays prior to and at 72h and 96h after autologous blood transfusion in 6 males (24±1 yr, 182±7 cm, 71.0±3.7 kg). Functional Gene Ontology (GO) annotation clustering of differentially expressed transcripts was performed and a gene expression score (GES) assigned, representing statistical significance with a high GES. Quantitative RT-PCR was performed for selected genes to confirm microarray expression findings.

**RESULTS:** At 72h, 728 transcripts were differentially expressed (639 transcripts up-, 89 transcripts down-regulated) while at 96h, 659 transcripts (594 transcripts up-, 65 transcripts down-regulated) were regulated. The most significant GO clusters of regulated genes at 72h included leukocyte immunoglobulin receptors (GES=7.44), toll-like receptor pathway (TLR, GES=2.25), adaptive immune response (GES=2.21) and cell death/apoptosis (GES=2.21) as well as regulation of endocytosis of surface receptors (GES=2.51) and the TLR pathway (GES=1.62) at 96h, respectively. The qRT-PCR confirmed significant up-regulation of TLR4, TLR5, TLR6, AATK and LRP1 at 72h as well as TLR6 at 96h.

**CONCLUSIONS:** Autologous blood transfusion triggers a distinct immune reaction. The observed up-regulation of genes involving immune cell activation and apoptosis may be related to the so-called storage lesion. Although having pilot character, this study may aid in the development of a practicable method to detect autologous blood doping based on molecular immune response measurements.

**2593 Board #238 May 29 8:00 AM - 9:30 AM**

**Lc-ms-ms Screening Method For The Simultaneous Detection Doping In Diuretics And Stimulants**

Ku-Fu Hsu<sup>1</sup>, Su-Fan Lin<sup>2</sup>, Mei-Chieh Hsu<sup>1</sup>, Guo-Ping Chang-Chien<sup>2</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>2</sup>ChengShiu University, Kaohsiung, Taiwan.

(No relationships reported)

Diuretics and stimulants were prohibited substances by World Anti-Doping Agency (WADA). Recently, the excellent suitability of liquid chromatography tandem mass spectrometry for the analytical screening of prohibited substances has been demonstrated. However, far fewer simultaneous methods have been reported for diuretics and stimulants by LC-MS-MS.

**PURPOSE:** A fast and selective liquid chromatography-tandem mass spectrometric (LC-MS-MS) method for the screening of diuretics and stimulants in human urine was developed.

**METHODS:** For the sample preparation prior to LC-MS-MS analysis, the urine sample was solid phase extracted and filtered through 0.45 μm syringe filter. The assay by LC-MS-MS in positive and negative ionization mode uses an electrospray ionization source (ESI) and multiple reaction monitoring (MRM) as the acquisition mode.

**RESULTS:** All stimulants and diuretics were separated in less than 13.1 min. The limits of detection were in the range of 5~500ng/mL for diuretics, and in the range of 5~50ng/mL for stimulants.

**CONCLUSIONS:** Thus satisfying the minimum required performance limits (MRPL) set by the WADA for the accredited anti-doping laboratories. This method can both shorten the pre-processing period and reporting time.

(No relationships reported)

Doping in sports is a problem that should not be underestimated; neither in competitive nor recreational but particularly not in fitness sports.

**PURPOSE:** In a five year follow up study, we examined to what extent the use of doping substances and illicit drugs by fitness center athletes has changed since the study in 2002.

**METHODS:** A total of 438 members of 84 of the fitness studios which were part of the 2002 study were questioned using an anonymous questionnaire. Athletes were questioned about their use of doping substances, their sources of information, and suppliers.

**RESULTS:** The prevalence of doping decreased by 2.7% to a total of 10.8%. In contrast to this, the use of illicit drugs increased by 8.4% to a total of 24.3%. Anabolic androgenic steroids, used by 76.6%, remained the most commonly used doping substance. The number of athletes who received doping substances through the health care system decreased by 11.9% to 36.2%. The main sources of supply named were other athletes (59.6%) and the black market outside the fitness center (57.4%). Reasons for using doping substances were still primarily body styling and increasing strength. Athletes reported that their sources of information were mainly physicians (45.7%) and the internet (40.0%). While only 0.3% of the questioned athletes reported having had legal problems due to doping, 6.5% reported legal problems related to illicit drugs.

**CONCLUSION:** Our results show a simultaneous reduction of doping substance use and an increase of illicit drug use, despite the observation that the number of athletes reporting legal problems as a result of their use of illegal substances is more than 20 times higher. A stricter law regarding the use of doping substances, therefore, does not look promising. Rather, based on their specialized knowledge, sports physicians and pharmacists should take on the responsibility of educating athletes about the possible harmful consequences of using doping substances. The decrease in the number of doping substances obtained through the health care system appears to be a step in the right direction.

#### **Chasing The Kids: Does It Count? An Examination Of Physical Activity In Middle Aged Mothers**

Kelli M. O'Neil, Kathleen F. Janz, FACSM. *University of Iowa, Iowa City, IA.*

Email: kelli-oneil@uiowa.edu

(No relationships reported)

Middle aged mothers with young children are one population in which more activity-based research is needed in order to plan gender-specific physical activity interventions.

**PURPOSE:** To examine the amount and pattern of physical activity obtained by middle aged mothers with young children, and compare those activity patterns to national physical activity guidelines.

**METHODS:** Fifty eight women ( $36.9 \pm 4.1$  years) with young children ( $< 6$  years) wore the Actigraph accelerometer for 7 days and completed a self report that consisted of the Kaiser Physical Activity Survey (KPAS) and the physical activity section of the Behavioral Risk Factor Surveillance System (BRFSS). Cross tabulation tested agreement between Actigraph and BRFSS data. Spearman rank correlation coefficients expressed associations among physical activity variables (Actigraph, KPAS, BRFSS) and between physical activity and demographic variables. Participants were sorted as meeting or not meeting physical activity guidelines, and differences in the context of physical activity were tested using Kruskal-Wallis analyses.

**RESULTS:** Actigraph data indicated that 31.7% of the women meet physical activity guidelines, while responses to BRFSS questions indicated 65.5%. Actigraph and BRFSS data were most concordant in the least active women. Spearman rank correlation coefficients indicated associations between older age ( $r = .32, p < .05$ ) and higher level of education ( $r = .34, p < .01$ ) with higher levels of physical activity, while working full-time, compared to homemaking, was associated with higher levels of physical inactivity ( $r = .27, p < .05$ ). KPAS sports/exercise index scores were positively associated with MVPA ( $r = .30, p < .05$ ), as measured by the Actigraph, and MVPA ( $r = .72, p < .01$ ) and frequency of MVPA ( $r = .60, p < .01$ ), as measured by BRFSS questions. KPAS household/care giving index scores, which includes chasing the kids, were not associated with meeting activity guidelines ( $r = .01$ ).

**CONCLUSION:** In this sample of middle aged mothers with young children, sports/exercise participation enhanced the likelihood of meeting physical activity guidelines, while it appeared that "chasing the kids" did not.

#### **Maternal Physical Activity And Risk Of Small-for-gestational-age Among Latina Women**

Audra L. Gollenberg, Penelope Pekow, Elizabeth Bertone-Johnson, Patty S. Freedson, FACSM, Lisa Chasan-Taber, FACSM. *University of Massachusetts-Amherst, Amherst, MA.*

(No relationships reported)

The majority of studies of physical activity and risk of adverse birth outcomes have focused on leisure time physical activity and have not assessed other types of activity relevant to women of reproductive age (e.g. household, childcare, occupational).

**PURPOSE:** To estimate the association between multiple domains of physical activity before and during pregnancy and risk of small-for-gestational-age (SGA).

**METHODS:** We utilized data from 1,040 members of the Latina GDM Study, a prospective cohort of Latina prenatal care patients in Western Massachusetts. Physical activity was assessed by bilingual interviewers using a modified version of the Kaiser Physical Activity Survey in early (mean=15 weeks) and mid pregnancy (mean=28 weeks). Physical activity (i.e., sports/exercise, household, occupational, and active living) in pre, early and mid pregnancy was categorized in quartiles. Gestational age and birth weight were abstracted from medical records. SGA was classified as  $< 10$ th percentile of birth weight for gestational age.

**RESULTS:** Fourteen percent ( $n=148$ ) of participants were classified as having delivered an SGA infant. After adjusting for maternal age, parity, body mass index, and education, activity in pre and early pregnancy was not associated with SGA. In mid pregnancy, women with the highest level of total activity had a decreased risk of SGA ( $OR=0.44, 95\% CI 0.22, 0.86; p_{trend}=0.003$ ) as compared to women with low levels of total activity. Findings were similar, but not consistently statistically significant, for the highest levels of household activity ( $OR=0.69, 95\% CI 0.34, 1.39; p_{trend}=0.10$ ) and active living ( $OR=0.64, 95\% CI 0.36, 1.14; p_{trend}=0.05$ ). In contrast, women in the highest quartile of sports/exercise activity in mid pregnancy had an increased risk of SGA ( $OR=2.01, 95\% CI 1.01, 4.33$ ) as compared to women in the lowest quartile, however there was not a significant dose-response association ( $p_{trend}=0.34$ ). In addition, mean birth weight did not differ significantly across levels of sports/exercise.

**CONCLUSIONS:** Risk of SGA differed by domain and timing of physical activity. Results support prior studies in predominantly non-Hispanic women that activity has an overall neutral or favorable effect on fetal growth.

#### **Examining The Stability Of Activity Monitors In Pregnancy**

Jennifer M. DiNallo<sup>1</sup>, Danielle Symons Downs<sup>1</sup>, Guy C. LeMasurier<sup>2</sup>. <sup>1</sup>*Pennsylvania State University, University Park, PA.* <sup>2</sup>*Vancouver Island University, Nanaimo, BC, Canada.*

Email: jmd422@psu.edu

(No relationships reported)

The amount of time pregnant women spend in physical activity (PA) is not well-understood due to the conceptual and methodological issues with measuring PA in this

population. Objective measures provide a more accurate assessment of PA and have been well-studied and validated in non-pregnant populations. However, no studies have assessed the stability of objective PA measures across the pregnancy trimesters.

**PURPOSE:** To assess the stability of three PA monitors during a controlled treadmill walking protocol in pregnant women at 20- and 32-weeks gestation.

**METHODS:** Women (N = 17, M age = 31±5 yrs; BMI = 27±5 k.g.m<sup>-2</sup>) wore Actigraph accelerometers, NL1000 and Yamax pedometers, and walked on a treadmill for 5 min at four different speeds (54 m.min<sup>-1</sup>, 67 m.min<sup>-1</sup>, 80 m.min<sup>-1</sup>, and 94 m.min<sup>-1</sup>) at 20- and 32-weeks gestation. Measures included waist circumference, accelerometer tilt, BMI, heart rate (HR), and min-by-min VO<sub>2</sub>. Stability was determined using paired-samples t-tests.

**SUMMARY OF RESULTS:** A significant difference in Actigraph activity counts from 20- (20,399±2,546 counts) to 32-weeks gestation (16,678±2,833 counts) was observed at 94 m.min<sup>-1</sup>, t(9) = 3.58, p = 0.01. A significant difference was also observed for BMI from 20- (26.8±5.2 k.g.m<sup>-2</sup>) to 32-weeks gestation (29.3±5.6 k.g.m<sup>-2</sup>), t(15) = -11.04, p < 0.001; however, no significant differences were found for steps (NL1000 and Yamax), min of MVPA (NL1000), waist circumference (mm), tilt (degrees), VO<sub>2</sub> (ml.kg.min<sup>-1</sup>), and HR (bpm) at any of the four speeds from 20- to 32-weeks.

**CONCLUSION:** While tilt and waist circumference did not change, BMI significantly increased and the stability of the Actigraph activity counts was compromised at the fastest speed. Steps and min of MVPA remained consistent across pregnancy trimesters confirming the stability of the Yamax and NL1000 pedometers. It is possible that the distribution of weight gain may affect the stability of the Actigraph at increased speeds; however, further research is needed to test this assumption.

**Physical Activity Beliefs, Barriers, and Enablers Among Postpartum Women: The Pin Postpartum Study**

Kelly R. Evenson, FACSM<sup>1</sup>, Semra A. Ayur<sup>1</sup>, Katja Borodulin<sup>2</sup>. <sup>1</sup>UNC-Chapel Hill, Chapel Hill, NC. <sup>2</sup>National Public Health Institute, Helsinki, Finland.

(No relationships reported)

Physical activity during postpartum is both a recommended and essential contributor to maternal health. Understanding the beliefs, barriers, and enablers to physical activity during postpartum can more effectively tailor physical activity interventions to the needs of mothers.

**PURPOSE:** The objective of this study was to document maternal self-reported beliefs, barriers, and enablers to physical activity among a cohort of women queried at 3- and 12-months postpartum.

**METHODS:** Five questions about beliefs regarding physical activity and exercise were asked of 667 postpartum women at 3-months postpartum who were enrolled in the PIN Postpartum Study. Two open-ended questions about their main barriers and enablers to physical activity were also self-reported. Among the sample, 530 answered the same questions about barriers and enablers to physical activity at 12-months postpartum. These barriers and enablers were coded into categories according to the socio-ecologic framework, including intrapersonal, interpersonal, environmental/policy, and organizational levels.

**RESULTS:** Agreement on all five beliefs statements were high (≥90%), indicating that women agreed that exercise and physical activity were appropriate at 3-months postpartum, even if continuing to breastfeed. When exploring differences across groups, the only differences found were by education; those with less education reported lower agreement on the belief statements. For the cohort, the most common barrier to physical activity at both 3- and 12-months postpartum was lack of time (47% and 51%, respectively), followed by issues with child care (26% and 22%, respectively). No barrier changed by more than 5% from 3- to 12-months postpartum. The most common enablers at 3-months postpartum were partner support (15%) and desire to feel better (13%). From 3- to 12-months postpartum, only one enabler changed by more than 5%; women reported baby reasons (e.g., baby healthier, more active) more often at 12-months than at 3-months postpartum (32% vs. 10%). Environmental/policy and organizational barriers and enablers were reported less often than intrapersonal or interpersonal barriers at both time points.

**CONCLUSIONS:** This study provides information to create more successful interventions to help women be physically active during postpartum.

(No relationships reported)

Knee pain is a common public health concern in older people. Predictors of its onset among community-dwelling elderly women have not been clear.

**PURPOSE:** To investigate determinants of onset of knee pain in community-dwelling elderly Japanese women.

**METHODS:** A prospective cohort study with 1-year follow-up was conducted among community-dwelling elderly women aged 50 and over in Kakeya, Unnan City, Shimane Prefecture, in rural Japan. 126 subjects without knee pain at baseline were prospectively followed over a 1-year period and assessed self-reported knee pain. Baseline surveys of potential predictors were physical (body mass index, low back pain), demographic (age, employed), psychological (depression) variables and physical activity (intensity of daily activity, daily means of transportation), and physical function (maximum walking speed, anteflexion). Predictors related to onset of knee pain were assessed by calculating odds ratios (OR) and their 95% confidence intervals (CI) adjusted for all measures at baseline using logistic regression.

**RESULTS:** The incidence of knee pain at the 1-year follow-up was 19.0% (24/126) among subjects with no knee pain at baseline. Baseline factors significantly associated with onset of new knee pain were overweight (BMI ≥ 25, OR 5.08, 95% CI 1.33-19.40, depression (OR 4.10, 95% CI 1.28-13.19), vigorous daily activity (OR 5.62, 95% CI 1.20-26.41) and low back pain (OR 2.96, 95% CI 1.02-8.60). Using inactive transportation (bus, train, car and motorbike) showed a somewhat increase but statistically insignificant OR (2.93, 95% CI 0.93-9.26, p=0.067) as compared with active transportation (walking and bicycle).

**CONCLUSIONS:** Overweight, depression, vigorous daily activity, and low back pain were associated with onset of knee pain among rural Japanese elderly women.

Email: tbain@cooperinst.org

(No relationships reported)

Physical activity (PA) is an important aspect of a healthy lifestyle when conducted at sufficient frequency, duration, and intensity to achieve a health benefit. Obesity is a major health issue that can affect morbidity and mortality risk. Previous studies have shown that PA attenuates many health risks associated with overweight and obesity.

**PURPOSE:** To determine the relationship between body habitus and self-reported (SR) PA behaviors.

**METHODS:** Body habitus measures obtained at baseline included body fat, height, weight, and BMI. Demographics included race and age. PA levels were estimated from self-reported moderate and vigorous PA (MVPA) and step count (SC) obtained weekly for up to 1.8 years (mean 0.8 ± 0.4). 556 women (mean age 52.3 ± 12.9) were categorized into 2 PA groups defined as whether they met sufficient MVPA level (≥500 MET-min/wk) and whether they met sufficient SC (≥7500 steps/day). Correlations were calculated between body habitus variables and PA measures. We used logistic regression (LR) models to evaluate body habitus measures as predictors of sufficient PA

level after adjustment for age and race separately for PA measures. LR was conducted with sufficient/insufficient defined from PA via 1) MET-min/week and 2) average steps/week. Variables in the LR model included body habitus, age, and race.

**RESULTS:** Bivariate correlations confirm that increased BMI relates to reduced SR-MVPA MET-min ( $r = -.20, p < .0001$ ) and SC per week ( $r = -.30, p < .0001$ ). Similar results were obtained for body fat ( $r = -.20, p < .0001$  and  $r = -.31, p < .0001$ ) for SR-MVPA MET-min and SC per week, respectively. Four LR models controlling for age and race indicated that unit increases in BMI or percent fat resulted in approximately a 5% decrease ( $0.93 < ORs < .96$ ;  $CI = 0.91-0.98$ ) in the odds that an individual would be categorized as meeting sufficient PA guidelines for a health benefit. Age and race were unrelated in both body fat models. Race ( $OR = 1.64$ ;  $95\%CI = 1.03-2.60$ ) was related in the MET-min/BMI model and age ( $OR = 0.98$ ;  $95\%CI = 0.98-0.99$ ) was related in the steps/BMI model.

**CONCLUSIONS:** In a population of free-living women, increases in body habitus are related to decreases in PA levels. Using long-term PA assessment, these results confirm the relationship between BMI, body fat, and measures of PA.

**Do Sex Steroids Contribute Significant Information Above Central Obesity In The Prediction Of Metabolic Risk?**

Eduard Tiozzo<sup>1</sup>, Arlette Perry<sup>1</sup>, Xuewen Wang<sup>2</sup>, Ronald Goldberg<sup>3</sup>, Robert Ross<sup>4</sup>, Loreto Jackson<sup>5</sup>. <sup>1</sup>The University of Miami, Coral Gables, FL. <sup>2</sup>Washington University, School of Medicine, St. Louis, MO. <sup>3</sup>The University of Miami, Miller School of Medicine, Miami, FL. <sup>4</sup>Queen's University, Kingston, ON, Canada. <sup>5</sup>Clemson University, Clemson, SC.  
Email: tiozzoe@hotmail.com  
(No relationships reported)

**PURPOSE:** Sex steroids and sex hormone binding globulin (SHBG) have been used to predict cardiometabolic variables (CMV) associated with coronary heart disease risk and diabetes. Since waist circumference (WAIST) and visceral adipose tissue (VAT) are suitable anthropometric surrogates of CMV, this study was conducted to evaluate the contribution of androgens and SHBG to the prediction of CMV above that of WAIST and VAT.

**METHODS:** A total of 66 overweight/obese premenopausal Caucasian (CA) ( $n=36$ ) and African-American (AA) ( $n=30$ ) women interested in receiving weight management information, volunteered to participate in the study. All women were "apparently healthy" and none were taking any medications that would affect CMV. In addition to anthropometric measurements, serum samples were taken following an overnight fast to evaluate CMV.

**RESULTS:** Our findings showed that SHBG significantly predicted serum insulin ( $p = 0.003$ ) insulin resistance ( $p = 0.006$ ) and HDL<sub>2</sub> ( $p = 0.011$ ) above that of WAIST. In contrast, TT predicted many more variables above that of WAIST including: systolic ( $p < 0.001$ ) and diastolic ( $p < 0.001$ ) blood pressure (BP) total cholesterol (TChol) ( $p = 0.002$ ) TChol/HDL cholesterol ( $p = 0.052$ ) and Apo B ( $p = 0.002$ ). Free testosterone using the Free Androgen Index (FAI) predicted the most CMV above WAIST including: systolic BP ( $p = 0.004$ ) diastolic BP ( $p = 0.002$ ) fasting insulin ( $p = 0.009$ ) insulin resistance ( $p = 0.016$ ) TChol ( $p = 0.035$ ) HDL Cholesterol ( $p = 0.036$ ) LDL Cholesterol ( $p = 0.029$ ) and Apo B ( $p = 0.042$ ). There was also a significant race by FAI interaction for serum glucose ( $p = 0.029$ ) with CA women showing a positive relationship between FAI and glucose above WAIST ( $r = 0.477$ ;  $p = 0.004$ ) and AA women showing no relationship ( $r = -0.074$ ;  $p = 0.721$ ). Substituting VAT for WAIST almost mirrored the results obtained using sex steroids and SHBG to predict CMV.

**CONCLUSION:** In contrast to SHBG, both TT and FAI contributed to numerous CMV above that of central obesity measures, thereby providing a more comprehensive evaluation of metabolic risk in overweight/obese CA and AA women. It should be noted, however, that FAI may not provide sufficient information regarding glucose status in AA women.

---

**2602 Board #247 May 29 8:00 AM - 9:30 AM**

**Comparison Of Subjective And Objective Assessments Of Physical Activity In Healthy Women**

J. Erin Mabry, Katrina L. Butner, Kyle W. Creamer, William G. Herbert, FACSM. Virginia Tech, Blacksburg, VA.  
Email: jemabry@vt.edu  
(No relationships reported)

Valid assessment and quantification of physical activity (PA) status remains a challenge; specifically for studies that seek definitive answers to questions of health efficacy of PA in sub-populations at risk for disease. Overestimation is a concern for self-report and questionnaire assessments, but low cost and ease of administration make them the most common methods for assessing PA. The pedometer is a valid and more precise option for assessing PA in research; however, it cannot provide important contextual information. A combination of subjective and objective assessments may be useful to better evaluate and understand the health-efficacy of PA in various sub-populations.

**PURPOSE:** To compare pedometer step count (an objective method for assessing PA) and MET\*min/day (a combination method for assessing PA), with activity recall questionnaires in healthy women.

**METHODS:** Sixty-two women (Age: Mean  $\pm$  SD =  $38.6 \pm 4.5$  yr, BMI =  $25.2 \pm 5.6$  kg/m<sup>2</sup>) completed a physical activity questionnaire (PAQ) to quantify recent and long-term PA patterns (Paffenbarger et al. N Engl J Med 1986). Energy expenditure from recreational activities over the last year was expressed in kcals/week. Subjects wore pedometers for 4 days to determine an average daily step count (PA range: 2,593-18,878 steps/d). Subjects also completed a 4-day self-reported PA log to account for more strenuous activities when the pedometer was removed; an average MET\*min/day was calculated which incorporated the activity log and pedometer step count.

**RESULTS:** Pedometer step count correlated with daily blocks walked reported in the last year from the PAQ ( $r=0.46, p<0.01$ ), but not with recreational PA. MET\*min/day correlated only with the yearly recreational PA recall ( $r=0.35, p<0.01$ ).

**CONCLUSIONS:** While pedometer step count reflects incidental daily activity, it does not account for many types of planned physical activity. MET\*min/day, which combines both subjective and objective measures of PA, provides a more complete assessment of chronic PA patterns in healthy women. An overall assessment of PA using MET\*min/day may provide greater insight into the health efficacy of PA, which is of interest to researchers and health professionals.

**2603 Board #248 May 29 8:00 AM - 9:30 AM**

**Lumbar Spine Flexion And Extension Extremes Of Motion In Women Of Different Age And Racial Groups**

Elaine Trudelle-Jackson<sup>1</sup>, James R. Morrow, Jr., FACSM<sup>2</sup>, Lisa A. Fleisher<sup>1</sup>, Nicole P. Borman<sup>1</sup>, Georita M. Frierson<sup>3</sup>. <sup>1</sup>Texas Woman's University, Dallas, TX. <sup>2</sup>University of North Texas, Denton, TX. <sup>3</sup>The Cooper Institute and Southern Methodist University, Dallas, TX.  
Email: ejackson@twu.edu  
(No relationships reported)

Spinal range of motion (ROM) is one of the AMA Guides criteria used to estimate level of impairment and subsequent compensation entitlement. Studies show that spinal ROM varies with age, gender and possibly race/ethnicity but adequate normative values for women in different age and racial/ethnic groups do not exist.

**PURPOSE:** To provide normative values of lumbar flexion and extension for women of different age and racial groups using inclinometric measurements and compare lumbar flexion and extension values between age and racial groups.

**METHODS:** Participants were a cohort of free-living women who were recruited for the Women's Injury Study (WIN) at the Cooper Institute in Dallas, Texas. Nine hundred and seventeen women between the ages of 20 and 83 ( $M=52 \pm 13$ ) underwent an orthopedic examination that included lumbar spine flexion and extension measurement using an electronic inclinometer. Measurements were taken in the fully extended and fully flexed positions, respectively. This was done in order to remove the influence of initial

resting posture and is appropriately termed “extreme of motion” (EOM) as opposed to ROM. Comparisons between age and racial groups were made using a 2-way MANOVA with appropriate post hoc tests.

**RESULTS:** Means (+ SD) were calculated for racial (Caucasian, N = 619, African-American, N =147) and age groups (young; 20-39yrs, n=126, middle; 40-59yrs, n=412, older; > 60yrs, n=228). Lumbar extension for African-American women (60.1°) was significantly greater ( $p<0.05$ ) than for Caucasian women (52.6°) but flexion was not different (15.2° and 17.0°), respectively. Extension EOM for the young group (61.6°) was greater ( $p<0.05$ ) than the middle (56.6°) and older (50.8°) groups. The extension difference between the middle and older groups was also statistically significant. Flexion EOM for the young group (20.1°) was greater ( $p<0.05$ ) than the middle (15.2°) and older (12.8°) groups. The difference in flexion between the middle and older groups was not significant.

**CONCLUSION:** Normative values of lumbar extension are different for Caucasian and African-American women. Values for lumbar flexion and extension are different between age groups. Therefore, different criteria should be used to estimate impairment level in women of different racial and age groups.

**Seasonal Variation And Objective Measures Of Physical Activity In Women Aged 65-75 Years**

Maureen C. Ashe, Teresa Y.L. Liu-Ambrose, Erin Gorman, Lindsay Nettlefold, Heather A. McKay. *UBC, Vancouver, BC, Canada.* (Sponsor: Dr. Karim Khan, FACSM)

(No relationships reported)

Physical activity is an important component of a healthy lifestyle. Many factors can influence the uptake and adherence of an exercise program including the weather or reduced daylight hours. There are few reports on the seasonal variation of physical activity in older women, and even fewer that have used objective measures to capture physical activity patterns.

**PURPOSE:** To investigate the influence of season on daily moderate to vigorous physical activity (MVPA) minutes in healthy older women.

**METHODS:** The physical activity measures were part of a one-year randomized controlled trial of resistance training for community-dwelling women aged 65-75 years. Participants (N=77) wore a waist-mounted uni-axial accelerometer (GT1M ActiGraph, LLC, Fort Walton Beach, FL) 10 or more hours/day for at least four days over one week at four different times of the year. Days were included if participants had 10 hours of valid wear time. We used the cutpoints established by Freedson and colleagues for MVPA ( $\geq 1952$  counts). We compared seasonal variation in MVPA over time using repeated measures ANOVA. We also determined adherence to guideline recommendations by calculating the percentage of participants who met 30 minutes of MVPA.

**RESULTS:** Women had a mean age of  $69.7 \pm 2.8$  years and mean BMI of  $26.3 \pm 4.3$ . The mean ( $\pm$  SD) number of MVPA minutes for summer was  $27.4 \pm 23.0$ ; in fall was  $23.5 \pm 19.2$ ; in winter was  $23.5 \pm 20.7$ ; and in spring was  $26.6 \pm 23.4$ . There was no significant difference between seasons for minutes of MVPA. In summer 42% of participants met activity guidelines and approximately 30% of participants met guidelines during the other seasons.

**CONCLUSION:** In this group of healthy community-dwelling older women, we note there was no significant seasonal variation in objectively measured MVPA over one-year.

**Influence Of Menopausal Status On Lipids And Lipoproteins And Fat Mass Distribution: The Pioneer Project**

Melinda Villarreal, Ronique Pleasant, Nancy M. DiMarco, FACSM, Barney C. Sanborn, FACSM, Joshua S. Wooten. *Texas Woman's University, Denton, TX.*

Email: vsunshine83@aol.com

(No relationships reported)

Following menopause, fat redistribution and increased risk for dyslipidemia are common. The influence of menopause; however, on the associations between total and regional fat mass with lipids and lipoproteins remains unclear.

**PURPOSE:** The purpose of this investigation was to determine the influence of menopausal status on associations between total and regional fat mass and lipids and lipoproteins.

**METHODS:** Sedentary, non-smoking women (n=209) were grouped based on current menstrual status: premenopausal (n=143, mean $\pm$ SD; age=42.7 $\pm$ 7.7 yr, BMI=24.5 $\pm$ 4.0 kg·m<sup>-2</sup>, WC=77.4 $\pm$ 9.9 cm) or postmenopausal (n=66, mean $\pm$ SD; age=52.9 $\pm$ 5.3 yr, BMI= 24.9 $\pm$ 4.2 kg·m<sup>-2</sup>, WC=78.8 $\pm$ 9.9 cm). Fasting (12 hr) serum samples were analyzed for total cholesterol (TC), triglyceride (Tg), LDL-C, HDL-C, HDL<sub>2</sub>-C, and HDL<sub>3</sub>-C concentrations. Total (TF), abdominal (AF), hip (HF) and mid-thigh (MTF) fat mass were quantified by DXA. A MANCOVA was used to determine differences between groups for total and regional fat mass and lipids and lipoproteins controlling for HRT status. Stepwise multiple regression analysis was used to determine if menopausal status influenced the association of total and regional fat mass with lipids and lipoproteins. The criterion reference for statistical significance was set at a  $P < 0.05$ .

**RESULTS:** Postmenopausal women had significantly greater TC, HDL-C, LDL-C and HDL<sub>3</sub>-C concentrations than premenopausal women. No significant differences were observed between groups for total and regional fat mass. In premenopausal women, AF predicted TC, but no associations were observed in postmenopausal women. In premenopausal women, AF+HF and AF+MTF were significant predictors of Tg and LDL-C, respectively. In contrast, only AF predicted Tg and LDL-C in postmenopausal women. AF+MTF best predicted HDL-C in premenopausal women; however, TF+MTF best predicted HDL-C in postmenopausal women. In premenopausal women, no associations were observed with HDL<sub>2</sub>-C or HDL<sub>3</sub>-C. TF and TF+MTF were best predictors of HDL<sub>2</sub>-C and HDL<sub>3</sub>-C, respectively in postmenopausal women.

**CONCLUSION:** Menopausal status has an effect on lipid and lipoprotein-cholesterol concentrations, but not on total and regional fat mass. In addition, menopausal status had an influence on the associations of total and regional fat mass with lipids and lipoproteins.

**Habitual Physical Activity Affects Brachial Artery Reactivity In Women Who Are Postmenopausal And Overweight**

Carl M. Maresh, FACSM, Kate E. Sanders, Kevin D. Ballard, Jeffrey M. Anderson, Jaci L. VanHeest, Jeff S. Volek, William J. Kraemer, FACSM. *University of Connecticut, Storrs, CT.*

Email: carl.maresh@uconn.edu

(No relationships reported)

The growing awareness of cardiovascular disease in women has intensified the concern for excess body weight in older age, especially after menopause. Furthermore, the inverse relationship of frequent, moderate-intensity exercise and all-cause mortality in post-menopausal women has been documented, but the mechanisms have received sparse attention in research.

**PURPOSE:** To examine brachial artery reactivity in women who exercise regularly, and who are post-menopausal and overweight.

**METHODS:** Regularly exercising women (EX: n=17; 55 $\pm$ 3 yrs; consistently exercising > 6 mo) were compared to sedentary women (CON: n=8; 56 $\pm$ 7 yr; sedentary > 6 mo) for cardiovascular fitness, measures of body composition, and brachial artery reactivity via flow mediated dilation (FMD). All of the women reported the complete cessation of menses for > 12 mo and were non-users of hormone therapy, medications or nutritional supplements that might have vasoactive properties. All were non-smokers and were weight stable over the previous six months. Exercise was defined by self-reported physical activities that, when equated for METs, represented > 3days/wk of moderate intensity (50-60% of VO<sub>2</sub>max) cardiovascular training. t-tests corrected for multiple comparisons were run for all appropriate measurements.

**RESULTS:** The groups were similar in body fat via DEXA (EX, 42.8±5.5 vs CON, 45.5±3.8%). Estimated VO<sub>2</sub>max was insignificantly higher in EX than CON (28±5 vs 24±4 ml/kg/min). FMD was greater (P<0.002) in EX (10.2±2.4%) than CON (6.6±2.2%).

**CONCLUSIONS:** We demonstrated that regularly performed exercise of a primarily aerobic nature appears to contribute to a higher FMD, presumably reducing endothelial dysfunction, in women who are both post-menopausal and overweight.

#### **Comparison Of Body Fat Content And Distribution Of Familial Amyloidotic Polyneuropathy Patients Versus Healthy Subjects**

Nuno Pimenta<sup>1</sup>, Helena Santa-Clara<sup>2</sup>, Maria Teresa Tomás<sup>3</sup>, Estela Monteiro<sup>4</sup>, Jan Cabri<sup>5</sup>, António Freire<sup>6</sup>, Eduardo Barroso<sup>6</sup>, Luís Bettencourt Sardinha<sup>5</sup>, Bo Fernhall, FACSM<sup>7</sup>. <sup>1</sup>*Sport Sciences School of Rio Maior, Politechnic Institute of Rio Maior, Rio Maior, Portugal.* <sup>2</sup>*Faculty of Human Kinetics, Technical University of Lisbon, Lisbon, Portugal.* <sup>3</sup>*Health Technologies School, Polytechnic Institute of Lisbon, Lisbon, Portugal.* <sup>4</sup>*Faculty of Medicine, University of Lisbon, Lisbon, Portugal.* <sup>5</sup>*Faculty of Human Kinetics, Technical University of Lisbon, Lisbon, Portugal.* <sup>6</sup>*Curry Cabral Hospital, Lisbon, Portugal.* <sup>7</sup>*University of Illinois Urbana-Champaign, Champaign, IL.*

Email: npimenta@esdm.pt

(No relationships reported)

The deposition of amyloid fibers at the peripheral nervous system can induce motor neuropathy in Familial Amyloidotic Polyneuropathy (FAP) patients. This produces progressive reductions in functional capacity. The only treatment for FAP is a liver transplant, followed by aggressive medication that can affect patients' metabolism. To our knowledge, there are no data on body fat distribution or comparison between healthy and FAP subjects, which may be important for clinical assessment and management of this disease.

**PURPOSE:** To analyze body fat content and distribution between FAP patients and healthy subjects.

**METHODS:** Body fat content and distribution were measured through Double Energy X-ray Densitometry (DXA) in two groups. Group 1 consisted of 43 Familial Amyloidotic Polyneuropathy patients (19 males, 32 ± 8 Yrs, and 24 females, 37 ± 5 yrs), who had liver transplant less than 2 months before. Group 2 consisted of 18 healthy subjects of similar age (8 males, 36 ± 7 yrs, and 10 females, 39 ± 5 yrs).

**RESULTS:** Healthy subjects showed higher values than FAP patients for: BMI (24.2±2.3 kg/m<sup>2</sup> vs 22.3±3.8 kg/m<sup>2</sup> respectively, p<0.05), % trunk BF (26.21±8.34 kg vs 20.78±9.05 kg respectively, p<0.05), % visceral BF (24.43±7.97% vs 19.21±9.30% respectively, p<0.05), % abdominal BF (26.63±8.51% vs 20.63±10.35% respectively, p<0.05) abdominal subcutaneous BF (0.533±0.421 kg vs 0.353±0.257 kg respectively, p=0.05), abdominal BF/BF ratio (0.09±0.02 vs 0.08±0.02 respectively, p<0.05) and abdominal BF/trunk BF ratio (0.19±0.03 vs 0.17±0.03 respectively, p<0.05).

**CONCLUSIONS:** These results showed that FAP patients soon after liver transplantation exhibited a healthier body fat profile compared to controls. However, fat content and distribution varied widely in FAP subjects, suggesting an individualized approach for assessment and intervention rather than general guidelines. Future research is needed to investigate the long term consequences on body fat following liver transplant in this population.

#### **Visceral & Abdominal Subcutaneous Fat And Body Composition In Motor Complete Spinal Cord Injury**

Ashraf S. Gorgey<sup>1</sup>, Anthony E. Chiodo<sup>2</sup>, Gianna M. Rodriguez<sup>2</sup>, David R. Gater<sup>1</sup>. <sup>1</sup>*Hunter Holmes McGuire VA Medical Center, Richmond, VA.*

<sup>2</sup>*University of Michigan, Ann Arbor, MI.* (Sponsor: Jeffrey Horowitz, FACSM)

Email: agorgey@gmail.com

(No relationships reported)

Visceral adiposity (VA) and abdominal subcutaneous adipose tissue (SAT) are associated with increased risks of metabolic and cardiovascular diseases. Waist circumference (WC) has been used as an accurate surrogate of VA. The distribution of VA and SAT in individuals with spinal cord injury (SCI) is yet to be investigated.

**PURPOSES:** 1-To measure the distribution of VA and SAT in multi-axial slices using magnetic resonance imaging (MRI) in motor complete SCI. 2-To determine if L4-L5 slice could be used as surrogate for VA. 3- To determine the relationship between VA and SAT (MRI) and trunk and body fat (DXA) and anthropometrics (tape measure).

**METHODS:** Five men and one woman (34 ± 8 yrs, 24 ± 4 Kg/m<sup>2</sup>, 10 ± 6 yrs post-injury; C6-T11; ASIA A and B) participated in the current study. Abdominal adipose tissue was measured by MRI from the first slice with iliac crest to the Xiphoid process (9-12 slices, slice thickness 10 mm and interslice space 10 mm). Images were matched at L4-L5 and at the level of umbilicus. Total and trunk body fat was measured using a total body DXA scans. Waist and abdominal circumferences were measured from lying and sitting positions.

**RESULTS:** The cross-sectional area (CSA) of VA ranged from 85 ± 27 (L4/L5) to 122 ± 25 (4 cm proximal to L4/L5) cm<sup>2</sup> in male. However, the VA ranged from 15 (L4/L5) to 49 (2 cm distal to L4/L5) cm<sup>2</sup> in the single woman. The CSA of VA<sub>L4/L5</sub> was correlated to the average CSA from multi-axial slices (r = 0.97, p < 0.0001). L4/L5 had the greatest SAT accumulation 201 ± 50 and 240 cm<sup>2</sup> in male and female, respectively. Neither waist nor abdominal circumferences were related to VA or SAT. However, waist (r = 0.76; p = 0.041) and abdominal (r = 0.88; p = 0.010) circumferences were related to the sum of VAT and SA. Finally, VA was related to the gynoid (r = 0.77; p = 0.036) region and SAT was related to the trunk (r = 0.74; p = 0.044) and total fat mass (r = 0.91; p = 0.005) as measured by DXA.

**CONCLUSION:** In individuals with SCI, VA and SAT appeared to be unevenly distributed in multi-axial slices. A single slice at L4/L5 can be used to reflect VA CSA, but it underestimates the actual magnitude. WC may be a valid surrogate to measure the sum, but not individual compartment, of VA and SAT. DXA cannot be used to measure VA, but can provide a reliable measure for SAT.

### **2609 Board #3 May 29 2:00 PM - 3:30 PM**

#### **The Effects Of Exercise And Diet On Body Composition And Anabolic Hormones In Lactating Women**

Heather L. Collieran, Melanie Bopp, Heather L. Mackie, Laurie Wideman, Cheryl Lovelady. *The University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Dr. Allan Goldfarb, FACSM)

(No relationships reported)

**PURPOSE:** To determine the effects of exercise and diet on body composition and anabolic hormone levels in lactating women.

**METHODS:** At 4wks postpartum (PP), women were randomized to either exercise group [EG, n=10, aerobic exercise (3 d/wk, 45 min/d) and 3 d/wk of resistance exercise] or control group (CG, n=10, no exercise) for 16 wks. Measurements were conducted at 4 and 20 wks PP for body composition, diet, and hormones. Weight, fat mass (FM), lean body mass (LBM), and appendicular (App) LBM were measured by DXA. LBM was defined as total non-bone lean mass and App LBM was defined as the sum of non-bone lean mass in arms and legs. The Nutrition Data System was used to obtain 2-24 hour dietary recalls. Growth hormone (hGH), insulin-like growth factor (IGF-1), and its associated binding protein-3 (IGFBP-3) were analyzed by ELISA. RMANCOVA was used to test for differences in body composition and anabolic hormones controlling for dietary intake. Data are reported as mean (SE).

**RESULTS:** Strength increased in the EG significantly more than in the CG after 16 wks. Energy intake decreased significantly in both groups (EG = 31.3 to 30.6 kcal/kg/d and CG = 31.0 to 26.0 kcal/kg/d), with no significant difference between groups after 16 wks. There were no differences in protein intake over time or between groups (EG = 1.3 to 1.2 g/kg/d and CG = 1.1 to 1.2 g/kg/d). Since energy intake and protein intake were highly correlated ( $r^2 = 0.6$ ,  $p < 0.0001$ ), we only controlled for protein intake in analyzing differences in body composition and hormones. Both groups lost the same amount of weight [EG = 3.6 (0.7) kg and CG = 3.5 (0.7) kg]. However, EG lost more weight from FM [2.9 (0.6) vs. CG = 1.9 (0.6) kg,  $p = 0.20$ ] and less weight from LBM [EG = 0.6 (0.3) kg vs. CG = 1.7 (0.3) kg,  $p = 0.04$ ]. EG gained more App LBM 0.02 (0.2) kg while CG lost 0.4 (0.2) kg ( $p = 0.02$ ). There were no differences in hGH, IGF-1, and IGFBP-3 levels over time or between groups.

**CONCLUSIONS:** These results suggest that aerobic and resistance exercise may slow the loss of total LBM while increasing LBM in the arms and legs during lactation and weight loss. There was no effect on hGH, IGF-1, and IGFBP-3 levels with exercise in this small sample of subjects.

**Angiotensin-converting Enzyme Insertion/deletion Genotype And Body Composition In Pulmonary Disease Patients**

Michael J. Berry, FACSM, Barbara J. Nicklas, FACSM, Walter J. Rejeski, Norman E. Adair. *Wake Forest University, Winston-Salem, NC.*

Email: berry@wfu.edu

*(No relationships reported)*

The insertion/deletion (I/D) polymorphism of the angiotensin-converting enzyme (ACE) gene has been shown to be associated with differences in strength and body composition in healthy older adults and to be associated with strength in chronic obstructive pulmonary disease (COPD) patients.

**PURPOSE:** The purpose of this study was to examine the effect of polymorphisms of the ACE gene on measures of body composition in COPD patients.

**METHODS:** The study included 148 COPD patients (82 M, 66 F) who were identified as having the II (33), ID (89) or DD (26) genotype and underwent a DEXA scan for body composition analysis.

**RESULTS:** After controlling for disease severity, there were no differences in body mass index or total body mass among the genotypes in men or women. However, measures of fat were significantly lower in men with the DD genotype. Adjusted means for men are shown in the table below. There were no differences in measures of fat among the three genotypes in women.

Body Composition for Men	II	ID	DD	P
Total Fat Mass (kg)	28.5±2.3	26.1±1.2	15.2±3.9	.019
Trunk Fat Mass (kg)	15.8±1.5	14.1±0.7	7.2±2.5	.018
Appendicular Fat Mass (kg)	11.5±0.9	10.8±0.5	6.9±1.5	.043
Leg Fat Mass (kg)	8.2±0.6	7.7±0.3	5.2±1.1	.066
Arm Fat Mass (kg)	3.3±0.3	3.1±0.2	1.7±0.5	.042
Total Body Fat (%)	29.8±1.4	28.6±0.7	22.0±2.3	.019
Trunk Fat (%)	32.2±1.7	30.3±0.9	22.3±2.9	.020
Appendicular Fat (%)	27.9±1.3	27.5±0.7	21.9±2.3	.062
Leg Fat (%)	27.8±1.4	27.4±0.7	22.3±2.3	.108
Arm Fat (%)	27.9±1.6	27.6±0.8	20.7±2.6	.046

**CONCLUSION:** After controlling for disease severity, men with the DD ACE genotype had lower amounts and percentages of body fat as compared to those with the II and ID genotypes.

**Assessment Of Energy Expenditure In Chronically Undernourished Indian Orphans**

Michael J. Webster, FACSM, Rachel B. Odom, Miriam N. Webster. *University of Southern Mississippi, Hattiesburg, MS.*

Email: Michael.Webster@usm.edu

*(No relationships reported)*

Undernutrition during critical periods of development can permanently change the structure and function of developing systems. The current profile of rural Indian orphan children is that they are small statured and chronically undernourished.

**PURPOSE:** To assess physical activity (PA) and energy expenditure (EE) in chronically undernourished Indian orphans.

**METHODS:** 48 children (32 males, 16 females; age 12.9, BMI 14.8) in residence at the Indian Christian Mission Center, Salem, India ([www.icmcindia.org](http://www.icmcindia.org)) were assessed for PA and EE. Accelerometers (Mini-Mitter Inc., Bend, Oregon) were attached to the ankle for three consecutive days with d-2 used to assess PA. Additionally, accelerometer validity was assessed by having each child perform a 2-stage submaximal step test (stepping rates 20 and 27 step/minute, step ht. 17.6 cm) wearing an accelerometer and simultaneously being measuring for EE via indirect calorimetry (New Leaf Fitness, St. Paul, MN).

**RESULTS:** Using a single regression model, daily EE was estimated at  $1233 \pm 40$  kcal.  $49.7 \pm 7.0\%$  of the day was spent performing sedentary PA and  $49.4 \pm 9.2\%$  was spent performing light to moderate intensity PA. At stepping rates of 20 and 27 steps/minute, oxygen consumption was  $18.4 \pm 2.0$  and  $23.0 \pm 2.6$  ml/kg/min, respectively. Estimations of oxygen consumption from accelerometers were calculated at  $11.4 \pm 0.5$  and  $13.7 \pm 0.8$  ml/kg/min at stepping rates of 20 and 27 steps/min, respectively. Oxygen consumption estimations using ACSM metabolic calculations determined these stepping workloads to elicit an oxygen consumption of 15.9 and 20.9 ml ml/kg/min, respectively.

**CONCLUSION:** The ACSM calculation slightly underestimates oxygen uptake measured using indirect calorimetry and significantly overestimates EE via accelerometers. In these children, our findings bring into question the assessment of energy expenditure using accelerometers.

*Supported by New Leaf Fitness, St. Paul, MN*

**Self Efficacy, Physical Activity, And Fitness In Overweight And Obese African American Breast Cancer Survivors**

Randall J. Gretebeck, FACSM<sup>1</sup>, Gregory K. Karapetian<sup>1</sup>, Kimberlee A. Gretebeck<sup>2</sup>, Zora Djuric<sup>2</sup>. <sup>1</sup>Wayne State University, Detroit, MI. <sup>2</sup>University of Michigan, Ann Arbor, MI.

Email: r.gretebeck@wayne.edu

(No relationships reported)

**PURPOSE:** The purpose of this investigation was to evaluate measures of self efficacy in relation to physical activity and fitness in overweight and obese African American breast cancer survivors.

**METHODS:** Forty five African American Women (age  $55.0 \pm 8.1$  y, weight  $87.7 \pm 13.7$  kg, %fat  $41.9 \pm 4.1$ ) participated in the study. Self efficacy questions were asked concerning diet, exercise, ability to stick to goals, and control over home and work environments using a 0-4 point scale. Physical activity levels were assessed using the Seven Day Physical Activity Questionnaire. Objective measures included submaximal graded exercise testing which consisted of stationary cycling for 3 minute stages progressing at 25 watt (W) increments until subjects reached 85% of heart rate reserve or reached an RER in excess of 1.1. Respiratory gas exchange was measured continuously by open circuit spirometry indirect calorimetry and was used to determine ventilatory threshold as a measure of submaximal exercise capacity. Body composition was determined using DEXA.

**RESULTS:** Self efficacy concerning exercise was negatively associated with % body fat ( $r = -.40$ ), and positively associated with ventilatory threshold ( $r = .24$ ) and amount of time spent in hard physical activity during weekdays ( $r = .27$ ) and weekends ( $r = .26$ ). Ventilatory threshold was also associated with self efficacy over control of home environment ( $r = .35$ ), and work environment ( $r = .36$ ). Mean ventilatory threshold for this population was  $5.8 \pm 1.1$  ml/kg/min, and mean  $\text{VO}_{2\text{peak}}$  was  $10.0 \pm 2.0$  ml/kg/min. The Seven Day Physical Activity Questionnaire did not perform well in this population, possibly because moderate physical activity was defined as activities of three METs or greater (1 MET = 3.5 ml/kg/min) which is greater than the mean  $\text{VO}_{2\text{peak}}$  for this population.

**CONCLUSIONS:** These results suggest that even though this population has a very low aerobic capacity, measures of self efficacy related to exercise and environment are associated with measures of fitness. In addition, Physical activity assessment in this population using survey methods need to take into account the low aerobic capacity of this population.

---

**2613 Board #7 May 29 2:00 PM - 3:30 PM**

**Safety Of Aerobic And Resistance Exercise Training In Early Breast Cancer Survivors**

Janet R. Wojcik<sup>1</sup>, Melanie Poudevigne<sup>2</sup>, Suzana Simonishvili<sup>3</sup>, Betty Lane<sup>2</sup>, Marty Polovich<sup>4</sup>. <sup>1</sup>Winthrop University, Rock Hill, SC. <sup>2</sup>Clayton State University, Morrow, GA. <sup>3</sup>Emory University, Atlanta, GA. <sup>4</sup>Duke Oncology Network, Durham, NC. (Sponsor: Dr. Allen Jackson, FACSM)

Email: wojcikj@winthrop.edu

(No relationships reported)

**PURPOSE:** Breast Cancer Survivors (BCS) who were sedentary before treatment are likely to experience low aerobic fitness and strength. There are limited data on following American College of Sports Medicine (ACSM) recommendations for both aerobic and resistance training in BCS, especially early survivors less than two years. Therefore, the purpose of the study was to examine if early BCS can safely perform aerobic and resistance training.

**METHODS:** The participants were 20 female early BCS (mean age = 56.0 years, SD = 8.5) recruited at three sites. They underwent lumpectomy or mastectomy along with chemotherapy and/or radiation without other co-morbid conditions. Physician clearance was required. The women received personal training onsite for a total of 60 minutes 3 times per week for 12 weeks. Strength was measured by 1-repetition maximum (1-RM) at baseline and every 3 weeks on the chest press, lat pull-down, lumbar extension, shoulder press, biceps curl, triceps extension, and leg press. Resistance training intensity was set at 70% of 1-RM to elicit 8-12 repetitions. Each resistance training session was 30 min. The participants also performed 30 min of aerobic training on cardio machines (elliptical, treadmill, stationary cycle) at 60%HRR. Heart rate (HR) and ratings of perceived exertion (RPE) were collected at rest and 5 min intervals of aerobic training, while blood pressure was collected at rest and every 10 min. Appropriate HRR was maintained by increasing intensity of the exercise. Orthopedic problems were monitored at each session. Hemoglobin levels were measured at baseline and every 4 weeks to check anemia ( $< 11.0$  Hb). The 1-RM was re-assessed every 4 weeks to ensure accurate training loads.

**RESULTS:** The attendance rate was 90%. There were no changes in HR, RPE, or blood pressure, which remained consistent throughout the sessions. All participants were able to perform resistance training and 1-RM testing. There were no reports of musculoskeletal injuries. No participants developed anemia.

**CONCLUSIONS:** These data suggest aerobic and resistance training at ACSM recommended levels is safe in early BCS. More data in these women are needed to support these findings, in addition to evaluation of programs beyond 12 weeks duration and in women who are longer survivors.

**2614 Board #8 May 29 2:00 PM - 3:30 PM**

**Effects Of Exercise During Pregnancy On Maternal Insulin Sensitivity And Offspring Growth**

Sarah A. Hopkins<sup>1</sup>, James C. Baldi, FACSM<sup>2</sup>, Wayne S. Cutfield<sup>1</sup>, Lesley McCowan<sup>1</sup>, Janene B. Biggs<sup>1</sup>, Paul L. Hofman<sup>1</sup>. <sup>1</sup>The University of Auckland, Auckland, New Zealand. <sup>2</sup>Northern Arizona University, Flagstaff, AZ.

Email: s.hopkins@auckland.ac.nz

(No relationships reported)

Epidemiological studies have demonstrated a relationship between abnormal fetal growth and increased risk of childhood obesity and later adult disease. Previous studies have suggested that the maternal metabolic environment, in particular a reduction in maternal insulin sensitivity, contributes significantly to fetal growth. Regular aerobic exercise may therefore influence offspring size by regulating appropriate nutrient supply to the fetus, through an effect on maternal insulin sensitivity.

**PURPOSE:** To determine the effects of regular exercise during pregnancy on maternal insulin sensitivity, potential hormonal regulators of fetal growth, neonatal and offspring size.

**METHODS:** Healthy nulliparous women ( $30 \pm 4$  yrs, BMI  $25.5 \pm 4$  kg/m<sup>2</sup>) were randomized to either a monitored stationary cycling program ( $n=47$ ) or control ( $n=37$ ) from 20 weeks gestation to term. Maternal insulin sensitivity was assessed at 19 and 35 weeks using minimal model analysis of the frequently sampled intravenous glucose tolerance test. Neonatal auxology was assessed within 48 hours of delivery and at one year.

**RESULTS:** Offspring of exercisers had lower birth weights (Z-score control  $0.24 \pm 0.8$ ; exercise  $0.19 \pm 0.9$ ;  $p=0.03$ ) and BMI at birth (Z-score control  $0.40 \pm 0.9$ ; exercise  $-0.01 \pm 0.4$ ;  $p=0.04$ ). The reduction in maternal insulin sensitivity with advancing gestation was not affected by exercise ( $p=0.45$ ), and was unrelated to offspring birth size. However, exercise offspring had lower cord serum IGF-II ( $p=0.04$ ) and a trend towards lower IGF-I ( $p=0.08$ ), supporting an effect of exercise on endocrine regulation of fetal growth. Offspring size at one year remained lower in the exercise group, although not statistically significant due to reduced sample size at follow-up (BMI Z-score control  $-0.09 \pm 1.1$ ; exercise  $-0.40 \pm 1.1$ ;  $p=0.26$ ).

**CONCLUSIONS:** Regular exercise resulted in lower birth weights and leaner neonatal offspring with preliminary follow-up data suggesting a persistent effect at 1 year. However, exercise effects on offspring growth occurred independently of alterations in insulin sensitivity or markers of the maternal environment and unlike previous studies, maternal insulin sensitivity was not predictive of offspring birth size.

## Exaggerated Postprandial Triglyceride Response Identified In Individuals With Spinal Cord Injury With Cardiac Risk Factors

Racine R. Emmons<sup>1</sup>, Christopher M. Cimigliaro<sup>1</sup>, Jeremy M. Moyer<sup>1</sup>, Carol Ewing Garber, FACSM<sup>2</sup>, Steven C. Kirshblum<sup>3</sup>, Ann M. Spungen<sup>1</sup>, William A. Bauman<sup>1</sup>. <sup>1</sup>James J. Peters VA Medical Center, Bronx, NY. <sup>2</sup>Teacher's College, Columbia University, New York, NY. <sup>3</sup>Kessler Institute for Rehabilitation, West Orange, NJ.  
Email: racine.emmons@va.gov  
(No relationships reported)

Able-bodied individuals who have a greater number of cardiac risk factors and greater abdominal adiposity have increased difficulty in metabolizing fat loads, resulting in prolonged elevation of postprandial triglyceride. The lipemic response to a high fat meal and its relationship to abdominal adiposity and coronary heart disease (CHD) is unknown in individuals with spinal cord injury (SCI).

**PURPOSE:** To compare the postprandial lipemic (PPTG) responses, abdominal adiposity and CHD factors between able-bodied (AB) and individuals with SCI.

**METHODS:** Twenty-five men with SCI (13 paraplegia, 12 tetraplegia) and 13 able-bodied (AB) men participated. The CHD risk factors were determined and subjects were stratified as having low risk (2 or less risk factors) or elevated risk (3+ risk factors). Following a 10-hour fast, a high-fat milkshake was consumed to deliver approximately 1.3 g fat, 1.2 g carbohydrate, and 0.2 g protein per kilogram body mass. Blood samples were drawn at baseline, 2, 4, and 6 hours to measure PPTG, determined as the area under the curve. Total abdominal fat (TAF) was measured by abdominal ultrasonography.

**RESULTS:** SCI and AB subjects were similar in age, height, and weight. In AB and SCI subjects, TAF was significantly related to PPTG responses ( $R=0.49$ ,  $P=0.02$ ). TAF in low risk SCI was significantly less in AB with elevated risk ( $P=0.02$ ) and SCI with elevated risk ( $P=0.01$ ). SCI with elevated risk had the greatest PPTG response compared to low and elevated risk AB ( $2053\pm911$  vs.  $1356\pm633$ , and  $1725\pm981$  units, respectively), which was significantly greater than low risk SCI ( $1016\pm333$  units,  $P=0.01$ ). When controlling for TAF, the groups with SCI at low and elevated CHD risk had a PPTG response that was greater by  $183\pm83$  and  $366\pm83$  units, respectively, than the low risk AB group ( $P=0.001$ ).

**CONCLUSIONS:** Individuals with SCI appear to exhibit a greater postprandial response after a fat load than their able-bodied counterparts. An exaggerated postprandial response may be associated with greater overall cardiac risk in SCI.

#### Moderate Intensity Exercise Training Improves Lipid Profile In Hiv-infected Men.

Gregory A. Hand, FACSM<sup>1</sup>, Jason R. Jagers<sup>1</sup>, G. William Lyerly<sup>1</sup>, Wesley D. Dudgeon<sup>2</sup>, Kenneth D. Phillips<sup>3</sup>, J. Larry Durstine, FACSM<sup>1</sup>, Stephanie Burgess<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>The Citadel, Charleston, SC. <sup>3</sup>University of Tennessee, Knoxville, TN.  
(No relationships reported)

**PURPOSE:** To determine the effects of a moderate dose of exercise training on blood lipids in HIV-infected men.

**METHODS:** Sixteen HIV-infected men were recruited for this study and randomized into either an exercise (EX) training group, or control (CON) group who attended the sessions but did not participate in exercise training. The EX subjects participated in a 6 week program of moderate intensity resistance training at 60% of their 3-rep max (approximately 20 min), as well as aerobic exercise for 30 min at 60% of their age predicted heart rate max (twice per week). The CON group received standard care during the same 6 week period and did not increase their activity level. All subjects provided a 12-hour fasting blood draw at pre- and post-treatment.

**RESULTS:** Results show that at baseline LDL cholesterol was in the "high risk" range for CVD ( $182\pm55$  mg/dl) and baseline triglyceride was in the "borderline high" range ( $155\pm70$  mg/dl). Pre- to post-intervention analysis showed a significant reduction in triglyceride level ( $155\pm70$  to  $110\pm30$  mg/dl) and a trend ( $p=0.07$ ) towards a decrease in LDL cholesterol ( $182\pm55$  to  $171\pm33$  mg/dl). Measurement of occupational and leisure activity showed no change in either group.

**CONCLUSIONS:** These data show moderate dosage of combined aerobic and resistance training can decrease HIV-associated high levels of circulating triglycerides and cholesterol after only 6 weeks. The results suggest that HIV infection does not reduce the beneficial effects of moderate intensity exercise training on blood lipids, and that training can reduce the risk of CVD in this population.

This project was Supported by the NIH/NCMHD (5P20MD001770-03) and the American College of Sports Medicine.

#### Aerobic Exercise Is Safe And Effective In Systemic Sclerosis

Fernanda R. Lima, Natalia Oliveira, Claudia Borges, Livia Sabbag, Ana Lucia S. Pinto. University of Sao Paulo, SP, Brazil.  
Email: ferlima@mac.com  
(No relationships reported)

**PURPOSE:** Pulmonary involvement is a major determinant of SSc morbidity and mortality. It is therefore relevant to evaluate if aerobic exercise training in female Systemic Sclerosis (SSc) is a safe and effective intervention to improve lung capacity.

**METHODS:** Seven SSc patients without pulmonary impairment (normal CT, FVC > 75% predicted, DLCO > 75% predicted, PASP < 40mmHg) and 7 healthy controls, sedentary and paired by age and body mass index (BMI), were enrolled in an 8-week program consisting of moderate intensity aerobic exercise twice a week. Aerobic capacity was assessed by treadmill ergospirometry. Blood lactate was evaluated once a week and oxygen saturation was registered in all exercise sessions (before and at peak of the exercise) **RESULTS:** The exercise program was well tolerated by both groups and adherence was 100%. At entry, VO2 peak and lactate parameters were comparable in patients and controls ( $p>0.05$ ), whereas rest and peak oxygen saturation were lower in patients ( $p=0.032$  and  $p=0.034$ , respectively) than controls. SSc patients and controls had a significant improvement in their VO2 peak ( $19.72\pm3.51$  vs.  $22.27\pm2.53$  and  $22.94\pm4.70$  vs.  $24.55\pm3.00$ , respectively,  $p=0.006$ ) after 8 weeks of exercise, but difference between groups was not statistically significant ( $p=0.149$ ). Reinforcing this finding, at the end of the study SSc and controls were able to perform a significantly higher exercise intensity when compared to the baseline, as measured by peak blood lactate ( $1.43\pm0.51$  vs.  $1.84\pm0.33$  and  $1.11\pm0.45$  vs.  $1.59\pm0.25$ , respectively,  $p=0.01$ ). SSc group showed an improvement in peak exercise oxygen saturation at the 8th week of training when compared to the baseline ( $84.14\pm9.86$  vs.  $90.29\pm5.09$ ,  $p=0.048$ ), but the same improvement was not observed in control group ( $96.29\pm1.70$  vs.  $95.86\pm2.12$ ,  $p=0.732$ ). Rodnan score was similar before and after the intervention ( $15.84\pm7.84$  vs.  $12.71\pm4.31$ ,  $p=0.0855$ ). Digital ulcers and Raynaud's phenomenon remained stable.

**CONCLUSION:** Our data support the notion that achieving improved lung capacity is a feasible goal in SSc management. The long term benefit of this intervention needs to be determined in large prospective studies.

### 2618 Board #12 May 29 2:00 PM - 3:30 PM

#### A 6-week Protocol Based On Exercise And Antioxidant Supplementation Reduced Malondialdehyde In Mentally Retarded Athletes

Francisco J. Ordonez<sup>1</sup>, Sergio E. Andrade<sup>2</sup>, Ignacio Rosety<sup>1</sup>, Antonio Diaz<sup>1</sup>, Loubna Boukhzar<sup>3</sup>, Ramon Alvero<sup>4</sup>, Manuel Rosety-Rodriguez<sup>1</sup>.

<sup>4</sup>University of Malaga, Malaga, Spain.  
Email: franciscojavier.ordonez@uca.es  
(No relationships reported)

In the last years, there has been a major increase in opportunities for sports and physical activities for persons with mental retardation. Accordingly, it is also necessary to improve medical assessment of these athletes that may be focused on several issues such as oxidative stress. Firstly if we take into account individuals with mental retardation have been generally described as having high levels of oxidative stress. And secondly since it is widely accepted high physical performance may be associated to oxidative damage.

**PURPOSE:** The present study was undertaken to ascertain the influence of a mixed protocol based on regular exercise and antioxidant supplementation in lipoperoxidation in athletes with mental retardation.

**METHODS:** Fifty-five high-performance athletes with mental retardation from Special Olympics volunteered for this study (21.6±1.8 years-old). Forty were randomly included in experimental group to perform a 6-week protocol including exercise (low-moderate intensity aerobic exercise before breakfast 3 times per week) and supplementation (1g ascorbic acid + 400 UI  $\alpha$ -tocopherol; 6 times per week). Control group included 15 age, sex, trained and BMI-matched athletes with mental retardation that did not perform our protocol. Written informed consent was obtained from their relatives. Further our protocol was approved by an institutional ethic committee. Plasmatic MDA were determined by high performance liquid chromatography (HPLC) with fluorimetric detection as described elsewhere 72-hours before starting the protocol (pre-test) and after its ending (post-test). Comparisons were made by using Student "t" test for paired data. Significance was ascertained at p value <0.05.

**RESULTS:** When compared to baseline plasmatic MDA levels were decreased significantly after our 6-week protocol (0.50±0.12 vs 0.36±0.09  $\mu$ mol/l-1; p<0.05). No changes were reported in controls.

**CONCLUSION:** It was concluded a 6-week mixed protocol based on fasting exercise and antioxidant supplementation improved significantly lipoperoxidation in athletes with mental retardation. Further studies on this topic are highly required.

**Biceps And Triceps Oxygenation Changes In Competitive Wheelchair Racers With Spinal Cord Injury**

Yagesh Bhambhani<sup>1</sup>, Rohit Malik<sup>1</sup>, Peter Erikssen<sup>2</sup>. <sup>1</sup>University of Alberta, Edmonton, AB, Canada. <sup>2</sup>Road to Excellence, Ottawa, ON, Canada.  
(Sponsor: Robert Haennel, FACSM)  
Email: yagesh.bhambhani@ualberta.ca  
(No relationships reported)

Electromyographic evidence has indicated that the biceps and triceps muscles are recruited during different phases of the wheelchair propulsion cycle. However, the localized hemodynamic changes during this exercise mode have not been examined.

**PURPOSE:** To examine the alterations in muscle oxygenation and blood volume during incremental wheelchair exercise to voluntary fatigue in competitive wheelchair racers using Near Infrared Spectroscopy (NIRS).

**METHODS:** Written informed consent was obtained from 20 competitive male wheelchair racers with spinal cord injury (SCI, lesion levels C7 to L3; mean age = 33.8 ± 8.8 yrs). Each subject completed an incremental velocity wheelchair test to voluntary fatigue in their racing wheelchair mounted on frictionless rollers. Cardiorespiratory responses were recorded using a wireless metabolic system. Biceps and triceps blood volume (Bbv and Tbv) and oxygenation (Box and Tox) were recorded simultaneously using two dual-wave NIRS units for two minutes at rest and continuously during exercise.

**RESULTS:** Oxygen consumption and heart rate increased systematically until voluntary fatigue. The peak values attained were 34.4 ± 8.7 ml/kg/min and 172 ± 21.3 bpm respectively. There was considerable inter-subject variation in the hemodynamic responses of the two muscles during the incremental wheelchair test. In most subjects, Bbv and Tbv increased until approximately 50% to 60% of peak VO<sub>2</sub> and then leveled off or decreased slightly. In contrast, Box and Tox decreased simultaneously until approximately 80% of peak VO<sub>2</sub> and then leveled off or increased slightly. The absolute changes (peak minus resting value) in mean Box and Tox (-0.17 vs -0.18 OD units) were not significantly different (p > .05).

**CONCLUSIONS:** In competitive wheelchair racers with SCI: (1) the biceps and triceps reached their maximal capacity to extract oxygen before the onset of fatigue, thereby suggesting a peripheral limitation, and (2) there was a similar degree of aerobic metabolic activity in the biceps and triceps during wheelchair propulsion. These findings have important implications in designing aerobic training programs for Paralympic wheelchair athletes.

**Combination Nutrition And Exercise Program For Cancer Survivors**

Philip M. Anton<sup>1</sup>, Amy L. Eggemeyer<sup>2</sup>, Angela D. Cress<sup>1</sup>, Allison M. Jurgens<sup>1</sup>. <sup>1</sup>Southern Illinois University Carbondale, Carbondale, IL. <sup>2</sup>Southern Illinois Illinois Healthcare, Carbondale, IL. (Sponsor: Carole M. Schneider, FACSM)  
Email: panton@siu.edu  
( P.M. Anton, Southern Illinois Healthcare, Salary.)

Low to moderate exercise intensity training has been shown to improve fitness parameters and quality of life (QOL) in cancer survivors. The influence of dietary modification concurrent with an exercise intervention is less clear.

**PURPOSE:** To determine if additional physical/QOL benefits may be achieved via combination dietary modification/exercise vs. exercise alone and usual care.

**METHODS:** Subjects were of various cancer types, both in and out of treatment. Group 1 (G1) (32 subjects; 20 female, 12 male; age 62±3 yrs), participated in a 12-week intervention that included two, 1-hour sessions of exercise training (flexibility, balance, resistance, aerobic) per week plus a weekly 40 minute group dietary informational session (this group also tracked a variety of dietary variables). Group 2 (G2) (27 subjects; 21 female, 6 male; age 60±7 yrs) participated in the exercise program, but not the nutrition intervention. Group 3 (G3) (19 subjects; 12 female, 7 male; age 58±3 yrs) received usual care for their cancer, but participated in no structured exercise or nutrition intervention. All subjects were tested pre and post on fatigue and QOL status, as well as several physical tasks: sit to stand, stair climb/descent, lift/carry (all timed tests), and treadmill walking (endurance time). All subjects completed a nutritional habits survey, pre and post. Repeated-measures ANOVA was used to analyze the data (.05 level of significance).

**RESULTS:** G1 reported increased consumption of fruits/vegetables, calcium, and fiber (p=.045). G2 and G3 reported no significant changes in diet. G1 and G2 improved significantly on treadmill walking (G1: 38%, p = .011; G2: 19%, p = .048), lift/carry (G1: -47%, p = .018; G2: -24%, p = .044), and sit to stand (G1: -20%, p = .046; G2: -31%, p = .022). G1 improved on fatigue (-27%, p = .023) and QOL (24%, p = .029), while G2 did not experience any significant changes in these variables or stair climb/descent (trend toward improvement). G3 had no significant change in any of the physical tasks (trend toward decline), but experienced a decline in QOL (-33%, p=.039) and an increase in fatigue (31%; p=.027).

**CONCLUSIONS:** Both G1 and G2 improved during the course of the study, but it appears that a nutrition intervention given in conjunction with exercise may offer additional benefit for cancer survivors.

**A Long-term Longitudinal Survey Of The Training Effects On Cardiorespiratory System In Paraplegics**

Arsenio Veicsteinas, Emiliano Cè, Giampiero Merati. *Don C. Gnocchi Foundation Onlus-IRCCS, Milan, Italy.*  
Email: gpmerati@alice.it  
(No relationships reported)

Cardiovascular risk is higher in spinal cord injured (SCI) patients than in able-bodied people, mainly due to physical inactivity. Sedentary lifestyle can lead to the “hypokinetic syndrome”, characterized by progressive loss of functional muscular mass and cardiovascular fitness. In particular, left ventricle “electrical predominance” is not evident in sedentary SCI patients, whose ECG is often characterized by a right shift of cardiac electric axis.

**PURPOSE:** To evaluate the effects of long term regular aerobic sport practice on cardiac response to exercise, ventilatory function and ECG in SCI patients.

**METHODS:** Six SCI patients (lesion level T<sub>1</sub>-T<sub>10</sub>; age 34.6±2.8 yrs [m±SD], lesion duration 15.7±8.2 yrs) participated in the study. All the subjects were aerobically trained twice a week for two hours. Body weight (BW), ventilatory parameters (FVC, Forced Vital Capacity, FEV<sub>1</sub>, Forced Expiratory Volume in 1 Second) and ECG parameters (PQ, QT, electrical axis, heart rate [HR]) were monitored for 10 years, in occasion of yearly medical controls. All the patients were evaluated on a wheelchair ergometer, by means of an incremental maximal exercise test. ECG was recorded at rest (HR<sub>rest</sub>) and HR<sub>rec</sub> did not change. QT and PQ showed no changes throughout the observation period. Mean electric axis progressively shifted leftwards, from 68° to 43° (p<0.05).

**RESULTS:** BW monotonically increased through the observation period, from 61.1±8.0 Kg to 69.7±14.4Kg (p<0.05, year 1 vs year 10). CV and FEV<sub>1</sub> decreased from 3.6±0.7 to 3.0±1.2 l and from 3.1±0.8 to 2.4±1.1 l, respectively (p<0.05). Achieved maximal speeds decreased from 7.2±1.0 to 5.9±0.8 Km·h<sup>-1</sup> (p=ns). Although not significantly, HR<sub>max</sub> increased from 110±20 to 135±20 bpm, whereas HR<sub>rest</sub> and HR<sub>rec</sub> did not change. QT and PQ showed no changes throughout the observation period. Mean electric axis progressively shifted leftwards, from 68° to 43° (p<0.05).

**CONCLUSIONS:** Our results suggest an important role for physical activity in the cardio-respiratory reconditioning of SCI patients. Although in these patients BW, respiratory function and HR were not affected by long term aerobic training, myocardium positively adapted to chronic exercise, presumably by an increase of left ventricular mass. Thus, physical exercise may slow down the progressive deterioration of cardiovascular function in paraplegics.

**2622 Board #16 May 29 2:00 PM - 3:30 PM**  
**Reference Values For Six Minute Walk Distances In Subacute Stem Cell Transplant Patients**

G. Stephen Morris<sup>1</sup>, Christopher M. Hearon, FACS<sup>2</sup>, Pamela R. Massey<sup>1</sup>, Janet S. Scheetz<sup>1</sup>, Elaine A. Brannan<sup>1</sup>. <sup>1</sup>UT MD Anderson Cancer Center, Houston, TX. <sup>2</sup>Texas A&M University-Kingsville, Kingsville, TX.  
Email: gsmorris@mdanderson.org  
(No relationships reported)

**PURPOSE:** The six minute walk test (6-MWT) is widely used to assess the functional status of subacute stem cell transplant (STC) recipients. However, reference values for the 6-MWT in this population have not been published. Therefore this study sought to both provide a performance description and to develop reference values for this patient population.

**METHODS:** The protocol was approved by the UTMDACC Institutional Review Board. 6-MWT results were extracted retrospectively from the medical records of 118 consecutive STC recipients referred to Rehabilitation Services for physical therapy. Patients were asked to walk as far as they could in 6 min. on the level track that followed the perimeter of the Rehabilitation Services gym. Patients pushed their IV pole during the test and received verbal encouragement at 1-minute intervals. Hemodynamic status and oxygen saturation levels were monitored during and after this test.

**RESULTS:** These STC recipients (N=118) were 54 + 12 yrs. old, were 50 + 34 days post transplant and walked 402 + 140 m in 6 min.. The 6-MWT performance differed (p<0.05) by gender [male (n=84)= 423 + 134 m; female (n=34)= 351 + 142 m] but not (p>0.05) with regard to corticosteroid treatment status [treatment (n=64)= 392 + 136 m; no treatment (n=54)= 415 + 144 m]. While neither body weight nor height correlated significantly with 6-MWT performance (p>0.05), a significant relationship (p<0.05) was determined between 6-MWT performance and both body mass index (BMI) (r = -0.20) and time elapsed since SCT (r = -0.18). No significant relationship between 6-MWT performance and age was detected, but a trend was observed (r = -0.16, p=0.07).

**CONCLUSIONS:** These results provide a description of 6-MWT performance and reference values for subacute SCT patients which can be used to grade their relative functional status. Additionally, these data may be useful in developing 6-MWT performance norms for this population.

**Six Vs Three Months Of Combined Exercise Training In Patients With Chronic Obstructive Pulmonary Disease**

Angela M. Pereira<sup>1</sup>, Helena Santa-Clara<sup>1</sup>, Ernesto Pereira<sup>2</sup>, Sérgio Simões<sup>3</sup>, Luís Carrão<sup>3</sup>, India Remédios<sup>2</sup>, Jan Cabri<sup>1</sup>, Bo Fernhall, FACS<sup>4</sup>. <sup>1</sup>Faculty of Human Kinetics, Lisbon, Portugal. <sup>2</sup>Garcia de Orta Hospital, Almada, Portugal. <sup>3</sup>Egas Moniz Health School, Almada, Portugal. <sup>4</sup>University of Illinois Urbana-Champaign, Urbana-Champaign, IL.  
Email: amcfap@gmail.com  
(No relationships reported)

Expiratory airflow limitation is the main characteristic of chronic obstructive pulmonary disease (COPD). Exercise intolerance is frequently present in these patients, leading to a reduced ability to participate in activities of daily living and to a reduced health-related quality of life (HRQoL). Aerobic exercise training has been demonstrated to reduce the functional limitations imposed by this disease. Combined aerobic and strength training, increases muscle strength and improves endurance and functional capacity, and activities of daily living to a greater extent than aerobic training alone. However, the effects of the length of the training program are not well known.

**PURPOSE:** The purpose of this study was to compare the effects of 3 or 6 months of combined training on functional ability in patients with COPD.

**METHODS:** Twenty nine men with moderate COPD performed combined exercise training for 3 and 6 months, 3 times a week. Fifteen patients (FEV<sub>1</sub> 48,3±12,6%); were assigned to the 3 months group (3MG) (age, 66±5 yrs; weight, 78±8.0 kg; height, 168±8.3 cm) and fourteen patients (FEV<sub>1</sub> 45,2±12,9%) were assigned to the 6 months group (6MG), (age, 65 ±4.7 yrs; weight, 75,4±8.7 kg; height, 170,1±4,9 cm). The aerobic exercise was set at 60-70% HR reserve for 30 minutes and the resistance exercise was performed in 5 weight machines, 2 sets of 8-12 repetitions at 50-70% of 1RM, for both groups. The physical parameters assessed were strength, aerobic endurance, flexibility and agility/balance by the Fullerton's functional fitness tests.

**RESULTS:** The pre-values of the functional fitness test were similar for both groups. After training, the values of the functional fitness test were different (p<0.05) between 6MG and 3MG groups for 30-second chair stand 22.93±3 vs. 18.2±2.4; arm curl 24,37±2,0 vs. 18,6±2,8; 8-foot up-and-go 3,17±0,5 vs. 4,10±0,6; chair sit-and-reach 7,87±12,2 vs. 3,2±10,4; 6-minute walk 617,17±50,4 vs. 568,2±52,8; back scratch -2,07±3,0 vs. -7,4±10,2 respectively.

**CONCLUSION:** In conclusion, 6 months of combined exercise training produced greater improvement in functional ability, than 3 months of exercise training.

**Increased Aerobic Fitness In Late Pregnancy Predicts Shorter Labor In Nulliparous, But Not Multiparous, Women.**

Kristin R. Kardel<sup>1</sup>, Bjørn Johansen<sup>2</sup>, Nanna Voldner<sup>2</sup>, Per Ole Iversen<sup>1</sup>, Tore Henriksen<sup>1</sup>. <sup>1</sup>University of Oslo, Oslo, Norway. <sup>2</sup>Rikshospitalet University Hospital, Oslo, Norway.  
Email: k.r.kardel@medisin.uio.no  
(No relationships reported)

Similar to the general population, the level of physical activity is inadequate among pregnant women. The ensuing state of over-nutrition as a consequence of physical inactivity prolongs labor and thereby the risk of several obstetrical implications including fetal asphyxia, infections and obstetrical fistulas. Well-trained women who maintain physical exercise during pregnancy have shorter labor compared to those who stop training before the end of the first trimester. Much less is known about whether aerobic fitness in a general cohort of pregnant women is related to duration of labor.

**PURPOSE:** We wanted to investigate the effect of aerobic fitness on duration of labor among nulli- and multiparous women using two valid indicators, namely measurement of maximal oxygen uptake and calculation of anaerobic threshold.

**METHODS:** Maximal oxygen uptake and anaerobic threshold were measured in 59 nulli- and 51 multiparous women at 36 weeks of gestation. Duration of labor was defined as the time between three cm cervical dilation with regular uterine contractions and delivery. Unpaired sample t-test, Pearson correlation test and multiple linear regression were used for statistical analysis.

**RESULTS:** Maximal oxygen uptake was similar for both groups (mean 2.1 L/min). Labor was as expected longer ( $p < 0.001$ ) in the nulliparous compared to the multiparous women:  $9.3 \pm 5.0$  and  $4.5 \pm 2.3$  hours, respectively. For nulliparous women who started labor spontaneously, duration of labor was inversely associated with maximal oxygen uptake ( $p=0.03$ ). This indicates that for an increase in maximal oxygen uptake of 0.1 L/min, labor would be shortened by on average 33 minutes. In contrast, in multiparous women who started labor spontaneously, anaerobic threshold was positively associated with duration of labor ( $p=0.002$ ). This indicates that an increase in anaerobic threshold of 0.1 L/min would prolong labor by on average 22 minutes.

**CONCLUSION:** Increased maximal oxygen uptake is associated with shorter labor in nulliparous women who start labor spontaneously, whereas increased anaerobic threshold is associated with prolonged labor in multiparous women.

**Running Efficiency Of A Trans-tibial Amputee With Different Prosthetic Stiffness: A Case Study**

Robert M. Otto, FACSM<sup>1</sup>, John Wygand<sup>1</sup>, Sarah Wright<sup>1</sup>, Cortney Whitebay<sup>1</sup>, Josh O'Brien<sup>1</sup>, Tara Plusch<sup>1</sup>, Eric Schaffer<sup>2</sup>, Philip Krueter<sup>2</sup>. <sup>1</sup>Adelphi University, Garden City, NY. <sup>2</sup>A Step Ahead, Hicksville, NY.  
Email: otto@adelphi.edu

( R.M. Otto, Ossur America's, Inc., Contracted Research.)

Intense training, along with the advent of new materials and technology available for development of prosthesis, are allowing amputee athletes to reach greater success in sport. To improve run performance, trans-tibial amputee athletes strive to improve efficiency of movement, which in part, is attributed to the amount of rebound provided through their prosthetic. The popular carbon fiber Ossur running foot, Flex Run, is manufactured with nine specific categories of stiffness, each with a difference in the coefficient of restitution. Currently, guidelines are provided by the manufacturer for fitting the appropriate running foot stiffness to the athlete based on body mass and fitness.

**PURPOSE:** To objectively quantify run efficiency based on the energy cost of different running feet.

**METHODS:** A sub- 3:10 marathon BK runner (age 40 yr, body mass 74.5 kg and ht.175 cm) participated in a treadmill run GXT to Max  $\dot{V}O_2$  ( $62.2 \text{ mL/kg}\cdot\text{min}^{-1}$ ) starting at  $187.6 \text{ m/min}$  with increments of  $13.4 \text{ m/min}$  every 3 min. AnT was determined from the max GXT at  $262.6 \text{ m/min}$  ( $52.4 \text{ mL/kg}\cdot\text{min}^{-1}$  or 87% max  $\dot{V}O_2$ ). The subject completed three randomly assigned double blind trials at AnT with three consecutive categories of running foot stiffness. The running foot stiffness categories included one standard category recommended by the manufacturer (S), as well as one category above (S+) and one below (S-) the standard.

**RESULTS:** The following data were obtained:  $\dot{V}_e$  (106.4, 108.5, &  $113.4 \text{ L/min}$ ), HR (164, 159, 165 b/min) and  $\dot{V}O_2$  (58.5, 57.6 &  $59.5 \text{ mL/kg}\cdot\text{min}^{-1}$ ) at S-, S, and S+ trials, respectively. All trials resulted in the same 186 foot strikes/min and the same stride length. His energy cost was 4.4%, 2.8%, and 6.2% greater than the ACSM prediction equation for S-, S, and S+ trials, respectively. Although the athlete reported the greatest comfort during the S+ trial, his  $\dot{V}O_2$  was elevated 3.2% above the S trial.

**CONCLUSION:** The prosthesis does not appear to offer any advantage in terms of efficiency. The evaluation of additional subjects and running speeds are necessary to effectively quantify running efficiency attributed to prosthetic running foot stiffness.

**The Physical Activity Scale For Individuals With Physical Disabilities: Limited Validity In People With Sci**

Sonja de Groot<sup>1</sup>, Marcel WM Post<sup>2</sup>, Christof AJ Smit<sup>1</sup>, Lucas HV van der Woude<sup>3</sup>. <sup>1</sup>Revalidatiecentrum Amsterdam, Amsterdam, Netherlands. <sup>2</sup>Revalidatiecentrum De Hoogstraat, Utrecht, Netherlands. <sup>3</sup>VU University Amsterdam, Amsterdam, Netherlands. (Sponsor: TWJ Janssen, FACSM)  
Email: s.d.groot@rcamsterdam.nl  
(No relationships reported)

Physical activity is an important part of a healthy lifestyle in people with spinal cord injury (SCI). The Physical Activity Scale for Individuals with Physical Disabilities (PASIPD) was developed to assess the physical activity level of individuals with a disability (Washburn et al., 2002). The PASIPD has not yet been validated for use in people with SCI.

**PURPOSE:** To determine the construct and divergent validity of the PASIPD in people with SCI.

**METHODS:** Construct validity was examined by relationships between PASIPD scores and measures of fitness (peak oxygen uptake, peak power output, muscular strength) and activities (wheelchair skills, Utrecht Activity List, mobility range and social behaviour subscales of the SIP68) in 139 persons with SCI 1 year after discharge from inpatient rehabilitation. Divergent validity was determined by comparing group scores of people with different personal (age, gender, body mass index) and lesion characteristics (level (paraplegia/tetraplegia), completeness, time since injury).

**RESULTS:** PASIPD scores showed low correlations with fitness parameters (0.25-0.36,  $p < 0.05$ ) and low to moderate correlations with activities (0.36-0.51,  $p < 0.01$ ). Persons with a tetraplegia or long time since injury had significantly lower PASIPD scores compared to those with a paraplegia ( $p < 0.02$ ; effect size: 0.17) or a short time since injury ( $p < 0.03$ ; effect size: 0.30).

**CONCLUSION:** The PASIPD showed a weak relationship with fitness measures and a moderate relationship with activity parameters in people with SCI. This construct validity is comparable to well established self-report questionnaires from the general population. The divergent validity of the PASIPD was low. Therefore, the PASIPD should be used with caution in persons with SCI, however, more research is needed to obtain better insights in the PASIPD.

**A Peer-guided Exercise Program For Youth With Intellectual Disabilities**

Heidi Stanish<sup>1</sup>, Vivienne Temple<sup>2</sup>. <sup>1</sup>University of Massachusetts Boston, Boston, MA. <sup>2</sup>University of Victoria, Victoria, BC, Canada.  
Email: heidi.stanish@umb.edu  
(No relationships reported)

Youth with intellectual disabilities (ID) do not engage in sufficient physical activity and, in turn, have lower fitness levels and higher body fat than their peers. This group faces unique barriers to physical activity participation due to cognitive, social, motor and behavioral limitations. Peer support is an important determinant of physical activity among adolescents and may be one strategy to address barriers encountered by youth with ID. Although peer modeling and peer-tutoring have been associated with positive physical activity outcomes in youth with ID, additional research is needed to determine if peer mediated interventions are effective.

**PURPOSE:** To investigate the extent to which youth with and without ID adhered to a peer-guided exercise program, and to determine if participation enhanced health-related fitness. **METHOD:** Twenty adolescents with mild ID were paired with a trained partner (i.e. nondisabled adolescent) to exercise 2 days/week for 1 hour over 15 weeks. Each pair provided reciprocal support during structured, individualized exercise sessions led by certified fitness trainers. The intervention was implemented at two YMCA fitness centers and daily sessions included 20 min each of aerobic exercise, weight training, and core strengthening activities.

**RESULTS:** Attendance and adherence to the program was high and no adolescents with ID dropped out of the study. All youth successfully engaged in the planned exercises, although a greater proportion of the aerobic and core activities were completed compared to the weight training. Repeated measures ANOVA with Group (Participant or Partner) as a factor revealed there was significant improvement in modified curl-ups  $F(1,32) = 11.45, p = .002, h^2 = .263$  and 6-minute walk distance  $F(1,32) = 43.087, p < .001, h^2 = .574$ . There was no change in grip strength  $F(1,32) = .760, p = .390, h^2 = .023$ ; sit and reach  $F(1,30) = 2.148, p = .153, h^2 = .067$ ; or BMI  $F(1,32) = 4.133, p = .050, h^2 = .114$ . In addition, there were no significant Group x Fitness variable interactions ( $p > .05$ ).

**CONCLUSION:** This peer-guided model integrates social and instructional support for adolescents with ID and was effective for engaging our sample in exercise. The findings are encouraging for health promotion in an underserved population of youth. The project was funded by the Medical Foundation.

**2628 Board #22 May 29 2:00 PM - 3:30 PM**

**Physical And Motor Fitness And Physical Activity In Adolescents With Asperger Syndrome: A Comparative Study**

Erwin Borremans<sup>1</sup>, Pauli Rintala<sup>2</sup>, Jeff McCubbin<sup>3</sup>. <sup>1</sup>Keskuspuisto Vocational Institute, Helsinki, Finland. <sup>2</sup>University of Jyväskylä, Jyväskylä, Finland.

<sup>3</sup>Oregon State University, Corvallis, OR. (Sponsor: Tony Wilcox, FACSM)

Email: erwin.borremans@gmail.com

(No relationships reported)

Physical fitness and physical activity are vital for a healthy lifestyle for individuals with and without disabilities. Not only has low motor and physical fitness a negative effect on daily life of individuals with Asperger syndrome (AS), at the same time it increases the likelihood of becoming less physically active.

**PURPOSE:** To compare motor fitness and health related physical fitness, and physical activity levels in adolescents with and without AS.

**METHODS:** Thirty adolescents, diagnosed with AS ( $X=17.2\pm1.2$  yrs), agreed to participate in the study together with thirty age and gender matched neurotypical peers ( $X=16.9\pm0.8$  yrs). Physical fitness evaluations were done using the EUROFIT test (Oja & Tuxworth, 1995). In addition, a research questionnaire regarding the participants' physical activity during leisure time was administered to all participants (Baecke et al., 1982). A 2X2 multivariate analyses of variance, with standard scores on all EUROFIT subtests, were conducted to assess whether differences between groups (AS vs. controls) and genders on fitness items exist. Differences between the groups' average scores on the Baecke questionnaire were analyzed using t-test for independent groups.

**RESULTS:** Adolescents with AS scored significantly lower than the comparison group on all subtests of motor skill (MSRF)- and health related (HRF) physical fitness in the EUROFIT ((MSRF)=.428,  $F(1,58)=18.37 (p<.001)$  and (HRF)=.432,  $F(1,58)=11.63 (p<.001)$ ). Effect size across items ranged from  $h^2=.09$  to  $.53$ . Adolescents with AS were less physically active than adolescents in the comparison group ( $p<.001$ ).

**CONCLUSION:** Adolescents with AS have lower levels of physical fitness in balance, coordination, flexibility, muscular strength, running speed and cardio-respiratory endurance and have higher levels of physical inactivity when compared to age matched peers. Engagement in physical activities and individualized training adapted for individuals with AS is recommended.

Supported by Finnish Ministry of Education Grant (Finland, OPM 2008)

**Predicting Exercise Training Intensity in Obese African American Breast Cancer Survivors**

Gregory K. Karapetian<sup>1</sup>, Randall J. Gretebeck, FACSM<sup>1</sup>, Zora Djuric<sup>2</sup>. <sup>1</sup>Wayne State University, Detroit, MI. <sup>2</sup>University of Michigan, Ann Arbor, MI.

Email: gregorykarapetian@hotmail.com

(No relationships reported)

**PURPOSE:** Physical activity is an effective recommendation for weight loss, however little information is available regarding exercise capacity in obese African American breast cancer survivors. The purpose of this study was to evaluate alternative methods for establishing exercise training intensity levels during progressive cardiovascular exercise in ( $n = 20$ ) obese African American breast cancer survivors.

**METHODS:** Submaximal graded exercise testing consisted of stationary cycling for 3 min stages progressing at 25 watt (W) increments until subjects reached 85% of their heart rate reserve or a respiratory exchange ratio (RER) in excess of 1.1. Continuous heart rate and RR interval measurements (time duration between two consecutive R waves of the EKG) were recorded via a Polar® heart rate monitor with computer interface, where 20 sec averages were used for analysis of heart rate variability. Body composition was determined using DEXA.

**RESULTS:** Ventilatory threshold occurred at  $5.32 \pm 1.07$  ml·kg<sup>-1</sup>·min<sup>-1</sup> and heart rate variability threshold occurred at  $5.23 \pm 1.06$  ml·kg<sup>-1</sup>·min<sup>-1</sup>. The two thresholds correlated well with each other ( $r = 0.82$ ). The mean pRER was  $1.16 \pm 0.09$ , where 30% of the participants had a pRER in excess of 1.20. Measurements of body composition reported  $42.46 \pm 4.05$  % body fat. Peak VO<sub>2</sub> was  $10.29 \pm 2.16$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, where 40% of participants had a peak VO<sub>2</sub> that was  $>10$  but  $\leq 14$  ml·kg<sup>-1</sup>·min<sup>-1</sup> (reduced exercise capacity) and 55% had a peak VO<sub>2</sub>  $\leq 10$  ml·kg<sup>-1</sup>·min<sup>-1</sup> (severely reduced exercise capacity). While 75% of participants did not reach their target heart rate, 15% reported between 13-14 (somewhat hard), 45% reported between 15-16 (hard), 40% reported  $\geq 17$  (very hard), on the Borg scale rating of perceived exertion.

**CONCLUSIONS:** Given the importance of regular exercise in a weight loss program, this study considered a variety of exercise guidelines and determined some of them to be unsuitable for this population.

**Exercise Mode Effect On Ankle Strength, Activity Balance, And Functional Fitness Of Stroke Patients**

Jin Wook CHUNG<sup>1</sup>, Eun Kyung PARK<sup>2</sup>, Hye Young LEE<sup>2</sup>, Young Soo JIN<sup>1</sup>, Kwang Jun KIM<sup>3</sup>, Han Nah YANG<sup>4</sup>. <sup>1</sup>University of Ulsan, Seoul, Republic of Korea. <sup>2</sup>Asan Medical Center, Seoul, Republic of Korea. <sup>3</sup>Korean Institute of Sport Science, Seoul, Republic of Korea. <sup>4</sup>Baekseok University, Cheonan, Republic of Korea.

Email: cjw826@hotmail.com

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effective exercise mode in improving ankle strength, activity balance, and functional fitness of stroke patients.

**METHODS:** 14 stroke patients volunteered to participate and divided into two groups ( $n=14$ ): ball exercise group ( $n=7$ ), treadmill exercise group ( $n=7$ ). All of them were capable of independent walking without other's aid. Cybex770 and activity balance coefficient scale were used to evaluate ankle isokinetic strength and activity balance, respectively. 6min walking, sit to stand, grip strength, sit & reach, 3m up & go, reaction time, functional reach, and closed one leg stand were measured for functional fitness before and after the 12-week of exercise training.

**RESULTS:** In ankle isokinetic test, although there was no interactions, right 60 °/sec dorsal flexion increased significantly in time ( $p=.019$ ). Significant interaction ( $p=.002$ ) and time difference ( $p=.018$ ) were shown in activity balance after training. In functional fitness, left grip strength ( $p=.043$ ), closed one leg stand ( $p=.005$ ), functional reach ( $p=.015$ ) showed significant interaction and closed one leg stand ( $p=.000$ ), sit to stand ( $p=.003$ ), reaction time ( $p=.029$ ), and 3m up & go ( $p=.002$ ) showed significant time differences.

**CONCLUSIONS:** Even though, both exercises proved to increase ankle isokinetic strength, activity balance, and functional fitness, ball exercise seems to more affect on activity balance and functional fitness compare to treadmill exercise by increasing core stability. Therefore, ball exercise is recommended for improving balance and functional fitness.

**2631 Board #25 May 29 2:00 PM - 3:30 PM**  
**Analysis Of Education Programming For Personal Trainers: Exercise Implementation For Clients With Neurological Impairments**

Mary K. Wehde. *Mayo Clinic, Rochester, MN.* (Sponsor: Edward Laskowski, MD, FACSM)  
Email: wehde.mary@mayo.edu  
(No relationships reported)

**PURPOSE:** Increasing numbers of people suffer from diseases related to inactivity or obesity and this problem is of greater magnitude for those with disability. Lack of resources and knowledgeable providers is a key factor that prevents access to services for this population in the community. Personal trainers, key community providers, do not typically have training for working with this population. This project included development and implementation of an educational program for personal trainers in exercise management for clients with neurological impairments focusing on cerebrovascular accident, spinal cord injury, Parkinson's disease, multiple sclerosis and acquired brain injury.

**METHODS:** A six-hour program was taught to twenty personal trainers. Subjects had certifications in personal training from the American College of Sports Medicine and/or the National Strength and Conditioning Association or degrees in exercise management. Program curriculum was based on current evidence-based literature and texts. Subjects completed a pre-test and a post-test for outcome analysis.

**RESULTS:** Improvement of scores was statistically significant. The mean pretest score was 44.2 +/- 11.2%. The mean posttest score was 87.4 +/- 10.0%. Utilizing a paired t-test, the mean improvement score of 44.2% was significant ( $t[19] = 12.577$ ,  $p < 0.001$ , 95% CI of the improvement is 36.0% to 50.4%). Of the sixteen items comprising the exam, performance was significantly improved on ten items. Analysis was done with McNemar test using exact binomial probability calculations. Validity of exam questions was verified using analysis of point biserial correlation. Fifteen items were found to be valid with a positive point biserial correlation. One item had a negative point biserial correlation meaning subjects who overall did well on the exam tended to get this question wrong. This item was not included in analysis.

**CONCLUSIONS:** This educational program was proven to be effective in improving the personal trainers' knowledge base regarding exercise implementation for clients with neurological impairments.

**The Effect Of Vision On Muscle Power In Trained And Untrained Males And Females**

Shanna Killebrew, Robert W. Hensarling, Alan P. Jung, John K. Petrella. *Samford University, Birmingham, AL.*  
(No relationships reported)

Recent studies have documented significant isokinetic strength and power differences in the visually impaired compared to age-and-sex matched sighted individuals. However, these differences have been solely attributed to a decreased activity level in the visually impaired.

**PURPOSE:** The purpose of this study was to determine if vision affects muscle power production. In addition, the ability of a regular lower body strength training regimen (2x's per wk) to accommodate for the absence of vision was also examined.

**METHODS:** Thirty college-aged participants performed a seated leg press with and without vision (blindfold) in two separate counterbalanced trials. Quadriceps' power was calculated using the following variables: distance the leg press footplate was displaced, time of concentric muscle activity, and an individualized force variable for each participant (60% of 1 Repetition Maximum). Muscle activity was measured using surface electromyography. An alpha level of .05 was established and separate repeated measures analysis of variance were performed to determine the effect of visual stimuli, training status, and gender on muscle power production.

**RESULTS:** A significant main effect was found for visual stimuli ( $p < .01$ ). There was a significant interaction between vision x training status ( $p < .05$ ), but not vision x gender ( $p = .147$ ). A Tukey HSD revealed untrained females saw the greatest decrease in power ( $p < .001$ ). Power significantly decreases in the absence of vision, but a regular strength training program in the visually impaired can be implemented to help counteract such occurrences.

**CONCLUSIONS:** Strength and power differences in visually impaired individuals are rightfully attributed to activity level, but these findings suggest the role of vision in muscle power production should also be considered.

**2633 Board #27 May 29 2:00 PM - 3:30 PM**  
**Relation Between Heart Sound Amplitude And Diastolic Time During Exercise In Persons With Cardiac Disease**

Takuro Matsuda<sup>1</sup>, Shigeru Obara<sup>2</sup>, Peter H. Brubaker, FACSM<sup>3</sup>, Hiroaki Tanaka<sup>1</sup>. <sup>1</sup>*Fukuoka University, Fukuoka, Japan.* <sup>2</sup>*The University of Tokushima, Tokushima, Japan.* <sup>3</sup>*Wake Forest University, Winston-Salem, NC.*  
(No relationships reported)

**PURPOSE:** The amplitude of the first heart sound (AHS1), an index of the left ventricular contractility, increases during graded exercise and results in a clear break-point called the heart sounds breaking point (HSBP). The workload corresponding to HSBP has been demonstrated to be closely associated with the  $\dot{V}O_{2\max}$  and the workload at the LT. The systolic and diastolic time (DT) can be observed from the timing of the first heart sound (S1) and the second heart sound (S2). A close correlation between the DT (DT/RR interval (%)) and ST depression in exercise in patients with effort angina has been reported, however, the ischemic threshold of the DT was not related to the corresponding values of the RR interval. The heart sound is a convenient and noninvasive technique for assessing cardiac performance and may provide valuable information regarding exercise stress. Consequently, this study investigated the relationship between the HSBP and DT.

**METHODS:** Nineteen subjects, aged 71+10 years with a BMI of 26.4+3.4 kg/m<sup>2</sup>, underwent a submaximal graded cycle ergometer test. The work rate started at 15 watts and then increased at 15 watts every 90 sec until reaching an RPE of 15. The AHS1 was expressed by the ratio of amplitude immediately after exercise versus rest. For determining the HSBP of each subject, AHS1 of each stage was plotted on a graph versus workload. The point of the abrupt increase in AHS1 versus the workload was determined from visual inspection. The %DT was measured at rest and at each stage of exercise. Values of the %DT were calculated by the formula [(RR-S1S2 interval)/RRx100].

**RESULTS:** The HSBP was obtained in 16 subjects. The HSBP was not obtained in 3 subjects due to weak heart sounds. The average of HSBP and %DT at HSBP were 61.1 + 23.7 watts, 54.0 + 6.0 %. The correlation between the HSBP and age was statistically significant (HSBP vs. age,  $r = -0.64$ ,  $p < 0.01$ ). The correlation between the HSBP and %DT was not statistically significant.

**CONCLUSION:** Monitoring heart sound appears to provide valuable information related to level of exercise stress. This information may be useful when determining an appropriate exercise prescription.

*This study was partly Supported by grants from the Japanese Ministry of Education, Science, Sports, and Culture (No. 19200049) and a Global FU Program by Fukuoka University.*

**2634 Board #28 May 29 2:00 PM - 3:30 PM**  
**Validity Of Talking Pedometers In Measuring Steps: Effect Of Free-living, Speed, And Stair Climbing**

Carolyn Albright, Gerald Jerome, Parker Rhodes, James Bickley, Kurt Light. *Towson University, Towson, MD.* (Sponsor: Jill A. Bush, FACSM)  
Email: calbright@towson.edu

(No relationships reported)

Talking pedometers are commercially available for individuals with visual impairment as a tool for objectively monitoring physical activity. The functions of these pedometers for individuals who may have difficulty reading pedometer read-outs or function data makes them usable for both research and in the general population.

**PURPOSE:** To examine the accuracy of 4 electronic talking pedometers in measuring steps during free-living, stair climbing, and increasing walking speeds. Pedometers included: Oregon Scientific (OS), Sportline (SL), Brookstone (BS), and Accusplit Alliance (AA).

**METHODS:** Twenty participants, 10 young adults (avg. 24+5 years) and 10 older adults (avg. 73 years), wore each talking pedometer simultaneously with a criterion pedometer (Digiwalker SW-200) during a 24-hour period. Participants recorded steps at the end of each day on a log. Both young and older adults completed the stair climbing section by walking up and down a flight of stairs wearing the talking pedometers on a waistbelt while actual steps were hand-tallied (HT) by the investigator. To determine the effect of speed on pedometer validity, the 10 young participants completed a 5-stage treadmill test at increasing speeds of 54, 67, 80, 94 and 107 m[Unsupported Character - &#903;]min<sup>-1</sup>. Each stage was 4-minutes, with actual steps measured using HT.

**RESULTS:** There was no effect for age on free-living measurement, with the AA being the only valid pedometer in step counting when compared to the criterion ( $p=0.748$ ; % error = -1.72%). There was also no effect for age on step measurements during stair climbing for any pedometers, with the BS being the only valid pedometer for both upstairs and downstairs when compared to HT ( $p>0.05$ , avg % error = -8.03% ). There was an effect for walking speed on pedometer validity for OS and SL, with both becoming more accurate with increasing speeds. BS (avg % error = -0.89% ) and AA (avg % error = 1.01%) were valid at all walking speeds ( $p>0.05$ ).

**CONCLUSION:** In general, the AA was the most valid of all talking pedometers in measuring steps during free-living and at different walking speeds. The BS was the only valid talking pedometer for measuring steps during stair climbing. These results show that there are valid pedometers available for those with visual impairment to objectively monitor daily step accumulation.

---

## **F-23 Free Communication/Poster - Determinants of Physical Activity and Health Behaviors in Various Populations**

### **2635 Board #29 May 29 3:30 PM - 5:00 PM**

#### **Correlates Of Child Activity And Television: The Contribution Of Children's Athletic Identity**

Louise C. Masse<sup>1</sup>, Cheryl B. Anderson<sup>2</sup>, Karen J. Coleman<sup>3</sup>, Hong Zhang<sup>4</sup>, Shine Chang<sup>4</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada. <sup>2</sup>Baylor College of Medicine, Houston, TX. <sup>3</sup>Southern California Permanente Medical Group, Pasadena, CA. <sup>4</sup>University of Texas M.D. Anderson Cancer Center, Houston, TX.

Email: lmasse@cw.bc.ca

(No relationships reported)

There is evidence that athletic self-concept can be both an important outcome and/or a mediating variable for physical activity in children and adolescents. However much less is known about the relationship between sedentary behaviors, such as television with athletic self-concept.

**PURPOSE:** This study examined the contribution of children's athletic self-concept to physical activity and sedentary behavior over and above effects of demographic factors related to child activity.

**METHODS:** Two age groups of children (N = 1503) completed the 40-item Athletic Identity Questionnaire (AIQ), measuring athletic appearance, competence, importance of physical activity and sports, and encouragement for activity from parents, teachers, and friends. Hierarchical multiple regression analysis assessed the effects of athletic identity, ethnic group, gender, and overweight status on moderate-to-vigorous physical activity and television watching in each age group. Secondary analyses considered the contribution of each factor of athletic identity to both behavioral outcomes.

**RESULTS:** In both age groups of children, the global score of athletic identity was independently related to physical activity ( $p < .0001$ ,  $p < .0001$ ) and television ( $p = .01$ ,  $p = .002$ ). More variance in physical activity was explained in younger (23%) than older children (5%), with almost equal amounts for television across age (2%, 4%). Secondary analyses showed that relationships for competence, importance, and parental encouragement persisted independent of the effects of demographic factors on behavior.

**CONCLUSIONS:** Results support the potential role of athletic self-concept in promoting exercise, sports, and physical activity behavior, but provide less support for substantially reducing time spent watching television. Although the positive influence of self-concept operated over and above the effects of gender, ethnicity, and overweight status, these demographic variables influence specific self-conceptions, which should be recognized in the development of interventions to change active and sedentary behaviors.

---

### **2636 Board #30 May 29 3:30 PM - 5:00 PM**

#### **A Two Year Comparison Of The Psychosocial Correlates Of Physical Activity For Middle School Youth**

Teresa Fitts. Westfield State College, Westfield, MA. (Sponsor: Mark Blegen, FACSM)

Email: tfitts@wsc.ma.edu

(No relationships reported)

**PURPOSE:** To conduct a two-year comparison of the reported physical activity (PA) levels and psychosocial variables influencing the PA of 6<sup>th</sup> and 7<sup>th</sup> Graders within the context of the Youth Physical Activity Promotion Model.

**METHODS:** The Children's Physical Activity Correlates Scale (CPAC), Physical Activity Enjoyment Scale (PACES) and Physical Activity Questionnaire for Older Children (PAQ-C) were administered in two consecutive years to middle school youth. In Year 1, 77 6<sup>th</sup> (n = 34) and 7<sup>th</sup> (n = 43) graders completed the surveys. In Year 2, 66 7<sup>th</sup> (n = 24) and 8<sup>th</sup> (n = 42) of the same students, boys (n = 31) and girls (n = 35), completed the surveys. Physical activity was measured by the average of the scores reported on the PAQ-C which was administered twice during the semester.

**RESULTS:** Significant differences were found in the reported PA levels and psychosocial correlates of the participants. The mean PA scores were significantly ( $p < .01$ ) lower in Year 2 than in Year 1. Scores reported for 'enjoyment' of PA were also significantly ( $p < .01$ ) lower in Year 2 than in Year 1. The predisposing factor of 'Attract' (liking games and sports, finding physical exertion fun, liking exercise, finding exercise important) was significantly lower ( $p < .01$ ) in Year 2 than in Year 1. However, 'perceived competence' was not significantly ( $p > .05$ ) different from Year 1 to Year 2. Reinforcing factors relating to the perception of 'parent influence' and perception of 'parent role modeling' were not significantly ( $p > .05$ ) different from Year 1 to Year 2. 'Self-esteem' was significantly ( $p < .05$ ) lower in Year 2 than in Year 1. 'Peer Acceptance' was the only factor that was significantly ( $p < .05$ ) higher in Year 2 than in Year 1.

**CONCLUSIONS:** In the transition from 6<sup>th</sup> to 7<sup>th</sup> and 7<sup>th</sup> to 8<sup>th</sup> Grade, reported PA levels of boys and girls decreased. Some psychological and social variables that influence PA also decreased. Students tended to enjoy PA less, have lower self-esteem and were less attracted to PA. How these students perceived their parent's support, encouragement and function as role models did not change. The role of peers in the acceptance of PA increased. Additional research is needed to develop programs focusing on ways to make PA more likable and appealing in peer-accepted settings.

2637 Board #31 May 29 3:30 PM - 5:00 PM

**Physical Activity And Social Support For Exercise In A Sample Of Sorority And Fraternity Members**

Dixie L. Thompson, FACSM, Jennifer A. Bennett, Leslee A. Fisher, Eugene C. Fitzhugh. *University of Tennessee, Knoxville, TN.*

Email: dixielee@utk.edu

(No relationships reported)

Many factors, including social support, influence the decision to be physically active. College students' physical activity patterns have been examined, but less is known about these patterns among college students belonging to fraternities and sororities, a potential source of social support.

**PURPOSE:** 1) to provide a description and comparison of the levels of physical activity and social support for exercise among fraternity and sorority members, and 2) to examine the relationship between social support for exercise and physical activity in fraternity and sorority members.

**METHODS:** Fraternity and sorority members at a large university were recruited online via email and asked to complete a survey. The online survey included the International Physical Activity Questionnaire, the Social Support for Exercise Survey, and demographic questions. Physical activity was contrasted and modeled using MANOVA and stepwise multiple regression in SPSS version 15.0.

**RESULTS:** Three hundred thirty-seven members of fraternities and sororities completed an online survey (74.8% female). The majority (90%) of fraternity and sorority members reported some moderate or high intensity physical activity. However, most (62.3%) were not vigorously active 3 days per week for at least 20 minutes per session. Males were significantly more likely to report being active than females ( $p < 0.001$ ). There were moderate correlations between social support for exercise from friends and moderate activity ( $r = 0.27$ ,  $p < 0.01$ ) and vigorous activity ( $r = 0.39$ ,  $p < 0.01$ ). Social support for exercise from friends and gender predicted 22% of the variance in moderate and vigorous physical activity.

**CONCLUSION:** Consistent with previous studies, less than half of these students engaged in recommended levels of vigorous exercise. Also similar to previous reports of male and female college students, fraternity members reported more participation in vigorous activity than did sorority members. Social support for exercise from friends was higher in both male and female students reporting structured moderate and vigorous exercise. This suggests that friends provide an important source of encouragement for those who exercise. The strongest predictors of moderate and vigorous exercise in these students were social support from friends and gender.

2638 Board #32 May 29 3:30 PM - 5:00 PM

**A Description Of Internet Usage For Health And Fitness Information Among Middle-aged And Older Adults**

Erica M. Jackson<sup>1</sup>, Angela B. Lanier<sup>2</sup>, David G. Wilson<sup>1</sup>, Danielle Lorenz<sup>1</sup>. <sup>1</sup>College of William and Mary, Williamsburg, VA. <sup>2</sup>Berry College, Rome, GA. (Sponsor: Michael R. Deschenes, FACSM)

Email: emjack@wm.edu

(No relationships reported)

Census data indicate that almost one third of adults have used the internet for health information. That number is reported to be much higher for older adults. There is limited research on internet use for exercise or fitness information among older adults.

**PURPOSE:** This descriptive study examined internet usage for health and fitness information among middle-aged and older adults.

**METHODS:** Participants (N= 140; 50 - 94 yrs) completed a questionnaire that assessed personal demographics and characteristics of internet use for health and fitness information.

**RESULTS:** Participants were mostly women (63.4%) and Caucasian (93.6%), and 95% had completed at least some college. Most participants (91%) had internet access for personal use and 79% reported using the internet multiple times per week or daily. Of participants who seek health information, 46.8% indicated the internet was a primary source for health information. Only 17.9% of those who seek fitness information listed the internet as a primary source, but 37% reported they had ever used it for exercise or fitness information. Half reported checking the credentials of their primary sources for health information, and only 31% reported checking credentials of their primary sources for fitness information. Over half (56%) use a regular website for health information, but few (26.7%) used a regular site for fitness information. Only 37.3% of participants reported never receiving inaccurate health information from a primary source, but 60.2% indicated they had never received inaccurate fitness information from a primary source. Participants rated internet information as good or excellent for health (87.2%) and fitness (88.6%). The ability to understand information was reported as the most important criterion for evaluating the quality of health (47.2%) and fitness (43.6%) websites.

**CONCLUSION:** The internet was a common source for health information, but was used less for fitness information. Participants typically did not check the credentials of sources, but rated internet information as good or excellent. Being able to understand information was considered most important. Health and fitness professionals should educate older adults on evaluating internet information and be able to provide them with quality websites for health and fitness information.

**A Social Ecological Approach To Increase Walking Among Sedentary Women**

Amy E. Speed-Andrews, Janet Buckworth, FACSM, Rick L. Petosa, Randi Love. *The Ohio State University, Columbus, OH.*

(No relationships reported)

Less than half of American women are sufficiently active to reduce their risk for chronic disease. Current evidence emphasizes the importance of creating programs to increase physical activity that encompass multiple levels of the social environment.

**PURPOSE:** To evaluate the efficacy of a social ecological intervention to increase walking among sedentary women.

**METHODS:** We delivered the intervention at the organizational level (church), and we operationalized walking as average steps/day, measured by the New-Lifestyles Digi-Walker SW 200 pedometer. A convenience sample of N = 7 Christian churches in the Greater Columbus area participated in the study, and women were recruited from cooperating churches into the social ecological intervention (SE: n = 20) or a self-monitoring only comparison group (SM: n = 18). Both groups monitored steps/day over the 10 week study. Women in the SE group only attended four sessions targeting intrapersonal (self-efficacy, self-regulation), and interpersonal (social network, group cohesion) levels of the social environment.

**RESULTS:** Women in the SE group increased steps/day more than women in the SM comparison group (~ 2660 vs. ~ 1316,  $p < .05$ ). Additionally, the SE intervention had a significant impact on self-regulatory self-efficacy ( $p < .05$ ) and social network index church ( $p < .001$ ). Self-regulation and social support for physical activity significantly increased over time ( $p < .001$ ), but the difference between the groups was not significant. Associations between change in steps/day, self-regulatory self-efficacy, and the social network index church ( $r = .309$ ,  $r = .305$ , respectively), suggest they were possible mediators of the intervention on steps/day. Associations between change in steps/day with BMI ( $r = .435$ ), age ( $r = .453$ ), and education ( $r = .391$ ), imply their role as moderators.

**CONCLUSIONS:** The findings support including multiple levels of the social environment in interventions to increase physical activity among sedentary women.

2640 Board #34 May 29 3:30 PM - 5:00 PM

**Factors Predicting Adherence To 9 Months Of Supervised Exercise In Healthy Older Women**

Erin Olson, Amanda Visek, Loretta DiPietro, FACSM. *The George Washington University School of Public Health and Health Services, Washington, DC.* (Sponsor: Loretta DiPietro, FACSM)

Email: [olsoneo@gwu.edu](mailto:olsoneo@gwu.edu)

(No relationships reported)

The determinants of physical activity participation in older people have been well-documented. Less is known, however, about factors affecting adherence to highly-structured and supervised exercise programs.

**PURPOSE:** To determine factors related to adherence to a 9-month exercise trial among previously-inactive, healthy older (> 65 y) women (N=30).

**METHODS:** Subjects were randomized into a: 1) higher- ( $AT_H$  - 80%  $VO_{2peak}$ ); or 2) moderate- ( $AT_M$  - 65%  $VO_{2peak}$ ) intensity aerobic; or 3) lower-intensity resistance ( $RT_L$ ; 50%  $VO_{2peak}$ ) group. All three groups were identical in exercise frequency (4 days/week); however, subjects in the  $AT$  groups exercised for a duration necessary to expend 300 kcal/session. All sessions were supervised at on-site facilities and subjects exercised in groups to enhance convenience and social support. Heart rate was measured continuously and recorded throughout exercise. Attendance was defined as the proportion of completed to prescribed exercise sessions (N=144). Adherence was defined as the proportion of prescribed sessions in which subjects achieved their: 1) prescribed heart rate; and 2) their prescribed duration. Determinants of adherence included age, BMI, lean mass (kg), %body fat,  $VO_{2peak}$ , prescribed intensity (METs) and prescribed duration (min), and exercise self-efficacy score.

**RESULTS:** Age,  $VO_{2peak}$ , and body composition were similar among the three groups. Attendance was greatest in the  $AT_H$  group (94%) and lowest in  $AT_M$  (90%). Adherence to the prescribed duration was 95%, 91%, and 85% in the  $RT_L$ ,  $AT_H$ , and  $AT_M$  groups, respectively. Adherence to the prescribed intensity was 100% for all three groups. We observed a positive (rather than inverse) correlation between the prescribed METs and attendance ( $r=0.48$ ;  $p<0.03$ ), as well as adherence to the prescribed duration ( $r=0.53$ ;  $p<0.01$ ). Prescribed duration was not associated with attendance ( $r=0.14$ ;  $p<0.46$ ); however, the prescribed duration of each session was the strongest determinant of adherence to that duration ( $r=-0.72$ ;  $p<0.0001$ ).

**CONCLUSIONS:** Exercise duration (not intensity) may negatively affect adherence to structured exercise programs. Programs comprising exercise of shorter duration, but greater frequency may be more effective in helping older adults achieve the health benefits of an active lifestyle.

**Relationship Between Prepregnancy Body Mass Index, Psychological Health, And Physical Activity In Pregnancy**

Erica L. Rauff, Danielle Symons Downs, Jennifer M. DiNallo. *Pennsylvania State University, University Park, PA.*

Email: [elr12@psu.edu](mailto:elr12@psu.edu)

(No relationships reported)

Women's prepregnancy body mass index (BMI) is an independent predictor of pregnancy complications including poor psychological health. Regular physical activity (PA) is one strategy for improving women's psychological health, however, the research examining the association between BMI, psychological health, and PA during pregnancy is scant.

**PURPOSE:** To examine the moderating influence of prepregnancy weight status on psychological health and PA behaviors during the second pregnancy trimester.

**METHODS:** Women ( $N = 40$ ,  $M$  age =  $29 \pm 5$  yrs; prepregnancy BMI =  $26 \pm 8$   $kg\ m^{-2}$ ) completed self-reported measures of depression (CES-D), body satisfaction (BASS), anxiety (STAI), and wore NL1000 pedometers at 20- weeks gestation. Participants were categorized by their prepregnancy BMI as either normal weight ( $19.8$  to  $24.9$   $kg\ m^{-2}$ ) or overweight ( $> 25$   $kg\ m^{-2}$ ); and one-way ANOVA's with Bonferroni correction were used to examine group differences across the study measures.

**RESULTS:** Women classified as normal weight prior to pregnancy had significantly higher body satisfaction ( $M = 29$ ) compared to overweight women ( $M = 23$ ),  $F(1, 26) = 5.8$ ,  $p < .05$ . In addition, normal weight women accumulated more min of moderate-vigorous PA (MVPA;  $M = 33$ ) per day compared to the overweight women ( $M = 21$ ),  $F(1, 28) = 3.4$ ,  $p < .05$ . No significant group differences were observed for the CES-D and STAI ( $p$ 's  $> .05$ ).

**CONCLUSION:** These preliminary findings illustrate that prepregnancy BMI may have an important influence on psychological health and PA behaviors in pregnancy. Women who were classified as normal weight prior to pregnancy reported feeling more satisfied with their bodies and exercised at a higher intensity during pregnancy compared to women who were overweight prior to pregnancy. These findings have important implications for the role of preconceptional interventions in promoting healthy weight before women are pregnant in an effort to improve psychological health and PA and reduce complications during pregnancy.

**2642 Board #36 May 29 3:30 PM - 5:00 PM**

**Perceived Control And Physical Activity Determinants And Behaviors Among Pregnant Women With Gestational Diabetes**

Danielle Symons Downs, Jennifer M. DiNallo, Erica L. Rauff, Amy C. Minogue. *Pennsylvania State University, University Park, PA.*

Email: [dsd11@psu.edu](mailto:dsd11@psu.edu)

(No relationships reported)

Perceived control is an important determinant of physical activity (PA) motivation and behavior, and it may be particularly salient for pregnant women with complications such as gestational diabetes (GDM). While PA is safe and recommended as a strategy for controlling blood sugar, most GDM women are inactive. Little is known about how GDM women feel about engaging in PA during pregnancy and whether perceived control influences their PA determinants and behaviors during this time.

**PURPOSE:** To prospectively examine PA determinants and behaviors among GDM women with low and high perceived control using the framework of the Theory of Planned Behavior.

**METHODS:** Women with GDM ( $N = 45$ ,  $M$  age =  $29 \pm 4$ , 78% Caucasian) completed self-reported measures of their PA attitude (ATT), subjective norm (SN), intention (INT), and perceived behavioral control (PBC), and wore Actigraph accelerometers and NL1000 pedometers during their 2nd and 3rd trimesters. Based on their PBC scores, women were classified as having low or high perceived control for PA; one-way ANOVAs with Bonferroni correction were used to determine significant group differences across the study variables.

**RESULTS:** In the 2nd trimester, the high PBC group had significantly higher ATT ( $M = 44$ ), SN ( $M = 20$ ), INT ( $M = 19$ ), and Actigraph activity counts/min ( $M = 340$ ) compared to the low PBC group ( $M = 37$ , 15, 14, 267, respectively;  $p$ 's  $< .001$ ). No significant differences for the NL1000 steps/day or min of moderate-vigorous PA (MVPA) were observed. In the 3rd trimester, the high PBC group had significantly higher ATT ( $M = 42$ ), SN ( $M = 18$ ), INT ( $M = 18$ ), Actigraph activity counts/min ( $M = 317$ ), NL1000 steps/day ( $M = 6,689$ ), and NL1000 MVPA min ( $M = 22$ ) compared to the low PBC group ( $M = 32$ , 14, 10, 255, 4,404, 12, respectively,  $p$ 's  $< .01$ ).

**CONCLUSION:** These preliminary data suggest that perceived control may be an important factor influencing GDM women's PA determinants and behaviors, particularly in later pregnancy when there are more physical and psychological barriers to PA participation. Increasing GDM women's perceived control for PA may help this group to increase their PA and better manage their diabetes, which in turn, can result in better health outcomes for these women and their offspring.

**2643 Board #37 May 29 3:30 PM - 5:00 PM**

**Physical Activity Levels Of Adults With Mild Intellectual Disabilities**

Sharon Hsu<sup>1</sup>, Bo Fernhall, FACSM<sup>2</sup>, Stanley Hui, FACSM<sup>3</sup>, James Halle<sup>4</sup>, James Halle<sup>2</sup>. <sup>1</sup>California State University, Northridge, Northridge, CA. <sup>2</sup>University of Illinois at Urbana-Champaign, Champaign, IL. <sup>3</sup>Chinese University of Hong Kong, Hong Kong, Shatin, Hong Kong. <sup>4</sup>University of Illinois at Urbana-Champaign, Champaign, CA.

Email: sharon.hsu@csun.edu

(No relationships reported)

**PURPOSE:** Regular physical activity participation is considered as a critical element in health promotion. Little is known regarding physical activity levels of individuals with intellectual disabilities. The purpose of this study was to investigate levels of physical activity among adults with mild intellectual disabilities (MID) in Taiwan.

**METHODS:** A national sample of 116 adults with MID recruited from four major geographical regions in Taiwan participated in this study. Step counts were gathered from each participant for 7 consecutive days. Additionally, direct caregivers recorded physical activity logs of participants with MID for 3 days using the Bouchard three-Day Physical Activity Record.

**RESULTS:** The results indicated that participants spent 15.6 hours in sedentary activity, 6.8 hours in mild physical activities, and 1.6 hours in moderate and vigorous physical activities (MVPA) on average per day. On average, participants walked 9,273 steps per day. Approximately 34% of participants met the 10,000 steps per day recommended physical activity level.

**CONCLUSION:** A unique and unexpected finding of this study was the overall level of physical activity as reflected in the step counts and time engaged in the MVPA.

Although this finding is likely related to the younger age of the adult sample and the selective recruitment from work sites in which manual labor was often part of their job responsibilities, it remains a provocative outcome. The potential interactive effect of work-related and leisure time physical activity, as well as age, gender, and health status ought to be further explored in health promotion practices for this population.

**Body Mass Index, Function, And Physical Activity In Hypertensive Older Adults: Theory Of Planned Behavior**

LeAnn M. Sabatini<sup>1</sup>, Kimberlee A. Gretebeck<sup>1</sup>, Laura Struble<sup>1</sup>, David Ronis<sup>1</sup>, David R. Black<sup>2</sup>, Carolyn L. Blue<sup>3</sup>, Randall J. Gretebeck, FACSM<sup>4</sup>.

<sup>1</sup>University of Michigan, Ann Arbor, MI. <sup>2</sup>Purdue University, West Lafayette, IN. <sup>3</sup>University of North Carolina Greensboro, Greensboro, NC. <sup>4</sup>Wayne State University, Detroit, MI.

(No relationships reported)

Physical activity (PA) participation declines with age and may result in the development of chronic disease and disability. The theory of planned behavior (TPB) has been shown to explain PA behavior.

**PURPOSE:** To identify the predictors of intention and PA behavior of older adults with hypertension.

**METHODS:** A secondary analysis was conducted in a sub-sample (n=404) of hypertensive older adults (M age= 75.8 years,  $\pm$  6.5) from an initial survey of 2056 retirees from a large Midwestern university.

**RESULTS:** Multiple regression analyses revealed that a modified TPB model that included functional ability (FA) and BMI explained 54.3% of the variance in *intention* to be physically active and 30% of *PA behavior* ( $p < .05$ ). Perceived behavioral control (PBC), attitude and FA influenced *intention* to participate in PA ( $b = .44$ ,  $b = .33$ ,  $b = .11$ ,  $p < .05$  respectively) while FA, intention and BMI influenced *PA behavior* ( $b = .49$ ,  $b = .16$ ,  $b = .13$ ,  $p < .01$  respectively). Further analyses of BMI status revealed that FA was the strongest predictor of *PA* across all groups: normal weight, overweight, and obese ( $b = .54$ ,  $b = .43$ ,  $b = .47$ ,  $p < .01$  respectively). Perceived behavioral control was the strongest predictor of *intention* in all groups: normal, overweight, and obese ( $b = .42$ ,  $b = .38$ ,  $b = .52$ ,  $p < .01$  respectively). For the overweight group, age and gender ( $b = -.22$ ,  $b = .15$ ,  $p < .05$  respectively) predicted *PA*, while gender ( $b = .25$ ,  $p < .05$ ) predicted *PA* in the obese group. Attitude predicted *intention* across all weight groups ( $p < .01$ ) while subjective norm did not. Gender predicted *intention* in the normal weight group ( $b = .16$ ,  $p < .01$ ) and age was a significant predictor in the overweight group ( $b = .18$ ,  $p < .05$ ). Further analyses of gender indicated that men were significantly more physically active and had higher FA than women across all weight groups. Obese men had the highest PA and FA scores while obese women had the lowest.

**CONCLUSION:** PA interventions need to be individualized for older adults across different weight groups. FA, gender, and age should also be considered when designing interventions for older adults with hypertension.

**Demographic and Lifestyle Correlates of Physical Activity: The Shanghai Physical Activity Study**

Tricia M. Peters<sup>1</sup>, Steven C. Moore<sup>1</sup>, Wong-Ho Chow<sup>1</sup>, Bu-Tian Ji<sup>1</sup>, Xiao-Ou Shu<sup>2</sup>, Wei Zheng<sup>2</sup>, Yong-Bing Xiang<sup>3</sup>, Charles E. Matthews<sup>4</sup>, Michael F. Leitzmann<sup>5</sup>. <sup>1</sup>NIH/NCI, Bethesda, MD. <sup>2</sup>Vanderbilt University School of Medicine, Nashville, TN. <sup>3</sup>Shanghai Cancer Institute, Shanghai, China.

<sup>4</sup>Vanderbilt University Medical Center, Nashville, TN. <sup>5</sup>University of Regensburg, Regensburg, Germany.

Email: peterst@mail.nih.gov

(No relationships reported)

**BACKGROUND:** To understand the mechanisms by which physical activity influences health and to target public health recommendations, it is important to determine factors correlated with activity.

**METHODS:** We examined demographic and lifestyle factors in relation to questionnaire and accelerometer measured physical activity in 251 men and women aged 40 to 70 years in Shanghai, China. Physical activity over the past year was assessed by a newly developed questionnaire (PAQ) during two in-person interviews one year apart and by Actigraph accelerometer worn for four one-week periods over the same year. We evaluated both total physical activity energy expenditure (PAEE) and time in moderate to vigorous activity (MVPA) per day by averaging the PAQs and the four accelerometer wears, and categorizing each physical activity domain into two levels split at the median. Multiple logistic regression examined the association of demographic, anthropometric, lifestyle, and female reproductive factors reported at baseline with PAEE and MVPA as measured by PAQ and by accelerometer.

**RESULTS:** Over 70% of the study population achieved at least 60 minutes of average MVPA per day. In multivariate logistic regression analyses, a number of covariates were differentially associated with physical activity depending on the method of activity assessment. A high level of physical activity was less common among older men and women when measured by accelerometer, but more common when measured by self-report. In addition, while women self-reported higher PAEE, men showed suggestively higher accelerometer-assessed PAEE.

Certain dietary and reproductive factors (intake of fish, fruit, and poultry; number of pregnancies) also showed distinct associations depending on method of activity assessment, although occupation, waist-hip ratio, and smoking were consistently correlated with physical activity regardless of physical activity measurement method.

**CONCLUSION:** The association of physical activity with demographic, anthropometric, and lifestyle factors may vary according to method of physical activity measurement. However, these methods likely differ in the ability to capture certain domains of physical activity.

**My Baby, My Move: Examination Of Perceived Barriers And Motivating Factors To Antenatal Physical Activity**

Jenn Leiferman, Tracy Swibas. Colorado School of Public Health, Denver, CO. (Sponsor: Andrea Dunn, FACSM)

Email: jenn.leiferman@uchsc.edu

(No relationships reported)

**PURPOSE:** The American College of Obstetrics and Gynecologists recommends that pregnant women who are free of obstetrical complications engage in regular leisure physical activity (RLPA), but pregnant women engage in less RLPA than their nonpregnant counterparts. Given the low rates of RLPA among pregnant women, especially those of low socioeconomic status (SES),

coupled with the many maternal benefits associated with antenatal RLPA, there is a definite need to promote engagement in antenatal RLPA among pregnant women. Based on a socio-ecological model framework, the present study compared and contrasted multi-level barriers and facilitators related to physical activity engagement during pregnancy to better understand what motivates and prevents pregnant women from engaging in RLPA and whether or not and to what extent these may differ among level of activity, parity, and SES.

**METHODS:** Informant interviews and focus groups were conducted with 60 pregnant women (aged 18-46 yrs, 17-40 weeks gestation). Atlas/Ti software was used to code the verbatim interview transcripts by organizing codes into categories that reflect symbolic domains of meaning, and within domains, relational patterns, and finally overarching themes.

**RESULTS:** Perceived barriers and motivating factors differed between groups at various intra- and interpersonal, social and environmental levels. For example, sources of interpersonal support among low income women centered more on support from friends and family whereas healthcare providers played a primary support role among women from higher income levels.

**CONCLUSIONS:** Future interventions should take into account key motivating factors and barriers pertaining to SES groups, in order to tailor more meaningful advice for pregnant women.

*This work was funded by the CDC 1 K01 DP001127-01*

**Determinants Of Physical Activity In Older Adults With Peripheral Vascular Disease.**

Kimberlee A. Gretebeck<sup>1</sup>, Dusty Filliung<sup>1</sup>, David R. Black<sup>2</sup>, Carolyn Blue<sup>3</sup>, Randall J. Gretebeck, FACSM<sup>4</sup>. <sup>1</sup>University of Michigan, Ann Arbor, MI. <sup>2</sup>Purdue University, West Lafayette, IN. <sup>3</sup>University of North Carolina Greensboro, Greensboro, NC. <sup>4</sup>Wayne State University, Detroit, MI. (Sponsor: Randall J. Gretebeck, FACSM)  
Email: kagreteb@umich.edu  
(No relationships reported)

Functional impairment limits participation in leisure activities and decreases the ability to perform activities of daily living for older adults with peripheral vascular disease (PVD). The Theory of Planned Behavior has been found to explain older adult physical activity (PA). The determinants of PA are unclear for older adults with PVD.

**PURPOSE:** To examine a modified Theory of Planned Behavior model and identify the determinants of PA for older adults with PVD.

**METHODS:** Older adults with PVD (n=132), 66-97 years old (M age=75.8 years,  $\pm 6.5$ ), completed a cross-sectional survey. Measures included the TPB questionnaire, Physical Activity Scale for the Elderly and the Physical Functioning Scale.

**RESULTS:** The sample was mostly sedentary (M PA score=96.7,  $\pm 58.9$ ) with moderate limitations (M=55.8,  $\pm 28.8$ ) in functional ability (scores were 0=unable to do to 100=no difficulty). Linear regression analyses revealed that the modified TPB model that included functional ability explained 64% of the variance in intention to be physically active ( $p < .05$ ) and 35% of the variance in PA behavior ( $p < .01$ ). Attitude had the greatest influence on intention ( $b = .51$ ,  $p < .01$ ), followed by subjective norm, perceived behavioral control and functional ability ( $b = .17$ ,  $b = .17$ ,  $b = .15$ ,  $p < .05$ , respectively). Functional ability was the strongest predictor of PA ( $b = .39$ ,  $p < .01$ ), followed by intention ( $b = .24$ ,  $p < .01$ ). This population of older adults with PVD identified moderate difficulty in each functional ability task measured including performing heavy housework (M=46.5,  $\pm 37.5$ ), walking (M=50,  $\pm 35$ ), climbing stairs (M=53,  $\pm 31$ ), lifting/carrying 10 lb. (M=53,  $\pm 34.6$ ), light housework (M=66,  $\pm 32.8$ ), and rising from a chair (M=67.7,  $\pm 29$ ).

**CONCLUSIONS:** Exercises that promote increasing functional ability, with emphasis on activities related to daily living such as walking, stair climbing and housework, should be incorporated into the management of older adults with PVD.

**The Relationship Between Perceived Stress And Health Promoting Behaviors In Male And Female Undergraduate Students.**

Amanda L. Divin. Oklahoma State University, Stillwater, OK. (Sponsor: Steve Edwards, FACSM)  
Email: amanda.divin@okstate.edu  
(No relationships reported)

During college, students are inundated by a variety of stressors. Stress and the inability to effectively cope with stress can be detrimental. A relationship exists between stress and health-risk behaviors. However little research has examined the relationship between stress and health-promoting behaviors.

**PURPOSE:** To examine the relationship between perceived stress levels and health promoting behaviors in undergraduate students.

**METHODS:** Two surveys, the Perceived Stress Scale (PSS) and the Health Promoting Lifestyle Profile II (HPLP-II), were administered as part of a larger study to undergraduates enrolled in a wellness class at a small, private Midwestern university. A regression was performed with the perceived stress score (predictor) and health promoting lifestyle profile score (criterion). Correlations were performed with each subscale of the HPLP-II to examine their relationship to stress.

**RESULTS:** Pearson correlation co-efficient between the variables was  $-0.324$  ( $p = .005$ ). \*  $R^2 = .105$  [ $F(1,61) = 7.039$ ;  $p = .010$ ]. All subscales revealed a negative correlation with stress.

**CONCLUSIONS:** As stress increases, participation in a health promoting lifestyle and health promoting behaviors decreases. These results suggest that stress is harmful not only because it may influence individuals to engage in risky behaviors, but also because it is negatively associated with participation in health promoting behaviors.

---

**2649 Board #43 May 29 3:30 PM - 5:00 PM**  
**Caregiving And Perceptions Of Health**

Ro DiBrezzo<sup>1</sup>, Barbara Shadden<sup>1</sup>, A. Page Glave<sup>1</sup>, Melissa Powers<sup>2</sup>, Michelle Gray<sup>2</sup>. <sup>1</sup>University of Arkansas, Fayetteville, AR. <sup>2</sup>University of Central Oklahoma, Edmond, OK. (Sponsor: Dr. Barry Brown, FACSM)  
(No relationships reported)

It is generally accepted that caregiving responsibilities have a detrimental effect on the health of the caregiver.

**PURPOSE:** The purpose of this research was to examine the effects of caring for a relative on the perceived health of the caregiver.

**METHODS:** Participants were 31 female employees at a local university. Caregivers ( $n = 12$ ) were defined as those currently providing care for a family member and those who had been a caregiver at some point in the past year. Six caregivers were members of the faculty. The *Perceived Stress Scale* (PSS) was used to assess how much stress the participants were experiencing. The *Short Form 36* (SF-36) was used to assess general perceptions of health. The mental component score (SFMC) and physical component score (SFPCS) were used as generalized measures of mental and physical health. A MANOVA was used to test for multivariate significance, with follow up univariate ANOVA tests when appropriate. Multivariate significance was set at  $p < .10$ . Significance for the univariate follow-up tests was set at  $p < .03$ .

**RESULTS:** Caregivers scored higher on the PSS ( $18.75 \pm 6.18$  vs.  $13.21 \pm 5.89$ ). Non-caregivers scored higher on the SFMC ( $53.18 \pm 6.12$  vs.  $46.32 \pm 13.41$ ) and the SFPCS ( $52.93 \pm 4.35$  vs.  $50.33 \pm 6.02$ ). The multivariate  $F$  test was significant for the caregivers versus non-caregivers comparison ( $F_{3,25} = 2.58$ ,  $p = .08$ ). The follow-up univariate tests showed significance only on the PSS ( $F_{1,27} = 6.59$ ,  $p = .02$ ). Multivariate significance was not found for faculty caregivers compared to staff caregivers. Effect size was large for both the caregiver-non-caregiver ( $D^2 = 0.98$ ) and faculty caregiver-staff caregiver ( $D^2 = 1.49$ ) comparisons.

**CONCLUSIONS:** These data indicate differences in perceptions of health in caregivers compared to non-caregivers. The majority of the perceived health differences is

accounted for by differences in perceived stress. This indicates caregivers perceive their stress levels to be significantly higher than do non-caregivers. Additional research into the health ramifications of caregiving is needed. Research should focus on both caregivers compared to non-caregivers and caregivers with differing types of employment. Health should also be assessed objectively (i.e. blood pressure or cortisol levels) to determine whether the health differences are objective.

**2650 Board #44 May 29 3:30 PM - 5:00 PM**

**A Description Of Adolescent Twins' Body Composition And Physical Activity**

Erin E. Kuffel, Kelly L. Klump, S. Alexandra Burt, James M. Pivamik, FACSM. *Michigan State University, East Lansing, MI.*

Email: kuffeler@msu.edu

(No relationships reported)

Limited research is available regarding body composition and physical activity (PA) patterns among twins during adolescence.

**PURPOSE:** Our purpose was to evaluate body composition and physical activity in monozygotic (MZ) and dizygotic (DZ) adolescent twins.

**METHODS:** Participants were 296 adolescent female (n=202; 92 MZ, 110 DZ) and male (n=94; 52 MZ, 42 DZ) twins (age=12.4±1.4 yr). Body fatness (%Fat) was assessed by bioelectrical impedance analysis and PA by a 3-Day Physical Activity Recall. Participants reported activities completed in 30 min increments over 3 consecutive days. MET values were assigned to each activity and then used to calculate time spent in moderate to vigorous PA, as well as, whether the study participant achieved current physical activity recommendations (≥60 min/day of moderate to vigorous PA). Intraclass correlations, chi-square, t-test, z-scores, and Mann-Whitney U tests were used to assess the relationships and differences in % Fat and PA among MZ and DZ twins as appropriate.

**RESULTS:** There were no significant differences between average±SD %Fat (females: MZ 26.2±7.1 % DZ 26.8±7.8 %; males: MZ 21.6±7.2 % DZ 20.3±8.7 %), total number of blocks spent in moderate to vigorous PA over three days (females: MZ 9.7±7.8 blocks DZ 8.9±6.8 blocks; males: MZ 11.6±10.1 DZ 14.1±11.9 blocks), or the proportion of twins meeting PA recommendations (females: 28.3 % MZ vs 30.9% DZ; males: 36.5 % MZ vs. 38.1% DZ;  $\chi^2 = 1.6$ , nonsignificant) by zygosity. %Fat was more tightly correlated in MZ twin pairs (females  $r = 0.97$ ; males  $r = 0.92$ ) compared to DZ twin pairs (females  $r = 0.76$ ; males  $r = 0.80$ ). However, female DZ twin pairs showed a significantly stronger correlation for spending similar time in moderate to vigorous PA ( $r = 0.79$ ) than did female MZ twins ( $r = 0.41$ ), while the male twins did not show a significant difference in this relationship (MZ  $r = 0.86$ , DZ  $r = 0.82$ ).

**CONCLUSION:** Twin zygosity did not significantly alter body composition or PA when comparing group means or the proportion of twins meeting PA recommendations. However, while anthropometric similarities were greater in both male and female MZ twins, physical activity profiles were not. Future studies should examine the reasons why gender appears to modify physical activity behavior among adolescents with identical genetic profiles.

**The Correlates Of Physical Activity In Older Adults With Arthritis**

Megan E. Grimstvedt, Cheryl Der Ananian, Barb E. Ainsworth, FACSM. *Arizona State University Polytechnic, Mesa, AZ.*

Email: mgrimstv@asu.edu

(No relationships reported)

Older adults with arthritis are less active than those without arthritis. Understanding the correlates of PA in persons with arthritis can help in the design of more effective interventions.

**PURPOSE:** To examine the correlates of PA in black and white older adults (age 50+) with a self-report of diagnosed arthritis.

**METHODS:** A cross-sectional study grounded in the Social Cognitive Theory was conducted. Questionnaire data (demographics, self-efficacy, social support, arthritis impact, environmental factors, etc.) were obtained from people with arthritis. Participants were recruited through advertisements in community settings (e.g., senior centers, fitness centers) and Arthritis Foundation mailings. Bivariate associations between PA (meets/does not meet AHA/ACSM PA recommendations) and potential correlates were examined with  $\chi^2$  and simple logistic regressions stratified by race. A stepwise logistic regression was conducted to examine which factors best predicted PA.

**RESULTS:** Participants (n=209) were fairly diverse (median age 67; 56% white, 44% black; 87% female; 22.2% had a HS diploma or less, and 41.9% had a college degree or higher) and 29% met PA recommendations. BMI ( $\chi^2 = 9.98$ ,  $p=0.0187$ ) and race ( $\chi^2 = 6.03$ ,  $p=0.014$ ) were associated with PA level. A larger proportion of overweight (71%) and obese individuals (81%) did not meet PA recommendations compared to normal weight individuals (56%). More whites (36%) met PA recommendations than blacks (20%). Race stratified simple logistic regression analyses found no association between PA and age, gender, exercise outcome expectations, social support for exercise, affect, arthritis pain, arthritis self-efficacy or environmental factors in whites or blacks. Education (OR=1.54 CI=1.03-2.3), BMI (OR=0.86 CI=0.79-0.94), exercise self-efficacy (OR=1.14 CI=1.05-1.24) and physical function (OR=0.56 CI=0.35-0.88) were associated with PA in whites only. Stepwise logistic regression indicated BMI, exercise self-efficacy and age were the strongest PA predictors.

**CONCLUSIONS:** Findings suggest BMI, exercise self-efficacy and age are important predictors of PA in older adults with arthritis. Findings also suggest that factors associated with PA in people with arthritis may differ by race.

**Preventing Type 2 Diabetes: Recommendations On Achieving Lifestyle Change From The Image Guideline Development Project**

Colin J. Greaves. *Peninsula Medical School, Exeter, United Kingdom.*

Email: Colin.Greaves@pms.ac.uk

(No relationships reported)

**PURPOSE:** The IMAGE project (European Commission grant No: 2006309) is developing evidence-based guidelines on diabetes prevention and a training curriculum for prevention managers. To inform these guidelines, we aimed to summarise, with an emphasis on behaviour change methods, the evidence from prior systematic reviews on interventions for promoting physical activity and weight loss in populations at risk of type 2 diabetes.

**METHODS:** We searched electronic bibliographic databases and other sources for systematic reviews, published between 1998 and 2008 on interventions for adults at risk of developing type 2 diabetes. Two reviewers undertook selection and data extraction and methodological quality was assessed using the Overview Quality Assessment Questionnaire (OQAQ).

**RESULTS:** Of 3856 identified articles, 30 met our quality and selection criteria. We identified 150 analyses using descriptive, meta-analytic and meta-regression approaches to investigate the association of intervention components with effectiveness. Results related to Overall Effectiveness; Theoretical basis; Behaviour change techniques; Mode of delivery, Intervention provider, Intervention intensity and Target population. Recommendations for practice include that interventions should target both diet and physical activity, use established behaviour change techniques (eg. goal-setting, relapse prevention, self-monitoring), engage social support wherever possible, include a clear focus on behaviour maintenance, and maximise intensity during the initial intervention stage. Recommendations for future research will also be presented.

**CONCLUSIONS:** It is possible to achieve clinically meaningful behaviour change in dietary and physical activity at an individual level. A training curriculum reflecting the recommendations is being developed for implementation with adults at risk of type 2 diabetes.

**Identifying Culturally Sensitive Physical Activities Using Dif Analysis**

Yong Gao<sup>1</sup>, Weimo Zhu, FACSM<sup>2</sup>. <sup>1</sup>Boise State University, Boise, ID. <sup>2</sup>University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)  
Email: yonggao@boisestate.edu  
(No relationships reported)

Promoting physical activity (PA) among traditionally disadvantaged PA subgroups as a means to reduce PA disparities is very important to help with the elimination of health disparities. However, the success of PA promotion and intervention programs for these subgroups has been very limited. Lack of culturally sensitive PA in the promotion and intervention is likely one of the reasons.

**PURPOSE:** To identify subgroup preferred PA using differential item functioning (DIF) analysis.

**METHODS:** A sub-unweighted sample of 3,083 (males = 1,511 and females = 1,572) from the National Health and Nutrition Examination Survey (NHANES 2003-2004) PA questionnaire data was used for the analyses. Using Mantel-Haenszel and SIBTEST DIF methods, 33 specific items related to leisure time moderate and vigorous PA (MVPA) were analyzed for DIF across race/ethnicity, gender, education, income and age groups.

**RESULTS:** Approximately 12% to 39% of MVPA questions used in NHANES PA questionnaire were identified as large DIF items according to widely accepted DIF identification criteria in educational and psychological measurement practice. The presence of DIF in this study implies a subgroup is more comfortable with a specific activity due to likely its social and cultural context; therefore, persons in that group report a preference to participate in that activity when engaging in the same amount of total leisure time MVPA as another group. For example, basketball and dance favored non-Hispanic Blacks while golf and hiking favored non-Hispanic Whites; Dance, hiking and soccer favored Hispanics while bicycling, golf, swimming, and walking favored non-Hispanic Whites; Aerobics, dance, stretching and walking favored females while basketball, fishing, golf, running, soccer, weightlifting and hunting favored males; Jogging, treadmill and yoga favored persons with high education levels; Golf and treadmill favored persons with high incomes; and finally basketball, dance, jogging, running, and weightlifting favored adults while walking and golf favored older adults.

**CONCLUSIONS:** DIF methods were able to identify subgroup preferred PA, which provides information to allow a deeper understanding of a subgroup's PA pattern which in turn can help design culturally sensitive, targeted interventions for disadvantaged PA subgroups.

**Comparison Of Completers Versus Non-completers Of A Community-based Youth Physical Activity And Nutritional Counseling Program**

Laura A. Milliken, Jessica A. Whiteley, Scott E. Crouter, Megan Suyematsu, Kyle J. McInnis, FACSM. *University of Massachusetts Boston, Boston, MA.*  
Email: laurie.milliken@umb.edu  
(No relationships reported)

Because the attrition rate in community-based health promotion programs for youth can be high, determining demographic and behavioral differences between completers and non-completers is important to inform retention strategies.

**PURPOSE:** To determine whether differences existed in demographics, self-reported sedentary and physical activity (PA) behaviors in girls 9 - 15 years who completed (C) versus those who did not complete (NC) a community-based PA and nutritional promotion program.

**METHODS:** Sedentary girls (n = 311, 51% white) were recruited from 3 YMCA/YWCAs in eastern Massachusetts to participate in a 12-week physical activity and nutritional counseling program. At baseline, girls completed a food and activity questionnaire developed by the Massachusetts Department of Public Health and had their height and weight measured. Differences between C (n = 169) and NC (n = 142) for body mass index (BMI), self-reported "screen time" (sum of TV, videos, video games, and computer time), and self-reported PA were determined using either independent t-tests or chi-square analyses. Significance was set at  $p < 0.05$ .

**RESULTS:** NC were older than C ( $12.4 \pm 1.4$  yrs vs  $11.7 \pm 1.2$  yrs,  $p < 0.001$ ). The percent that were white was 40.4% for the NC group and 60.1% for the C group ( $p < 0.001$ ). BMI was higher in NC ( $27.9 \pm 6.2$  kg/m<sup>2</sup>) than C ( $26.4 \pm 6.2$  kg/m<sup>2</sup>,  $p = 0.04$ ) but the percent defined as overweight ( $> 85^{\text{th}}$  percentile for age and gender) was not different between groups (58.6% for C, 61.3% for NC,  $p = 0.63$ ). The number of TVs in the household was similar for C ( $3.2 \pm 1.3$ ) and NC ( $3.4 \pm 1.4$ ) ( $p = 0.17$ ) and a higher percent of NC (67.4%) had TVs in their rooms than C (56.6%) ( $p = 0.055$ ). The percent of C and NC who were allowed to watch unlimited TV was similar (34.3% and 41.8% for the C and NC, respectively,  $p = 0.17$ ). "Screen time" was high ( $6.1 \pm 4.0$  hrs/day for C and  $6.93 \pm 4.6$  hrs/day for NC) but was not different between groups ( $p = 0.12$ ). C reported higher amounts of vigorous PA than the NC ( $p = 0.008$ ) but light PA was similar between groups ( $p = 0.82$ ).

**CONCLUSIONS:** Non-completers in this study were mostly minorities, overweight, and less active than those completers. Therefore, community PA promotion programs should implement innovative retention strategies targeted to retain minority populations who are overweight and inactive.

**Spartners For Heart Health: Baseline Characteristics Of Physical Activity And Self-efficacy Behavioral Correlates**

Darjan Suton, Karin A. Pfeiffer, FACSM, Joey C. Eisenmann, Kimbo E. Yee, Deborah L. Feltz, Joseph J. Carlson. *Michigan State University, East Lansing, MI.*  
Email: sutond@gmail.com  
(No relationships reported)

The prevalence of cardiovascular disease (CVD) risk factors including low physical activity (PA) is rapidly increasing among children in Michigan and in the United States. (S)Partners for Heart Health is a school-based PA and nutrition intervention designed to promote healthy behaviors and improve selected PA correlates as a means of primary CVD prevention.

**PURPOSE:** The purposes of this study were: 1) to compare baseline characteristics for PA to national recommendations (survey and pedometer) and 2) to examine the relationships between PA and self-efficacy (SE) and outcome/expectancy (OE).

**METHODS:** Participants were 134 5<sup>th</sup> grade students (55 boys, 79 girls; mean age  $10.4 \pm 0.7$  yrs) from three Michigan primary schools. Habitual PA was assessed by a pedometer over a one-week period and a self-report PA question. Screen time (TV, video, & computer) was also self-reported. SE was assessed using a 5-point scale questionnaire designed for children. OE was assessed using one question with a 4-point Likert scale. Descriptive statistics, t-tests, Pearson and Spearman correlations were used for analyses.

**RESULTS:** Boys and girls averaged 12,117  $\pm$  4,927 and 13,321  $\pm$  10,932 steps per day, respectively. The proportion of students meeting recommendations ( $\geq 13,000$  steps-d<sup>-1</sup> for boys,  $\geq 11,000$  steps-d<sup>-1</sup> for girls) was 44% for boys (n = 23) and 41% for girls (n = 42). The PA survey question revealed that 51% of boys and girls met the recommendations of at least 60 min  $\geq 5$  days/week. SE scores were  $3.3 \pm 0.5$  for boys and  $3.1 \pm 0.6$  for girls. Average OE scores for boys and girls were  $2.2 \pm 0.9$  and  $2.2 \pm 0.7$ , respectively. Screen time was similar between boys ( $4.3 \pm 2.9$  hrs) and girls ( $4.5 \pm 10.7$  hrs). The proportion of girls meeting recommendations ( $< 4$  hrs-d<sup>-1</sup>) (74%) was significantly higher compared to boys (55%;  $p < 0.001$ ). The correlations between PA and SE and OE were  $r = 0.48$  and  $0.34$  ( $p < 0.01$ ) for boys and  $r = 0.64$  and  $0.23$  ( $p < 0.05$ ) for girls, respectively.

**CONCLUSIONS:** This sample of Michigan students' PA levels are slightly above national levels. Correlations between SE and reported PA were higher than those for OE and PA. The strong correlation of the SE for PA with PA indicates the SE measure has potential utility for predicting PA levels in this age group.

# **Body Mass Index And Physical Activity As Predictors Of All-cause Mortality In White, Black, And Mexican American Men**

Carlos J. Crespo, FACSM<sup>1</sup>, Christopher M. Torres<sup>1</sup>, Ross E. Andersen, FACSM<sup>2</sup>, Ellen Smit<sup>3</sup>, Gloria Diaz<sup>1</sup>. <sup>1</sup>Portland State University, Portland, OR. <sup>2</sup>McGill University, Montreal, QC, Canada. <sup>3</sup>Oregon State University, Corvallis, OR.

Email: ccrespo@pdx.edu

(No relationships reported)

**Background** - Physical inactivity and obesity may be independently related to all cause and cardiovascular mortality. As these conditions continue to increase in the population it is important to assess the independent effect they have among specific segment of the population that may be disproportionate affected by them. Therefore, the purpose of this study is to examine the effects of body mass index (BMI) and leisure time physical activity (LTPA) on all cause and cardiovascular mortality using a nationally representative sample of Non-Hispanic White, Non-Hispanic Black, and Mexican American men.

**METHODS:** This study uses data from the Third National Health and Nutrition Examination Survey (NHANES III) conducted between 1988 and 1994 and the mortality follow up (2002) among adults 20 years of age and older. Anthropometric measurements were obtained at a mobile examination center by a health technician and leisure time physical activity was obtained via a questionnaire. Other covariates analyzed were age, education, smoking, and presence of chronic disease conditions. SAS and SUDAAN software programs were used estimate relatives risk of mortality and to take into account the complex sample design.

## **RESULTS:**

Relative Risk ratio with 95% confidence interval of all cause mortality among non-Hispanic White, non-Hispanic Black and Mexican American men, 20 yrs and older.						
	Non-Hispanic White		Non-Hispanic Black		Mexican American	
	BMI no PA	BMI with PA	BMI no PA	BMI with PA	BMI no PA	BMI with PA
Women						
Normal weight	1.0	1.0	1.0	1.0	1.0	1.0
Overweight	0.75 (0.59-0.95)	0.75 (0.59-0.95)	0.73 (0.56-0.95)	0.74 (0.58-0.96)	0.75 (0.54-1.04)	0.75 (0.54-1.04)
Obese	0.80 (0.60-1.06)	0.76 (0.56-1.03)	0.94 (0.70-1.25)	0.96 (0.74-1.26)	0.65 (0.42-1.00)	0.65 (0.43-0.99)
Physical Activity						
Frequent Active*		1.0		1.0		1.0
Infrequent Active**		1.07 (0.83-1.38)		0.92 (0.71-1.20)		0.91 (0.57-1.45)
Sedentary***		2.06 (1.47-2.88)		1.72 (1.24-2.38)		1.28 (0.87-1.88)

\* 5+ times per week \*\*1-4 times per week \*\*\* < 1 time per week

**CONCLUSION:** Sedentary behavior was an independent predictor of all cause mortality and cardiovascular mortality. Overweight status in men was found to be protective of all-cause mortality or cardiovascular mortality, even when physical activity was included in the model. More research is needed to examine the effect of other more precise measurements of adiposity.

## **F-24 Free Communication/Poster - Exercise and Diabetes**

# **Aerobic Conditioning And Hepatic Steatosis Markers In Exercise-trained Diabetic Rats**

Leandro P. Moura, Ricardo J. Gomes, José Alexandre C. Leme, Fabricio A. Voltarelli, Rodrigo F. Moura, Michel B. Araújo, Carla Ribeiro, Eliete Luciano, Maria Alice R. Mello. *UNESP, São Paulo State University, Rio Claro, Brazil.*

Email: leandropereiram@hotmail.com

(No relationships reported)

**PURPOSE:** The present study aimed to analyze the effects of exercise performed at aerobic/anaerobic transition intensity on both aerobic conditioning and on non-alcoholic hepatic steatosis (NAHS) markers, as Aspartate Aminotransferase (AST) and Alanine Aminotransferase (ALT) enzymes, in diabetic rats.

**METHODS:** Adult (90 days) male Wistar rats were divided into 4 groups: Sedentary Control (SC), Trained Control (TC), Sedentary Diabetic (SD) and Trained Diabetic (TD). At the beginning of the experiment, all the animals were submitted to maximal lactate steady state (MLSS) test in order to identify the aerobic/anaerobic metabolic transition intensity during swimming exercise. The trained groups were submitted to swimming, supporting overloads (% of body weight - bw) equivalent to aerobic/anaerobic metabolic transition intensity, 1h/day, 5 days/week, during 8 weeks. We analyzed: body weight, aerobic conditioning (MLSS after the training period), total lipid concentrations in the

liver, and serum ALT and AST concentrations as well as serum glucose and FFA levels.

**RESULTS:** The DS group showed higher serum glucose in relation to the other groups (SC= 102 ± 10; TC= 105 ± 9; SD= 323 ± 12; TD= 301 ± 13). The diabetic groups showed higher serum FFA (SD= 15.5 %; D= 17.4%) and weight loss (SD= 0.8%; TD= 10.5%) when compared to control groups. The aerobic/anaerobic metabolic transition intensity (overload, in % of bw) obtained by MLSS test was similar in TD (4.7%) and TC (5.6%) groups after exercise-training. The NAHS markers (U/L) did not show differences (two-way ANOVA,  $P < 0.05$ ) between groups (AST: SC= 81.6 ± 15.0; TC= 87.0 ± 23.2; SD= 69.8 ± 47.3 and TD= 78.7 ± 29.9; ALT: SC= 39.7 ± 14.6; TC= 38.9 ± 9.4; SD= 40.0 ± 17.4 and TD= 44.6 ± 17.0). The same was observed for total liver lipid concentrations (mg/100mg) (SC= 3.5 ± 0.4; TC= 3.5 ± 0.5; SD= 3.6 ± 0.6 and TD= 3.7 ± 0.8).

**CONCLUSION:** Taken together, the results of the present study suggest that physical training performed at the aerobic/anaerobic metabolic transition intensity was able to maintain the aerobic conditioning of diabetic rats similar to the control animals as well as to improve the glycaemic condition of the DT group. In addition, serum ALT and AST enzymes proved to be adequate markers of liver lipid levels in this animal model.

**Impaired Heart Rate Variability In Type 2 Diabetes: Roles Of Major Cardiovascular Disease Risk Factors**

Michael J. Simmonds<sup>1</sup>, Clare Minahan<sup>1</sup>, Gregory Gass<sup>2</sup>, Luke Haseler<sup>1</sup>, Surendran Sabapathy<sup>1</sup>. <sup>1</sup>Griffith University, Gold Coast campus, Australia.

<sup>2</sup>Bond University, Gold Coast, Australia.

Email: m.simmonds@griffith.edu.au

(No relationships reported)

Heart rate variability (HRV) is sensitive to the presence and development of numerous disease processes, including cardiovascular disease (CVD). Individuals with type 2 diabetes mellitus (T2DM) are at increased risk of CVD and also present with reduced HRV (particularly HRV indices related to parasympathetic output) when compared to nondiabetic controls.

**PURPOSE:** To examine HRV indices between older women with T2DM and non-diabetic women matched for age, aerobic power, BMI and lipid profile.

**METHODS:** Fifteen subjects with uncomplicated T2DM (age 69 ± 2 yr; BMI 29 ± 6 kg·m<sup>-2</sup>; aerobic power 19.9 ± 3.8 ml·kg<sup>-1</sup>·min<sup>-1</sup>; Chol/HDL 3.7 ± 1.1) and fifteen nondiabetic matched controls (age 68 ± 4 yr; BMI 27 ± 4 kg·m<sup>-2</sup>; aerobic power 21.5 ± 4.4 ml·kg<sup>-1</sup>·min<sup>-1</sup>; Chol/HDL 3.4 ± 1.0) were recruited for this study. All thirty subjects were using lipid-lowering medication (statins). Following 20 min of supine rest, RR intervals were recorded over 5 min and subsequent HRV analysis included key indices of time, and frequency domains. Auto-regression (AR model) was used to extract frequency characteristics from the data sets.

**RESULTS:** No significant differences were observed in any of the key time-domain parameters: standard deviation of RR intervals (RRSD;  $p = 0.145$ ), square root of the mean of squared differences between successive intervals (RMSSD;  $p = 0.709$ ), the percentage of consecutive normal-to-normal RR intervals differing by more than 50 ms (pNN50;  $p = 0.744$ ). There were no significant differences between the groups for absolute ( $p = 0.164$ ) and normalised ( $p = 0.473$ ) units of power in the high-frequency (HF) range. While absolute low-frequency (LF) power was significantly reduced in the T2DM compared to the nondiabetic group (mean difference = 128.9 ms<sup>2</sup>,  $p = 0.002$ ), normalised LF power was similar between groups ( $p = 0.469$ ). Additionally, the LF/HF ratio was not significantly different between groups ( $p = 0.264$ ).

**CONCLUSION:** Time-, and frequency-domain indices of HRV were not altered in individuals with uncomplicated T2DM compared with nondiabetic matched controls. Specifically, HRV indices of parasympathetic output (e.g. pNN50, HF power) were similar between the two groups.

This project was Supported by the National Health and Medical Research Council of Australia.

**Low Intensity Strength Training In Women With Type 2 Diabetes: Effect On Hba1c And Lipids**

Hans C. Heitkamp, Christoph Hepe, Arno Hipp, Stefan Grau, Andreas M. Niess. Medical Clinic, University of Tuebingen, Tuebingen, Germany.

Email: hans-christian.heitkamp@med.uni-tuebingen.de

(No relationships reported)

Strength training for patients with type 2 diabetes has reached evidence level A.

**PURPOSE:** To investigate the effects of low dose strength training in women with type 2 diabetes.

**METHODS:** We included 15 women in the training (T) and 6 in the control group (C). Before training, the patients were tested for HbA1c, cholesterol, HDL, LDL and triglycerides as well as for strength on a rowing machine, abdomen crunch machine, leg press, chest press and back extension. Patients then completed 12 weeks of training two times a week for 60 minutes with an intensity of about 50% of 1 - RPM. The intensity of the strength training was increased by 10% every 4 weeks. HbA1c was reduced from 7.02 ± 0.77 in T to 6.61 ± 0.73 ( $p < 0.001$ ) and from 7.05 ± 0.65 to 6.88 ± 0.32 in C.

**RESULTS:** Cholesterol remained constant at 197 mg/dl, triglycerides were reduced from 146 ± 43 to 134 ± 56 mg/dl, LDL remained nearly constant with 130 ± 39 and 132 ± 42 mg/dl, HDL rose from 37 ± 9.9 to 46 ± 9.3 ( $p < 0.001$ ). The risk indicator LDL/HDL decreased ( $p < 0.05$ ). Bodyweight and waist circumference were slightly reduced as well as triceps, subscapular and abdominal skinfolds. No changes were found in C. Strength increased on the rowing machine by 63%, and abdominal crunches by 62%, leg press by 82%, chest press by 62% and back extensions by 57%, which were all highly significant. C showed no significant differences.

**CONCLUSIONS:** Low dose strength training has beneficial effects on carbohydrate metabolism and also on increasing HDL. Strength training for large muscle groups should be recommended for diabetic women.

**Training With Joba Core Trainer For Obese Patients With Type 2 Diabetes**

Antonio Sgadari, Matteo Tosato, Andrea Manto, Giuseppe Scavone, Sara Aquila, Giovanni Ghirlanda, Roberto Bernabei. Catholic University of Sacred Heart, Rome, Italy.

Email: antonio\_sgadari@rm.unicatt.it

(No relationships reported)

Physical activity (PA) and weight control are important in diabetes prevention and management. However, PA programs often fail to achieve optimal results in diabetic patients. The Joba® Core Trainer (JOBA) is an ergometric device, simulating horseback riding, which has been proved to improve insulin sensitivity in diabetic patients.<sup>1</sup>

**PURPOSE:** To assess if a training program with JOBA improves endothelial function, glycaemic control, and body mass in obese patients with type 2 diabetes mellitus (DM).

**METHODS:** 24 obese pts. with DM were randomly allocated either to an Exercise (EX) group (3 sessions with JOBA/week for 12 weeks) or to usual care (C). Endothelial function, fasting glucose, insulin, glycated haemoglobin (HbA1C), body weight and composition were measured before and after the intervention.

**RESULTS:** In the C group no significant changes were observed. In the EX group the endothelial-dependent (ED) dilation of the brachial artery significantly increased after training (4.6±3.2 vs. 7.0±3.6,  $p < 0.045$ ). Although fasting glucose was significantly reduced (142.0±41.9 vs. 118.7±40.8,  $p < 0.001$ ), HbA1C and insulin levels were not. Finally, Body Mass Index (BMI) and Fat Mass (FM) were not influenced by the intervention.

	EX (n=12)	C (n=12)
--	-----------	----------

	Before	After	Before	After
ED Dilation (% increase)	4.6±3.2	7.0±3.6*	4.8±2.9	5.0±3.1
Non-ED Dilation (% increase)	9.5±4.2	9.4±5.6	9.3±4.4	9.5±4.7
Fasting glucose (mg/dL)	142.0±41.9	118.7±40.8**	146.0±47.3	142.4±41.2
Insulin (μU/mL)	22.7±14.9	17.6±10.5	23.2±13.2	21.4±11.3
HbA1C (%)	7.2±1.3	7.2±1.1	7.3±1.4	7.4±1.3
BMI (Kg/m <sup>2</sup> )	36.7±6.1	36.7±5.9	35.9±5.1	36.2±6.4
FM (%)	38.9±6.7	37.5±6.3	37.3±6.2	37.2±6.9
* p<0.045	** p<0.001			

**CONCLUSION:** Training with JOBA resulted in a slight increase of ED vasodilation. Little effect, if any, was observed on glycaemic control. The training program did not affect body mass. It may be that the training intensity of JOBA exerts a favourable effect on vascular function, but it is not sufficient to influence metabolic control and body mass of obese pts. with DM.

(No relationships reported)

N-terminal-pro-brain (B-type) natriuretic peptide (NT-pro-BNP) is a hormone released from ventricles in response to myocyte stretch.

**PURPOSE:** The aim of the study was to investigate the influence of 3-4 wk exercise training on plasma NT-pro-BNP and selected variables in 54 patients with diabetes.

**METHODS:** 54 patients (mean age: 65.7±10.4 yrs, 50 males, 4 females, body mass index (BMI) 29.5±4.6) with documented coronary heart disease in 47 patients, 7 patients with valve replacement therapy with and without aortocoronary bypass surgery and 36 patients with hypertension entered a (average=26 d) residential exercise and lifestyle intervention program at a rehabilitation facility in central Austria. Standard pre and post completion measurements included: fasting plasma measurements of NT-pro-BNP, hemoglobin A1C (HbA1C), glucose (GLUC), cholesterol (CHOL), high density lipoprotein-cholesterol (HDL-C), low density lipoprotein-cholesterol (LDL-C), triglyceride (TRIG), heart rate (HR), heart rate reserve (HR-R), physical working capacity (PWC), estimated relative VO<sub>2</sub>peak determined on a cycle ergometer, and systolic (SBP) and diastolic (DBP) blood pressure. Training included supervised daily exercise (20 min cycling and 45 min walking at 60% HRmax), nutrition/diet prescription depending on individual needs, and pharmacologic intervention.

**RESULTS:** Program participation significantly reduced NT-pro-BNP (-20%) (P55% (-32%), EF 45-55% (-23%), EF 30-44% (-18%), EF<30% (-10%), respectively. PWC, VO<sub>2</sub>peak and heart rate reserve increased significantly by 19%, 16% and 13%, (P<0.001, P<0.001, P<0.001), respectively. Post completion GLUC, HbA1C, CHOL, LDL-C and TRIGs were reduced significantly (P<0.001). There was a consistent inverse relationship between NT-pro-BNP and PWC, VO<sub>2</sub>peak, HR-R. BMI was reduced significantly (P<0.001) in all patients. There were no significant changes in prescription for beta-blockers, ACE inhibitors, AT II receptor blockers or diuretics; however, there was a significant increase in statin prescription (P<0.002).

**CONCLUSION:** Our results indicate that 3-4 wk of exercise intervention reduces NT-pro-BNP levels and improves exercise capacity in diabetic patients.

## 2662 Board #56 May 29 2:00 PM - 3:30 PM Relationship Between Regional Adiposity And Risk For Type II Diabetes In College Age Individuals

Aileen M. Hoyne, David Q. Thomas, FACSM. *Illinois State University, Normal, IL.* (Sponsor: Dr. Dale Brown, FACSM)  
Email: amhoyne@ilstu.edu  
(No relationships reported)

Research has determined several risk factors associated with the development of Type II diabetes, including adipose tissue distribution. However, this relationship has not been investigated in college aged populations. Adiposity around the trunk has been cited as being indicative of future health problems. This study investigated how body composition variables in college age individuals are associated with the risk of this metabolic disease.

**PURPOSE:** To determine the relationship between regional adiposity and risk for type II diabetes in college age individuals.

**METHODS:** A total of 23 male and female students (mean age of 20 years, SD ±1.06) participated in the study. Institutional Review Board approval was obtained. Each subject completed an informed consent, medical health history, two surveys (Assessing Your Diabetes Risk [ADR] and Diabetes Risk Test [DRT]). Physical measurements were then taken including height and weight (to calculate BMI), waist and hip circumference (to calculate WHR) and peripheral and appendicular skin folds measurements. Air displacement plethysmography (ADP) was then used to assess overall body composition.

**RESULTS:** Descriptive statistics (means and standard deviations) were calculated for all data and Pearson Product-Moment Correlations were used to determine the relationship between regional adiposity and diabetes risk. There were significant correlations between BMI (r=0.77 DRT; r=0.59 ADR), truncal adiposity (r=0.82 DRT; r=0.62 ADR), and ADP (r=0.64 DRT; r=0.72 ADR) with diabetes risk. Only the Diabetes Risk Test showed a relationship between WHR (r=0.45) and diabetes risk. **DISCUSSION:** There appears to be a significant relationship between diabetes risk and selected measures of body composition in this population. A relationship was found between truncal skinfolds, a measure of regional adiposity, and diabetes risk. Future research should be conducted to determine why these relationships exist and how they might impact health.

## 2663 Board #57 May 29 2:00 PM - 3:30 PM Acceleration Training In Diabetic Patients

Jorge E. Franchella, FACSM, Alejandro Radzinski, Kevin D. Steele, Edzard B. Zeinstra. *University of Buenos Aires, Vicente López, Argentina.*  
Email: jfranchella@masvida.com  
(No relationships reported)

It is well known the importance of Physical Activity (PA) in diabetic patients. But also the problem to prescribe traditional activities at Gym because of comorbidity and specially for the possibility of skin damage :

**PURPOSE:** To determine the effect, efficiency and safety of an acute program of four weeks Acceleration Training with Power Plate in this patients. It works increasing acceleration instead of mass to increase force. :

**METHODS:** 30 patients both gender. Ages from 18 to 65, Type 1 and Type 2 diabetes, including patients with different comorbidities excepting retinopathy III-IV or recent cardiac events developed a program trying to improve mostly total body metabolic effects during four weeks. People with peripheral arterial disease were included. Working on Power Plate pro5 AIRdaptive™ warming up consisted in four different activities during 30 seconds each. Low intensity and no rest between them. Work out: six activities from 30 to 60 seconds 30Hz. 60 to 30 second rest. Cooling down: four activities High intensity, 60 seconds 35Hz without rest between them. Measurement before and after each session of glycemic levels, cardiac frequency, and blood pressure. At the beginning and end of the study Fructosamine and Hormones: Testosterone, catecholamine, cortisol. :

**RESULTS:** Easy and quick adaptation. Excellent tolerance. During each session glucose levels were reduced from 10 to 27%. Cardiac frequency rised in a range of 44 to 62 %. Systolic pressure rised 10 to 20%. Diastolic pressure showed no changes or 5% reduction. No changes in Hormonal measurements were seen. :

**CONCLUSIONS:** Power Plate Acceleration Training does appear to be a good option to develop programs of physical activity to contribute to better diabetes treatment and prevention. :

**2664 Board #58 May 29 2:00 PM - 3:30 PM**  
**Translating Scientific Knowledge into Better Diabetes Self-Management with Basic, Nutrition, and Exercise Education**

Emily Carolyn Johnson, FACSM<sup>1</sup>, Sue N. Butkus<sup>2</sup>, Sandra G. Brown<sup>2</sup>, Shirley M. Broughton<sup>2</sup>. <sup>1</sup>Washington State University Spokane College of Pharmacy, Spokane, WA. <sup>2</sup>Washington State University Extension, WA.

(No relationships reported)

An estimated 7.8% of the U.S. population (~23.6 million people) have diabetes.<sup>1</sup> Associated annual costs of diabetic complications are estimated at \$173 billion,<sup>2</sup> but diabetic complications can be prevented if diabetes is properly managed.<sup>3</sup> Patient education and self-management are crucial for improving health outcomes and decreasing costs of diabetes.<sup>1</sup>

**PURPOSE:** To determine the effectiveness of a scientifically-based diabetes education program taught in a community setting on health indicators of diabetes outcomes.

**METHODS:** All participants (type 2 diabetics; n=24; >45 YO) received a basic diabetes lesson, then had lessons on: 1) nutrition; 2) physical exercise; or 3) a combination of nutrition/exercise. Data were collected before (pre) and 3 mo after (post) lessons. Outcome measures were: blood glucose; A1c; height; weight; waist circumference; BMI; blood pressure; blood lipids (total cholesterol, LDL, HDL); distance walked in 6 min; physical activity level; and knowledge, attitude, and psychological distress variables. Data were analyzed for pre-post differences by paired t-tests with all subjects grouped together.

**RESULTS:** Preliminary results for 18 subjects completing the 3-mo study (mean age=63.5 yr) indicate significant (p<0.05) pre to post improvements in knowledge and attitudes of subjects, ie: knowing what they need to do; confidence in managing their diabetes; and increased understanding of A1c, microalbumin, LDL levels, portion control, and correct food portions. Some physiological variables also improved. Direction and mean of significant (p<0.05) changes are shown in parentheses after each variable and were: systolic (-8 mmHg) and diastolic (-7 mmHg) blood pressure, weight (-6.2 pounds), A1c (-0.44%), LDL (-20.9 mg/100 mL), 6-min walk distance (+2.4 laps). Future analyses will be done on 6-mo post data and by individual groups.

**CONCLUSIONS:** These results suggest that scientifically-based diabetes education taught in a community setting can cost-effectively improve physiological and psychological indicators of better diabetes management.

**2665 Board #59 May 29 2:00 PM - 3:30 PM**  
**Metabolic And Functional Improvements In Diabetic And Nondiabetic Veterans Following A Cardiac Rehabilitation Program**

Susan G. Beckham, FACSM<sup>1</sup>, Kristi A. Fitz<sup>2</sup>, Conrad P. Earnest, FACSM<sup>3</sup>, Maram Museitit<sup>4</sup>, Manisha J. Shah<sup>4</sup>. <sup>1</sup>The Cooper Institute, Dallas, TX. <sup>2</sup>Consultants in Cardiology, Ft. Worth, TX. <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>4</sup>Department of Veteran's Affairs, Dallas, TX.

(No relationships reported)

**PURPOSE:** To examine the effect of an 8-12 week cardiac rehabilitation program on glucose control, blood lipids, BMI, and functional capacity in diabetics vs. nondiabetics.

**METHODS:** We performed a retrospective database review of 56 male veteran patients with diabetes and 43 patients without diabetes (mean + SD; age 62.7 + 8.3 y; weight 94.3 + 38.8 kg) who participated in a Phase II cardiac rehabilitation program between 2003 and 2006 at the Veteran's Affairs Medical Center, Dallas, Texas. Primary outcomes included hemoglobin A1C (HbA1C), TG/HDL, and blood glucose. Secondary outcomes included blood lipids and sub-maximal functional aerobic capacity (FC). We examined mean change scores with ANOVA and Tukey post-hoc tests including 95% CI. Data were log normalized when appropriate.

**RESULTS:** Patients with diabetes had a higher BMI (31.2 + 5.5 vs. 28.8 + 4.6 kg/m<sup>2</sup>, p<0.03), HbA1C (6.7 + 1.2 vs. 5.7 + 0.6 %, p<0.001), and lower FC (2.9 + 1.0 vs. 3.7 + 1.6 METs, p<0.001) compared to patients without diabetes at baseline. Following rehabilitative exercise, we observed significant reductions in log normalized HbA1C (p<0.007) for diabetic (-0.68%; 95% CI, -0.97, -0.39) and non-diabetic patients (-1.28%; 95% CI, -0.96, -1.59). Nondiabetic patients exhibited a greater reduction in HbA1C compared to diabetic patients (p<0.05). In addition, both diabetic (-0.55; 95% CI, -1.02, -0.07) and non-diabetic (-0.81; 95% CI, -1.53, -0.11) patients exhibited a significant reduction in log normalized TG/HDL ratio. The TG/HDL ratio is a surrogate marker for identifying insulin resistance in overweight, nondiabetic patients. Functional capacity improved significantly in diabetic (1.46 METs; 95% CI, 0.97, 1.96) and non-diabetic (1.47 METs: 0.91, 2.04) patients; however, no differences were observed for glucose or triglycerides.

**CONCLUSIONS:** Though exercise training appears to improve HbA1C and functional capacity in both diabetic and non-diabetic patients, longer interventions may be necessary to produce more robust changes in markers associated with glucose control.

G. Davison presenting

(No relationships reported)

**PURPOSE:** To examine the effects of chronic exercise training on insulin sensitivity, glycaemic control and multimeric adiponectin concentration in obese patients with impaired glucose tolerance (IGT).

**METHODS:** Eleven obese patients (mean  $\pm$  SD, 48  $\pm$  9yrs; 168  $\pm$  7cm; 91 kg  $\pm$  17kg; BMI 32  $\pm$  7kg/m<sup>2</sup>) diagnosed with IGT completed a 12 week chronic exercise training programme. This involved undertaking 30 minutes moderate intensity exercise equivalent to 65% of maximum heart rate (HR), on 5 days of the week. Anthropometrical measurements and blood pressure (BP) were measured prior to and following intervention. Venous blood samples were drawn for the determination of glucose, glycosylated haemoglobin (% HbA<sub>1c</sub>), blood lipids, insulin and multimeric adiponectin concentration.

**RESULTS:** Following intervention, body mass (89  $\pm$  17 vs. 86  $\pm$  16kg), total body fat (48  $\pm$  10 vs. 44  $\pm$  10%), systolic BP (145  $\pm$  15 vs. 135 $\pm$ 15 mmHg), diastolic BP (86  $\pm$  14 vs. 78  $\pm$  10 mmHg), waist (102  $\pm$  17 vs. 97  $\pm$  14cms) and hip circumference (118  $\pm$  13 vs. 106  $\pm$  14cms) decreased significantly ( $P < 0.05$ ). High density lipoprotein cholesterol (HDL) increased from 1.23  $\pm$  0.24 to 1.27  $\pm$  0.24 mmolL<sup>-1</sup>. Plasma concentrations of glucose, triacylglycerol, total cholesterol, low density lipoprotein cholesterol (mmolL<sup>-1</sup>) and insulin ( $\mu$ mol/L) although decreased, were not statistically significant ( $P > 0.05$ ). All multimeric forms of adiponectin (total, high, the ratio total: high, medium and low) were not found to be statistically different following 12 weeks exercise.

**CONCLUSIONS:** These findings suggest that a 12 week chronic exercise training programme is effective in eliciting positive changes to the cardiovascular risk profile in obese patients with IGT.

#### **Soccer Skill Performance And Hydration Level in Female Intercollegiate Soccer Players**

Astrid E. Mel<sup>1</sup>, Tiffany Anderson<sup>2</sup>, Kate Battista<sup>2</sup>, Tracey Mathews<sup>2</sup>, John Gibson<sup>2</sup>, Vincent Paolone, FACSM<sup>2</sup>. <sup>1</sup>Methodist University, Fayetteville, NC.

<sup>2</sup>Springfield College, Springfield, MA. (Sponsor: Dr Vincent Paolone, FACSM)

Email: amel@methodist.edu

(No relationships reported)

Exercising promotes fluid loss resulting mostly from sweat evaporation from skin to the ambient air. Hydration is an important factor to consider when participating in an outdoor sport such as soccer, due to the extended duration of matches and the intermittent high-intensity pace of the game. Sweating characteristics differ distinctly between men and women, influencing how each gender adjusts to stresses imposed on thermoregulation.

**PURPOSE:** To compare female soccer skill performance under three different hydration conditions: no hydration (NH), ad libitum (AL), and replacement equal to sweat loss (ESL).

**METHODS:** Mean ambient T<sup>o</sup> was controlled at 17.94°C ( $\pm$  1.32), with a mean RH% of 53.85 ( $\pm$  13.82%). Soccer skill performance of NCAA Division III female intercollegiate soccer players (N = 15) was measured using the Modified Loughborough Soccer Passing Test (MLSPT), under three separate hydration conditions: NH, AL, ESL. Performance was measured before, at midpoint, and at the end of the Loughborough Intermittent Shuttle Test (LIST) which is designed to closely approximate the activity pattern occurring during a soccer game. Hematocrit (H<sub>c</sub>), lactate (L<sub>a</sub>), rate of perceived exhaustion (RPE), and core temperature (T<sub>c</sub>) were the physiological variables measured. A 3 X 3 repeated measures ANOVA was computed to compare differences between performance and hydration level, and 3 X 4 repeated measures ANOVAs were computed for the physiological variables.

**RESULTS:** Average dehydration levels for the NH, AL, and ESL trials were 1.54% ( $\pm$  0.54), 0.63% ( $\pm$  0.73), and 0.01% ( $\pm$  0.50), respectively. No significant interactions ( $p > 0.05$ ) were found for soccer skill performance across trials. No significant interactions ( $p > 0.05$ ) were found for H<sub>c</sub>, L<sub>a</sub>, and HR across trials. Significant interactions ( $p < 0.05$ ) were found for mean RPE and T<sub>c</sub> across trials. Significant main effects for time existed for HR and L<sub>a</sub>.

**CONCLUSION:** Based on the results, hydration status does not appear to affect soccer skill performance in female intercollegiate soccer players in a temperate climate, when dehydration is less than 2%.

### **2668 Board #62 May 29 2:00 PM - 3:30 PM**

#### **Effect Of Hypohydration And Intermittent Running In The Heat On Field Hockey Skill Performance**

Hannah Macleod, Caroline Sunderland. Nottingham Trent University, Nottingham, United Kingdom.

Email: hannah.macleod@ntu.ac.uk

(No relationships reported)

The development of hyperthermia during intermittent running in the heat results in a decline in skill performance. If players begin a match in a state of hypohydration, the thermoregulatory system is stressed further. However, there is limited research into the influence of hypohydration on skill performance during sports that are multifaceted in their demands, such as field hockey.

**PURPOSE:** To determine the influence of moderate hypohydration on field hockey skill performance following simulated field hockey exercise in the heat.

**METHODS:** Seven elite female field hockey players completed two 70-min field hockey-specific intermittent treadmill running trials (FHITP), separated by ~7 days, in a randomised crossover design. The evening preceding each trial, participants performed a baseline skills tests before dehydrating via passive hyperthermia to elicit 2% dehydration. Subjects then either immediately rehydrated (EUH) or remained dehydrated (DEH). The next morning subjects completed a skills test pre- and post performing the FHITP in the heat (33°C, 60% rh). Hydration status was maintained with ad libitum water intake. Heart rate (HR), rectal temperature (T<sub>rec</sub>), rating of perceived exertion (RPE) and thirst sensation (TS) were measured during exercise. Total Time (TT), Decision Time (DT) and Penalty Time (PT) were recorded during the skills test.

**RESULTS:** PT was higher post-FHITP in the DEH trial (EUH: 8.4  $\pm$  3.4 vs. DEH: 14.6  $\pm$  6.1 s;  $P < 0.05$ ). TT and DT were slower post-FHITP, with no difference between trials ( $P = 0.02$  and  $P = 0.01$ , respectively). DT was faster in the EUH trial compared to DEH (EUH: 4.06  $\pm$  0.20 vs. DEH: 4.18  $\pm$  0.23 s;  $P = 0.01$ ). There was a significant difference in body mass loss between trials at the start on the FHITP (DEH: 1.8  $\pm$  0.6% vs. EUH: 0.1  $\pm$  0.4%;  $P < 0.05$ ) and at the end of the FHITP (DEH: 2.1  $\pm$  0.5% vs. EUH: 0.2  $\pm$  0.6%;  $P < 0.05$ ). T<sub>rec</sub> increased over time ( $P < 0.01$ ) with a concomitant increase in HR in the 2<sup>nd</sup> half ( $P < 0.01$ ), with no difference between trials. No difference in RPE or TS was evident ( $P > 0.05$ ).

**CONCLUSIONS:** Mild hypohydration may increase decision time and error rate without any detrimental effects to physiological parameters. Furthermore, field hockey specific intermittent running in the heat decreases skill performance, which may be linked to increased thermoregulatory strain.

---

### **2669 Board #63 May 29 2:00 PM - 3:30 PM**

#### **Impact Of Dehydration To 3% Body Weight On A Full Body Resistance Training Protocol**

Justin Kraft<sup>1</sup>, James M. Green, FACSM<sup>2</sup>, Phillip A. Bishop<sup>3</sup>, Mark T. Richardson<sup>3</sup>, Yasmine Neggers<sup>3</sup>, James Leeper<sup>3</sup>. <sup>1</sup>Missouri Western State University, St. Joseph, MO. <sup>2</sup>University of North Alabama, Florence, AL. <sup>3</sup>University of Alabama, Tuscaloosa, AL.

Email: jkraft@missouriwestern.edu

(No relationships reported)

While resistance training is a common training mode, the potential impact of dehydration is not well-understood. If dehydration impairs daily resistance training overload, then subsequent training-induced gains may be sub-optimal.

**PURPOSE:** This study examined effects of dehydration (3% of bodyweight) on resistance training performance.

**METHODS:** Ten males completed two trials: heat exposed (~39° C hot water bath) with water replacement offsetting dehydration (HE) and heat exposure with 3% dehydration (DEHY). Using their 12 rep max resistance (12RM), participants performed three sets to failure of bench press (bench), lat pull down (lat), overhead press (press), barbell curl (curl), triceps press (tri), and leg press (leg).

**RESULTS:** A paired *t*-test showed a significant difference for total reps (HE: 169.4 ± 29.1 vs. DEHY: 144.1 ± 26.6). ANOVAs showed significantly lower reps for DEHY vs. HE for bench, lat, press, curl, tri, and leg (DEHY average ~1-2 reps lower per exercise). Pre-set RPE was significantly higher in DEHY vs. HE for bench, lat, press, curl, tri, and leg (DEHY ~0.6 to 1.1 units higher on average). Pre-set heart rate (HR) was significantly higher for DEHY than HE for bench, lat, press, curl, tri, and leg (DEHY ~6 -13 b•min<sup>-1</sup> higher on average). Session RPE approached significance (DEHY: 8.6 ± 1.9, HE: 7.4 ± 2.3) (*p* = 0.06), with recovery HR significantly higher for DEHY (116 ± 15) vs. HE (105 ± 13).

**CONCLUSIONS:** Dehydration (3%) significantly reduced repetitions performed during a whole body resistance training session. Furthermore, elevated pre-set HR and RPE with dehydration indicated attenuated recovery between sets. Recovery HR was also higher for DEHY than HE also suggesting dehydration impaired recovery. Current results suggest dehydration may inhibit maximum performance in routine strength training. Dehydration magnifies feelings of exertion (RPE) and may lead to sub-optimal overload, compromising training-induced gains.

---

**2670 Board #64 May 29 2:00 PM - 3:30 PM**  
**Endurance Performance After Modest Hypohydration Evoked By Prolonged Fluid Restriction And Exercise Or Diuretics**  
Jennifer Heaney<sup>1</sup>, Mahdi Jibani<sup>2</sup>, Juliet Milne<sup>2</sup>, Samuel J. Oliver<sup>1</sup>. <sup>1</sup>Bangor University, Bangor, United Kingdom. <sup>2</sup>North West Wales NHS Trust, Bangor, United Kingdom.  
(No relationships reported)

Different dehydration methods may explain previous contrasting findings concerning the effect of modest hypohydration (2-3% body mass: BM) on endurance performance in a temperate environment. Greater performance decrements may be related to diuretics causing greater cardiovascular strain during exercise compared with fluid restriction and exercise.

**PURPOSE:** To examine the effect of modest hypohydration evoked by different dehydration methods on endurance performance and cardiovascular function.

**METHODS:** Seven males (mean ± SEM: age 25 ± 1 y; VO<sub>2peak</sub> 59 ± 3 mL•kg<sup>-1</sup>•min<sup>-1</sup>) completed three randomised trials prior to completing a time to exhaustion (TTE) at 70% peak power output on a cycle ergometer in temperate conditions (21°C, 61% RH). On the control trial (C) participants received water equal to 40 mL•kg•bm•d<sup>-1</sup>. To achieve hypohydration prior to the TTE, on one trial participants received 40 mg of the diuretic Furosemide (D) and on another trial completed exercise followed by 48 hours of fluid restriction (FR: 239 ± 129 mL•d<sup>-1</sup>). This exercise bout was also completed with fluid replacement on C and D. BM, plasma volume change (PV) and osmolality (POsm) were assessed pre and post these interventions. During the TTE heart rate (HR), stroke volume (SV), cardiac output (Q) and ratings of perceived exertion (RPE) were assessed. Data were analysed by repeated measures ANOVA and Post hoc Tukeys test.

**RESULTS:** Prior to TTE, BM and PV were significantly decreased on D (-2.0 ± 0.3 and -9.5 ± 1.9%) and FR (-2.3 ± 0.1 and -10.2 ± 4.4%) compared with C (0.2 ± 0.3 and 3.1 ± 4.8%; *P* < 0.01). POsm was significantly greater on FR compared with D and C (FR, 299 ± 2; D, 293 ± 1; C, 286 ± 3 mOsmol•kg<sup>-1</sup>; *P* < 0.01). TTE was significantly decreased on D but not on FR compared with C (D, 17:51 ± 2:10; FR, 19:30 ± 2:40; C, 22:49 ± 2:35 min:sec; *P* < 0.05, ES = 0.41). Compared with C, HR was greater on D during the TTE (C, 167 ± 2; D, 173 ± 2 bpm; *P* < 0.01) and SV and Q were lower in the final minute of exercise on D and FR (*P* < 0.05). RPE was not significantly different between trials.

**CONCLUSIONS:** These results show a detrimental effect for modest isotonic hypohydration evoked by diuretics, which may be related to greater cardiovascular strain, but no significant effect of hypertonic hypohydration evoked by exercise and fluid restriction on endurance performance in a temperate environment.

---

**2671 Board #65 May 29 2:00 PM - 3:30 PM**  
**Effect Of Sports Beverage Temperature On Body Temperature And Cycling Performance In The Heat**  
Catriona A. Burdon<sup>1</sup>, Helen T. O'Connor<sup>1</sup>, Janelle A. Gifford<sup>2</sup>, Philip G. Chapman<sup>1</sup>, Susan M. Shirreffs<sup>3</sup>. <sup>1</sup>University of Sydney, Sydney, Australia. <sup>2</sup>NSW Institute of Sport, Sydney, Australia. <sup>3</sup>University of Loughborough, Loughborough, United Kingdom.  
(No relationships reported)

Rising body temperature may influence the evolution of fatigue during exercise in the heat. Cooler beverage temperature may attenuate the rise in body temperature in the heat by generating a heat sink or via oral sensory mechanisms.

**PURPOSE:** To determine the effect of a cold (4°C; C) or thermoneutral (37°C; N) sports beverage on evolution of body temperature and exercise performance in the heat and explore the influence of sensory factors to ingesting a cold stimulus (ice puree).

**METHODS:** Seven non-acclimatised males (age 32.8±6.1y, mass 81.1±11.1kg) were recruited to complete C, N, and N plus ice (NI) trials in randomised order. Subjects cycled for 90 min at 65% VO<sub>2peak</sub> (SSE) followed by a 15 min time trial (TT) in 28°C, 70% relative humidity and ingested 3.5 mL•kg<sup>-1</sup> of 7.4% carbohydrate-electrolyte drink every 10 mins including 30ml ice puree every 5 mins in NI during SSE. Rectal (T<sub>re</sub>) and skin temperature (T<sub>sk</sub>) were measured, and mean body temperature (T<sub>mb</sub>), heat storage (HS), and total body heat content (TBHC) calculated from these. Total work (TW), distance (D), average and peak power output (AP, PP) were measured during TT. One and two factor repeated-measures ANOVAs were used to evaluate differences in performance and physiological variables across time and within trials respectively. Statistical significance was set at *p*<0.05.

**RESULTS:** Differences in T<sub>re</sub>, T<sub>sk</sub> or between C, N, and NI were not significant across SSE however for C versus N, rise pre to post in T<sub>sk</sub> (0.22±1.10°C v 1.14±0.90°C; *p*=0.02) and (1.2±0.3 v 1.6±0.3°C; *p*=0.03), and HS (45.1±8.8J•°C<sup>-1</sup>•kg<sup>-1</sup>•min<sup>-1</sup> v 60.1±1.0J•°C<sup>-1</sup>•kg<sup>-1</sup>•min<sup>-1</sup>) were lower. There was a significant improvement in TW (263±60kJ v 252±63kJ; *p*<0.01), AP (296.0±66.3W v 287.0±71.3; *p*=0.03) and D (10.1±0.09km v 9.8±0.9km; *p*=0.01) over the TT on C compared to the N trials. Difference in TW and AP for C compared to the N trial was 4.9% and 3.9% respectively. Although most measures tended to improve with I, results were not significant when compared to N.

**CONCLUSIONS:** Consumption of cold sports beverage during prolonged exercise in the heat improves body temperature measures and performance. Provision of ice did not reveal a sensory response, but requires further study as frequency of ingestion may have masked the sensory effect by generating a minor heat sink.

**Neck Cooling Enhances Running Capacity And Thermal Tolerance During Exercise In Hot Conditions**  
Christopher J. Tyler, Caroline D. Sunderland. Nottingham Trent University, Nottingham, United Kingdom.  
Email: christopher.tyler@ntu.ac.uk  
(No relationships reported)

Exercise performance can be improved in hot conditions by cooling the neck via a practical cooling device. The mechanisms by which this works are not fully understood, however it appears that cooling this region may disrupt the pacing mechanism by providing a false signal regarding the body's thermal state.

**PURPOSE:** To investigate the effects of cooling the neck region on treadmill running capacity in the heat.

**METHODS:** Seven well-trained males completed four runs to exhaustion at 70%  $\dot{V}O_{2max}$  in the heat (32°C; 52% rh) following an 8-minute warm-up. All trials were separated by 7-days. The first two trials (F1 and F2) were non-collar for all participants and they wore a cold collar around the neck during one of the other trials. The order of the third non-collar (NC) and the cold collar (CC) trial was randomised and counter-balanced. Rectal temperature, neck temperature, heart rate, RPE, thermal sensation (whole-body and neck) were measured every 5-mins and at the point of exhaustion in NC and CC. Time to exhaustion was recorded for all trials. The reliability of the test to exhaustion was assessed via the coefficient of variation (CV) between F1 and F2 and between F2 and NC trials. The distances covered and the variables recorded at the termination of exercise in CC and NC trials were compared using a one-way ANOVA. Results are presented as percentages for CV and mean  $\pm$  standard deviation for distances and variables.

**RESULTS:** The CV between F1 and F2 and between F2 and NC was 9.2% and 7.8% respectively ( $P > 0.05$ ). Subjects ran longer in CC than NC ( $42:41 \pm 13:46$  v  $37:42 \pm 12:32$  (mm:ss);  $P = 0.02$ ). All subjects ran for longer in CC than NC- improvement range: 11.3 to 22.4%. Despite no significant differences at the beginning of NC and CC trials subjects terminated the CC trial at a higher core temperature ( $39.68 \pm 0.5$  v  $39.19 \pm 0.75$  °C;  $P = 0.22$ ) and heart rate ( $180 \pm 6$  v  $176 \pm 8$  bpm;  $P = 0.039$ ) with no difference in RPE ( $P = 1.00$ ) or whole body thermal sensation ( $P = 0.061$ ). Neck temperature and neck thermal comfort were both significantly lower in CC compared to NC ( $P = 0.003$  and  $P = 0.006$  respectively).

**CONCLUSIONS:** Cooling the neck improved exercise capacity in the heat. The current data supports the idea that cooling the neck can provide a false signal of the body's thermal state allowing for a greater strain to be tolerated before exercise is voluntarily terminated.

**Cool Shirt™ Use As An Ergogenic Aid In Distance Runners Training In North Louisiana**

Kelly Brooks-Friery<sup>1</sup>, Matt Nipper<sup>2</sup>. <sup>1</sup>Louisiana Tech University, Ruston, LA. <sup>2</sup>University of Louisiana at Monroe, Monroe, LA. (Sponsor: Jeff Chandler, FACSM)

Email: kbrooks@latech.edu

(No relationships reported)

Distance runners compete in a variety of environments such as hot humid conditions for extended periods of time. Extended performance in hot humid environments negatively affects running performance.

**PURPOSE:** The purpose of this study was to investigate the effects of a Cool Shirt™ worn by male and female distance runners training in a hot humid environment.

**METHODS:** Fourteen distance runners participated in the study. Testing was performed in Human Performance Lab at the University of Louisiana at Monroe. Subjects  $\dot{V}O_{2max}$  was measured using open circuit spirometry on a treadmill ergometer. On two separate occasions participants returned to the lab for treadmill run in a hot humid environment at the speed and grade at which 85% of the subject's predetermined  $\dot{V}O_{2max}$  was maintained. Randomly assigned, each participant conducted a control run and a run utilizing a Cool Shirt™. Heart rate, Borg's Rate of Perceived Exertion, temperature of the auditory canal, and sweating rate were measured. Statistical analysis was conducted using SPSS 13.0. Significance level was preset at  $p < .05$ .

**RESULTS:** No significant difference in RPE, HR, and run to exhaustion time was found between Cool Shirt™ runs and control runs.

**CONCLUSIONS:** The materials that are used to create the Cool Shirt™ may be the largest factor that prevents the effective cooling of the user. The cotton material used may absorb sweat and contribute to more energy expenditure needed to support the weight of the shirt. More research is needed to determine if the weight of the shirt outweighs the possible benefits that it could possibly provide for users. In the current state of development, this product is not feasible for use during most training situations and competition because of its lack of portability by the individual user. With the development of a smaller portable storage tank and pump along with the development of a shirt with lighter, more technical materials, ergogenic effects could be possible. More research is needed in this area to confirm the feasibility, use and benefits. Cool Shirt™ use for a precooling protocol may be a more applicable and more efficient use of the current product. An area of future research with Cool Shirt™ could be to investigate use as a precooling agent and to develop precooling protocols for optimal performance.

**Effect Of Hydration Pattern On Thermoregulation During Exercise In Dehydrated Females: Preliminary Data And Trends**

Patrick W. Davidson, Katie J. Bouley, Christine A. Craig, Sean M. Collins, Gregory C. McMahon, Mary C. Pieklo, Jan E. Redmond, Jason C. Sawyer, Deborah L. VanLagen, Vincent J. Paolone, FACSM. Springfield College, Springfield, MA.

Email: pdpdavidson@gmail.com

(No relationships reported)

Rehydrating dehydrated females during exercise is critical for maintaining proper thermoregulation and blood values; however, the optimal timing for administering doses of water is unclear. Administering 1L of water with 2 doses of 500 ml shows trends of maintaining blood values and allowing for more efficient thermoregulation compared to ingesting 1L of water with 4 doses of 250 ml.

**PURPOSE:** to compare the effect of varying the timing and volume of ingesting 1L of water during 1-h of steady state exercise with moderately fit dehydrated females.

**METHODS:** Four moderately fit females performed two experimental rides on a Velotron training system at between 65-75% of peak oxygen uptake ( $\dot{V}O_{2peak}$ ) for 1-h. During the ride, the subjects drank a total of 1L of water. During one experimental condition, subjects ingested 250 ml of water immediately prior to and during exercise at 15, 30, and 45 min (RH250). During the second experimental condition, subjects ingested 500 ml of water at 30 and 45 min into exercise (RH500).

**RESULTS:** The RH250 group demonstrated trends of increased body heat storage (RH250, 238.05 kcal; RH500, 207.76 kcal) sweat rate (RH 250, 16.89 ml/min; RH 500, 12.98 ml/min), and heat dissipation via evaporation (RH250, 388.75 kcal; RH500, 218.86 kcal) and radiation and conduction (RH250, 284.46 kcal; RH500, 85.23 kcal) compared to the RH500 group. The RH500 group showed trends of having higher values for delta blood volume (RH250, -0.12%; RH500, 4.39%), cellular volume (RH250, -3.59%; RH500, 2.76%), and plasma volume (RH250, 2.62%; RH500, 5.70%) in comparison to the RH250 group. There were no trends for differences in degrees Celsius for core temperature (RH250 38.73; RH500, 38.42), mean skin temperature (RH250, 33.97; RH500, 34.07), and core to shell gradient (RH250, 4.76; RH500, 4.34).

**CONCLUSION:** drinking 1L of water with two doses of 500 ml appears to be better for maintaining blood values as compared to drinking 1-L of water with four doses of 250 ml due to a decrease in the need to dissipate heat via sweating and evaporation for moderately fit dehydrated females.

**Neuro-muscular Fatigue Development During Repeated Cycling Sprints In A Hot Environment**

Fuad A. Almudehki<sup>1</sup>, Olivier Girard<sup>1</sup>, Justin Grantham<sup>1</sup>, Nicolas Berger<sup>2</sup>, Sebastien Racinais<sup>1</sup>. <sup>1</sup>ASPETAR-Qatar Orthopaedic and Sport Medicine Hospital, Doha, Qatar. <sup>2</sup>University of Teesside, Middlesbrough, United Kingdom.

Email: fuad\_aaj@yahoo.com

(No relationships reported)

The mechanisms contributing to the alteration in neuromuscular function during repeated sprints have been recently documented. However, the effect of hot environment on these neuro-muscular alterations remains unclear.

**PURPOSE:** To investigate the contributions of central and peripheral factors in the development of neuro-muscular fatigue during repeated sprints in a hot environment

**METHODS:** Ten male subjects ( $23.1 \pm 3$  yrs) performed two 38 min repeated sprint trails consisting of eight 6sec sprint of maximal cycling interspaced by 5 min of active recovery (1W/kg body weight). Trails were performed in control (CON; 24°C - 24% rH) and hot (HOT; 40°C - 40% rH) environmental conditions in random order After each sprint, maximal percutaneous electrical stimulations were applied to the femoral nerve both at rest and during maximal voluntary contraction (MVC). To examine potential impairment in central drive,

changes in EMG activity of the *vastus lateralis* muscle normalized to the M-wave amplitude (RMS/M) as well as muscle activation (VA) were quantified during MVC of knee extensors. Peripheral fatigue was assessed by examining the amplitude of the M-wave and twitch contractile properties following single stimuli. Both Core and skin temperatures were monitored throughout by telemetric pill and patches respectively.

**RESULTS:** RPE, HR, and skin temperature were significantly (all  $P < 0.05$ ) higher in HOT compared to CON; RPE:  $15 \pm 3$  vs.  $13 \pm 3$ , HR:  $141 \pm 10$  vs.  $123 \pm 15$  bpm. However core temperature, peak power production, MVC and muscle electrical activity during the MVC's or the cycling sprints was not influenced by the environmental condition in this pattern of exercise.

**CONCLUSION:** Despite HR, RPE, and skin temperature being higher in hot than control, the body was able to produce the same power in both conditions. These findings suggest that there are no anticipatory decrements in power production when it comes to repeated sprints even if, RPE do increase in hot environment.

#### **Force And Unloaded Shortening Velocity During Fatigue In Skeletal Myosin Light Chain Kinase Deficient Muscles**

William J. Gittings<sup>1</sup>, Rene Vandenboom<sup>1</sup>, Jian Huang<sup>2</sup>. <sup>1</sup>Brock University, St Catharines, ON, Canada. <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX.

(No relationships reported)

The myosin regulatory light chain (R-LC) of type II fibers is phosphorylatable. Contraction-induced activation of a skeletal muscle specific  $Ca^{2+}$  - calmodulin-dependent myosin light chain kinase (MLCK) catalyzes the phosphorylation reaction, an event that may modulate myosin motor behavior. The influence of this molecular mechanism on the contractile performance of fatigued fast twitch skeletal muscle remains unclear, however.

**PURPOSE:** To determine the effect of skeletal muscle MLCK gene ablation on the fatigability of force and velocity in mouse extensor digitorum longus (EDL) muscles.

**METHODS:** Muscles from wildtype (WT) and skeletal MLCK knockout (KO) mice ( $n=10$ ) were studied in vitro at 25° C during a fatigue protocol consisting of 5 minutes of repetitive high frequency stimulation (150 Hz for 1000 ms every 5 sec). Isometric twitch (Pt) and tetanic (Po) forces and unloaded shortening velocity (Vo) were assessed throughout the fatigue protocol.

**RESULTS:** Pt was increased to a greater extent in WT than in KO muscles ( $36.8 \pm 5.9\%$  vs.  $14.9 \pm 2.7\%$ ,  $p < 0.05$ ) during the initial stages of stimulation when Po was depressed less than 40% in both muscle types; thereafter, Pt declined to similar levels in both WT and KO muscles (to ~ 35% of initial levels). On the other hand, values for Vo were greater for WT than for KO muscles ( $10.3 \pm 0.90$  vs.  $8.4 \pm 0.36$  fiber lengths/s) during the final stages of stimulation, when Po was reduced ~ 90% in both muscle types.

**CONCLUSION:** These results suggest that MLCK gene ablation selectively impairs low frequency force during moderate fatigue and impairs unloaded shortening velocity during severe fatigue of fast twitch skeletal muscle.

#### **Muscle-specific MicroRNAs Are Not Altered In Human Muscle Following Ingestion Of Leucine-enriched Essential Amino Acids**

Micah J. Drummond, Erin L. Glynn, Chris S. Fry, Elena Volpi, Blake B. Rasmussen. University of Texas Medical Branch, Galveston, TX. (Sponsor: Elizabeth Protas, FACSM)

(No relationships reported)

**INTRODUCTION:** Essential amino acid (EAA) ingestion results in a significant increase in mixed muscle protein synthesis in humans. The muscle-specific microRNAs (miR-1, -133a, and -206) have been postulated to participate in the regulation of skeletal muscle size by inhibiting translation of specific target mRNAs. Our laboratory has recently shown that miR-1 expression decreased immediately following the combined anabolic stimulus of resistance exercise and EAA ingestion.

**PURPOSE:** We hypothesized that expression of miR-1, -133a, and -206 would be decreased immediately following ingestion of leucine-enriched EAA in young healthy humans.

**METHODS:** Five young subjects (2 men, 3 women,  $31 \pm 2$  yr) ingested leucine-enriched (35%) EAA (10g) following an overnight fast. Muscle biopsies were sampled before and 1 and 2h following EAA ingestion. Standard laboratory procedures were utilized to isolate RNA. This was followed by real-time PCR using commercially available kits (mirVana) and primers in order to determine the expression of miR-1, -133a, and -206.

**RESULTS:** The expression levels of miR-1, -133a, and -206 were unaltered following EAA ingestion as compared to baseline.

**CONCLUSION:** We conclude that the muscle-specific microRNAs (miR-1, -133a, and -206) are not associated with the acute increase in human skeletal muscle protein synthesis during the first couple of hours following essential amino acid ingestion. Therefore, it appears that the changes we detected in microRNA expression following resistance exercise and EAA ingestion were likely due to muscle contraction rather than increased amino acid availability. However, future studies are needed to determine the individual effect of resistance exercise on microRNA expression and whether increased amino acid availability post-exercise is a contributing factor.

#### **Hsp Responses To Chronic Muscle Overload In Rat And Mouse Hindlimb Muscle**

Kimberly A. Huey<sup>1</sup>, Hui Zhong<sup>2</sup>, Roland R. Roy, FACSM<sup>2</sup>. <sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>UCLA, Los Angeles, CA.

Email: khuey@illinois.edu

(No relationships reported)

The importance of heat shock proteins (Hsps) in muscle structure and function continues to be elucidated and data support a major role in muscle adaptation to increased loading. To date, the only functional overload (FO, removal of major synergists) studies investigating Hsps have utilized rats. The availability of transgenic mouse models, however, warrants determination of the Hsp responses in mouse muscles to further elucidate specific factors modulating Hsp expression during chronic FO.

**PURPOSE:** The purpose of this study was to examine species, time, and muscle dependent changes in Hsp25, Hsp20,  $\alpha$ -crystallin, and Hsp90a in response to FO in the rat and mouse soleus and plantaris.

**METHODS:** Protein levels of the Hsps were quantified with Western analysis in the rat or mouse soleus and plantaris after 3 or 7 days of FO. Two-way ANOVAs were used to assess main effects of days of FO, muscle, and their interaction.

**RESULTS:** Baseline levels of all Hsps were higher in soleus than plantaris in rats, whereas only baseline Hsp20 was higher in soleus than plantaris in mice. Baseline Hsp25

and Hsp90a levels were higher in the mouse than rat plantaris. Baseline Hsp20 and ab-crystallin levels were lower in the mouse than rat plantaris and soleus. ab-crystallin levels in plantaris were higher than pre-FO at 3 and 7d or 7d post-FO in mice and rats, respectively. Hsp20 levels in the rat plantaris were higher than pre-FO at 7d post-FO. Hsp25 and Hsp90 levels in both muscles and species were higher than pre-FO at both time points, except for Hsp25 in the mouse soleus at 3d.

**CONCLUSIONS:** Muscle-specific baseline Hsp expression was different between species and the effects of chronic overloading on Hsp content appear to be Hsp and muscle specific. Hsp25 and Hsp90 showed the most consistent response, i.e., higher post-FO compared to pre-FO at almost all time points in both muscles. Hsp20 was the least responsive to FO, whereas ab-crystallin was affected specifically in the plantaris muscle. These results suggest that in both rats and mice the effects of FO on Hsp protein levels are muscle specific and time dependent and that the mouse is an appropriate model to investigate regulation of Hsp expression in response to FO.

**Exposure To Pressure Stimulus Suppresses Myogenin Expression In Differentiating L6 Myoblasts**

Noriteru Morita<sup>1</sup>, Kenji Iizuka<sup>2</sup>, Yoshiki Fujisawa<sup>3</sup>, Takuji Machida<sup>3</sup>, Masahiro Horiuchi<sup>4</sup>, Isao Kambayashi<sup>1</sup>, Masahiko Hirafuji<sup>3</sup>, Koichi Okita<sup>4</sup>.

<sup>1</sup>Hokkaido University of Education, Iwamizawa, Iwamizawa, Japan. <sup>2</sup>Health Sciences University of Hokkaido, Tobetsu-cho, Japan. <sup>3</sup>Health Sciences University of Hokkaido, Tobetsu-cho, Japan. <sup>4</sup>Hokusho University, Ebetsu, Japan.

Email: n-morita@iwa.hokkyodai.ac.jp

(No relationships reported)

When skeletal muscle contracts during exercise and/or physical activity, elevated intramuscular pressure is generated in the contracted muscular tissues. We previously reported that artificial pressure stimulus without deformation of cell shape enhanced glucose uptake and energy metabolism associated with protein synthesis in L6 myoblasts. The pressure-induced metabolic activation and protein synthesis are supposed to be related to some myogenetic responses of the pressurized myoblasts.

**PURPOSE:** The purpose of the present study was to examine the effects of elevated pressure on myogenetic responses in L6 skeletal myoblasts.

**METHODS:** L6 myoblasts were cultured with growth medium containing 10% fetal calf serum and seeded onto new dishes 3 days before experiment (~40% confluent). On the previous day (~95% confluent), culture media was changed to differentiation medium supplemented with 2% horse serum and the cells were cultivated for 24 h. After incubation, atmospheric pressure at 160 mmHg to the cells was applied for 3 h daily for 3 days; and the control cells were kept under normal pressure condition at the same time. For protein and mRNA analyses, cells were harvested on the first, second and third day after pressurization or control treatment.

**RESULTS:** The number of fused myoblasts by morphological measurement of Giemsa-stained cells reduced compared with control cells after 3 days pressurized cells. Myogenin protein levels in the pressurized cells were lowered at day 1 (30%, p<0.05) and day 3 (54%, p=0.09) compared with the control cells. Myogenin mRNA levels significantly decreased at day 1 (72%, p<0.05) and day 3 (62%, p<0.05) compared with the control cells. Unexpectedly, myostatin mRNA content in the pressurized cells was 62% lower than that in the control cells at day 2 (vs control, p<0.05). In intracellular signaling, pressure application increased phosphorylated ERK (2.7-fold, p<0.01) and JNK (1.9-fold, p<0.01), but not affected p38 MAPK phosphorylation at day 1.

**CONCLUSIONS:** These results suggest that elevated intramuscular pressure may suppress myogenic differentiation from myoblasts to myotubes in contracted skeletal muscles. Further studies are needed to clarify functional implications of the pressure-induced metabolic activation (e.g., proliferation) in skeletal myoblasts.

**Effects Of Clenbuterol On Pgc-1, Foxo1 And Atrogin-1 In Presenile Rats**

Takashi Kitaura, FACSM, Shoki Suzuki. Kanazawa University, Kanazawa-city, Kakuma-town, Japan.

Email: kitaura@ge.kanazawa-u.ac.jp

(No relationships reported)

Clenbuterol is one of the beta-2 adrenergic receptor agonists with powerful muscle anabolic and lipolytic effects and is prohibited to use as doping drug for athletes, but it is one of candidates of counter measure for sarcopenia with aging. Since previously we have reported that clenbuterol induced the muscular hypertrophy in young male rats and the transition of muscle fiber type from slow to fast-type (JAP 91(1), 85-90, 2001). However, the effects of clenbuterol on aged animals muscles were not clear yet and the side effects should be cleared.

**PURPOSE:** This study investigated the different effects of clenbuterol on the molecular adaptation system of muscles between young and presenile rats.

**METHODS:** In the present study, clenbuterol was subcutaneously administered in 30wks male Sprague-Dawley rats (PCLE: n=6) during 2 weeks. The effects of clenbuterol on slow-twitch soleus (SOL) and fast-twitch EDL muscles were examined using western blotting and reverse-transcription polymerase chain reaction (RT-PCR) analysis of the mRNAs of beta-2 adrenergic receptor, IGF-1, MyoD, PGC-1a, FOXO1, Atrogin-1, and wwp1.

**RESULTS:** The muscle wet weights did not change in both SOL and EDL muscles of presenile rats, but heart increased significantly. The PGC-1a (-22 %) and FOXO1 (-19%) mRNAs decreased significantly in SOL. The Atrogin-1 (+16%) increased in only SOL and wwp1 increased in both SOL (+11%) and EDL (+7%) muscles. The beta-2 adrenergic receptor (-7%), MCT1 (-7%), and MyoD (-8%) mRNAs decreased significantly in EDL by clenbuterol. However, the protein contents of MCT1, MyoD were no change.

**CONCLUSIONS:** These results suggest that the clenbuterol showed different effects on presenile rats skeletal muscles from young rats via complicated mechanism both of protein synthesis by IGF-1 and proteolysis by PGC-1a, FOXO1, and ubiquitination with aging. It is necessary to carry out more detail experiments to explain the specific adaptation mechanism and to get a useful counter measure for the treatment of sarcopenia.

**2682 Board #76 May 29 2:00 PM - 3:30 PM**

**Nandrolone Decanoate Administration And Growth-related Signaling During Muscle Recovery From Myotoxin-induced Injury**

James P. White, Shuichi Sato, James A. Carson, FACSM. University of South Carolina, Columbia, SC.

(No relationships reported)

Androgens can induce muscle mass accretion and regulate protein turnover. Although androgen administration has the potential to enhance muscle recovery from injury, androgen regulation of muscle regeneration is not well understood. Signaling through the IGF-1/PI3 kinase pathway is a known regulator of muscle fiber growth. Activation of Akt (PKB) by growth factor signaling induces protein synthesis and attenuates protein degradation.

**PURPOSE:** To determine the effect of nandrolone decanoate (ND), a synthetic testosterone, on the activation of the IGF-1/PI3 kinase pathway during tibialis anterior (TA) muscle recovery from injury.

**METHODS:** Castrated C57 BL6 mice were placed into 4 treatment groups; uninjured control (Con; n=6), Uninjured with nandrolone decanoate administration (Con+ND; n=6), bupivacaine-induced injury (Inj; n=6) and bupivacaine-induced injury with nandrolone decanoate administration (Inj +ND; n=6). Muscles were examined after 5 and 14 days of recovery. Akt activity was determined by western blot analysis. The ratio of phospho (ser473) to total forms of the protein was used as activity.

**RESULTS:** At 5 days of recovery, injured muscle increased Akt activity by 6.8 fold (p=.001) while nandrolone decanoate administration in uninjured muscle increased Akt activity 5.5 fold (p=.002). There was no significant interaction between injury and nandrolone decanoate administration at 5 days of recovery. However, at 14 days of recovery there was a significant interaction between injury and ND. There was an 8 fold increase (p= <.001) in Akt activation in the Inj+ND group compared to control. ND administration alone in uninjured muscle increased Akt activity 3.5 fold (p=.001) compared to control. Injured muscle without ND had no increase in Akt activity at 14 days.

**CONCLUSION:** Akt activity is increased 5 days after injury, without a further activation by ND administration. However, at 14 days of recovery, there is an additive induction

**Creatine Attenuates Overload-induced Heat Shock Protein Upregulation In Fast Fiber Subpopulation Of Young Rats**

Mark D. Schuenke<sup>1</sup>, Naomi E. Brooks<sup>2</sup>, Brittnee Greenleaf<sup>1</sup>, Marc Bouchard<sup>1</sup>, Robert S. Hikida<sup>3</sup>. <sup>1</sup>University of New England, Biddeford, ME.

<sup>2</sup>Stellenbosch University, Stellenbosch, South Africa. <sup>3</sup>Ohio University, Athens, OH. (Sponsor: Fredrich Hagerman, FACSM)

Email: mschuenke@une.edu

(No relationships reported)

We have previously shown Heat Shock Protein (HSP) 70 expression to be upregulated in overloaded plantaris muscle and that this upregulation is attenuated in aging muscle [#1763 MSSE 40(5): S294]. This HSP70 upregulation may be due to an overload-induced depletion of energy.

**PURPOSE:** This research investigated whether (1) creatine supplementation alters HSP production in overloaded muscle, and (2) this response is altered in aging muscle.

**METHODS:** Young (17 wk) and older (90 wk) F344 rats were subjected to one of four conditions: 1) control (YC, OC); 2) creatine supplementation (YCr, OCr); 3) surgical overload (YS, OS); or 4) overload + creatine (YScr, OSCr). Rats in creatine groups received creatine solution (4.45g/L, 5% dextrose in drinking water), *ad libitum*. Rats in overload groups underwent bilateral surgical ablation of the gastrocnemius muscle to promote compensatory hypertrophy in synergist muscles. Four weeks post-surgery, serial cross-sections of the plantaris muscle were immunohistochemically assayed for myosin heavy chains (MHC) and HSP70. MHC staining properties of individual fibers were compared to discern muscle fiber types. Pixel density was used to assess HSP70 staining intensity. Cross-sectional area (CSA) was measured on at least 50 fibers per fiber type. Group comparisons were made using a two-way ANOVA. Significant interactions were determined with Tukey's post hoc tests.

**RESULTS:** Fiber CSA was significantly larger in YCr and YScr groups, relative to YC. Creatine alone had no effect on the CSA of fibers in older rats, regardless of fiber type. However, fiber CSA was significantly larger in type I and IIA fibers of OSCr than of OC or OCr groups. Creatine alone had no effect on HSP70 content in any fiber types, regardless of age. However, type IIA fibers in YScr animals had significantly lower HSP70 content than in YS ( $P < 0.05$ ). HSP70 content did not differ in type IIA fibers between YScr, YC, or YCr. Creatine also did not affect HSP70 expression in any of the aging groups, regardless of fiber type.

**CONCLUSION:** These data suggest creatine alone does not alter muscle HSP70 content, but may prevent overload-induced HSP70 upregulation in faster-twitch fibers of young rats. This indicates an interaction between energy stores and HSP content. The data also imply an age-related loss of responsiveness to creatine.

**Insulin Administration Associated To Strength Training: Effects On Skeletal Muscle Of Rats**

Maria Alice R. de Mello, Michel Barbosa Araújo, Leandro Pereira Moura, Carla Ribeiro, Clécia Soares Alencar Mota, Fabricio Azevedo Voltarelli. *Sao Paulo State University (Unesp), Rio Claro, Brazil.*

Email: mellomar@rc.unesp.br

(No relationships reported)

**PURPOSE:** The present study aimed to investigate the strength training effects, associated to insulin administration, on skeletal muscle growth of rats.

**METHODS:** Male Wistar rats (90 days of age) were separated into 4 groups ( $n=10$ /group): Sedentary Control (SC); Trained Control (TC); Sedentary Insulin Treated (SIT) and Trained Insulin Treated (TIT). Simple commercial insulin, 30mU/100g of body weight (bw), was administered 3 days/week (alternated days), during 12 weeks. The animals belonging to TIT and TC groups performed a strength training program, consisted by jumps in tank with water, carrying overload equivalent to 50% of bw. The training was composed by 4 series of 10 jumps, 1 min of rest between the series, 5 days/week, during 12 weeks. We determined the total protein and DNA contents as well as the protein/DNA ratio and the protein synthesis and degradation rates of the soleus muscle of the animals. At the end of the experiment, we verified the glycaemia of the animals. ANOVA two way, followed by Bonferroni, was used in order to indicate the statistical differences ( $P < 0.05$ ).

**RESULTS:** There was not difference in the glycaemia (mg/dL) when compared all experimental groups ( $SC=105.2 \pm 13.2$ ;  $SIT=103.1 \pm 12.4$ ;  $TC=104.4 \pm 13.8$ ;  $TIT=105.8 \pm 13.6$ ). Muscle protein synthesis rates (pmol/mg.h) were higher in the TIT group ( $71.3 \pm 3.6$ ) if compared to the other groups ( $SC=44.3 \pm 2.1$ ;  $SIT=45.2 \pm 1.6$ ;  $TC=62.3 \pm 2.5$ ). TC also showed significantly higher values if compared to SC and SIT groups. No differences were found between the groups when analyzed the protein degradation rates (pmol/mg.h) ( $SC=271.4 \pm 25.2$ ;  $SIT=268.9 \pm 23.1$ ;  $TC=270.3 \pm 20.9$ ;  $TIT=269.8 \pm 22.4$ ). In addition, an improvement in muscle growth was observed in the TI group in relation to the other groups, as indicated by the total protein (g/100g) and DNA (g/100g) contents and protein/DNA ratio values (Total protein:  $SC=3.3 \pm 0.2$ ;  $SIT=3.4 \pm 0.5$ ;  $TC=4.7 \pm 0.3$ ;  $TIT=5.9 \pm 0.3$  - DNA:  $SC=0.148 \pm 0.03$ ;  $SIT=0.147 \pm 0.04$ ;  $TC=0.153 \pm 0.02$ ;  $TIT=0.169 \pm 0.05$  - Protein/DNA:  $SC=22.3 \pm 0.1$ ;  $SIT=23.1 \pm 0.3$ ;  $TC=30.7 \pm 0.2$ ;  $TIT=35.0 \pm 0.4$ ).

**CONCLUSION:** Taken together, these results suggest that the efficiency of the strength training protocol in promoting muscle growth was improved by insulin treatment in the conditions of the present study.

**Skeletal Myocyte-specific VEGF Gene Deletion In Adult Mice Leads To Impaired Exercise Capacity Without Evidence Of Capillary Regression Or Altered In Vitro Muscle Contraction**

Amy E. Knapp, Kechun Tang, FACSM, Michael C. Hogan, FACSM, Peter D. Wagner, Ellen C. Breen. *University of California, San Diego, La Jolla, CA.*

Email: aeknapp@ucsd.edu

(No relationships reported)

Vascular endothelial growth factor (VEGF) is involved in controlling skeletal muscle capillarity, an essential component of exercise capacity.

**PURPOSE:** Determine the mechanisms by which skeletal myocyte VEGF maintains exercise capacity.

**METHODS:** Inducible, skeletal myocyte-specific VEGF gene-deleted mice were generated by crossing *VEGFLoxP* mice with *HSA-Cre<sup>ERT2</sup>* mice (*skmVEGF<sup>-/-</sup>*) in which *cre* recombinase is under control of a human skeletal actin (HSA) sequence and can be conditionally induced with tamoxifen. VEGF levels were measured in several organs and in the gastrocnemius muscle by ELISA, 2 and 7 weeks after tamoxifen delivery to adult (*skmVEGF<sup>-/-</sup>*) and control (*VEGF<sup>+/+</sup>*) mice. Exercise capacity was evaluated by recording the maximum running speed and time to exhaustion. Contractile function in isolated EDL and soleus muscles was assessed by peak force, time to fatigue and the force-frequency relationship.

**RESULTS:** *skmVEGF<sup>-/-</sup>* mice showed 95% and 92% reductions in skeletal muscle VEGF protein 2 and 7 weeks after tamoxifen delivery, respectively, with no reduction in other organs. Two-weeks after tamoxifen, maximum running speed (-10%) and endurance capacity (-47%) were reduced in *skmVEGF<sup>-/-</sup>* mice compared to controls. Seven weeks post-tamoxifen, maximum running speed remained low in *skmVEGF<sup>-/-</sup>* mice, with a non-significant trend towards lower endurance capacity. Body and muscle weights, muscle cross-sectional areas, peak force or time to fatigue and capillary to fiber ratios were not different between *skmVEGF<sup>-/-</sup>* mice and *VEGF<sup>+/+</sup>* at either time point. Analysis of skeletal muscle force-frequency relationships also did not reveal any difference at 2 weeks in the EDL or soleus, though by 7 weeks a significant right shift in the force-frequency curve was observed in the EDL.

**CONCLUSION:** Mice with VEGF-deficient skeletal myocytes exhibit a limitation to exercise that does not stem from an inability of the muscle to contract or the number of capillaries that supply muscle fibers.

(No relationships reported)

Paraplegia results in significant skeletal muscle atrophy. We have previously shown that chronic paraplegia and a chronic increase in physical activity both downregulate the mammalian target of rapamycin (mTOR) pathway, a key regulator of muscle protein synthesis. Recent work has identified a novel SIRT1-p53 pathway that is capable of regulating cell proliferation and muscle protein synthesis independent of mTOR.

**PURPOSE:** To determine whether physical activity or inactivity alters the SIRT1-p53 pathway in skeletal muscle.

**METHODS:** Soleus muscle was collected from 4 male Sprague-Dawley sedentary rats (Control), 5 male rats exposed to 9 weeks of free access to running wheels (Active), and 6 male rats 10 weeks following complete T(4)-T(5) spinal cord transection (Inactive). Peak running distance for the Active rats was 6.3±0.7 km/day. We utilized immunoblotting methods to measure the phosphorylation status of p53 and the total protein abundance of silent information regulation 2 homolog 1 (SIRT1) and FoxO3a.

**RESULTS:** Preliminary data show that the total protein content of SIRT1, an upstream regulator of both p53 and FoxO3a, was ~35% lower in the Inactive rats with no differences between the Active and Control groups. The phosphorylation of p53 on Ser15 was increased (an indicator of enhanced p53 activity) in the Inactive group as compared to the Active and Control rats indicating a suppression of muscle protein synthesis. Phosphorylation of p53 was the lowest in the Active group. Total FoxO3a protein appears to be reduced in the Inactive rats as compared to the Control rats which may suggest a downregulation of proteolysis with severe physical inactivity.

**CONCLUSIONS:** Severe physical inactivity, in the form of chronic paraplegia, appears to downregulate SIRT1, which has been shown to activate p53, resulting in a suppression of muscle protein synthesis. Future work is needed to determine whether exercise rehabilitation can improve muscle protein turnover by restoring cell signaling in situations associated with severe physical inactivity or other muscle wasting conditions.

**Implications Of Angiogenic Factors And Thrombospondin-1 Underlying Capillary Regression In Chronically Unloaded Rat Soleus Muscle**

Hidemi Fujino<sup>1</sup>, Akihiko Ishihara<sup>2</sup>, Shinichiro Murakami<sup>1</sup>, Hiroyo Kondo<sup>3</sup>, Hui Zhong<sup>4</sup>, Roland R. Roy<sup>4</sup>, V Reggie Edgerton, FACSM<sup>4</sup>. <sup>1</sup>Himeji Dokkyo University, Himeji, Japan. <sup>2</sup>Kyoto University, Kyoto, Japan. <sup>3</sup>Suzuka University of Medical Science, Suzuka, Japan. <sup>4</sup>University of California, Los Angeles, Los Angeles, CA.

Email: fujinolab@gmail.com

(No relationships reported)

Capillary regression is induced by chronic unloading of skeletal muscles. The mechanisms involved, however, are not fully understood. At least two independent mechanisms can be considered, i.e., adaptations in the levels of specific angiogenic factors such as vascular endothelial growth factor (VEGF) and angiopoietin, and of thrombospondin-1 (TSP-1), an inhibitor of angiogenesis that induces apoptosis in endothelial cells.

**PURPOSE:** The aim of present study was to determine the responses of pro- and anti-angiogenic factors in rat soleus capillaries after 2 weeks of hindlimb unloading (HU).

**METHODS:** Male Wistar rats (8-9 weeks of age) were assigned randomly into a control or HU group. Frozen transverse sections from the soleus mid-belly were stained for alkaline phosphatase which is present in the capillary endothelium. Apoptotic endothelial cells were identified by von Willebrand factor and DNA fragmentation (TUNEL) using immunofluorescent staining. VEGF, KDR, Flt-1, angiopoietin-1 (Ang-1), Ang-2, Tie-2, HIF 1 alpha, and TSP-1 mRNAs were determined by TaqMan probe-based real-time PCR reactions.

**RESULTS:** The capillary-to-fiber ratio was 23% lower in HU than control rats. TUNEL-positive endothelial cells were observed only in HU rats and TSP levels were higher in HU than control rats, suggesting capillary regression with vascular endothelial cell apoptosis. mRNA levels of angiogenic factors VEGF and Ang-1, their receptors, and HIF 1 alpha were lower in HU than control rats whereas Ang-2 levels were unaffected. As a result, the Ang-2/Ang-1 ratio increased, suggesting that the vasculature was destabilized. Ang-2 expressed in the absence of VEGF also results in vessel regression.

**CONCLUSIONS:** These data indicate that a decrease in angiogenic factors and an increase in TSP-1 expression may play an important role in capillary regression associated with chronic unloading.

**Neuromuscular Control During A Drop Jump Between Healthy Women And Women With Semitendinosus-gracilis Acl Reconstruction**

Elena Roman, Gloria D. Colon, Luis A. Rivas, Marizabel LaPuerta, Lourdes Reus, Heidi Venegas, Alexis Ortiz. University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico. (Sponsor: William Micheo, FACSM)

Email: elena.roman@upr.edu

(No relationships reported)

Women with anterior cruciate ligament (ACL) reconstruction have shown neuromuscular compensatory strategies to maintain the stability of the knee during landing tasks. ACL reconstruction with hamstring-gracilis (SG) autograft is one of the preferred surgical reconstruction options in women.

**PURPOSE:** To compare neuromuscular recruitment strategies of the quadriceps and hamstrings between young women 1-5 years post SG ACL reconstruction and non-injured women.

**METHODS:** Twenty-nine young women (non-injured = 15, SG = 15) performed five trials of a double-legged drop jump from a 60-cm height box. Participants had five bipolar Ag pre-amplified surface EMG electrodes on the skin over the vastus medialis, vastus lateralis, rectus femoris, medial and lateral hamstrings on the dominant leg for the non-injured women and in the reconstructed leg for women with ACL reconstruction. EMG data was collected at 1kHz. A dynamic normalization procedure was used while subjects performed multiple tuck jumps over five seconds. Data from all the quadriceps and hamstring muscles were averaged to represent each muscle group, respectively.

Rectified and normalized EMG activities for the quadriceps, hamstrings and quadriceps/hamstring co-contraction (CCR) ratio were the variables of interest. The CCR was calculated as the EMG activity of the less active muscle divided by the most active muscle as a representation of dynamic knee stability. ANOVA were used for group comparisons on the average of five trials for all three variables.

**RESULTS:** Non-injured women exhibited as twice as much normalized neuromuscular activity for the quadriceps (non-injured:  $27.56 \pm 38.35$ ; SG:  $13.49 \pm 3.25$ ) and hamstrings (non-injured:  $14.41 \pm 11.92$ ; SG:  $7.69 \pm 3.16$ ) and similar CCR (non-injured:  $56.88 \pm 20.19$ ; SG:  $54.58 \pm 17.90$ ). However, these differences were not statistically significant for quadriceps ( $p=0.22$ ), hamstrings ( $p=0.07$ ) and quadriceps/hamstrings CCR ( $p=0.76$ ) variables.

**CONCLUSIONS:** It appears that women with SG ACL reconstruction possess similar neuromuscular activation patterns that women without knee surgery. Nonetheless, some of these differences could be related to the high variability presented by the non-injured subjects. NIH Grants G12RR03051 and 1P20 RR11126, and NSCA Foundation supported this project.

**Comparison Of Landing Mechanics During A Drop Jump In Semitendinosus-gracilis Acl-reconstructed Females And Noninjured Females**

Carmen E. Capo-Lugo, Luis Rivas, Elena Roman, Gloria Colon, Marizabel LaPuerta, Heidi Venegas, Alexis Ortiz. *University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.* (Sponsor: William Micheo, FACSMM)

Email: carmen.capo@upr.edu

(No relationships reported)

Women with different types of anterior cruciate ligament (ACL) reconstruction have shown similar landing mechanics as non-injured women. ACL reconstruction using the Semitendinosus-gracilis (SG) graft is one of the preferred options for ACL reconstruction in women.

**PURPOSE:** To compare knee valgus between non-injured women and women with SG ACL reconstruction during a 60-cm double-legged drop jump.

**METHODS:** Twenty-nine females 21-35 years of age (non-injured =15, weight:  $60.25 \pm 10.63$  Kg, height:  $161.24 \pm 6.70$  cm; SG = 15, weight:  $67.20 \pm 11.46$  Kg, height:  $166.92 \pm 8.44$  cm) participated in this investigation. Participants performed 5 trials of a double-legged drop jump from a 60-cm height box. The double-legged landing task involved landing from the 60-cm drop box and immediately jumping vertically as high as possible (countermovement jump). Reflective markers were attached over bony prominences of both legs according to the model embedded in the software. A static trial was used to estimate each subject's joint centers. Five infrared cameras (120 Hz) were used to capture the trajectory of reflective markers during the drop jump. Knee valgus was defined as the minimum distance between markers placed at the lateral femoral epicondyles during the ground contact phase. The ground contact phase was defined as the moment of initial contact until the participant cleared both feet from the floor during the maximal vertical jump push-off. The average valgus from five trials was used for analysis using an Analysis of Variance (ANOVA) to compare knee valgus among groups.

**RESULTS:** The ANOVA revealed no statistically significant differences ( $p=0.842$ ) between groups for knee valgus during the ground contact phase of the drop jump.

**CONCLUSION:** Young women with SG ACL reconstruction presented similar knee valgus as young women without knee surgery on a 60-cm double-legged drop jump. It appears that young women who undergo ACL reconstruction with SG autograft do not experience long term landing mechanics deficits that could predispose them to re-injury. NIH Grants G12RR03051 and 1P20 RR11126, and NSCA Foundation supported this project.

**Isometric Thigh Muscle Torque Does Not Change From Early Follicular To Post- Ovulatory Phases**

Melissa M. Montgomery, Sandra J. Shultz, FACSMM. *The University of North Carolina at Greensboro, Greensboro, NC.*

(No relationships reported)

Changes in circulating sex hormones during the menstrual cycle may interact with the muscle in a way that may alter its force-producing capability. While some studies report increased knee flexor / extensor torques around ovulation, others do not. Few studies obtained hormone concentrations to confirm cycle phase.

**PURPOSE:** To compare maximal voluntary isometric contraction (MVIC) torque of the knee flexors (KF) and extensors (KE) between the early follicular (EF) and early (EL) and late (LL) luteal phases as confirmed by serum hormone concentrations. It was expected that MVIC torques would increase from EF to EL once estradiol peaked and prior to significant exposure to progesterone.

**METHODS:** 51 physically active females were measured daily for serum estradiol (E2) and progesterone (P4) for 6 days following onset of menses and 8 days following evidence of ovulation for 2 consecutive months. In the third month, subjects provided a blood sample and performed KF and KE MVICs on one day during menses and one day post-ovulation. To ascertain the time of testing in the luteal phase for each female, E2 and P4 concentrations obtained on the luteal MVIC test date were aligned with their hormone profiles of the previous 2 months. Subjects were then grouped as being tested during an anovulatory cycle (AN = peak P4 <3 ng/mL), during EL (post ovulation through the first 3 days of the P4 rise), or during LL (near or post P4 peak). Repeated measures ANOVA compared groups on mean normalized KF and KE MVICs (Nm/kg) between their early follicular and luteal tests.

**RESULTS:** The timing of the luteal test could be reliably determined in 44 females ( $163.4 \pm 6.5$  cm,  $60.1 \pm 8.3$  kg,  $21.5 \pm 2.6$  yrs); 9 AN (E2=  $95.1 \pm 74.6$  pg/mL, P4=  $1.1 \pm 0.6$  ng/mL), 14 EL (E2=  $113.0 \pm 36.6$  pg/mL, P4=  $7.0 \pm 2.7$  ng/mL) and 21 LL (E2=  $133.9 \pm 42.1$  pg/mL, P4=  $13.5 \pm 6.2$  ng/mL). Results revealed no difference in MVIC torque between the follicular and luteal phases ( $p=0.265$ ), or between phases by group ( $p=0.765$ ) or muscle ( $p=0.869$ ), or group by muscle ( $p=0.134$ ). KE was greater than KF MVIC ( $2.31 \pm 0.06$  vs.  $1.73 \pm 0.06$  Nm/kg;  $p<.001$ ).

**CONCLUSIONS:** KE and KF MVIC torque in physically-active females did not change from the early follicular phase (when E2 and P4 were at their nadirs) to times in the luteal phase that followed an unopposed E2 rise, or combined E2 and P4 rise.

**Sensorimotor Control Of Collegiate Football Players**

Kevin Laudner<sup>1</sup>, Mike Moline<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>Casper College, Casper, WY. (Sponsor: David Thomas, FACSMM)

Email: klaudne@ilstu.edu

(No relationships reported)

Shoulder instability is one of the most common injuries among athletes participating in contact sports, such as football. Previous research has shown that this instability adversely affects the function of the sensorimotor system potentially leading to a pathological cycle of soft tissue damage, diminished sensorimotor control, and shoulder dysfunction. Although, previous research has investigated the effects of participating in overhead sports, such as baseball, softball, and tennis on sensorimotor control, currently there are no data detailing such effects among football players.

**PURPOSE:** To determine if differences exist in shoulder sensorimotor control between a group of collegiate football players and a control group.

**METHODS:** Forty-five Division I collegiate football players (age= $20.0 \pm 1.0$  years, height= $186.7 \pm 5.4$  cm, mass= $103.4 \pm 15.0$  kg) and 70 male control subjects with no previous experience in collision sports (age= $21.0 \pm 1.9$  years, height= $177.6 \pm 9.1$  cm, mass= $76.2 \pm 14.1$  kg) participated. All subjects had no recent history of upper extremity injury or neurological disorder. Each subject performed 3, 30 second upper extremity balance trials on each arm. The balance trials were conducted in a single arm push-up position with the test arm in the center of a force platform (Advanced Mechanical Technology, Inc., Newton, MA) and their feet on an unstable surface. The trials were averaged and the differences in radial area deviation (anterior-posterior and medial-lateral sway) between groups were analyzed using independent t-tests ( $P<.05$ ).

**RESULTS:** The football players had significantly more radial area deviation of the dominant ( $P=.02$ ) and non-dominant arms ( $P=.03$ ) when compared to the control group.

**CONCLUSIONS:** Our results suggest football players may have decreased sensorimotor control of the shoulder compared to individuals with no contact sport experience. Such decreases in sensorimotor control may be due to the frequent impacts to the shoulder during football participation. As such, football players may benefit from exercises which target the sensorimotor system. Our findings may also be beneficial in the evaluation and treatment of various shoulder injuries among football players.

**Interference To Force Accuracy With A Mechanical Disturbance To The Contralateral Hand During Bilateral Tasks**

Ryota Ishibashi<sup>1</sup>, Tadao Isaka<sup>2</sup>, Daisuke Ichikawa<sup>2</sup>, Sadao Kawamura<sup>2</sup>, Minoru Shinohara, FACS<sup>3</sup>. <sup>1</sup>Nagoya Institute of Technology, Nagoya, Japan.

<sup>2</sup>Ritsumeikan University, Shiga, Japan. <sup>3</sup>Georgia Institute of Technology, Atlanta, GA.

Email: rr001993@se.ritsumei.ac.jp

(No relationships reported)

Concurrent, bilateral movement control is commonly required in daily life including sports activity, but unconscious interferences to the ipsilateral hand with mechanical disturbances to the contralateral hand are not well known.

**PURPOSE:** We examined the interference between hands when a mechanical disturbance was applied to a hand during bilateral muscle contractions that maintained steady digit forces.

**METHODS:** Fifteen right-handed subjects controlled bilateral static force with their thumb and index finger. In a neutral pinching posture for both hands, subjects produced static force in the directions of digit flexion and extension in separate trials. The force direction during a trial was the same for both hands. Visual feedback of the target (10% of maximal force) and produced force was provided for each hand. Subjects were asked to match their force to the target as accurate and steady as possible for 10 s in each hand. In each force direction, the task was performed with (3 trials) and without (3 trials) a mechanical disturbance applied to the left hand 5 s after the onset of trial. The mechanical disturbance was induced by a linear actuator as rapid lateral displacement of the left-hand manipulandum (10 cm in 600 ms) against which the left digits produced force. The mean force in the right hand was calculated for the 2-s period immediately after the disturbance (from 5<sup>th</sup> to 7<sup>th</sup> s). As an index of accuracy, the relative deviation of the mean force from the target (error ratio) was compared between force directions and between disturbance conditions.

**RESULTS:** The error ratio in the right hand was significantly ( $P < 0.05$ ) higher in the extension direction ( $5.7\% \pm 4.3\%$ ) compared with the flexion direction ( $3.3\% \pm 2.4\%$ ) without the disturbance. With the mechanical disturbance to the left hand, the error ratio in the right hand increased more than 2 times ( $P < 0.05$ ), reaching  $16.2\% \pm 11.1\%$  in the extension and  $8.55\% \pm 3.92\%$  in the flexion directions.

**CONCLUSION:** The accuracy during bilateral force control was influenced by force direction and a mechanical disturbance to the contralateral hand. The results suggested that accuracy in a hand was lower in the force direction that is produced less frequently in daily life and was unconsciously reduced with a mechanical disturbance to the contralateral hand probably due to divided attention.

**Effectiveness Of Immediate Video Feedback On Wheelchair Propulsion Training For Patients With Spinal Cord Injuries**

Weerawat Limroongreungrat<sup>1</sup>, Li-Shan Chang<sup>2</sup>, Yong Tai Wang, FACS<sup>2</sup>, Christy Acker<sup>3</sup>, Chris Maurer<sup>3</sup>, Stephen Sprigle<sup>4</sup>. <sup>1</sup>Mahidol University,

Bangkok, Thailand. <sup>2</sup>Georgia State University, Atlanta, GA. <sup>3</sup>Shepherd Center, Atlanta, GA. <sup>4</sup>Georgia Institute of Technology, Atlanta, GA.

Email: weerawatl@gmail.com

(No relationships reported)

Studies have shown video feedback to enhance motor skill learning in healthy individuals since it allows learners not only to visualize themselves but also to evaluate discrepancies so erroneous performance can be corrected. However, effectiveness of video feedback on wheelchair training in early rehabilitation for spinal cord injury (SCI) patients has not been determined.

**PURPOSE:** To examine effects of real-time video feedback on level wheelchair propulsion training for people with SCI.

**METHODS:** Twenty-eight patients, matched on age, gender, wheelchair seat width and SCI level were randomly assigned to either video feedback (VG, mean<sub>age</sub> = 33.9+10.3 yrs) or control (CG, mean<sub>age</sub> = 29.6+10.4 yrs) groups. Two reflective markers were attached on the right 3<sup>rd</sup> metacarpophalangeal joint and wheel axle. Both groups received one 30-min propulsion training during which their performance of wheelchair propulsion were recorded by video cameras from the sagittal plane. After each task, the VG observed their own performance via video motion analysis software and received feedback from a therapist to correct errors while the CG received feedback normally given during rehabilitation. Pushrim kinematics and number of strokes (NS) were obtained and compared between four different times: baseline, post-training, retention and transfer tests. A mixed-model ANOVA (2 groups x 4 times) and Bonferroni pos hoc test ( $p < .05$ ) were employed to determine statistical differences.

**RESULTS:** No significant difference in kinematic variables and NS were found between VG and CG. However, NS of both groups in post-training decreased 50% as compared to baseline. Pushing angles significantly increased in both groups during post-training (CG=78.2°, VG=82.6°), retention (CG=80.1°, VG=83.4°) and transfer tests (CG=76.3°, VG=86°), compared to baseline (CG=68.8°, VG=72.9°). In VG, significantly increased cycle time during post-training (1.92 s) and retention test (1.93 s) was found, compared to baseline (1.12 s).

**CONCLUSIONS:** Wheelchair propulsion training improves stroke efficiency by increasing contact and total push angles in both groups. Although no significant differences between two groups are found, real-time video feedback seems helpful in terms of motivation and performance correction.

**Response Of Lumbar Muscles To Release Of The Trunk After Passive Cyclic Trunk Flexion-extension**

Michael W. Olson, Jeffery Denny. Southern Illinois University Carbondale, Carbondale, IL. (Sponsor: M. Daniel Becque, FACS<sup>3</sup>)

Email: mwolson@siu.edu

(No relationships reported)

Previous literature has indicated a modified response of the lumbar paraspinal (LP) muscles after fatigue and sustained passive trunk flexion, but not during cyclic trunk movement. LP response latencies are important to understand the etiology of injury to the trunk-spine system.

**PURPOSE:** To observe LP muscle response times to quick releases performed after passive cyclic trunk flexion-extension (TF-E) exercise.

**METHODS:** Participants were 4 men ( $23 \pm 3$  yrs,  $176 \pm 6$  cm, and  $82 \pm 6$  kg) with no back or lower extremity dysfunction. Participants sat on a backless chair positioned on a platform and abutted against a metal frame with a wooden backing. Thighs were perpendicular to the floor and the feet were positioned flat on the platform. An isokinetic dynamometer was positioned 80cm behind the participants with the axis aligned 10 cm higher than the participants' L5-S1 level. The attachment arm of the dynamometer was secured to a harness around the chest. The attachment arm was offset 20 deg from vertical to maintain gravitational moment  $> 0$ . Participants were taken through TF-E passively until released near end range of trunk extension. These were performed before and after two trials of 30 reps of cyclic passive TF-E. Participants were instructed to remain relaxed during sessions and respond naturally to the release. Surface electromyography (EMG) signals were collected from LP muscles bilaterally using Ag-AgCl gel electrodes. An elgon was positioned on the attachment arm and time synchronized with the EMG. Response time to the quick release and the 200 ms leading up to this event were analyzed. Repeated measures ANOVA (time) was used to analyze response times. A two factor (release block x time) ANOVA was performed to compare the 200 ms lead period in 10ms increments prior to the quick release. Alpha was set at 0.05.

**RESULTS:** There were no significant differences in response times of the LP muscles between release blocks (left LP:  $0.25 \pm 0.1$  s,  $0.22 \pm 0.2$  s,  $0.25 \pm 0.1$  s; right LP:  $0.16 \pm 0.03$  s,  $0.18 \pm 0.1$  s,  $0.22 \pm 0.1$  s, respectively,  $p > 0.05$ ). LP activation 200 ms prior to quick release was significantly different between blocks ( $p < 0.05$ ), but not over time.

**CONCLUSIONS:** Neither cyclic TF-E nor anticipatory activity influenced LP myoelectric response to the quick release. Greater numbers of participants are needed to verify these observations.

**Is Lower Plantarflexor Steadiness In The Elderly A Source Of Larger Postural Sway During Quiet Standing?**

Kei Masani<sup>1</sup>, Albert H. Vette<sup>1</sup>, Masaki O. Abe<sup>2</sup>, Kimitaka Nakazawa<sup>3</sup>, Milos R. Popovic<sup>1</sup>. <sup>1</sup>Toronto Rehab Institute, Toronto, ON, Canada.

<sup>2</sup>Northeastern University, Boston, MA. <sup>3</sup>National Rehabilitation Center for Persons with Disabilities, Saitama, Japan. (Sponsor: Minoru Shinohara, FACSM)

Email: k.masani@utoronto.ca

(No relationships reported)

Postural instability due to aging results in larger and faster postural sway in the elderly compared to the young. At the same time, the force fluctuation during isometric constant force exertion has been reported to be larger in the elderly as well. It is hypothesized that the larger force fluctuation causes the larger and faster postural sway in the elderly.

**PURPOSE:** To investigate the noise component in the postural control system using our newly developed methodology by which a neural-mechanical control scheme can be identified using quiet standing data, and to compare the noise component between the elderly and the young.

**METHODS:** Twenty-three young ( $27.3 \pm 4.7$  yrs) and twenty-two elderly ( $66.5 \pm 4.9$  yrs) subjects were asked to stand still on a force platform to acquire data for 30 s. The fluctuation of the body angle, the electromyogram of the right soleus muscle, and the ankle torque were measured. A postural control model was build, which consisted of a neural controller (a proportional-derivative controller), a neural feedback delay of 80 ms, the torque generation process (2nd order filter), and a mechanical controller (stiffness and small damping). In the first procedure, the natural frequency of the torque generation process and the stiffness were optimized using the measured muscle activity and postural sway as the inputs and the ankle torque as the output of the model. In the second procedure, the gains of the neural controller were optimized using the identified variables in the first procedure and the measured postural sway as the input and the ankle torque as the output of the model. The noise torque component was identified as the residual between the measured torque and the torque accounted for by the model.

**RESULTS:** The model fitting was quite good with percentage fits of  $98.9 \pm 0.5$  % and  $98.4 \pm 0.6$  % for the elderly and the young, respectively. The coefficients of variation of the noise torque components were significantly different between the elderly ( $1.8 \pm 0.7$  %) and the young ( $1.3 \pm 0.7$  %) ( $p = 0.017$ ). These values closely matched with the force fluctuation during isometric force exertion reported in the literature.

**CONCLUSIONS:** More erroneous torque control accompanied with constant force exertion in the elderly compared to the young may be a cause of larger and faster postural sway in the elderly.

**Test-retest Reliability Of Quadriceps Voluntary Activation**

Crystal Kean, Trevor B. Birmingham, S. Jayne Garland, Ian C. Jones. University of Western Ontario, London, ON, Canada. (Sponsor: Dr. Tony Vandervoort, FACSM)

Email: ckean@uwo.ca

(No relationships reported)

**PURPOSE:** To examine the test-retest reliability of quadriceps voluntary activation using both the interpolated twitch technique (ITT) ratio and the central activation ratio (CAR).

**METHODS:** 10 healthy active individuals (4 females, 6 males; age  $27.2 \pm 2.8$  yrs; mass  $69.9 \pm 12.4$  kg; height  $1.73 \pm 0.07$  m) completed two sessions separated by at least 24 hours and within 1 week. Participants were seated on the isokinetic dynamometer with hips and knees at  $90^\circ$  and the lower leg secured to the dynamometer arm. Stimulation electrodes were placed over the proximal vastus lateralis and distal vastus medialis. While resting, the amperage of a 400V square wave pulse (duration 100  $\mu$ s) was progressively increased to obtain a plateau in the resting twitch torque. Once this was determined participants performed two practice isometric maximal voluntary contraction (MVC) followed by 5 test MVCs. A stimulus was delivered approximately 1-2s into the MVC (superimposed twitch), when a plateau in torque was noted. A second stimulus was delivered to the relaxed muscle following the MVC (potentiated twitch). The %VA was determined using the torque values of the MVC, superimposed and potentiated twitches in the following formulas:

$$ITT = (1 - (\text{superimposed} / \text{potentiated})) * 100\%$$

$$CAR = (MVC / (MVC + \text{superimposed})) * 100\%$$

The test-retest reliability of ITT and CAR was evaluated using the intraclass correlation coefficient (ICC type 2, 1) and the standard error of measurement (SEM). The SEM was then used to calculate the minimal detectable change (MDC) at the 95% confidence interval (95%CI).

**RESULTS:** Based on paired t-tests, there was no significant difference in %VA on day 1 vs day 2 for either ITT ( $95.9 \pm 3.1$  % vs  $95.2 \pm 3.3$  %) or CAR ( $98.7 \pm 1.6$  % vs  $98.7 \pm 1.3$  %) ( $p > 0.05$ ). %VA calculated based on CAR was significantly higher than %VA calculated based on ITT ( $p < 0.01$ ). The ICCs for ITT was 0.81 (95%CI: 0.40-0.95) and CAR was 0.92 (95%CI: 0.74-0.98). The MDC at the 95%CI for ITT was 5.64% and for CAR was 3.74%.

**CONCLUSIONS:** ITT ratio and CAR demonstrate excellent test-retest reliability. Based on the MDC, the percentage of voluntary activation for 95% of young healthy participants would change by less than 5.64% (using ITT ratio) and 3.74% (using CAR) upon repeated testing. Therefore we can be confident that changes greater than these are true changes in voluntary activation.

**Balance And Strength Changes Following Injury Prevention Protocol In Female Soccer Players**

Matt Greig<sup>1</sup>, Rebecca Craven<sup>2</sup>, Lars McNaughton, FACSM<sup>2</sup>. <sup>1</sup>Edge Hill University, Ormskirk, United Kingdom. <sup>2</sup>University of Hull, Hull, United Kingdom.

Email: matt.greig@edgehill.ac.uk

(No relationships reported)

The prevention of sports injuries is characterised by a wide spectrum of approaches with multimodal programs most often advocated, evaluated based on epidemiology but typically failing to clarify which aspect of the intervention program contributed to the reduction in injury incidence.

**PURPOSE:** To quantify the effects of a multimodal injury prevention program previously shown to reduce injury incidence.

**METHODS:** Female collegiate soccer players ( $n=9$ ) completed the F-MARC 11 injury prevention program in addition to their soccer training over a duration of 6 weeks, whilst an age and training-age matched control group ( $n=9$ ) completed an equivalent amount of soccer training. Pre- and post-intervention, all players were assessed for isokinetic strength of the knee flexors and extensors in both concentric and eccentric mode at speeds of 1.05, 3.14 and 5.23  $\text{rad}\cdot\text{s}^{-1}$ , and dynamic posturography using sensory organisation and unilateral sway tests. Between group comparisons were made using repeated measures ANOVA, with significance accepted at  $p \leq 0.05$ .

**RESULTS:** Post-intervention, the F11 group displayed a significant increase in the somatosensory and vestibular contributions to balance during the sensory organisation test. The F11 group also displayed a significant post-intervention decrease in sway velocity during a unilateral stance test, for both eyes open and eyes closed conditions. No changes were observed for the

control group. There was no change in peak concentric or eccentric torque for either knee flexors or extensors post-intervention, irrespective of movement speed. There was however a significant change in the angle of peak torque for eccentric knee flexors at the slowest test speed. The control group showed no changes in isokinetic parameters.

**CONCLUSION:** The F11 injury prevention program created a change in the relative contributions to dynamic balance, with an increase in both the somatosensory and vestibular ratios, and no change in the visual ratio. Whilst peak torque was unaffected, there was evidence of a shift in the angle of peak eccentric hamstring torque at the slowest test speed post-intervention. Injury reduction might therefore be attributed to those exercises involving dynamic single-legged balance, enhancing movement control rather than maximal strength.

**Interference From Divided Attention With Additional Motor Or Cognitive Task To Motor Accuracy**

Ashley N. Johnson, Shikhar Vohra, Minoru Shinohara, FACSM. *Georgia Institute of Technology, Atlanta, GA.*

Email: ashley.johnson@gatech.edu

(No relationships reported)

Accuracy of motor output has often been studied for single unilateral tasks in laboratory settings. It is possible that accuracy of motor output may be interfered with an additional task due to divided attention.

**PURPOSE:** The purpose of the study was to examine the influence of divided attention with an additional motor or cognitive task on accuracy of isometric force matching with a hand muscle.

**METHODS:** Ten healthy right-handed adults ( $27.1 \pm 4.0$  yrs) performed a unilateral motor task with the right hand, a cognitive task, a bilateral motor task with both hands, and a concurrent motor-cognitive task in a randomized order. The motor tasks involved steady low-intensity isometric contraction of the first dorsal interosseus in the right or both hands. Abduction force of the index finger was recorded from both hands. In the unilateral motor task, subjects received visual feedback of force and were instructed to match and maintain 5% and 10% of their maximal voluntary contraction (MVC) force as accurate and steady as possible by abducting the index finger of the right hand. The bilateral motor task used the same protocol as the unilateral task but with both hands concurrently. The cognitive task involved arithmetic and memory. The concurrent motor-cognitive task corresponded to the concurrent performance of the unilateral motor and cognitive tasks. The abduction force for the steady 10-s period in the right hand was used for analyses. As an index of accuracy, the relative deviation of mean force from the target (error ratio) was calculated and averaged across 4 trials in each task.

**RESULTS:** The error ratio in the right hand tended to increase with an additional task at 5% MVC ( $8.8 \pm 4.9\%$  during the unilateral motor task,  $11.9 \pm 8.8\%$  during the bilateral motor task, and  $10.9 \pm 5.7\%$  during the motor-cognitive task) and at 10% MVC ( $7.6 \pm 3.8\%$  during the unilateral motor task,  $8.4 \pm 6.8\%$  during the bilateral motor task, and  $9.1 \pm 5.4\%$  during the motor-cognitive task), but these changes did not reach statistical significance.

**CONCLUSIONS:** Divided attention with an additional motor or cognitive task induced little interference to motor accuracy during a low-intensity motor task with simple steady isometric contraction of a hand muscle.

**2699      Board #93      May 29      3:30 PM - 5:00 PM**  
**The Influence Of Ankle Instability On The Kinetics Of Gait Termination**

Douglas A. Doidge<sup>1</sup>, Erik Wikstrom<sup>2</sup>, Shinichi Amano<sup>1</sup>, Chris J. Hass<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>University of North Carolina Charlotte, Charlotte, NC. (Sponsor: Paul Borsa, FACSM)

Email: ddoidge@hhp.ufl.edu

(No relationships reported)

Chronic ankle instability (CAI) is a common occurrence after an ankle sprain. Yet, some people (copers) maintain dynamic activities without recurrent injury. Alterations in both feed-forward and feedback control exist in CAI patients but little is known about alterations in copers. Understanding differences between copers and CAI patients may help elucidate the mechanism of CAI.

**PURPOSE:** To examine control differences among controls, CAI, and copers during gait termination (GT).

**METHODS:** Twenty controls ( $20.85 \pm 1.6$  yr), 20 with CAI ( $20.5 \pm 1.0$  yrs) and 20 copers ( $21.9 \pm 2.9$  yrs) participated. Copers and CAI patients had a previous moderate ankle sprain but copers resumed all pre-injury activity without limitation or recurrent injury while CAI patients had recurrent sprains. Each subject was tested bilaterally (each limb as the lead and brake limb) during ten planned and ten unplanned GT trials. An auditory signal cued subjects to stop during randomly selected trials (unplanned GT) and catch trials ensured that anticipation of the auditory signal did not occur. Ground reaction forces, collected at 1200Hz, from two adjacent force plates were used to calculate the maximum propulsion (lead limb) and braking forces (brake limb). A 3x2x3 mixed model (group [control, CAI, coper], limb [involved/uninvolved], and task [planned GT, unplanned GT, catch]) MANOVA examined differences among force variables.

**RESULTS:** Both control and coper subjects produced significantly less propulsive force than the CAI group (CAI:  $11.2 \text{ N}$  > healthy and  $9.9 \text{ N}$  > copers). Subsequently, braking forces were higher for CAI patients than controls ( $45.5 \text{ N}$  greater) or copers ( $26.8 \text{ N}$  greater).

**CONCLUSION:** CAI patients did not reduce their propulsive forces during GT trials (planned and unplanned) to the same extent as controls or copers and relied on greater braking forces to stop forward momentum. This indicates an altered motor program and slower neuromuscular response in CAI patients during GT. Further, both feed-forward and feedback neuromuscular control alterations appear to exist in CAI subjects. Copers, however, produce similar movement patterns as controls suggesting a return to normal neuromuscular control or successful compensation pattern which may represent a potential coping mechanism.

**Gender And Age-related Training Adaptations In Maximal Motoneuron Firing Rate**

Anita Christie, Gary Kamen, FACSM. *University of Massachusetts, Amherst, MA.*

(No relationships reported)

**PURPOSE:** To investigate potential age and gender differences in the training-related adaptations in muscular force and maximal motor unit firing rates.

**METHODS:** A total of 60 subjects; 30 young (mean age  $21.9 \pm 3.1$  years) and 30 older (mean age  $72.9 \pm 4.6$  years) individuals participated in the study, with equal numbers of males and females in each group. All subjects completed two testing sessions, separated by 2 weeks. During each testing session measures of maximal voluntary contraction (MVC) force of the dorsiflexors and maximal motor unit firing rates in the tibialis anterior were obtained. During the two week interval between testing sessions, individuals in the control group were asked to carry out their normal daily activities, while individuals in the training group were asked to participate in a total of 6 isometric strength training sessions (3 per week).

**RESULTS:** At baseline there were no differences in MVC force ( $p=.15$ ), or maximal firing rate ( $p=.44$ ) between the training and control groups. However MVC force was lower in older subjects than young ( $p=.002$ ) and lower in females than in males ( $p<.001$ ) at baseline. The trained group showed a significant 17.8% increase in MVC force ( $p<.001$ ) following training, while the control group showed little change (2.2% increase) ( $p<.001$ ). There was no significant Day\*Gender ( $p=.56$ ), or Day\*Age ( $p=.76$ ) interaction, suggesting that young and older males and females showed similar changes in MVC force in response to training. The maximal motor unit firing rate was lower at baseline in older than in young subjects ( $p=.002$ ), and lower in females than in males ( $p=.05$ ). The maximal motor unit firing rate increased 14.2% in the trained group across

the two days ( $p=.001$ ), while the firing rates in the control group showed a slight 4.3% increase. There was no significant Day\*Gender ( $p=.69$ ), or Day\*Age ( $p=.20$ ) interaction, suggesting that young and older males and females showed similar changes in maximal motor unit firing rate in response to training.

**CONCLUSIONS:** Although overall, older individuals and females had lower MVC force and lower maximal motor unit firing rates than young and male subjects, respectively, they show similar adaptations in MVC force and maximal motor unit firing rate following training.

**A Protocol For Measuring The Effect Of Cycling On Neuromuscular Control Of Running In Triathletes**

Andrew R. Chapman, Bill Vicenzino. *The University of Queensland, Brisbane, Australia.* (Sponsor: Andrew Chapman, FACSM)

(No relationships reported)

**PURPOSE:** The direct effects of cycling on neuromuscular control during running in triathletes are unknown. In this paper we outline and test a new protocol for investigating the influence of cycling on neuromuscular control during running in highly-trained triathletes. **METHODS:** We conducted three experiments investigating a) the repeatability (i.e. between-day reliability) of the protocol, specifically three-dimensional kinematic and electromyographic (EMG) measures of neuromuscular control, b) the ability of the protocol to investigate the direct influence of cycling on neuromuscular control during running independent of fatigue in highly-trained triathletes (by evaluating indicators of fatigue from EMG and force data), and c) the ability of the protocol to provide a sufficient control, or baseline, measure of neuromuscular control during running in highly-trained triathletes. **RESULTS:** Kinematic and electromyographic (EMG) measures of neuromuscular control during running showed moderate to high repeatability (mean coefficients-of-multiple-correlation (CMC) for repeatability of EMG and kinematics were  $0.816 \pm 0.014$  and  $0.911 \pm 0.031$ , respectively). There was no evidence that the protocol resulted in neuromuscular fatigue in highly-trained triathletes. The protocol provided a sufficient control, or baseline, measure of neuromuscular control during running for highly-trained triathletes (CMC for stability was  $0.827 \pm 0.023$ , and  $0.862 \pm 0.054$  for EMG and kinematics, respectively).

**CONCLUSION:** This protocol provides repeatable measures of neuromuscular control during running and can be used to differentiate any direct influence of cycling on neuromuscular control during running from the effects of a) fatigue, b) altered running speed, c) kinematic variations (the selection of an alternate, but not necessarily less efficient or less skilled, movement pattern), and d) continued running (changes in neuromuscular control that would occur during continued running irrespective of any prior cycling).

**Sex Differences In Brain Activation During Submaximal Isometric Contractions Of The Lower Extremity**

Sandra K. Hunter, FACSM<sup>1</sup>, Marnie L. Vanden Noven<sup>1</sup>, Tejin Yoon<sup>1</sup>, Matthew D. Verber<sup>2</sup>, McKenzie Fauth<sup>1</sup>, Katalin Skelton<sup>3</sup>, Kristy Nielson<sup>1</sup>.

<sup>1</sup>Marquette Univ., Milwaukee, WI. <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI. <sup>3</sup>Syracuse University, Syracuse, NY.

(No relationships reported)

Women can sustain isometric contractions for a longer duration than men but the influence of sex differences in brain activation on performance is not known.

**PURPOSE:** To compare brain activity in healthy young women and men during submaximal isometric contractions of the ankle dorsiflexor muscles using functional magnetic resonance imaging (fMRI).

**METHODS:** Fifteen young adults (9 women, 6 men 18-40 years of age) performed three sets of isometric contractions at 10%, 30%, 50% and 70% of maximal voluntary contraction force for 16 s at each intensity with the right ankle dorsiflexor muscles while lying supine in a 3.0 T MRI scanner. Subjects received force feedback during the contractions via a rear-projection visual display system. fMRI was used to quantify the blood oxygenation level dependent (BOLD) contrast (T2\* weighted imaging) overlaid on a T1 weighted anatomical image for each subject. An 8-channel array Radio Frequency receive head coil was used to obtain 36 sagittal plane slices (thickness = 4 mm) across the entire brain volume using an echo-planar imaging sequence (64 x 64 matrix, 240 x 240 mm<sup>2</sup> field of view, TE = 25 ms, TR = 2000 ms, flip angle = 77°).

**RESULTS:** Using voxelwise analysis to determine the differences in brain activation in men versus women, men demonstrated significantly greater intensity in the BOLD signal [whole brain corrected  $P < 0.01$ , ( $t = 2.817$ ), cluster size = 534  $\mu$ l] in the following areas compared with women: left cerebellum (2 distinct regions), right postcentral gyrus, right parietal lobe, left middle cingulate cortex, left middle temporal gyrus, right inferior frontal gyrus, and right superior temporal gyrus.

**CONCLUSIONS:** Men demonstrated a greater intensity of brain activity in motor and sensorimotor areas in the cortex compared with women. Sex differences in functional neural networks are present during submaximal isometric contractions of the lower extremity muscles despite men and women sustaining contractions of similar relative intensity. The more intense brain activation in men reflects a greater central drive to perform the same relative task for men compared with women.

**Effect Of Functional Isometric Squats On 40 Yard Dash In Males: Post-activation Potentiation Pilot Study**

Joseph M. Berning<sup>1</sup>, Michael J. Murphy<sup>1</sup>, Kent J. Adams, FACSM<sup>2</sup>, Carole A. Carson<sup>1</sup>, Chad Harris, FACSM<sup>3</sup>, Bryant A. Stamford, FACSM<sup>4</sup>. <sup>1</sup>New Mexico State University, Las Cruces, NM. <sup>2</sup>California State University, Monterey Bay, Seaside, CA. <sup>3</sup>Western New Mexico University, Silver City, NM. <sup>4</sup>Hanover College, Hanover, IN.

(No relationships reported)

Functional Isometrics is a form of weight training where a person lifts greater than 100% of their 1 repetition maximum (1RM) near the end of their range of motion moving the weight a short distance until the weight meets an immovable object, then pushing/holding the weight for 3-5 seconds. This technique has been used to hyper-stimulate the nervous system theoretically leading to one's ability to exert increased muscular force and power. This type of response is known as a Post-Activation Potentiation (PAP) effect.

**PURPOSE:** To investigate if trained males who performed a functional isometric squat at 150% of their 1RM for 5 seconds would increase counter movement vertical jump (CMJ) height.

**METHODS:** Five trained (experienced weight trainers: lift > 4 days/week) (age: 23.2±2.4 yrs, mass: 87.9±12.1 kg, ht: 180.0±10.0 cm) males participated in the study. Day 1: Forty Yard Dash was first determined using Speed Trap II timing device. Next, individual 1RM (1RM 143.6±35.6 kg) in the back squat was determined. Lastly, ½ squat heights were determined and subjects were allowed to practice the functional isometric squat technique using only the bar. Day 2: Subjects reported back to the testing area three to five days after initial testing. After an appropriate dynamic warm-up, subjects performed a five second functional isometric squat with 150% of their 1RM squat (150% 1RM: 215.5±38.8 kg). Immediately at the end of the five second squat, subjects walked 50 feet out of the building to the sprint area, sat and rested for 4 minutes. At the end of the rest period, subjects performed the 40-Yard dash.

**RESULTS:** A paired samples t-test revealed post-FI 40-Yard time was significantly ( $t(5) = 3.19$ ,  $p = 0.033$ ) shorter than pre-FI 40-Yard dash. Subjects decreased their 40-Yard dash time by mean of 0.28±0.20 seconds.

**CONCLUSIONS:** The results of this study suggest that a 5 second FI squat at 150% of dynamic squat 1RM is sufficient to elicit a significant PAP effect in trained males as measured by 40-Yard dash.

**Ischemia Increases Central Drive From The Motor Cortex During Submaximal Exercise In Healthy Adults**

Sean C. Forbes, Jill M. Slade, Joseph J. Carlson, Robert W. Wiseman, Ronald A. Meyer. *Michigan State University, East Lansing, MI.* (Sponsor: L.L. Ploutz-Snyder, FACSM)

Email: sforbes@msu.edu  
(No relationships reported)

The central nervous system may play a significant role in skeletal muscle fatigue in some conditions. Central fatigue could arise from spinal and supraspinal inputs, including motor cortex activation. Previous studies have shown that muscle activity measured by EMG increases at a faster rate during sustained submaximal contractions when the muscle is ischemic compared to a non-ischemic condition.

**PURPOSE:** To estimate motor cortical activity using functional magnetic resonance imaging (fMRI) during sustained submaximal handgrip muscle contractions performed with and without forearm ischemia.

**METHODS:** Eight healthy adults ( $27 \pm 13$  (SD) yrs old, 7 male) were positioned supine with a pressure cuff placed around their upper arm. The subjects performed 3 min isometric contractions at 15% of MVC with and without cuff occlusion (cuff inflated 80 Torr above systolic blood pressure). During the contractions, the subjects had direct visual feedback of force and MR images were acquired at 3T with an 8-channel head coil. Echo planar imaging was used for functional scans (TR=2000 ms, TE=35 ms, FOV=22 cm, matrix=64x64) and were overlaid on a high-resolution anatomical scan (fast GRE, TR=4.4 ms, TE=1.1 ms, TI=500 ms, FOV=22 cm). The rate of increase in motor cortex activity during the final 90 s of the contractions was estimated by the slope of the signal intensity (SI) using a linear regression analysis.

**RESULTS:** During the contractions, the SI of the images was characterized by reaching a plateau during the initial period (~90 s) followed by either maintaining a steady state level or a progressive increase. During the final 90 s of the contractions, the slope of SI was greater ( $p < 0.03$ ) in the ischemic ( $4.7E-05 \pm 1.4E-05$  SI/s, mean $\pm$ SE) than the non-ischemic condition ( $1.1E-05 \pm 1.5E-05$  SI/s).

**CONCLUSIONS:** The findings of this study indicate that motor cortex activity increases at a faster rate during ischemic submaximal exercise compared to the non-ischemic condition. Furthermore, the results support the notion that fMRI can be utilized to measure central drive during isometric skeletal muscle contractions. This may have valuable implications for studying central fatigue during athletic performance and in certain populations, such as individuals with chronic fatigue syndrome.

**2705      Board #99      May 29      3:30 PM - 5:00 PM**  
**Relationships Among The M-wave, H-reflex, Twitch Torque, And The Mechanomyographic Responses During Standard Recruitment Curves**

Joel T. Cramer, FACSM<sup>1</sup>, Preeti J. Deshpande<sup>2</sup>, Joseph P. Weir, FACSM<sup>2</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>Des Moines University - Osteopathic Medical Center, Des Moines, IA.  
Email: jcramer@ou.edu  
(No relationships reported)

**PURPOSE:** To examine the relationships among the M-wave, H-reflex, twitch torque (TT), and MMG responses recorded during standard recruitment curves.

**METHODS:** Six men (mean  $\pm$  SD age =  $25.0 \pm 1.7$  yrs; body mass =  $81.1 \pm 6.3$  kg; height =  $179.9 \pm 5.9$  cm) and 8 women ( $23.4 \pm 1.8$  yrs;  $64.1 \pm 4.6$  kg;  $169.9 \pm 5.8$  cm) lied prone on an isokinetic dynamometer with their left foot secured to the ankle attachment to measure plantar flexion TT. Self-adhering stimulating electrodes (1 cm x 1 cm) were taped in the popliteal fossa and over the patellar tendon. Pre-amplified bipolar surface electromyographic (EMG) electrodes were placed over the soleus muscle, while a miniature accelerometer was placed proximal to the EMG electrodes to record MMG. Five constant-current stimuli (1 ms pulse duration, 100-400 V) were delivered percutaneously to the tibial nerve at incremental intensities (1 - 99 mA). Individual recruitment curves were established, which included the TT, M-wave, H-reflex, and MMG response at each intensity. The sum of the H-reflex and the M-wave (Sum<sub>H-M</sub>) was also computed.

**RESULTS:** There were correlations ( $P < 0.05$ ) between TT and MMG (95% confidence interval for  $r = 0.78-0.98$ ), M-wave and MMG ( $r = 0.62-0.96$ ), Sum<sub>H-M</sub> and MMG ( $r = 0.84-0.98$ ), TT and M-waves ( $r = 0.58-0.95$ ), and Sum<sub>H-M</sub> and TT ( $r = 0.89-0.99$ ). H-reflexes were not related ( $P > 0.05$ ) to any of the other variables. The average Z-score-transformed correlation coefficients involving the M-wave ( $r = 0.85-0.87$ ) were less than ( $P < 0.05$ ) the average coefficients involving TT, MMG, and Sum<sub>H-M</sub> ( $r = 0.93-0.97$ ).

**CONCLUSION:** These findings indicated that the MMG responses during a standard recruitment curve were more related to TT and Sum<sub>H-M</sub> than the M-waves or H-reflexes. Since the MMG signal is not confounded by stimulus artifact, does not require a ground electrode, involves only one sensor, and tracks the TT response better than the M-wave, the MMG signal may be useful for determining the maximal twitch force and corresponding stimulus intensity when torque or force measures are not feasible. However, validation and reliability studies will be necessary to test this hypothesis.

**2706      Board #100      May 29      3:30 PM - 5:00 PM**  
**Spinal Mechanisms Contributing To Rate Of Force Development**

Sam Johnson, Kristof Kipp, Joonkoo Yun, Mark Hoffman, FACSM. Oregon State University, Corvallis, OR.  
(No relationships reported)

The neuromuscular system's ability to quickly generate force is important during fast movements and injury prevention. Rate of force development (RFD) is a common measure of this ability. However, it is unknown to what extent spinal control mechanisms contribute to RFD.

**PURPOSE:** To identify contributions of spinal control mechanisms to RFD.

**METHODS:** RFD of isometric plantarflexion was measured from 37 participants (19 male and 18 females) on a Biodex System 3 dynamometer with the ankle of the dominant leg secured at 90°. H-reflex, intrinsic pre-synaptic inhibition (IPI), and extrinsic pre-synaptic inhibition (EPI) recruitment curves were obtained from the soleus. IPI testing used the paired pulse conditioning protocol where two stimuli are delivered to the tibial nerve at the same intensity 100 ms apart. EPI was assessed through common peroneal nerve conditioning with 100 ms between the conditioning and test reflexes. Recurrent inhibition (RI), a form of post-synaptic inhibition, was assessed by setting stimulus 1 (S1) to 25% of  $M_{max}$  and stimulus 2 (S2) to  $M_{max}$ . Ten trials of both S1 alone and S1 followed 10 ms later by S2 were counterbalanced. Neural drive ( $V_{max} \cdot M_{max}$ ) was assessed by a  $M_{max}$  stimulation to the tibial nerve during an isometric maximum voluntary contraction (iMVC) of the soleus. Five trials with 60 seconds rest between each were collected. Additionally, three trials of iMVC with 60 seconds rest between each were collected to assess RFD. Standard multiple regression was used to determine the contribution of the independent variables to RFD. The independent variables were sex, the first derivative of the H-reflex, IPI, and EPI, RI (S1+S2/ S1), and  $V_{max} \cdot M_{max}$ .

**RESULTS:** The regression analysis revealed the model significantly predicted RFD ( $r^2 = 0.643$ ,  $p < 0.001$ ). The significant independent variables were sex ( $b = -0.564$ ,  $p < 0.001$ ), V-wave ( $b = 0.502$ ,  $p = 0.001$ ), and IPI ( $b = -0.450$ ,  $p = 0.016$ ).

**CONCLUSION:** Sex was a significant contributor, with males having greater RFD. Increased  $V_{max} \cdot M_{max}$  also significantly contributed. IPI, a measure of influence of reflex activation history and thought to reflect modulation of Ia afferent inflow from the muscle spindles significantly contributed to RFD. Based on the results, RFD is a result of increased neural drive, modulation of muscle spindle feedback, and sex differences.

**Gain Of Visual Feedback And Brain Activation During Submaximal Contractions Of The Lower Extremity**

Mamie L. Vanden Noven<sup>1</sup>, Tejin Yoon<sup>1</sup>, Matthew D. Verber<sup>2</sup>, McKenzie Fauth<sup>1</sup>, Katalin W. Skelton<sup>3</sup>, Kritsy Nielson<sup>1</sup>, Sandra K. Hunter, FACSM<sup>1</sup>.  
<sup>1</sup>Marquette University, Milwaukee, WI. <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI. <sup>3</sup>Syracuse University, Syracuse, NY.  
(No relationships reported)

Gain of the visual feedback influences the performance of a submaximal isometric contraction but the role of brain activation is not known.

**PURPOSE:** To compare brain activation patterns when the gain of the visual force feedback was altered during performance of submaximal isometric contractions at various

intensities.

**METHODS:** Nine young adults (3 males, 6 females, 20 - 40 years) attended two experimental sessions to perform three sets of isometric contractions at 10%, 30%, 50% and 70% of maximal voluntary contraction force for 16 s at each intensity with the right ankle dorsiflexor muscles while lying supine in a 3.0 T magnetic resonance imaging (MRI) scanner. Subjects received visual feedback during the contractions via a rear-projection visual display system and were required to track a horizontal target line on the display screen. During one of the sessions (*control*) the gain of the visual feedback was not altered and the target line for the different contraction intensities was relative to the height of the screen. In the other session (*gain*), the gain of the force feedback was varied so that the target line for the different contraction intensities was always in the center of the visual display screen. Functional MRI was used to quantify the blood oxygenation level dependent (BOLD) contrast (T2\* weighted imaging) overlaid on a T1 weighted anatomical image for each subject. An 8-channel array Radio Frequency receive head coil was used to obtain 36 sagittal plane slices (thickness = 4 mm) across the entire brain volume using an echo-planar imaging sequence (64 x 64 matrix, 240 x 240 mm<sup>2</sup> field of view, TE = 25 ms, TR = 2000 ms, flip angle = 77°).

**RESULTS:** When all intensities were combined, voxelwise analysis demonstrated a significant increase in BOLD activity during the *gain* condition [whole brain corrected  $P < 0.01$ , ( $t = 2.859$ ), cluster size = 534  $\mu$ l] in the right paracentral lobule ( $xyz = -8.5, 35.8, 50.4$ ) compared with the *control* condition.

**CONCLUSIONS:** The right paracentral lobule processes sensorimotor signals related to the lower extremities and appears to have an important role in modulating performance of submaximal isometric contractions at various intensities when the gain of the visual force feedback is altered.

#### **Physical Activity And Cardiovascular Risk Markers In South Asians Living In England**

Mark Hamer, Emmanuel Stamatakis, Tarani Chandola. *University College London, London, United Kingdom.*

Email: m.hamer@ucl.ac.uk

(No relationships reported)

South Asians (SA) living in England (originating from India, Bangladesh and Pakistan) have a higher incidence of diabetes and coronary heart disease compared with the white population. The role of physical activity in reducing cardiovascular disease (CVD) risk among SA remains poorly understood.

**PURPOSE:** To examine the association between physical activity and CVD risk markers in a representative sample of SA and whites living in England.

**METHODS:** Participants were 13,851 healthy (no history of CVD) men and women (3,550 SA, 10,301 white;  $45 \pm 17$  yrs old) drawn from the Health Survey for England. CVD risk factors included fasting glucose (fGL) and triglycerides (FTG), glycosylated haemoglobin (HbA1c), C-reactive protein (CRP), fibrinogen, cholesterol (C), waist circumference (WC), and mean arterial blood pressure (MAP). Self-reported questionnaires were employed to estimate physical activity levels. Participants were deemed to be sufficiently active if they reported at least 450 MET-min per week.

**RESULTS:** In comparison with whites, the SA were less likely to meet the physical activity guidelines (odds ratio = 0.41, 95% CI, 0.38 to 0.45). In general linear models that were adjusted for age and gender, SA had higher levels of fGL, FTG, HbA1c, CRP, and lower HDL-C compared with whites. In comparison with inactive SA, the active SA demonstrated lower FTG (adjusted beta, -0.19, 95% CI, -0.35 to -0.04,  $P=0.02$ ), HbA1c (-0.09, -0.18 to -0.01,  $P=0.03$ ), CRP (-0.48, -0.10 to 0.01,  $P=0.05$ ), WC (-1.59, -2.38 to -0.81,  $P=0.001$ ), MAP (-1.97, -3.29 to -0.66,  $P=0.003$ ), and greater HDL-C (0.08, 0.05 to 0.11,  $P=0.001$ ). Similar associations were observed in physically active whites compared to the sedentary.

**CONCLUSIONS:** Physical activity is associated with some important CVD risk markers in an at risk SA population. Physical activity should be promoted in SA living in England.

### **2709 Board #103 May 29 2:00 PM - 3:30 PM**

#### **Effect Of A Stretching Program On The Autonomic Modulation In Hemodialysis Patients: Pilot Study**

Alejandro Soler<sup>1</sup>, Catalina Abaunza<sup>2</sup>, Marcela Zapata<sup>3</sup>, Camilo Povea<sup>2</sup>. <sup>1</sup>Clinica del Country, Bogota, Colombia. <sup>2</sup>Universidad El Bosque, Bogota, Colombia. <sup>3</sup>Universidad del Rosario, Bogota, Colombia.

Email: soler.md@hotmail.com

(No relationships reported)

**PURPOSE:** To determine the effect of a stretching program over the autonomic modulation in chronic renal patients on hemodialysis.

**METHODS:** An intradialysis exploratory descriptive pilot study was performed executing stretching exercises for one month every other day. The sample consisted of 3 men ( $53 \pm 13.2$  yrs) and 4 women ( $26 \pm 5.7$  yrs) who signed an informed consent. They were evaluated by means of a heart rate variability registry, a challenge of the autonomic nervous system, and stretching tests. The registry was divided into three phases with a 21 minute duration: an initial one in supine position, an orthostatic challenge, and a final one in supine position again. At the end of the month, the patients were re-evaluated.

**RESULTS:** The standard deviation of the RR intervals showed the same tendency but in an opposite direction in women ( $29.9 \pm 11.1$  ms before vs  $23.7 \pm 12.6$  ms after), with respect to men ( $15.3 \pm 6.0$  ms before vs  $22.5 \pm 5.0$  ms after). The same result occurred with the total spectral power in women ( $2764.8 \pm 1108.5$  ms<sup>2</sup>/Hz before vs  $1574.2 \pm 1123.8$  ms<sup>2</sup>/Hz after) with respect to men ( $1162 \pm 437.4$  ms<sup>2</sup>/Hz before vs  $1646 \pm 220.2$  ms<sup>2</sup>/Hz after). The 30:15 index, which was abnormal in all at the beginning of the intervention ( $0.9 \pm 0.03$ ), showed an increment in all patients and was normalized in one young female (1.05). The net differences of the high frequency index ( $-5.9 \pm 7.9$  ms<sup>2</sup>/Hz before vs  $3.9 \pm 8.9$  ms<sup>2</sup>/Hz after) in the entire sample could indicate some degree of neurovegetative modification.

**CONCLUSION:** This study concludes the existence of an autonomic dysfunction in chronic renal patients confirmed by the differences in the 30:15 index, and the tendency towards a modification in parasympathetic reactivity by means of a stretching program.

#### **Impact Of Progressive Resistance Training On Lipids And Lipoproteins In Adults**

George A. Kelley, FACSM, Kristi S. Kelley. *West Virginia University, Morgantown, WV.*

Email: gkelley@hsc.wvu.edu

(No relationships reported)

Previous randomized controlled trials have yielded conflicting results regarding the effects of progressive resistance training (PRT) on lipids and lipoproteins in adults.

**PURPOSE:** Use the meta-analytic approach to examine the effects of PRT on lipids and lipoproteins in adult humans.

**METHODS:** Randomized controlled trials > 4 weeks dealing with the effects of PRT on lipids and lipoproteins in adult humans > 18 years of age and published between January 1, 1955 and July 12, 2007 were included. Primary outcomes included total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), ratio of total cholesterol to

high-density lipoprotein cholesterol (TC/HDL-C), non-high-density lipoprotein cholesterol (non-HDL-C), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG). A random-effects model was used for analysis with data reported as means and 95% confidence intervals.

**RESULTS:** Twenty-nine studies representing 1329 men and women (676 exercise, 653 control) were included. Statistically significant improvements were found for TC (-5.5 mg/dl, -9.4 to -1.6), TC/HDL-C (-0.5, -0.9 to -0.2), non-HDL-C (-8.7 mg/dl, -14.1 to -3.3), LDL-C (-6.1 mg/dl, -11.2 to -1.0) and TG (-8.1 mg/dl, -14.5 to -1.8) but not HDL-C (0.7 mg/dl, -1.2 to 2.6). Changes were equivalent to -2.7%, 1.4%, -11.6%, -5.6%, -4.6%, and -6.4%, respectively, for TC, HDL-C, TC/HDL-C, non-HDL-C, LDL-C, and TG.

**CONCLUSION:** Progressive resistance training reduces TC, TC/HDL-C, non-HDL-C, LDL-C and TG in adults.

**2711 Board #105 May 29 2:00 PM - 3:30 PM**  
**Maximal Exercise ECG Responses And Mortality Among Men With Metabolic Syndrome**

G. William Lyerly<sup>1</sup>, Xuemei Sui<sup>1</sup>, Carl J. Lavie<sup>2</sup>, Timothy S. Church<sup>3</sup>, Gregory A. Hand, FACSM<sup>1</sup>, Steven N. Blair, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Ochsner Medical Center, New Orleans, LA. <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
 (No relationships reported)

An abnormal ECG during maximal exercise testing is a powerful predictor of mortality in asymptomatic men. However, the relationship between exercise ECG (E-ECG) responses and the risk of mortality in men with metabolic syndrome (MS) is not well-studied.

**Figure 1.** Age- and examination year-adjusted CHD mortality rates by E-ECG results and number of MetS components in 5191 men with MetS. White bars represent the normal ECG, striped bars the equivocal ECG, and black bars the abnormal ECG. The p values are for a test of linear trend across ECG groups. The number of men (and CHD deaths) in the normal, equivocal, and abnormal ECG groups were 4349 (57), 549 (13), and 414 (18) in those with 3 MetS components; 2058 (21), 286 (8), and 215 (16) in those with 4 components; and 577 (9), 91 (4), and 52 (4) in those with 5 components, respectively.

**PURPOSE:** Our purpose was to evaluate the relationship between abnormal E-ECG responses and mortality in a large

population of asymptomatic men with MS.

**METHODS:** Participants were 9191 men (mean age 46.9) who met the criteria of having MS. All completed a maximal exercise treadmill test (years 1979 to 2001) and were without a previous cardiovascular disease (CVD) event or diabetes at baseline. Main outcomes were mortality from all-causes, CHD, and CVD. Cox regression analysis was used to quantify the mortality risk according to E-ECG responses.

**RESULTS:** During an average follow-up of 14 years, 633 deaths (242 CVD; 150 CHD) were identified. E-ECG test results were a strong predictor of CHD mortality risk (HR, 95% CI: 1.62, 1.02-2.56 for equivocal ECG and 2.45, 1.62-3.69 for abnormal ECG,  $p_{\text{trend}} < 0.0001$ ). After adjusting for risk factors, men with equivocal and abnormal E-ECG tests had a 40% and 91% higher CHD death risk ( $p_{\text{trend}} = 0.004$ ), a 14% and 75% higher risk of CVD death ( $p_{\text{trend}} = 0.003$ ), and a 24% and 24% higher risk of all-cause death ( $p_{\text{trend}} = 0.04$ ) than men with a normal E-ECG test, respectively. We also observed positive graphical trajectory for CHD mortality rates across E-ECG categories within 3, 4, or 5 MS components ( $P$  for trend  $< 0.05$ , respectively; see Figure 1).

**CONCLUSIONS:** Among men with MS, an abnormal E-ECG response was associated with a higher risk of all-cause, CVD, and CHD mortality. These findings underscore the importance of E-ECG tests as a determinant of cardiovascular outcomes.

**2712 Board #106 May 29 2:00 PM - 3:30 PM**  
**Physical Fitness And Nine-year Mortality In 70-year-old Population**

Mieko Shimada<sup>1</sup>, Yutaka Yoshitake<sup>2</sup>, Yasuo Kimura<sup>3</sup>, Naoki Nakagawa<sup>4</sup>, Hiroshi Nagayama<sup>2</sup>, Mamoru Nishimuta<sup>5</sup>, Masaharu Ohashi<sup>6</sup>, Hideo Miyazaki<sup>6</sup>. <sup>1</sup>Chiba College of Health Science, Chiba, Japan. <sup>2</sup>National Institute of Fitness & Sports in Kanoya, Kanoya, Japan. <sup>3</sup>Saga University, Saga, Japan. <sup>4</sup>Sanno University, Isehara, Japan. <sup>5</sup>National Institute of Health and Nutrition, Tokyo, Japan. <sup>6</sup>Niigata University, Niigata, Japan.  
 (No relationships reported)

**PURPOSE:** Since little is known about relationship between physical fitness ability and mortality among very elderly people, we evaluated this association in a Japanese population of 70-year-old community residents.

**METHODS:** In 1998, 600 (306 males and 294 females) individuals who were 70 years old resided in the Niigata Prefecture of Japan underwent physical fitness tests including hand-grip strength, isometric leg extensor strength, leg extensor power, stepping rate, and one-leg standing time with eyes open. In 2007, 367 (181 males and 186 females) who were 79 years old underwent physical fitness tests longitudinally. During 9-year follow-up period, 70 individuals (55 males and 15 females) died. Physical fitness ability was compared between individuals who underwent physical fitness tests (alive group) or individuals who were dead (dead group) during 9-year follow-up period.

**RESULTS:** The mean values for hand-grip strength at 70 years age for individuals who were alive and dead during 9-year follow-up period were  $39.7 \pm 5.6$ ,  $38.2 \pm 5.7$  kg for men, and  $24.6 \pm 3.8$ ,  $23.7 \pm 3.1$  kg for women, respectively. The mean values for isometric leg extensor strength for the two groups were  $1.21 \pm 0.29$ ,  $1.10 \pm 0.24$  kg/kg body mass for men, and  $0.86 \pm 0.25$ ,  $0.78 \pm 0.29$  kg/kg body mass for women, respectively. The mean values for leg extensor power for the two groups were  $14.8 \pm 3.4$ ,  $13.2 \pm 3.4$  watt/kg body mass for men, and  $9.1 \pm 2.7$ ,  $7.7 \pm 3.1$  watt/kg body mass for women, respectively. The mean values for the stepping rate for the two groups were  $80.7 \pm 14.0$ ,  $77.1 \pm 14.8$  times per 10 seconds for men, and  $71.0 \pm 12.4$ ,  $62.9 \pm 13.1$  times per 10 seconds for women, respectively. The mean values for the one-leg standing time with their eyes open for the two groups were  $75.4 \pm 42.5$ ,  $65.3 \pm 46.4$  seconds for men,  $52.9 \pm 44.0$ ,  $41.6 \pm 43.8$  seconds for women, respectively. All measurements regarding physical fitness were significantly higher for men than for women. In men and women, the leg extensor power and knee extensor strength were significantly higher in the alive group than the dead group.

**CONCLUSIONS:** This study suggests that isometric leg extensor strength and leg extensor power are useful predictors for assessing mortality in the future.

**2713 Board #107 May 29 2:00 PM - 3:30 PM**  
**Role Of Endurance And Inspiratory Resistive Diaphragmatic Breathing Training In Improving Asthmatic Symptomatology**

Ina Shaw<sup>1</sup>, Brandon S. Shaw<sup>2</sup>, Gregory A. Brown, FACSM<sup>3</sup>. <sup>1</sup>Vaal University of Technology, Vanderbijlpark, South Africa. <sup>2</sup>Tshwane University of Technology, Pretoria, South Africa. <sup>3</sup>Human Performance Laboratory, University of Nebraska at Kearney, Kearney, NE.  
 Email: inas@vut.ac.za  
 (No relationships reported)

The growing incidence and costs of asthma has resulted in a considerable financial- and health-burden that demands alternative and more cost-effective pulmonary rehabilitation treatment options.

**PURPOSE:** To compare endurance training (ET), inspiratory resistive diaphragmatic breathing training (IDT) and combined endurance and inspiratory resistive diaphragmatic

breathing training (ET+IDT) on asthmatic symptomatology.

**METHODS:** Eighty-eight inactive, moderate-persistent asthmatics were assigned to either a control group (CG) (n = 22), ET group (n = 22), IDT group (n = 22) or ET+IDT group (n = 22). The forced vital capacity (FVC), forced expiratory volume in one second (FEV<sub>1</sub>), forced expiratory volume in one second/forced vital capacity ratio (FEV<sub>1</sub>/FVC), peak expiratory flow (PEF), maximal voluntary ventilation (MVV), maximal oxygen consumption (VO<sub>2max</sub>) and medication usage was assessed pre- and post-training. The ET patients walked/jogged at 60% of their individual age-predicted maximal heart rate, IDT patients performed both inspiratory resistive breathing and diaphragmatic breathing for three sets of five to 10 repetitions at a 1:2 second inspiration to expiration ratio, three sets of 10 to 15 repetitions at a 2:4 ratio and three sets of 15 to 20 repetitions at a 3:6 ratio. The ET+IDT patients performed 15 minutes of walking/jogging and diaphragmatic breathing for two sets of each of the repetitions and ratios utilized by the IDT group.

**RESULTS:** ET, IDT and ET+IDT significantly (P<0.05) increased FVC, FEV<sub>1</sub> and PEF, while significantly decreasing medication usage. IDT and ET+IDT were effective at increasing FEV<sub>1</sub>/FVC. VO<sub>2max</sub> and MVV increased significantly following ET and ET+IDT training. Post-hoc analysis revealed that the ET+IDT was the most effective at improving VO<sub>2max</sub>, FVC, FEV<sub>1</sub>, FEV<sub>1</sub>/FVC, PEF and MVV.

**CONCLUSIONS:** These findings support the inclusion of ET+IDT for moderate-persistent asthmatics to improve asthmatic symptomatology due to ET+IDT's low risk and cost while allowing a patient to gain the unique benefits of both modes of exercise.

**2714 Board #108 May 29 2:00 PM - 3:30 PM**  
**Exercise And Type 2 Diabetes And Metabolic Syndrome**

Anna M. Chudyk, Elizabeth Russel-Minda, Robert J. Petrella, FACSM. *Lawson Health Research Institute, London, ON, Canada.*

Email: achudyk@uwo.ca

(No relationships reported)

**PURPOSE:** To review and quantify the effects of different modes of exercise training on measures of glucose control, body composition, and disease-related complications in individuals with metabolic syndrome or type 2 diabetes.

**METHODS:** The online databases PUBMED, SPORTDiscus, CINAHL and SCOPUS were searched for RCTs exploring the effects of progressive resistance training (PRT), aerobic exercise, or combined aerobic and PRT in adult type 2 diabetic or metabolic syndrome populations. Studies involving a mixed diet and exercise approach were included if the exercise component of the intervention could be quantified in terms of frequency, intensity, and duration. Selected studies were assessed for methodological quality using a modified version of the Downs and Black Checklist, and ranked according to levels of evidence. Statistical analyses and meta-analyses were conducted where feasible.

**RESULTS:** An initial literature search conditionally identified 30 RCTs for inclusion. Results are presented separately for metabolic syndrome and type 2 diabetic populations. Preliminary data suggest that both forms of exercise, in combination as well as alone, have beneficial effects on diabetic outcomes. There is limited data upon which to formulate conclusions regarding the efficacy of exercise on study outcomes in individuals with metabolic syndrome.

**CONCLUSIONS:** There is a lack of consistency among studies in the classification system used to identify participants with metabolic syndrome. This may partially explain the limited amount of studies upon which to formulate conclusions in the metabolic syndrome population. The area of exercise in type 2 diabetes is much better developed, with several new RCTs conducted since the last major review of this topic. Evidence-based conclusions regarding a dose-response relationship between exercise and study outcomes are forthcoming.

**2715 Board #109 May 29 2:00 PM - 3:30 PM**  
**Correlates Of Physical Activity In Men And Women With Osteoarthritis: Findings From Australia**

Kristiann C. Heesch, Norman Ng, Wendy J. Brown. *University of Queensland, Brisbane, Australia.*

Email: kheesch@hms.uq.edu.au

(No relationships reported)

Osteoarthritis (OA) is the leading cause of pain and disability in Australia, and physical activity is a preferred treatment for OA symptoms. However, most people with OA are not engaging in health-enhancing activities recommended to relieve symptoms. Understanding the modifiable factors associated with these activities is necessary to encourage participation.

**PURPOSE:** To examine the correlates of leisure-time physical activity (LTPA), strength training, and stretching exercises among individuals with OA.

**METHODS:** As part of a mail survey, 485 individuals, aged 68.0 (SD=10.6) years, with hip or knee OA were asked about current use of 17 therapies for OA relief as well as about demographic, health-related and psychological factors. Associations with each activity outcome were examined in a multivariable logistic regression model, separately for men and women.

**RESULTS:** Having the use of a walking aid was associated with LTPA in men and women (p<0.05). In men, attempting to lose weight and using massage therapy were associated with participation in both strength training and stretching exercises (p<0.05). In women, attempting to lose weight and taking an OA self-management program were associated with participation in strength training (p<0.05), and taking an OA self-management program, using orthotics in shoes, and the perceived benefits of physical activities were associated with stretching exercises (p<0.05).

**CONCLUSION:** This is the first study to show that use of certain OA therapies is associated with participation in physical activities. Acknowledging the limitations of the cross-sectional design, the findings indicate important channels, such as OA self-management programs for women and massage therapists for men, for promoting activity. They also indicate the perceived need for aids, like walking aids and orthotics, for participation in health-enhancing activities.

**Exercise And Global Well Being In Community Dwelling Adults With Fibromyalgia**

Kristi S. Kelley<sup>1</sup>, George A. Kelley, FACSM<sup>1</sup>, Jennifer M. Hootman, FACSM<sup>2</sup>, Dina L. Jones<sup>1</sup>. <sup>1</sup>West Virginia University, Morgantown, WV. <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA.

Email: kskelley@hsc.wvu.edu

(No relationships reported)

The effects of exercise on the range of problems experienced by those with fibromyalgia are not well known.

**PURPOSE:** Use the meta-analytic approach to determine the effects of exercise on global well-being in community-dwelling adults with fibromyalgia.

**METHODS:** Studies were included if they met the following criteria: (1) randomized controlled trials with the unit of assignment at the participant level, (2) adults > 18 years of age, (3) an exercise-only intervention group (aerobic, strength training, or both), (4) community accessible exercise interventions > four weeks, (5) a non-intervention control group, (6) English-language studies, (7) published and unpublished (master's theses and dissertations) studies, (8) studies published between January 1, 1973 and August 29, 2007, and (9) data for the overall score from the Fibromyalgia Impact Questionnaire (FIQ) available. A random-effects model and Hedge's standardized effect size (g), adjusted for small sample sizes, was used to pool results according to either per-protocol or intention-to-treat analyses.

**RESULTS:** Of the 1,025 studies screened, 7 representing 8 groups and 14 outcomes in 470 (280 exercise, 190 control) primarily female participants, 18 to 73 years of age were included. Both per-protocol and intention-to-treat analyses resulted in statistically significant (small to moderate) improvements in global well-being (per protocol, g and 95% confidence interval, -0.39, -0.70 to -0.09; intention-to-treat, -0.34, -0.53 to -0.14). No statistically significant heterogeneity was observed for either analysis (per protocol, I<sup>2</sup> = 36.8%, p = 0.16; intention-to-treat, I<sup>2</sup> = 0%, p = 0.53).

**CONCLUSION:** Exercise improves global well-being in community-dwelling adults with fibromyalgia.

**2717 Board #111 May 29 2:00 PM - 3:30 PM**  
**Assessment Of Cardiovascular Disease Risk Factors In College Students.**

Jeremy L. Knous<sup>1</sup>, Joshua J. Ode<sup>2</sup>, James M. Pivarnik, FACSM<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>Saginaw Valley State University, Saginaw, MI.  
Email: jknous@svsu.edu  
(No relationships reported)

Few studies have examined the prevalence of modifiable cardiovascular disease (CVD) risk factors in young adults attending college.

**PURPOSE:** To assess the determinants of modifiable CVD risk factors in college students.

**METHODS:** Participants were 192 (70% female; age:  $19.6 \pm 1.3$  yr) college students enrolled in a healthy lifestyles class, who completed a health assessment and an online survey during the Fall 2007 or Spring 2008. The health assessment included measured height (cm), weight (kg) and calculated body mass index ( $\text{kg/m}^2$ ). Seated blood pressure was assessed via automated cuff. Total and high density lipoprotein cholesterol were assessed after a non-fasting venous blood draw. Meeting physical activity recommendations (yes, no) and smoking (yes, no) were assessed via survey. All CVD risk factors were dichotomized based on the American College of Sports Medicine risk stratification criteria. For analysis, total number of CVD risk factors were summed and categorized as 0, 1, or  $\geq 2$ . To assess the determinants of CVD risk factors in study participants, the following exposure variables were assessed via survey: gender, age (18, 19, 20,  $\geq 21$  yr), major (Kinesiology, other), and grade point average (No,  $<3.0$ ,  $3.0-3.5$ ,  $>3.5$ )(GPA). To assess the impact of each exposure variable on CVD risk factors, multiple logistic regression was used to determine adjusted odds ratios and 95% confidence intervals (CI).

**RESULTS:** Our results indicated that 7% of our sample were hypertensive, 9% were smokers, 16% were dyslipidemic, 26% were overweight, and 51% were physically inactive. This resulted in 35% having 0 risk factors, 44% having 1 risk factor, and 21% having  $\geq 2$  risk factors. Compared to participants with a GPA of  $\geq 3.5$ , those with a GPA of  $<3.0$  were 9.5 (95%CI: 1.8-49.8) times more likely to have 1 risk factor and 23 (3.7-144.7) times more likely to have  $\geq 2$  risk factors. Non-kinesiology majors were 3.3 (1.5-7.4) times more likely to have 1 risk factor. Males were 4.4 (1.4-14.3) times more likely to have  $\geq 2$  risk factors. Discussion: Results show a larger than expected percentage of college students with  $\geq 2$  CVD risk factors. Results also showed a potential association between academic performance and CVD risk factors.

(No relationships reported)

Increased glucose levels above a threshold of 4.9 mmol/L are associated with a greater risk of cardiovascular disease (CVD). The menopause has been associated with impaired glucose control, including poor glucose tolerance, increased glycosylated haemoglobin (HbA1C) and fasting insulin concentration. The positive effect of increased cardio-respiratory fitness (CRF) upon glucose control in postmenopausal women (PM-women) is unclear.

**PURPOSE:** To determine the effects of CRF upon glucose control in PM-women.

**METHODS:** CRF was assessed via Bruce treadmill test in 79 sedentary-to-moderately active and 10 marathon running (MR) PM-women. Sedentary-to-moderately active women were classified into low, medium or high CRF levels according to  $\text{VO}_2$  peak. MR were a separate group. Assessment of glucose control included analysis of fasting venous glucose and insulin (thus the homeostasis model assessment (HOMA)) and HbA1c concentrations. The following additional CVD risk factors were assessed: body composition (skinfold analysis/waist and hip circumferences, BMI and body mass), flow mediated dilation (reactive hyperaemia) as an index of endothelial function, total cholesterol, high and low density lipoproteins, triglycerides and high sensitivity C-reactive protein (hsCRP). CRF level differences in glucose control variables were analysed via ANCOVA (all other variables as covariates), and multiple regression assessed which variables best predicted glucose control variables.

**RESULTS:** Fasting plasma glucose concentration was the only glucose control variable to differ between CRF levels with the MR group having significantly lower concentrations (4.1 mmol/L) than all other CRF levels (low CRF 5.7; medium CRF 5.5; high CRF 5.5 mmol/L). Additionally, MR women were the only group to have a glucose concentration less than 4.9 mmol/L (threshold for CVD risk). CRF was found to be the strongest predictor for glucose concentration. Conversely, body mass, waist circumference and hsCRP were the strongest predictors of insulin concentration and HOMA, whereas CRF had little predictive influence.

**CONCLUSION:** Very high levels of CRF similar to marathon runners may be required to lower glucose concentration in PM-women to levels below the threshold for increased risk of CVD.

**Depressive Symptoms Do Not Reduce The Benefits Of Physical Activity On Recurrent Cardiovascular Disease Events**

Joan M. Dorn, Michael J. Lamonte, FACSM, Kathleen M. Hovey, Maurizio Trevisan. University at Buffalo, Buffalo, NY.  
Email: jdorn@buffalo.edu  
(No relationships reported)

**PURPOSE:** To examine prospectively whether depressive symptoms attenuate the benefits recreational physical activity on the risk of recurrent CVD in a population based sample of primary incident MI survivors.

**METHODS:** Cases (1063 men, 430 women) 35-69 yrs old were recruited from 12 of 15 Western New York hospitals and completed an interviewer-administered survey and clinic exam (mean 4 months post-MI). Recreational physical activity (RPA) was assessed using the Stanford 7-day physical activity recall and depressive symptoms were assessed using the Center for Epidemiologic Studies Depression Scale (CES-D). A score of  $\geq 16$  on the CES-D was used to define depression. Recurrent events (RE) included non-fatal and fatal CVD (ICD9 390-450) and revascularizations (ICD9 36-39). Age and sex-adjusted Cox regression models were used to examine the effect of depression on the association between RPA and RE.

**RESULTS:** During a mean follow-up period of 2.4 yrs a total of 314 RE occurred. Depression was associated with an increased risk of recurrent events (HR 1.34 95%CI 1.02-1.75), whereas RPA had a protective effect on RE (HR 0.63 95%CI 0.50-0.79). The protective effect of RPA on RE remained after adjustment for age and sex (HR 0.66 95% CI: 0.52-0.83). Further adjustment for the presence of depressive symptoms did not change the association between RPA and RE (HR = 0.66, 95% CI: 0.52-0.83).

**CONCLUSIONS:** Depressive symptoms did not reduce the protective effect of RPA on recurrent events in this population-based prospective study of MI survivors. These findings have important implications for MI survivors since depression is common in CHD patients.

**The Risk For Cardiometabolic Disease In An Ethnically Diverse Sample Of Canadians**

Heather J A Foulds, Shannon S D Bredin, Darren E R Warburton. *University of British Columbia, Vancouver, BC, Canada.* (Sponsor: Dr. Keith George, FACSM)

(No relationships reported)

There is a growing body of evidence suggesting that there are ethnic based differences in the risk for cardiometabolic disease. In fact, ethnic-specific guidelines have recently been advocated for waist circumference and BMI to reflect the increased risk in varied ethnic groups for diabetes, the metabolic syndrome, and cardiovascular disease.

**PURPOSE:** To evaluate the risk for cardiometabolic disease in an ethnically diverse cohort of Canadians.

**METHODS:** We assessed self-report physical activity and direct measures of height, weight, blood pressure, lipid profile, blood glucose, and waist girth. The study sample consisted of Caucasian (n = 3563), Asian (n = 447), First Nations/Aboriginal (n = 287), South Asian (n = 223), South or Central American (n = 28) and Other (n = 105).

**RESULTS:** As a population there was a high prevalence of physical inactivity (45%), overweight and obesity (via BMI; 63%), central obesity (via waist girth; 35%), and hypertension (21%). There were clear ethnicity-based differences in the prevalence of risk factors for cardiometabolic disease. Persons of Aboriginal descent were at the greatest risk for central obesity (67%), abnormal blood glucose levels (17%), diabetes (8%) and overweight and obesity (79%). Moreover, they had the highest overall risk score with 69% being classified as moderate to high risk for cardiometabolic disease. Caucasians were at the greatest risk for elevated blood pressure (26%) and hypertension (22%). Individuals of Asian descent demonstrated the greatest risk for physical inactivity (54%). South Asian people demonstrated the greatest risk of high total cholesterol to HDL ratios (52%) and elevated total cholesterol levels (44%). South or Central Americans were at the greatest risk for low HDL levels (37%) and high total cholesterol (18%). With respect to CVD risk, Aboriginal, Asian, and South Asians individuals generally exhibited abnormalities in glucose, blood pressure, and dyslipidemia at a BMI values that were below a BMI of 30.

**CONCLUSIONS:** Within this population, significant differences in health risk indicators exist between ethnic groups. Persons of Aboriginal descent appear to be particularly susceptible to increased risk.

(No relationships reported)

**PURPOSE:** To describe physical activity (PA) of youth with and without diabetes and to examine the relationship between PA and perception of physical abilities in a sample of African-American, Hispanic, and non-Hispanic white youth participating in the SEARCH Case-Control Study.

**METHODS:** Diabetes cases and non-diabetic controls were recruited from healthcare providers. Complete data were available on 310 youth with type 1 diabetes, 50 youth with type 2 diabetes, and 128 non-diabetic control youth aged 10-20 years. Pedometers were used to objectively measure PA over 7 days. Participants with  $\geq 3$  valid days (1000 to 29999 steps) were included; the mean number of steps per day was calculated for each participant. Youth reported their physical abilities using the Self-Description Questionnaire (SDQ). This scale assessed self-concept regarding abilities in performing physical activities, sports, and games. Scores from the SDQ were standardized to population T-scores. Spearman correlation coefficients were calculated.

**RESULTS:** Mean steps per day were  $6944 \pm 3466$  in the total population and  $7332 \pm 3376$ ,  $4869 \pm 3229$  and  $6813 \pm 3497$  for type 1, type 2 and control youth, respectively. Males had more steps per day than females ( $7886 \pm 3522$  vs.  $6201 \pm 3239$ ). Non-Hispanic white youth had more steps per day ( $7356 \pm 3372$ ) than Hispanic ( $6942 \pm 3854$ ) and African-American youth ( $5481 \pm 3212$ ). Positive correlations were found between PA and physical abilities in the crude analyses ( $r=0.30$ ,  $p < .001$ ;  $r=0.31$ ,  $p=.03$ ;  $r=0.31$ ,  $p < .001$ ) for type 1, type 2, and control youth, respectively. After adjustment for sex, race/ethnicity, socioeconomic status, insulin use, diabetes duration, BMI z-score, and comorbidities, correlations remained significant for type 1 ( $r=0.28$ ,  $p < .001$ ) and control youth ( $r=0.23$ ,  $p=.01$ ). For type 2 youth the correlation was slightly attenuated but lost statistical significance due to limited power ( $r=0.28$ ,  $p=.09$ ).

**CONCLUSION:** Levels of PA were well below the recommended step counts of 12000 and 15000 steps per day for females and males, respectively, in this population of youth with and without diabetes. Youth with type 1 diabetes had higher PA levels than youth with type 2 diabetes and control youth. There is a moderate, positive correlation between PA and perception of physical abilities.

Email: katja.pahkala@utu.fi

(No relationships reported)

Exercise training improves vascular endothelial function in high-risk adolescents. The effect of leisure-time physical activity on endothelial function in healthy adolescents is unknown.

**PURPOSE:** To study the association of leisure-time physical activity and brachial artery endothelial function in adolescents.

**METHODS:** Physical activity habits and brachial artery flow-mediated endothelial function were assessed in 483 13-year-old adolescents participating in an atherosclerosis prevention study (STRIP). Endothelial function was examined with ultrasound and physical activity with a validated self-administered questionnaire. A leisure-time physical activity index (PAI; MET h/wk) was calculated by multiplying weekly mean leisure-time exercise intensity, duration and frequency [mean $\pm$ SD PAI: boys  $31.2 \pm 23.0$  MET h/wk, girls  $24.0 \pm 20.9$  MET h/wk; P(gender difference) $<0.001$ ]. Maximum flow-mediated dilatation (FMDmax; %) and total FMD response [the area under the dilatation curve 40-180 sec after hyperemia (FMDauc; % x s)], were used as measures of endothelial function.

**RESULTS:** In boys, FMDmax and FMDauc were directly associated with PAI in regression analyses adjusted for brachial artery diameter (FMDmax:  $P=0.020$ , FMDauc:  $P=0.0055$ ). The associations remained significant also after further adjustments for BMI, HDL-cholesterol, LDL-cholesterol, triglycerides, hs-C-reactive protein and systolic blood pressure. The similar association was not found in girls. A difference of  $\sim 50$  MET h/wk corresponding to  $\sim 10$  h of moderate intensity activity weekly between sedentary and active boys was associated with  $\sim 1$  % unit difference in FMDmax.

**CONCLUSIONS:** Leisure-time physical activity is directly associated with brachial artery FMD responses in 13-year-old boys. This confirms that physical activity beneficially influences endothelial function in healthy male adolescents. Lack of association in girls may be explained by their overall lower physical activity level. Indeed, girls and boys having the same leisure-time physical activity level have an identical FMDmax response.

**Associations Between Objectively-measured Physical Activity And Clustered Cvd Risk In Adolescents: Nhanes 2003-**

2006

Felipe Lobelo<sup>1</sup>, Russell R. Pate, FACSM<sup>2</sup>, Angela D. Liese<sup>2</sup>, Rebecca Meriwether<sup>2</sup>, William Riner<sup>2</sup>, Michael Pratt, FACSM<sup>3</sup>. <sup>1</sup>EIS Officer - Centers for Disease Control and Prevention, Atlanta, GA. <sup>2</sup>University of South Carolina, Columbia, SC. <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA.  
Email: hgn0@cdc.gov

(No relationships reported)

Cardiovascular disease (CVD) is accelerated by the clustering of CVD risk factors/metabolic syndrome, which in adults is strongly associated to physical activity (PA). However, this association has not been well studied in adolescents.

**PURPOSE:** To assess the association between clustered CVD risk and objectively-measured PA in a population-based sample of U.S. adolescents.

**METHODS:** Complete data on PA and CVD risk were available for 983 adolescents (mean age  $15.3 \pm 2.3$  years; 47.4% female) in the 2003-2004 and 2005-2006 NHANES cohorts. PA was measured with an ActiGraph AM-7164 accelerometer. At least 10 hours/day on 4 days were required for a valid record. Mean mins/day of moderate-to-vigorous physical activity (MVPA) and the proportion achieving the recommended 60 mins/day were calculated. A standardized CVD clustering score (MetSyn) relative to the International Diabetes Federation pediatric metabolic syndrome definition was constructed using age group- and gender-standardized values for waist circumference (WC), mean arterial blood pressure, fasting glucose, HDL-cholesterol and triglycerides. Positive scores indicate higher CVD risk. A second score was calculated without WC (MetSyn-WC) to assess the confounding effect of adiposity. Regression analyses were used to assess the associations between PA (independent variable) and MetSyn (dependent variable) while adjusting for monitor wear time, age, gender, race/ethnicity and socio-economic status as well as WC.

**RESULTS:** MVPA quintiles (Q) were <10, 11-21, 22-32, 33-52 and 53+ mins. MetSyn ranged from -3.04 to 1.87, with a mean of -1.37 (0.63). After adjusting for socio-demographic factors, a negative association was found between MetSyn and MVPA quintiles ( $p=0.009$ ) but it weakened after further adjustment by WC ( $p=0.06$ ). The mean MetSyn value for the first Q of MVPA differed from all the other Q ( $p<0.04$ ). Lower MetSyn and MetSyn-WC values were found for youth meeting vs. not meeting the MVPA recommendation ( $p=0.02$  and  $p=0.03$ , respectively).

**CONCLUSIONS:** A negative graded association was found between MVPA and MetSyn among U.S. adolescents. The association weakened after further adjustment by WC. MetSyn is lower in adolescents meeting the MVPA recommendations but those accumulating at least 11 mins of MVPA/day already exhibit lower MetSyn values.

**Assessing Quality-of-life, Roles, And Bmi In Type 2 Diabetes Patients Participating In Supervised Exercise**

Robert D. Chetlin, Jessica L. Brinkley, Andrea J. Spatafore, Diana L. Gilleland, William G. Hornsby, Steven D. Wheeler. *West Virginia University, Morgantown, WV.* (Sponsor: Robert R. Kraemer, FACSM)

Email: rchetlin@hsc.wvu.edu

(No relationships reported)

Nearly two-thirds of American adults are overweight (~127 million) or obese (~69 million); type 2 diabetes and obesity are often comorbid. West Virginia ranks third in obesity (~30% rate). Type 2 diabetes may adversely affect exercise participation and quality-of-life (QOL) in patients who self-report exercise.

**PURPOSE:** To examine the relationship of demographics, exercise, QOL and roles in type 2 diabetes patients engaged in structured exercise.

**METHODS:** Volunteers were recruited through the Human Performance Lab (HPL) at WVU (Morgantown, WV). Participants completed several inventories: Impact-of-Weight-on-Quality-of-Life-Lite (IWQOL-Lite) Scale; Role Checklist (RC), and; Satisfaction-with-Life Scale (SLS). We hypothesized that participation in structured exercise enhances roles and improves QOL measures in patients with type 2 diabetes.

**RESULTS:** No statistical inventory differences were found between supervised and unsupervised groups; thus, exercisers were combined into one group ( $n=37$ ) for additional analysis. Mean BMI for the combined group was  $31.9 \pm 7.9$ , indicating these patients were obese. Comparison between two independent sample means indicated the combined exercise group had higher IWQOL-Lite scores ( $p<0.05$ ) and lower BMI ( $p<0.05$ ) versus a non-exercise reference sample. BMI was negatively correlated to QOL instrument scales of Physical Function ( $r=-0.67$ ,  $p<0.001$ ); Self-Esteem ( $r=-0.59$ ,  $p<0.001$ ); Sexual Life ( $r=-0.62$ ,  $p<0.001$ ); Public Distress ( $r=-0.73$ ,  $p<0.001$ ); Work ( $r=-0.62$ ,  $p<0.001$ ), and; Total Score ( $r=-0.64$ ,  $p<0.001$ ). Three negative correlations existed between gender and these SLS areas: ideal life ( $r=-0.37$ ,  $p=0.03$ ); excellence of life conditions ( $r=-0.34$ ,  $p=0.04$ ), and; acquisition of important things in life ( $r=-0.33$ ,  $p=0.05$ ).

**CONCLUSIONS:** QOL measures were not different between self-reported and supervised exercisers. Compared to a type 2 diabetes reference sample, combined exercisers had higher QOL scores and lower BMI, indicating exercise had a beneficial effect on QOL and BMI regardless of exercise condition. QOL scores and BMI demonstrated a similar inverse relationship in both exercise and non-exercise conditions. Future research should examine the magnitude of exercise training effects upon QOL, SLS, and RC scores in patients with type 2 diabetes.

**Patterns Of Physical Activity In Less, Moderately And Highly Active Children**

Harriet Koorts<sup>1</sup>, Calum Mattocks<sup>1</sup>, Andy Ness<sup>2</sup>, Kevin Deere<sup>2</sup>, Steven N. Blair, FACSM<sup>3</sup>, Chris Riddoch<sup>1</sup>. <sup>1</sup>University of Bath, Bath, United Kingdom. <sup>2</sup>University of Bristol, Bristol, United Kingdom. <sup>3</sup>University of South Carolina, Columbia, SC.

(No relationships reported)

Little is known about how the types and patterns of physical activity vary between children of different activity levels. Knowing how more active children achieve their higher activity levels can inform the design of interventions to promote physical activity.

**PURPOSE:** The aim of this study was to assess how children of different activity levels differ in the types of physical activities they participate in, and the time of day they do this on school and non school days.

**METHODS:** A cross-sectional analysis using 3800 children (1794 males, 2006 females) participating in the Avon Longitudinal Study of Parents and Children (ALSPAC). The mean (SD) age of the children was 13.8 (0.19) years. Physical Activity was measured using an accelerometer, worn over a 7-day period. Children were categorised into gender-specific tertiles of activity (T1 = less active, T2 = moderately active, T3 = highly active), using both counts/min and min/d of moderate to vigorous activity (MVPA), using a cut-point of 3600 counts/min. Time of day and type of activity were assessed using an adapted version of the Previous Day Physical Activity Recall questionnaire (PDPAR). Activities were grouped as; 'housework', 'outside activities', 'TV', 'active job', 'sports' and 'travel'. The proportion of activity occasions within the tertiles, were analysed using the Chi squared test. Results for counts/min and MVPA were similar.

**RESULTS:** Based on counts/min, differences were seen for sports participation; T1 (26%) T2 (33.4%) T3 (40.5%) ( $X^2 = 185.79$ ,  $p<0.001$ ). These differences were observed on school days T1 (26.4%) T2 (33.7%) T3 (39.9%) ( $X^2 = 117.49$ ,  $p<0.001$ ), and non school days T1 (25.6%) T2 (32.5%) T3 (41.9%) ( $X^2 = 54.66$ ,  $p<0.001$ ). Overall, the least active children engaged in TV activities more often than moderately and highly active children, T1 (35.0%) T2 (33.1%) T3 (31.9%) ( $X^2 = 17.32$ ,  $p<0.001$ ). These differences were not observed on

school days, T1 (34.5%) T2 (32.8%) T3 (32.7%) ( $\chi^2 = 3.96$ ,  $p > 0.05$ ) or non school days alone, T1 (34.3%) T2 (33.2%) T3 (32.4%) ( $\chi^2 = 2.46$ ,  $p > 0.05$ ). The remaining activity behaviours showed no differences.

**CONCLUSIONS:** Sports participation and TV activities vary according to differences in children's total physical activity levels. These results have implications for the design of physical activity interventions for children.

**Energy Cost Of Physical Activity In Children**

Cheryl A. Howe<sup>1</sup>, Kristen Benya<sup>1</sup>, Patty S. Freedson, FACSM<sup>1</sup>, Henry A. Feldman<sup>2</sup>, Stavroula Osganian<sup>2</sup>. <sup>1</sup>*University of Massachusetts Amherst, Amherst, MA.* <sup>2</sup>*Boston Children's Hospital, Boston, MA.*

Email: cahowe@kin.umass.edu

(No relationships reported)

The estimated energy imbalance associated with childhood obesity is ~100 kcal/day<sup>-1</sup>. However, population-based physical activity interventions capable of resolving this imbalance have yet to be developed.

**PURPOSE:** The purpose of this study was to directly measure the energy cost of selected children's games that could be incorporated into a school-based intervention to address the energy imbalance.

**METHODS:** Third grade children (15 boys, 13 girls) were recruited from elementary schools to complete games selected on the basis of intensity, safety and enjoyment. We recruited equal samples of normal weight (BMI < 85<sup>th</sup> %ile) and overweight (BMI ≥ 85<sup>th</sup> %ile) children. Following a 3-hour fast, resting metabolic rate (RMR) was assessed using a hand-held O<sub>2</sub> analyzer after which they ate a standardized 150 kcal snack. All children performed one treadmill activity (2.5 mph @ 0% grade) and up to 10 randomly chosen children's games for 6 min with 3-min rest periods. The games were adapted from the CATCH PE program and the investigator's previous experience. Energy expenditure (EE) was measured with a portable respiratory gas exchange system and RMR was subtracted to determine physical activity EE (PAEE). Enjoyment of each game was assessed on a 9-point Likert scale using the Facial Affective Scale (FAS).

**RESULTS:** All the activities were classified as moderate to vigorous intensity ( $X \pm SD = 5.0 \pm 1.3$  METs, AEE =  $4.1 \pm 1.2$  kcal/min<sup>-1</sup>, respectively). The children judged most games as enjoyable with an average FAS score of  $7.3 \pm 2.0$  and PAEE was not significantly associated with FAS ( $p > 0.05$ ). Boys had a higher PAEE than girls ( $4.14 \pm 1.20$  vs.  $4.04 \pm 1.30$  kcal/min<sup>-1</sup>, respectively) and overweight children had a higher PAEE than children with a normal BMI ( $4.43 \pm 1.08$  vs.  $3.85 \pm 1.30$  kcal/min<sup>-1</sup>) ( $p < 0.0001$ ).

**CONCLUSIONS:** The energy expenditure of the measured activities differed between boys and girls and between normal weight and overweight children and was not related to enjoyment. However, all activities elicited a PAEE of at least 100 kcal in a 30-min period regardless of gender, weight status or enjoyment of the game. All 30 selected children's games measured in this study could be effectively used in a physical activity intervention designed to reduce the energy gap associated with childhood obesity.

**Tracking Of Physical Activity Patterns From Late Childhood To Young Adulthood**

Marta C. Erlandson<sup>1</sup>, Amber D. Mosewich<sup>2</sup>, Kent C. Kowalski<sup>1</sup>, Adam D. G. Batxer-Jones<sup>1</sup>. <sup>1</sup>*University of Saskatchewan, Saskatoon, SK, Canada.*

<sup>2</sup>*University of British Columbia, Vancouver, BC, Canada.*

Email: marta.erlandson@usask.ca

(No relationships reported)

Physical activity is a critical component of a healthy lifestyle throughout the lifespan and has been shown to be positively related to a variety of health outcomes. Despite these benefits and the speculation that activity levels during childhood tracks into adulthood, little is known about tracking of physical activity patterns due to the paucity of prospective data linking childhood and adult physical activity.

**PURPOSE:** To investigate trends and tracking of physical activity from late childhood into young adulthood.

**METHODS:** Between 1991 and 1993, 253 subjects (chronologically aged (CA) 8 to 15 years) were recruited into a mixed-longitudinal study examining the role of physical activity (PA) on body composition development during childhood and adolescence. In 2007, 169 participants remained in the study (CA 23 to 30 years). Biological age (BA) was calculated as years from peak height velocity. PA was assessed using the PAQ C/A/AD questionnaires. For this analysis subjects' required measurements in childhood and adulthood. PA was correlated at three, six, nine, and 12 year intervals. Paired-samples t-tests were used to find differences in PA levels between time points.

**RESULTS:** Physical activity was found to decrease ( $p < 0.05$ ) after 10 years of age reaching a plateau between 15 and 17 years ( $p > 0.05$ ). When aligned by BA PA peaked prior to PHV and declined thereafter ( $p < 0.05$ ), before reaching a plateau at a BA of +4 years. Males were more active than females between the ages of 10 and 16 years ( $p < 0.05$ ); however, no PA differences between genders were found at any BA ( $p > 0.05$ ). Interage CA correlations ranged from  $r = 0.31$ - $0.69$ ,  $0.17$ - $0.67$ ,  $-0.04$ - $0.5$  and  $-0.21$ - $0.4$  at three, six-, nine- and 12-year intervals, respectively. Correlations of BA intervals ranged from  $r = 0.05$ - $0.81$  ( $p < 0.05$ ) over the same interval lengths.

**CONCLUSION:** PA decreases with increasing CA and BA age, plateauing at 16 and 18 years (4 years after PHV) respectively for males and females. Tracking of PA was low to moderate and decreased in sensitivity with increasing interval time. These results suggest that high childhood PA does not predict high adult PA. Maintenance of PA throughout childhood, adolescence and young adulthood may be most beneficial for adult PA levels and positive health outcomes.

**Effect Of Adult Leader Participation On Physical Activity In Children**

Tanis J. Hastmann, Karla E. Foster, Richard R. Rosenkranz, Sara K. Rosenkranz, David A. Dziewaltowski. *Kansas State University, Manhattan, KS.*

(Sponsor: Craig A. Harms, FACSM)

Email: tanis@ksu.edu

(No relationships reported)

Participation in physically active games is one way to increase energy expenditure in children. However, researchers have not determined whether adult leader participation (LP) in games can impact children's physical activity (PA) levels.

**PURPOSE:** This study examined the effects of LP or No LP on sedentary, moderate-to-vigorous PA (MVPA), and vigorous PA (VPA) levels in children during active games.

**METHODS:** Children ( $n = 14$ ) in grades 4-6 (Male = 42.8%, White = 50%, Overweight/Obese = 42.8%) participated in four active games (adopted from the evidence-based Coordinated Approach to Child Health) across two consecutive days. Each day, children participated in two 16-minute games. Children received verbal encouragement every minute from an adult leader. Each game was divided into four minute intervals alternating between LP or No LP. LP was counter-balanced across two days. Each child wore an Actigraph GT1M accelerometer. Time spent in MVPA, VPA, and sedentary behavior was determined by Freedson's MET prediction equation. Body fat was measured using Dual-Energy X-Ray Absorptiometry and children were categorized as normal weight (< 85<sup>th</sup> percentile) or overweight/obese ( $\geq 85^{\text{th}}$  percentile) according to body fat percentile curves adjusted for age and gender. Data were analyzed using a condition (LP or No LP) by game repeated-measures ANCOVA.

**RESULTS:** Children participated in MVPA 52.3% of game time across all games. There were no differences in MVPA, VPA and sedentary behavior by gender, weight status, or ethnicity ( $p > 0.05$ ). LP and No LP conditions were not different for MVPA ( $F = 0.76$ ,  $p = 0.40$ ), VPA ( $F = 0.42$ ,  $p = 0.53$ ), or sedentary behavior ( $F = 0.30$ ,  $p = 0.59$ ).

**CONCLUSIONS:** These results show no effect of LP on PA in children during active games. It may be that LP could not increase PA because the children were already

exhibiting high levels of MVPA. Alternatively, the verbal encouragement provided under both conditions (LP and No LP) may have negated the effect of LP. Future studies should examine whether LP can increase the amount of PA in children during other physical activity contexts, such as free-play.

**2729 Board #123 May 29 3:30 PM - 5:00 PM**  
**Compliance With 30,60 And 90 Minutes Of Moderate To Vigorous Physical Activities**

Jose C. Ribeiro, Laetitia Teixeira, Maria Santos, Michael Sousa, Carla Almeida, António Sereno, Jorge Mota. *FADE, University of Porto, Porto, Portugal.*

Email: jribeiro@fade.up.pt

(No relationships reported)

Along the last years several recommendations for physical activity (PA) in children and youth have been proposed, and current recommendations call for at least 60 min-d-1 of moderate-to-vigorous physical activities (MVPA), daily or nearly every days of the week, as part of their lifestyle. Recently Andersen et al. (2006) suggested that current guidelines of at least 1 h/day of PA of at least moderate intensity could be an underestimation of the activity necessary to prevent clustering of risk factors in younger children, recommending that 90 min of daily activity might be necessary for children to prevent insulin resistance, which seems to be the central feature for clustering of cardiovascular disease risk factors.

**PURPOSE:** The aim of this study was to compare the fulfillment between boys and girls of 30, 60 and 90 minutes of MVPA during almost every days of the week.

**METHODS:** A random sample of 210 (12-18 years) boys (n, 80; age,  $15.11 \pm 1.63$ ; weight,  $62.4 \pm 14.3$ ; height,  $168.6 \pm 11.1$ ; BMI,  $21.7 \pm 3.6$ ) and girls (n, 130; age,  $14.8 \pm 1.8$ ; weight,  $53.7 \pm 9.5$ ; height,  $159.1 \pm 6.6$ ; BMI,  $21.2 \pm 3.3$ ) was evaluated. BMI was calculated and PA levels were evaluated with accelerometers (GT1M, MTI Actigraphs). The activity monitor was used as instrument to objectively measure daily PA. The study was conducted during at least 7 consecutive days.

**RESULTS:** Our results reveal that there's a difference between boys and girls in the compliance of 60 and 90MVPA ( $p < 0.05$ ), but not for 30MVPA. When comparing results in the different "recommendations" (30,60 and 90 MVPA) we can observe that 80% and 70% (boys and girls) accomplish for more than 5 days/week (d.w-1) of 30MVPA, but for the current guidelines (60 min.) we detect that 52 and 23% reach that recommendation for more than 5 d.w-1, and 30 and 61% does less than 3 d.w-1 of MVPA. For 90MVPA only 22.9 and 9.6% of boys and girls do more than 5 d.w-1, but 84 and 56% of girls and boys don't achieve 90MVPA in less than 3 d.w-1.

**CONCLUSIONS:** The prevalence of youth meeting the "guidelines" of 90MVPA for at least 5 d.w-1 is very small, although when comparing for the current recommendations of 60MVPA for at least 5 d.w-1 youth from this sample seems to achieve results similar to other studies, although for girls the percentage achieving for that recommendation is quite small.

**Spartners For Heart Health: Baseline Cardiovascular Disease Risk Factors Compared To Pediatric Recommendations**

Kimbo E. Yee, Joey C. Eisenmann, Karin A. Pfeiffer, FACSM, Darijan Sutton, Joseph J. Carlson. *Michigan State University, East Lansing, MI.*

(No relationships reported)

Currently there is concern about the cardiovascular disease (CVD) risk factor profiles of children, which is related to poor diet quality and a sedentary lifestyle. In an effort to maintain or promote a desirable CVD risk factor status, a multi-level school-based intervention, (S)Partners for Heart Health, was developed to promote physical activity and healthy nutrition in 5th grade students.

**PURPOSE:** To compare baseline CVD risk factors with national pediatric recommendations in 5th grade students participating in the (S)Partners for Heart Health pilot study.

**METHODS:** Participants included 146 (60 M, 86 F,  $10.6 \pm 0.4$  yrs) fifth grade students from three rural schools in central Michigan. CVD risk factors were assessed prior to initiating the intervention. Height and weight were measured and used to calculate BMI ( $\text{kg}/\text{m}^2$ ). Percent body fat (%BF) was measured by bioelectrical impedance. Blood samples were obtained via fingerstick in the non-fasted state and assayed for total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), and C-reactive protein (CRP). Resting blood pressure (BP) was measured in accordance with standard procedures. Maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ) was estimated from performance on the PACER test.

**RESULTS:** The mean BMI ( $19.9 \pm 4.3 \text{ kg}/\text{m}^2$ ) approximated the 65th percentile, and 17.9% were overweight and 20.7% were obese. The estimated %BF was  $23.6 \pm 8.6$  and 28% were overfat using FITNESSGRAM standards. The mean  $\pm$  SD and % not meeting pediatric recommendations, respectively, of CVD risk factors were as follows: TC:  $149.1 \pm 25.9 \text{ mg}/\text{dL}$ , 20.3%; HDL:  $45 \pm 10.4 \text{ mg}/\text{dL}$ , 26.5%; TC:HDL ratio:  $3.5 \pm 1.2$ , 38.5%; CRP:  $1.5 \pm 3.0 \text{ mg}/\text{L}$ , 11.1% (adult standards), systolic BP:  $102 \pm 9.4$ , diastolic BP:  $67 \pm 6.9$ , 6.9%. The estimated  $\text{VO}_{2\text{max}}$  was  $44.8 \pm 4.6 \text{ ml}/\text{kg}/\text{min}$  and 48% of males and 35% of females did not meet FITNESSGRAM recommendations.

**CONCLUSIONS:** The baseline results from this school-based intervention in mid-Michigan indicate that childhood overweight and obesity (39% of sample) and other CVD risk factors are a public health issue. These data justify the need for effective school-based CVD prevention interventions that promote physical activity, healthy nutrition, and cardiovascular health in children.

(No relationships reported)

**PURPOSE:** The purpose of this study was to reform physical education curriculum and instructional strategies to integrate the tenets of social cognitive theory as a means of modifying physical activity behaviors. This study established baseline measures of physical fitness, physical activity engagement, self-efficacy and intent to be physically active among 1600 students enrolled in high school physical education and to quantify the effect of reformed curricula. Intact class cohorts were assigned to health education (control) and physical education (treatment) groups.

**METHODS:** Pre/post measures were collected using Fitnessgram, 3-day physical activity recall (Weston et al., 2002), and surveys. Systematic observations of physical education classes, heart rate, and curriculum evaluation data were also collected.

**RESULTS:** Participants specifically identified physical education teachers as reasons for the increases in positive beliefs about physical activity. Minutes in MVPA during physical education rose from 19 to 27 minutes. Individual's intent and belief in the importance of physical activity was significantly higher ( $p < .01$ ) than the control group.

**CONCLUSIONS:** Reformed physical education curricula can change physical activity behaviors through attitudinal and physiological proxies.

**2732 Board #126 May 29 3:30 PM - 5:00 PM**  
**The Effectiveness Of A School Wide Intervention To Change Physical Activity Levels In High School Students**

Koren L. Fisher<sup>1</sup>, Sarah N. Oosman<sup>1</sup>, Karen E. Chad<sup>1</sup>, M Louise Humbert<sup>1</sup>, Cathy Kryzanowski<sup>2</sup>. <sup>1</sup>University of Saskatchewan, Saskatoon, SK, Canada. <sup>2</sup>Saskatchewan in motion, Regina, SK, Canada.  
(No relationships reported)

Saskatchewan *in motion* is a partner-based provincial initiative aimed at increasing physical activity for health, social, environmental and economic benefits. Given the rise in the prevalence in overweight and obesity among youth, engaging schools in this initiative has been an ongoing priority. An *in motion* high school is one that values and actively promotes the health benefits of physical activity and supports opportunities for students and staff to be physically active on a regular basis. Schools that adopt the *in motion* strategy commit to providing a minimum of 30 minutes of PA every day for every student purpose: To evaluate the impact of a 5-month school-wide PA intervention among high school students.

**METHODS:** A total of 339 students in grades 9-12 from 2 urban and 2 rural schools in a prairie province in Canada participated in the study. One urban (n=124) and one rural school (n=46) participated in the *in motion* initiative while the remaining urban (n=140) and rural (n=29) schools did not. Self-reported PA was assessed with the IPAQ and data were collected at the beginning of the initiative (January) and the end of the school year (May). Compliance to the *in motion* initiative was assessed using teacher records and logs.

**RESULTS:** There were no significant differences in PA scores from Time 1 to Time 2 in the urban *in motion* school. PA scores at the rural *in motion* school increased significantly from Time 1 to Time 2 (4,600.6 vs. 7,661. MET min/wk; p<.01). Among rural boys, participation in vigorous PA significantly increased (3,354.7 vs. 5,616.0 MET min/wk; p<.01), while among rural girls participation in moderate PA (821.5 vs. 1,655.8 MET min/wk; p<.05) and walking (1,000.2 vs. 2,021.7 MET min/wk; p<.05) was significantly higher.

**CONCLUSION:** The results suggest that the *in motion* initiative was effective at increasing PA levels among rural high school students. While boys increased their PA through vigorous activities, girls tended to increase their PA through low to moderate PA. Future research exploring gender differences and understanding more fully why such initiatives are more effective in rural vs. urban schools will enable programmers to further tailor such health promotion initiatives for high school students.

**2733 Board #127 May 29 3:30 PM - 5:00 PM**  
**The Effectiveness Of In Motion Schools On Physical Activity Levels Of Elementary School Age Children**

Sarah N. Oosman, Kori L. Fisher, Karen E. Chad, Louise M. Humbert, Cathie Kryzanowski. *University of Saskatchewan, Saskatoon, SK, Canada.*  
(No relationships reported)

Physical activity (PA) is critical for attaining optimal health, social, environmental and economic benefits. It has been suggested that forming partnerships with schools, families, communities and workplaces is critical to enhancing the health of children. Saskatchewan in motion is a province-wide initiative which has built such alliances in its effort to increase PA for individuals of all ages, including child and youth populations. Schools that adopt the *in motion* strategy are committed to providing a minimum of 30 minutes of PA every day for every student.

**PURPOSE:** To examine the impact of the *in motion* schools initiative on PA levels of students.

**METHODS:** Five schools within the province of Saskatchewan, Canada participated in the study, which included a total of 228 students in grades 4, 6, and 8. One urban (n=72) and two rural schools (n=50) participated in the *in motion* initiative while the remaining urban (n=53) and rural (n=53) schools served as the comparison group. The PAQ-C was used to assess self-reported PA and data were collected at the beginning (September) and the end (May) of the school year. *In motion* schools implemented the 30-minute PA initiative following the first data collection while non-*in motion* schools did not change their regular PA regimes. Compliance to the *in motion* initiative was assessed using teacher records and logs.

**RESULTS:** Overall, PA scores increased among students in *in motion* schools (p<.05) but remained unchanged among those in non-*in motion* schools. When stratified by gender, the increase in PA scores in the *in motion* classrooms was significant for males (p<.05) but not females. There were no differences in PA scores between urban and rural schools in either the *in motion* or non-*in motion* classrooms.

**CONCLUSION:** The results suggest that the *in motion* initiative was effective at increasing PA levels among students, regardless of whether they were enrolled in a rural or urban *in motion* school. However, further research is needed to examine why the *in motion* intervention was more effective in engaging male students in PA and to further identify potential barriers to engaging female youth in PA. :

**2734 Board #128 May 29 3:30 PM - 5:00 PM**  
**The Effects Of Community Free Swimming On Engagement And Moderate-to-vigorous Physical Activity In Young People**

Andy Pringle<sup>1</sup>, Nicholas Gilson<sup>2</sup>, Jim McKenna<sup>1</sup>, Martin Rivett<sup>1</sup>, Phil Brown<sup>3</sup>. <sup>1</sup>Leeds Metropolitan University, LEEDS, United Kingdom. <sup>2</sup>University of Queensland, Brisbane, Australia. <sup>3</sup>University College MARJON, Plymouth, United Kingdom.  
Email: a.pringle@leedsmet.ac.uk

( A. Pringle, This research was undertaken as part of a larger scale evaluation of community physical activity interventions Supported by funding from the Department of Health, Sport England and Natural England, Contracted Research.)

UK participation rates for moderate-to-vigorous physical activity (MVPA) in young people are low and free swimming has been proposed as an intervention to address inactivity.

**PURPOSE:** To examine the effect of a community-based free swimming (FS) pilot intervention on MVPA in young people (5-17years) in Southwest England.

**METHODS:** FS provided a series of programmed aquatic activities in community venues, including diving, water-based youth clubs and play sessions. Participants also received a free swim pass for casual swimming. Health practitioners e.g., General Practitioners and School Nurses could refer inactive young people to FS interventions. After ethical clearance participants completed demographics and MVPA using a validated, population-specific, 7-day self-report. Measurement occurred pre- and post-intervention up to 24 months. Following data cleaning, pre- versus post-intervention median MVPA scores (MET-minutes/week) were calculated. Using UK guidelines, participants were allocated to MVPA categories (sedentary-lightly-moderately-highly active). Cross-tabulation established MVPA change in three categories (reversal, stability and progression).

**RESULTS:** FS interventions attracted 1144 participants; 242 completed the evaluation (females 57.4%, N=139). For participants at pre-intervention 136 (56.1%) were not meeting guidelines (females 58%, N=79), compared with 47.1% (N=114) post-intervention (females 52.6%, N=60). At post-intervention, improvement in at least one MVPA category was reported by 64.7% (N=88) (females 59%, N=52), who were sedentary or lightly-active (N=136) at pre-intervention. 52.9% (N=128) met minimum physical activity guidelines post-intervention (females, 61.7% N=79).

**CONCLUSIONS:** FS engaged participants not meeting MVPA guidelines. Comparing pre- with post-intervention MVPA categorization, there was a decrease in the number participants not meeting guidelines. Over half of all participants were meeting physical activity guidelines post-intervention. Despite the limitations of low reporting rates, FS may be an effective community intervention for helping young people increase their MVPA category and for meeting the MVPA guidelines.

**Derivation Of Aerobic Fitness Cutpoints For Adolescents Using Receiver Operator Characteristic (ROC) Curve Analyses**

Gregory J. Welk, FACSM<sup>1</sup>, Joey C. Eisenmann<sup>2</sup>, Kelly R. Laurson, FACSM<sup>3</sup>. <sup>1</sup>Iowa State University, Ames, IA. <sup>2</sup>Michigan State University, East Lansing, MI. <sup>3</sup>Illinois State University, Normal, IL.  
Email: gwelk@iastate.edu  
(No relationships reported)

Although it is widely acknowledged that aerobic fitness is important for the health of children and adolescents, there remains no universally accepted classification system. The criterion-referenced standards for aerobic fitness in FITNESSGRAM are widely accepted but these standards were developed using adult risk profiles extrapolated by age.

**PURPOSE:** The purpose of this study was to develop age- and gender-specific aerobic fitness standards in youth using receiver operator characteristic (ROC) curves - a graphical procedure that facilitates consideration of both specificity (Se) and sensitivity (Sp).

**METHODS:** We combined data for aerobic fitness, anthropometrics and metabolic syndrome variables of 8 to 18 year olds across 2 cross-sectional waves of NHANES (1999-2000 and 2001-2002). Age-, gender- and race-specific distributions of aerobic fitness were first developed using LMS statistical procedures to depict the nature of the growth-related distributions (i.e., centiles) for boys and girls. Z-scores derived from the LMS procedure were then used in the ROC analyses to derive the optimal threshold to define risk. The ROC analyses were conducted to determine the aerobic fitness levels that best discriminate between youth with or without metabolic syndrome (defined as having 3 or more risk factors based on age-modified cutpoints of the ATP III criteria).

**RESULTS:** The resulting ROC curves showed large values for area under the curve (AUC) in both boys (87.4) and girls (77.2). The optimal threshold value from the ROC plots yielded good diagnostic characteristics for both boys (Se=86.8%; Sp=82.9%) and girls (Se=90.1; Sp= 61.3%). In girls, the ROC derived health-related standards decline from 40 ml/kg/min to 38 ml/kg/min between 12 to 18 years old. In boys, values increase from approximately 44 ml/kg/min to 49 ml/kg/min. The ROC derived health-related standards are higher (~2-5 ml/kg/min) than the current FITNESSGRAM values but the patterns were consistent.

**CONCLUSIONS:** The generally high AUC values and high Se / Sp values demonstrate that the aerobic fitness criteria have good utility for detecting risk of metabolic syndrome. A unique advantage of the proposed ROC-derived standards is that the sensitivity and specificity are equivalent across the entire adolescent age range.

---

**2736 Board #130 May 29 3:30 PM - 5:00 PM**  
**Family Physical Activity As A Predictor Of Aerobic Capacity In Schoolchildren**

Christine Voss, Gavin Sandercock, Ralph Beneke, FACSM. *University of Essex, Colchester, United Kingdom.*  
Email: cvoss@essex.ac.uk  
(No relationships reported)

**PURPOSE:** Ascertaining factors that relate to aerobic capacity in youth are important as low values track into adulthood and become a risk factor for cardiovascular disease. The purpose of the present study was to investigate whether the frequency of physical activity (PA) with adult family members was associated with aerobic capacity in schoolchildren.

**METHODS:** After gaining institutional ethics approval and parental consent, 2611 English schoolchildren (1439 boys) aged 10.0-15.9 years were recruited. Weekly PA with adult family members was assessed by questionnaire with the following options: "never" (never), "1 time in a week" (once), "2 or 3 times in a week" (sometimes), "4 or 5 times in a week" (often), or "every day" (daily). Aerobic capacity was assessed by the FITNESSGRAM PACER test and lower PACER "Healthy Fitness Zone" cut-offs were used to categorize participants as either: "unfit" or "fit". Binary logistic regression was used to calculate odds ratios (OR) for being classified as unfit for each category of PA. A  $p < 0.05$  indicated statistical significance (SPSS 16.0 for Windows).

**RESULTS:** The frequencies for activity with adult family members categories were: never, 16.8%; once, 22.1%; sometimes, 33.1% often; 13.3%, and daily, 14.7%. 560 participants (21.4%) were classed as "unfit". Frequency of PA with adult family members was a significant, univariate predictor for fitness classification ( $p < 0.05$ ). Using daily as the reference category (OR = 1), participants were more likely to be classified as "unfit" if they reported being active with adult family members: sometimes (OR = 1.4, 95% CI: 1.1, 1.8), once (OR = 2.0, 95% CI: 1.4, 2.8), or never (OR = 2.8, 95% CI: 2, 4.1).

**CONCLUSION:** The frequency of weekly family PA was significantly associated with aerobic capacity in a dose response manner. Further research into the underlying mechanisms of this association by way of multivariate analyses is warranted. Encouraging family PA may be a potential target for intervention to improve aerobic capacity in youth.

---

**2737 Board #131 May 29 3:30 PM - 5:00 PM**  
**School Day Physical Activity Levels In Children: Active Commuting Day Vs Non-active Commuting Day**

Andy J.w. Smith, Jim McKenna, Stephen P. Cobley, Duncan Radley, Jonathan Long. *Leeds Metropolitan University, Leeds, United Kingdom.*  
Email: a.j.w.smith@leedsmet.ac.uk  
(No relationships reported)

Previous studies have found that children who actively commute to school are more active throughout that day. It is not known whether the increase is because more active children actively commute or that the active commute causes an increase in activity.

**PURPOSE:** To compare active vs non-active commuting to school on total daily MVPA within the same children.

**METHODS:** All children in school years 4 (ages 8-9), 8 and 10 within a provincial city in the UK were selected and only those who (a) returned a complete data set and (b) who actively commuted to school between 1-4 days per week were used for the analysis ( $n=1377$ , 674 females). A 7-day diary recorded MVPA (mins) in 5 school day segments; (1) before school; (2) walking/ cycling to/ from school; (3) in school; (4) before/ after school clubs and (5) after school. Paired sample t-tests identified differences between the segments and total daily MVPA on active commuting ( $n=3909$ ) versus non-active commuting school days ( $n= 2976$ ).

**RESULTS:** Total daily MVPA was significantly higher on active commuting days ( $99.4 \pm 86.3$ .) compared to non-active commuting days ( $63.3 \pm 89.9$ ,  $p < 0.001$ .). Even when the contribution of active commuting ( $16.2 \pm 16.6$ ) was removed, significantly more minutes of MVPA were undertaken on an active commuting day compared to a non-active commuting days ( $83.1 \pm 82 \text{ min}$  v  $63.3 \pm 89.9 \text{ min}$ ,  $p < 0.001$ ). This resulted from significantly more minutes of MVPA being accumulated on active commuting days across the remaining four segments of the day; before school ( $4.6 \pm 9.9$  v  $3.04 \pm 8.9$ ,  $p < 0.001$ ), school day ( $31.1 \pm 30.2$  v  $20.7 \pm 31.3$ ,  $p < 0.001$ ), before/ after school clubs ( $9.9 \pm 26.4$  v  $6.36 \pm 27.8$ ,  $p < 0.001$ ), after school ( $37.6 \pm 52.4$  v  $33.3 \pm 66.9$ ,  $p < 0.05$ ).

**CONCLUSION:** Active commuting on school days leads to an increase in MVPA in the school day. When the same children undertake two different commuting behaviours different physical activity patterns result. This supports the notion that active commuting does increase levels of MVPA at other points during the school day.

**Addressing The Digital Divide In Web-based, Physical Activity Surveillance**

Merly Mathew<sup>1</sup>, James R. Morrow, Jr., FACSM<sup>2</sup>, Carolyn E. Barlow<sup>1</sup>, Georita M. Frierson<sup>3</sup>. <sup>1</sup>The Cooper Institute, Dallas, TX. <sup>2</sup>University of North Texas, Denton, TX. <sup>3</sup>Southern Methodist University, Dallas, TX. (Sponsor: Allen W. Jackson, FACSM)  
Email: mmathew@cooperinst.org  
(No relationships reported)

Health information and access to it are available in various forms, most recently through the Internet and health related web-sites. The difficulty in accessing and being able to navigate

these resources is commonly referred to as a 'digital divide'. Numerous public health issues are addressed via the Internet including physical activity (PA). The Internet may offer a means of large-scale PA assessment. The web-based, Women's Injury Study (WIN) utilizes the Internet in tracking PA. While validity of self-reported (SR) PA is of utmost importance, it must be verified that access to and use of the website is not compromised by age, computer skills, education, income, or race.

**PURPOSE:** To determine if an individual's level of Internet usage skills and demographic variables are related to percentage of (SR) PA Internet logging.

**METHODS:** For this observational study, 902 women completed weekly, Internet-based PA logs and reported steps accumulated via a pedometer and any musculoskeletal injuries incurred. Variables (age, race, education, income, and computer skills) were analyzed to determine relations to participants reporting  $\geq 75\%$ , or 3 out of 4 weeks, of logging per month. Bivariate correlations and logistic regressions (LR) were used to analyze relations between demographic variables and computer skills for logging adherence.

**RESULTS:** Bivariate correlations, while statistically significant for computer skills, income, and race, individually accounted for less than 4% of variation in Internet logging percentage. Logistic regressions with all variables in the model indicated that age (OR=1.02, 95%CI = 1.01-1.03), computer skills (OR=1.82, 95%CI =1.05-3.17; Good M = 92%  $\pm$ 11; Not-Good M = 86%  $\pm$ 22), and race (OR=.64, 95%CI = .46-.90; White M = 92%  $\pm$ 12; Non-White M = 87%  $\pm$ 16) were related to higher PA logging. Thus, older individuals, those with better computer skills, and Whites were more likely to log their PA behaviors online.

**CONCLUSIONS:** It is important to consider a digital divide when PA behaviors are obtained via the Internet. While correlations are relatively low, collectively, these confounders could influence the ability to have randomly representative samples of PA variables.

**Physical Activity And Separation From The Military**

Alyson J. Littman<sup>1</sup>, Isabel Jacobson<sup>2</sup>, Edward Boyko<sup>1</sup>, Timothy Wells<sup>3</sup>, Tyler Smith for the Millennium Cohort<sup>2</sup>. <sup>1</sup>University of Washington and Dept of Veterans Affairs, Seattle, WA. <sup>2</sup>Naval Health Research Center, San Diego, CA. <sup>3</sup>Air Force Research Laboratory, Wright-Patterson Air Force Base, OH.  
Email: alyson@u.washington.edu  
(No relationships reported)

The benefits of physical activity (PA) on physical and psychological health are well known. Data from national sources such as the Behavioral Risk Factor Surveillance System surveys provide important information for surveillance and assessment of trends across time and space. However, these kinds of surveys specifically exclude military personnel; no studies have described PA levels in former military personnel shortly after separation from the military. Nevertheless, military personnel and veterans are a particularly interesting population in which to evaluate PA levels because they represent a large population compelled by the circumstances of military service to maintain higher levels of PA and fitness, who can help us understand why individuals who performed a great deal of physical activity at one point in their lives become inactive or less active later in life.

**PURPOSE:** To examine the association between separation from the military and PA, overall and in subgroups defined by various demographic, service, and health-related characteristics.

**METHODS:** Data on military status and physical activity were collected from 55,021 Millennium Cohort Study participants who completed both a baseline and follow-up questionnaire approximately three years later (follow-up response rate = 71.4%). Of these individuals, approximately 10% separated from the military during the follow-up period. Data on usual duration, frequency, and ability to participate in vigorous PA were collected during the follow-up assessment.

**RESULTS:** Over half (54%) of those who separated from the military reported being inactive in terms of vigorous-intensity PA compared to an inactivity prevalence of about 32% in those still in active duty. Differences by various demographic, service, and health-related characteristics are presented.

**CONCLUSIONS:** The cross-sectional nature of the data precludes a causal interpretation, but strongly suggests a substantial reduction in vigorous PA among those recently separated from the military. If these associations are determined to be causal, interventions aimed at active duty personnel or veterans should be developed to encourage PA maintenance in order to prevent the adverse health consequences associated with inactivity and weight gain.

Surveillance of regular physical activity (PA) in health surveys provides key information for tracking prevalence and trends over time. However, many aspects of question design can influence the validity and reliability of such instruments.

**PURPOSE:** This study assessed the effect of temporal domain on questions concerning walking behavior (i.e., obtaining self-reports of either (a) number of days or (b) number of times walked per week).

**METHODS:** A subsample (n=6332) of the 2005 California Health Interview Survey (CHIS) were asked about leisure and transportation walking behaviors independently, using questions in both temporal domains. Respondents were asked the number of days or times they walked for both leisure and transportation in the past 7 days, and the usual amount of time spent per day or episode. Question order was randomized by temporal domain. Minutes walked per week (mean $\pm$ SE) and adherence to PA guidelines (i.e., minimum 150 min/wk) were assessed overall and by age, race/ethnicity, and education.

**RESULTS:** Minutes of leisure walking per week remained stable across temporal domain (days = 71.4 $\pm$ 2.5 min; times = 73.4 $\pm$ 2.4 min), but transportation walking was divergent (days = 70.4 $\pm$ 3.2 min; times = 52.5 $\pm$ 2.6 min). The pattern of higher reported transportation walking from the days domain was consistent across age, race/ethnicity, and education subgroups, with the exception of respondents with less than a high school education (days = 62.9 $\pm$ 4.7 min; times = 63.2 $\pm$ 4.7 min). Adherence to guidelines for leisure walking was stable across temporal domain (days = 14.9 $\pm$ 0.6%; times = 14.9 $\pm$ 0.6%), but varied as a function of domain for transportation walking (days = 10.4 $\pm$ 0.6%; times = 7.8 $\pm$ 0.5%). Concerning within-respondent effects, a large order effect (i.e., dependent on whether number-of-days versus times was asked first) was observed for reports based on days for transportation walking (days first = 87.8 $\pm$ 2.9 min; times first = 52.3 $\pm$ 2.5 min). In contrast, order effects for transportation walking in the times domain, and for leisure walking (in either domain) were less pronounced.

**CONCLUSION:** Temporal domain of PA questions within the CHIS survey influenced self-reported transportation walking time and resulting adherence estimates, with higher estimates reported based on "days" than "times" questions.

**Five Year Physical Activity Changes Among Older Men In The Mros Study**

Carol A. Janney<sup>1</sup>, Jane A. Cauley<sup>1</sup>, Peggy M. Cawthon<sup>2</sup>, Andrea M. Kriska, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>California Pacific Medical Center Research Institute, San Francisco, CA.  
Email: caj19@pitt.edu  
(No relationships reported)

**PURPOSE:** To describe the change in self-reported physical activity (total, leisure, household, occupational) among men aged 65+ years over a 4-5 year follow-up period, and

to identify socio-demographic and health factors that predict change in physical activity among older men.

**METHODS:** This prospective cohort study enrolled ambulatory community dwelling men (n=5995), 65 yrs or older, at 6 US clinical centers. Using the Physical Activity Scale for the Elderly (PASE), the men self-reported the intensity, frequency, and duration of their leisure, paid and volunteer occupational, and household activities over the past 7 days. Only men with PASE data at baseline and visit 2 were analyzed (n=5161). Linear regression models were built to examine the associations between change in total and subscale PASE scores (outcomes) and socio-demographic and health conditions measured at baseline.

**RESULTS:** The analytic cohort was 90% Caucasian, mean age 73.1 ± 5.5 yrs, median of 3 health conditions, 3% smoked, and 13% lived alone at baseline. Mean follow-up was 4.5 years. Total, leisure, occupational, and household physical activity scores declined (-19.5 ± 68.0, -3.0 ± 37.5, -6.3 ± 34.1, -10.2 ± 44.3, respectively; p<0.01). On average, total PASE scores decreased with age; -16 ± 72 for <70, -16 ± 67 for 70-74, -21 ± 67 for 75-79, and -30 ± 61 for 80+ yr olds. Declines in total physical activity were primarily attributed to occupational changes in 65-70 yr olds and household changes in 70+ yr olds. Participants exhibited a greater decline in physical activity if they lived alone (b=-12.9, SD=2.9), smoked cigarettes (b=-8.8, SD=5.6), or reported poor or very poor health (b=-17.3, SD=8.6) at baseline. Change in PASE scores was negatively associated with number of self-reported health conditions (b=-1.9, SE=0.4, p<0.01); a greater decline in PASE change scores was observed for older men with more health conditions. Significant predictors of change in PASE scores after adjusting for baseline PASE scores were living alone, age, smoking, and overall health status (p<0.01 for all).

**CONCLUSIONS:** All domains of physical activity declined with age especially among older men who reported health conditions, lived alone or smoked. Efforts are needed to identify interventions aimed to reverse the negative physical activity trends in older men.

**Recreational Activity Participation In African American, Hispanic, And White Adults: North Texas Healthy Heart Study**

Joan F. Carroll, FACSM, Beatrice A. Winters, Kimberly G. Fulda, Anna Espinoza, Lorna Brooks, Katandria L. Johnson, Vishwam Pandya, Roberto Cardarelli. *University of North Texas Health Science Center, Fort Worth, TX.*

Email: jcarroll@hsc.unt.edu

(No relationships reported)

**PURPOSE:** To determine if there were disparities in self-reported recreational activity participation in middle-aged and older African American, Hispanic and white adults.

**METHODS:** 200 men and women (75 African American, 75 Hispanic, 50 white) who enrolled in the North Texas Healthy Heart Study (NTHHS) completed the Modifiable Activity Questionnaire (MAQ). The average number of self-reported recreational activities was compared among groups with a one-way ANOVA and a Scheffe post-hoc test. Racial/ethnic differences in percentages of respondents participating in individual activities were compared overall and by sex with a chi-square test.

**RESULTS:** Overall, 89% of all respondents reported participating in at least one recreational activity, with no differences among racial/ethnic groups. However, whites reported a significantly greater number of activities (3.2±2.0) than African Americans (2.2±1.7) or Hispanics (2.1±1.8) (p≤0.001). Walking was the most popular activity reported (65%); jogging was also reported by 21% of respondents. There were no racial/ethnic differences in participation for walking or jogging. More whites reported gardening/yard work (66%) than did Hispanics (25%) or African Americans (24%) (p≤0.05). More whites (18%) and Hispanics (17%) reported swimming than did African Americans (5%) (p≤0.05). More white women reported participation in tai chi, horseback riding and strength training, while more African American women reported participation in volleyball. More white men reported hiking for recreation while more Hispanic men reported stairmaster use. However, these sex-related analyses were limited by a small number of participants in some groups.

**CONCLUSION:** Whites in the NTHHS reported participating in a greater number of recreational activities than African Americans and Hispanics. There was no racial/ethnic difference in the percentage of participants who reported walking, the most popular activity. There were racial/ethnic differences in the percentage of participants in other activities such as gardening and swimming. A larger sample size is needed to fully evaluate other noted trends in recreational activity participation. This information will prove important for activity programming decisions in this population.

**Lifestyle Factors In A Rural Population Of Madeira: Is There A Familial Association**

Ricardo D. Silva, Maria Joao CA Almeida, Ana Jose A. Rodrigues, Jose Pedro Fonseca, Rui F. Andrade. *University of Madeira, Funchal, Portugal.*

Email: jalmeida@uma.pt

(No relationships reported)

The parental influence on health and lifestyle of children and adolescents results from a combination of hereditary factors and the family lifestyle. Despite the genetic contribution to the development of some health problems, the factors related to lifestyle, because they are modifiable, play a vital role in the prevention of disease and risk factors.

**PURPOSE:** The purpose of the study was to examine the association between parents' lifestyle and their children regarding physical activity (PA), consumption habits (food, tobacco and alcohol), overweight, abdominal obesity (AO) and hypertension.

**METHODS:** Participants in this study were 176 students (86 M), 153 mothers aged 42.3 ± 6.1 years and 69 fathers aged 45.3 ± 8.4 years. Subjects were assessed for level of physical activity, food intake, tobacco and alcohol consumption, weight, height, waist circumference and blood pressure. Central obesity in students was classified according to the thresholds by Katzmarzyk et al. (2004), and for their parents, with the IDF (2006) criteria. Obesity was categorized according to Cole et al. (2000), in the children, and WHO (2002), in the adults. Hypertension in children was defined using the Task Force Definition (NHBP, 1996), and in their parents, according to the IDF (2006) definition.

**RESULTS:** Of all young participants, 17.0% were overweight (OW) and 2.3 % were obese (OB), whereas 31.4% of their mothers were OW, 28.1% OB, and 49.2% of fathers were OW and 12.7% OB. The prevalence of hypertension was 70.3% for fathers, 64.5% for mothers and 38.1% for their offsprings. For AO, 23.8% of the fathers had a risk, compared to 52.3% of mothers and 24.0% in the children. There were no risks associated with BMI and hypertension between mothers and fathers or between any of the parents with their children. Conversely, for there was a significant risk between mothers and their children (OR=2.48; CI 95%: 1.16-5.30). As for PA, tobacco and food consumption, there were significant risks between mothers and fathers but not between parents and children.

**CONCLUSIONS:** There were higher associations between both parents' lifestyles than between either parent and their children. For the latter, the only significant risk found was for AO.

**Geographic Distribution Of Physical Activity Patterns In Older Japanese Adults: The Nakanojo Study**

Hiroko Shimura<sup>1</sup>, Fumiharu Togo<sup>2</sup>, Hyuntae Park<sup>3</sup>, Sungjin Park<sup>3</sup>, Roy J. Shephard, FACSM<sup>4</sup>, Yukitoshi Aoyagi<sup>3</sup>. <sup>1</sup>University of Tokyo, Tokyo, Japan. <sup>2</sup>Japan National Institute of Occupational Safety and Health, Kanagawa, Japan. <sup>3</sup>Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

<sup>4</sup>University of Toronto, Toronto, ON, Canada.

Email: shimura@p.u-tokyo.ac.jp

(No relationships reported)

Previous investigations have shown associations between neighborhood attributes and habitual physical activity. However, studies to date have not dealt with this issue in terms of the geographic distribution of physical activity in the individual. We hypothesized that if the neighboring environment impacted physical activity, the geographic distribution of physical

activity patterns should be similar in both sexes. To test this possibility, we targeted older people. We reasoned that their physical activity would be particularly susceptible to neighborhood characteristics, given that most of them are no longer employed and thus spend much of their time in their immediate locality.

**PURPOSE:** To examine similarities in the geographic distribution of physical activity patterns between older men and women.

**METHODS:** Participants were 582 men (aged 72.9±5.8 years) and 643 women (aged 73.4±6.0 years) residing in Nakanojo (150 km northwest of Tokyo; level terrain, annual rainfall 1.3 m, mean summer and winter daytime temperatures 26 and 4°C, respectively). Activity patterns were assessed using the physical activity questionnaire for elderly Japanese (PAQ-EJ). Grid lines were created by geographic information system (GIS) every 100 m both horizontally and vertically across the study area, and the mean PAQ-EJ score (MPA) was then calculated for male and female participants living within 500-m radius of each grid point. Pearson's correlation coefficients assessed the relationship between men's and women's MPA in a given location, correlation coefficients also being weighted to adjust for differences in the number of participants within each circle.

**RESULTS:** Weak but significant relationships between men's and women's MPA were found both in Pearson's ( $r=0.205$ ,  $p<0.01$ ) and weighted ( $r=0.247$ ,  $p<0.01$ ) correlation coefficients.

**CONCLUSIONS:** These results suggest that location-specific characteristics may affect men and women similarly, neighborhood attributes influencing an older individuals' habitual physical activity level.

**A Minimum Variance Estimate In The Doubly Labeled Water Technique--Role Of Optimal Sampling**

George D. Swanson. *California State University, Chico, CA.*

Email: dswanson@csuchico.edu

(No relationships reported)

The doubly labeled water technique (DLW) is used to estimate free living energy expenditure in a variety of settings.

**PURPOSE:** The purpose of this investigation was to optimize the sampling scheme so as to minimize the estimate variance.

**METHODS:** DLW uses two stable isotopes, oxygen-18 ( $^{18}\text{O}$ ) and deuterium ( $^2\text{H}$ ), which can exist in a water form consumed by a subject. The elimination of the isotopes from the body is characterized by monoexponential functions. The difference in the two elimination rates yields an estimate of  $\text{CO}_2$  production ( $\text{rCO}_2$ ) in the body. The  $\text{CO}_2$  production rate (with fractionation ignored) is given by  $\text{rCO}_2 = (k_0\text{NO} - k\text{DND})/2$  where  $\text{NO}$  and  $\text{ND}$  are the body pool sizes obtained as  $\text{NO} = 1/I\text{O}$   $\text{ND} = 1/I\text{D}$ . The rate constants ( $k$ ) and the intercepts ( $I$ ) are associated with the monoexponential elimination curves as obtained by linear regression when the elimination data are transformed by natural logarithms.

**RESULTS:** Because the rate constant and intercept enter as an inverse product, an error in intercept, can cancel an error in the rate constant if the errors are of an optimal proportion as given by  $\text{DI}_0 = -1/k_0 \text{D}k_0$ . Using Monte Carlo simulation, the optimal proportion can be achieved by an optimal sampling scheme. Compared to a typical sampling scheme of days 2, 5, 9, an optimal sampling scheme of days 9, 13, 17 reduces the variance by half. Schemes beyond days 10,14,18 increase the variance.

**CONCLUSION:** A Monte Carlo simulation demonstrates an optimal sampling scheme exists. This optimal scheme can be used to guide future experimental designs for the DLW.

**Predicting Free-living Activity Energy Expenditure With Hip And Wrist Accelerometry Versus Doubly Labeled Water**

Daniel P. Heil, FACSM<sup>1</sup>, Alicia M. Hymel<sup>2</sup>, Corby K. Martin<sup>2</sup>. <sup>1</sup>Montana State University, Bozeman, MT. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA.

Email: dheil@montana.edu

(No relationships reported)

While accelerometry-based activity monitors (AMs) have been validated to predict activity energy expenditure (AEE) in controlled lab settings, their use for predicting free-living AEE is not well established.

**PURPOSE:** The purpose of this study was to compare the ability of hip- and wrist-worn AMs to predict free-living AEE in overweight and obese adults as compared with AEE from the doubly labeled water (DLW) technique.

**METHODS:** 28 subjects (20 women, 8 men; Mean±SD: 44±14 yrs age, 31.6±3.7 kg/m<sup>2</sup> BMI) wore the hip AM while a subset of 23 subjects (18 women, 5 men; 45±14 yrs age, 30.2±7.4 kg/m<sup>2</sup> BMI) also wore the wrist AM for seven complete days. AM output from both hip and wrist monitors were converted into average AEE over the 7-day period (AEE<sub>HP</sub> and AEE<sub>WR</sub>, respectively; kcals/day) using established 1R- and 2R-algorithms. Wrist AM data were also transformed with a smoothing algorithm prior to the AEE transformation (smoothed AEE<sub>WR</sub>). Direct measures of AEE (AEE<sub>DLW</sub>, kcals/day) were derived from total daily energy expenditure (TDEE) using the DLW technique after adjusting for measured resting metabolic rate (RMR) and the thermic effect of food (TEF), where  $\text{AEE}_{\text{DLW}} = \text{TDEE} - \text{RMR} - 0.1(\text{TEF})$ . 3-factor repeated measures ANOVA and correlations were used to compare 1R and 2R estimates of AEE<sub>HP</sub> with AEE<sub>DLW</sub>, while 1R and 2R estimates of both AEE<sub>WR</sub> and smoothed AEE<sub>WR</sub> were compared with AEE<sub>DLW</sub> ( $\alpha=0.05$ ).

**RESULTS:** 1R and 2R estimates of AEE<sub>HP</sub> (Mean±SE: 749±98 and 876±118, respectively) were similar to AEE<sub>DLW</sub> (782±88) but correlated poorly ( $r=0.31$ - $0.32$ ;  $P=0.11$ ). In contrast, using the subset of subjects, 1R and 2R estimates of AEE<sub>WR</sub> (3243±176 and 3119±174, respectively) differed significantly from AEE<sub>DLW</sub> (881±95;  $P<0.001$ ) but correlated moderately ( $r=0.49$ - $0.53$ ;  $P<0.02$ ). Lastly, 1R and 2R estimates of smoothed AEE<sub>WR</sub> (1076±58 and 1040±58, respectively) were statistically similar to AEE<sub>DLW</sub> and correlated moderately ( $r=0.49$ - $0.57$ ;  $P<0.02$ ).

**CONCLUSIONS:** Mean values of AEE from DLW were predicted accurately with AM-derived measures of AEE<sub>HP</sub> and smoothed AEE<sub>WR</sub>, but only smoothed AEE<sub>WR</sub> also correlated moderately with AEE<sub>DLW</sub>. These results indicate that both hip- and wrist-worn AMs may be capable of predicting free-living AEE for groups of overweight and obese adults, but only the wrist-worn AM rank ordered subjects reasonably well.

**Time Of Habitual Training Does Not Alter Circadian Rhythm Of Swim Performance**

Christopher E. Kline, Tina M. Devlin, Mark R. Zielinski, Teresa A. Moore, J. Larry Durstine, FACSM, J. Mark Davis, FACSM, Shawn D. Youngstedt. *University of South Carolina, Columbia, SC.*

Email: chriskline@sc.edu

(No relationships reported)

Some studies have found better athletic performance at the usual time of training relative to other times of day. These results could reflect either a change in the circadian system or a non-circadian adaptation that results in better performance at the accustomed time of training. However, other studies have provided equivocal or negative results.

**PURPOSE:** To examine whether the circadian rhythm of swim performance differs between individuals who habitually train at a certain time(s) of day compared to those who do not.

**METHODS:** 25 swimmers were assessed for 50-55 consecutive hr in the laboratory while adhering to a 3-hr ultra-short sleep/wake cycle, a common chronobiological technique. Swimmers performed 6 maximal 200-m swims, with each trial separated by 9 hr. Performances were z-transformed and expressed relative to time of day. The time of habitual training for each swimmer was obtained via questionnaire prior to the study. Estimates of swim performance rhythm amplitude (i.e., range of performance), acrophase (i.e., time of peak performance), and mesor (i.e., fitted mean value) were obtained via cosinor analysis and compared between groups with independent sample *t*-tests. Group data were analyzed via ANCOVA with trial number as a covariate and time of day and habitual training time as fixed factors.

**RESULTS:** Approximately ½ of the swimmers (*n*=12) reported no usual time of training. The half (*n*=13) who had habitual swim times trained daily between 0600-0900 hr, 1600-1800 hr, or at both of these times of day. Those who reported a habitual time of training had lower mesors (i.e., faster swim time; *p*<0.001), but did not have different performance rhythm acrophases or amplitudes compared to those without a specific time of training (*n*=12). No group differences were found in swim performance when analyzed via ANCOVA.

**CONCLUSIONS:** This study found minimal evidence of different swim performance rhythm characteristics between those who habitually trained at a particular time of day versus those who did not. No evidence was found for superior performance that was specific to the usual time of training. However, the data do not discount the possibility that such an advantage might be observed under usual diurnal conditions, due to variations in diet, sleep, rest, and performance preparation.

**2748 Board #142 May 29 3:30 PM - 5:00 PM**  
**Podcasting Mental Images: Technological Application Of Sport Imagery**

Tom V. Darling<sup>1</sup>, Steven W. Edwards, FACSM<sup>2</sup>. <sup>1</sup>University of Rochester Medical Center, Rochester, NY. <sup>2</sup>Oklahoma State University, Stillwater, OK.  
(No relationships reported)

It is widely accepted that mental training can contribute to increases in sport performance, particularly when it is combined with physical training. Mental training has been shown to be as effective as physical training and that the combination of mental training and physical training can be superior to physical training alone. What is not clear is whether technological applications (specifically podcasting) can enhance the sport imagery experience, thereby enhancing sport performance.

**PURPOSE:** The purpose of this study was to determine if guided imagery via podcasting can significantly increase Free Throw (FT) shooting performance among high school basketball players.

**METHODS:** The study sample included 36 (12 male, 24 female) Oklahoma high school basketball players. Subjects were assigned into three treatment groups (script, computer, iPod) and a control group and were tested in three phases (pretest, treatment, posttest). Treatment consisted of imagery training 3x per week, 5 min. each (1 supervised and 2 unsupervised) and weekly FT testing sessions (25 total, using a predetermined shooting format) for six weeks.

**RESULTS:** A comparison of group means and the grand mean for the six testing sessions indicated that the iPod group (18.1) performed higher than the computer group (16.7) and the script group (16.2). A one-way ANOVA of the posttest indicated that there were significant group mean differences (*p* < 0.05) and a Tukey post hoc test indicated that the true source of the significant group difference was between the iPod group and the control group. A comparison of posttest group means indicated that the iPod group (21.0) was the top performer, followed by the computer group (18.6), the script group (17.1), and the control group (15.8). Overall, the script group had the highest improvement (+ 3.8) while the control group had the lowest improvement (+ 0.7).

**CONCLUSION:** Results suggest that podcasting may be a valid technological application of sport imagery that can improve FT shooting performance among high school basketball players. Future studies need to verify study findings using a larger sample size and a longer study duration.

**Perceptions Of Collegiate Strength And Conditioning Coaches Regarding Desirable Characteristics**

Marcus W. Kilpatrick, Jeremy M. Powers, Candi A. Ashley, Bill Campbell, Robert F. Dedrick. University of South Florida, Tampa, FL. (Sponsor: John Bartholomew, FACSM)  
Email: mkilpatrick@coedu.usf.edu  
(No relationships reported)

The strength and conditioning profession has grown significantly in recent years at the professional, collegiate, and school age levels. Limited research is available describing the background of these professionals. Research has not yet considered what current strength and conditioning coaches believe is required to be an effective coach.

**PURPOSE:** Profile contemporary collegiate strength and conditioning coaches and determine how personal experience impacts perceived importance for success as a professional.

**METHODS:** One hundred fifty-six (34 female, 122 male, mean age = 33 years) full-time strength and conditioning coaches at NCAA Division 1 universities responded to an online questionnaire. Items included education, professional certifications, playing experience, coaching experience, physical activity level, and importance of background on effectiveness as a professional.

**RESULTS:** Descriptive data indicated that most coaches possessed a graduate degree (73%) and those degrees were in an exercise science-related area (67%). The most commonly held certifications were CSCS (78%), USAW (49%), and CSCCa (51%). Many coaches reported collegiate playing experience (54%) and few played sports professionally (14%). Coaches trained in exercise science rated exercise science training as more important than those trained in other areas (*p* < 0.05). Coaches with collegiate athletic experience rated collegiate playing experience as more important than those with no collegiate experience (*p* < 0.05). Coaches rating themselves as muscular indicated physical size as more important than those rating themselves as less muscular (*p* < 0.05).

**CONCLUSIONS:** Findings indicate that the profession is becoming increasingly educated and trained in exercise science-related fields. Findings further indicate that the background of the coach impacts perceptions regarding the importance of specific characteristics related to the quality of a job applicant in their discipline.

**Physical Education And Sports Teachers' Empathy Skills Analysis In Turkey**

Hakan Kolayis, Korkmaz Yigiter, İpek Eroglu Kolayis. sakarya university, sakarya, Turkey.  
Email: hkolayis@sakarya.edu.tr  
(No relationships reported)

**PURPOSE:** The purpose of this research was Physical Education and Sports Teachers' who worked in center of Kocaeli, empathy skill's analysis. In this research, test subjects who had age  $x=36,22\pm9,09$ ; year of profession  $x=12,64\pm8,62$ ; level of income  $x=1306,73\pm358,79$  were composed from 103 Physical Education Teachers as volunteer and 101 survey were evaluated.

**METHODS:** In this research, empathetic skill measure was improved by Dokmen (1988) was used. In the analysis of data descriptive statistical techniques, for determination of difference, independent sample *t* test, to determine relation of parameters test of Pearson correlation were fulfilled. The data were test in the SSPS 10,0 program and level of

significance were determined as 0.05.

**RESULTS:** In conclusion of correlation test, a significance relation was found with age between gender, year of profession, in condition if married or not, in condition if having child or not ( $P<0.05$ ). A significance relation was found with the gender between the year of profession ( $P<0.05$ ). A significance relation was found with the year of profession between in condition if married or not, in condition if having child or not, level of sport ( $P<0.05$ ). A significance relation was found with level of income between in condition if married or not ( $P<0.05$ ). A significance relation was found with in condition if married or not between in condition if having child or not ( $P<0.05$ ). A significance relation was not found with empathic skills points between other parameters ( $P>0.05$ ). Among Physical Education Teachers who join this research, empathic points of man  $x=136.52\pm14.87$ ; empathic points of female  $x=133.026\pm18.83$ ; empathic points of married teachers  $x=136.25\pm16.02$ ; empathic points of unmarried teachers  $x=131\pm15.90$ ; empathic points of graduated of university  $x=135.19\pm16.08$ ; empathic points of graduated of master's degree  $x=135.37\pm16.89$  were determined.

**CONCLUSIONS:** Consequently, it could be said that courses must be prepared for improving empathic skill of Physical Education and Sports Teachers

**The Profile Of The Absolute Power Spectrums Of Chinese Elite Boxers Before A Major Competition**

Fenghua Sun<sup>1</sup>, Zhenmin Zhang<sup>2</sup>, Stephen H.S. Wong, FACSM<sup>1</sup>. <sup>1</sup>*The Chinese University of Hong Kong, Hong Kong, China.* <sup>2</sup>*The National Research Institute of Sports Medicine, Beijing, China.*

Email: fhsun@cuhk.edu.hk

(No relationships reported)

**PURPOSE:** To assess the profile of the absolute power spectrums of the Chinese elite boxers before a major competition.

**METHODS:** Twenty male Chinese elite boxers (mean age = 20.7 yr) participated in this study. Their electroencephalograms (EEG) and the brain electrical activity mappings (BEAM) were measured by monopolar recording methods two weeks before the Asian Games. The absolute power of four types of band, i.e. D,  $\theta$ ,  $\alpha$  and  $\beta$ , were assessed in different brain regions during 1-min resting, 3-min hyperventilation (HV) and 1-min recovery period.

**RESULTS:** No significant differences were found in the absolute power between left and right brain hemispheres in the three periods. Compared with the resting level, the absolute power of D band in parietal region, occipital region, and all temporal regions was higher in HV period, but no significant differences in all brain regions were found between the resting and recovery periods. Compared with the resting level, the increase in the absolute power of  $\theta$  band was observed in all brain regions in HV period. Complete recovery in  $\theta$  band in recovery period was only observed in central area (resting vs. recovery:  $10.21 \pm 9.77$  vs.  $12.18 \pm 11.25$ , NS) and in middle temporal area (resting vs. recovery:  $10.73 \pm 6.90$  vs.  $13.81 \pm 12.48$ , NS). There were no significant differences in the absolute power of  $\alpha$  band among the three periods. Increased absolute power in  $\beta$  band was observed in all brain regions in HV period compared with that in resting period. Complete recovery in  $\beta$  band in recovery period was only observed in occipital region (resting vs. recovery:  $23.91 \pm 23.90$  vs.  $29.79 \pm 18.31$ , NS).

**CONCLUSIONS:** The brain functions of the left and right brain hemispheres of the Chinese elite boxers were well balanced. The absolute power in different brain regions were not influenced equally by the transient less brain blood flow (i.e. HV test).

**Exploring The Relationship Between Dimensions Of Psychological Need Satisfaction And Intrinsic Motivation In Athletes**

Anthony J. Amorose, Jillian Richardson, Anne Cox, Peter Smith. *Illinois State University, Normal, IL* (Sponsor: Kristen M. Lagally, FACSM)

Email: ajamorose@ilstu.edu

(No relationships reported)

**PURPOSE:** Research supports the prediction of self-determination theory (SDT: Ryan & Deci, 2002) that psychological functioning, motivation, and well-being are influenced by the degree to which one's needs for competence, autonomy, and relatedness are satisfied. Recently, Sheldon and Niemiec (2006) also found that the balance of need satisfaction is critical. They showed in a series of studies that students who reported greater balance or consistency across the three needs indicated more positive well-being relative to those reporting greater variability in need satisfaction, even when possessing similar levels of overall need satisfaction. Given the potential theoretical and practical implications of their results, determining if the balance of needs satisfaction contributes to our understanding additional outcomes warrants attention. Thus, the purpose of this study was to test whether the balance of need satisfaction predicts intrinsic motivation (IM) above and beyond the individual contributions of the three needs.

**METHODS:** High school athletes ( $N=264$ , 50% female) completed valid and reliable questionnaires assessing their perceived sport competence, autonomy, relatedness, and their IM. Consistent with Sheldon and Niemiec (2006), we calculated the balance of need satisfaction by computing a difference score between each pair of needs and then summing the absolute values of these scores. Thus, a lower score reflects greater balance of need satisfaction.

**RESULTS:** Bivariate correlations among the variables were all in the expected directions, including a negative relationship between balance of need satisfaction scores and IM ( $r=-.40$ ,  $p<.05$ ). A hierarchical regression analysis, with the three needs entered on Step 1 and the balance score entered on Step 2, provided the main test of our research question. Consistent with SDT, perceived competence, autonomy, and relatedness together significantly predicted athletes' IM ( $p<.01$ ,  $R^2=.375$ ). However, the balance score was found to significantly add to the prediction above and beyond the independent contributions of the three needs ( $\Delta R^2=.075$ ).

**CONCLUSIONS:** The results support the basic predictions of SDT, but also highlight the importance of considering balanced need satisfaction as a predictor of achievement-related outcomes.

**Intrinsic And Extrinsic Motivation Differences Between Ncaa Division-iii Championship And Non-championship Football Teams**

Mark Blegen, FACSM<sup>1</sup>, Dani Boner<sup>2</sup>, Matthew Stenson<sup>3</sup>, Tracey Matthews<sup>3</sup>. <sup>1</sup>*College of St. Catherine, St. Paul, MN.* <sup>2</sup>*Augsburg College, St. Paul, MN.* <sup>3</sup>*Springfield College, Springfield, MA.*

Email: mblegen@stkate.edu

(No relationships reported)

Reasons for participation in NCAA Division III athletics vary greatly. Athletes may participate to increase their knowledge of the sport while others participate for enjoyment or to achieve success. The reasons to participate constitute valuable information for the coaching staff as it may influence coach-player interactions and decision making.

**PURPOSE:** The purpose of this study was to investigate if motivation differences existed between championship and non-championship level NCAA Division III football teams.

**METHODS:** Players ( $N=221$ ) from three NCAA Division III football programs (one championship level and two non-championship level) were recruited. During the previous five seasons the championship level team had a combined record of 54-3 with three NCAA Division III National Championships. The non-championship level teams had a combined record of 23-77 with no NCAA Division III playoff appearances. All players completed the Sport Motivation Scale (SMS) and the results were analyzed using a 2X2 MANOVA to examine differences among the motivation variables for starter vs. non-starter and championship vs. non-championship teams. A one way MANOVA was utilized to examine differences across year in school.

**RESULTS:** Dependent variables included internal motivation to experience stimulation, internal motivation for accomplishment, internal motivation for knowledge, external

motivation for identification regulation, external motivation for introjection regulation, external motivation for external regulation, and amotivation. The interaction between starter status and team was not significant ( $L = 0.996, p > 0.40$ ). Additionally, there were no significant differences in the mean vector scores for starter vs. non-starter ( $L = 0.965, p = 0.378$ ). For team type, however, differences did exist across dependent variables ( $L = 0.898, p = 0.002$ ). For all variables except amotivation, the championship level team had significantly higher scores than the non-championship level teams.

**CONCLUSION:** Members of NCAA Division III championship level football teams have higher motivation to participate in their sport compared to non-championship team members. These results could have an impact on player morale, coaching strategies, and future success in athletic related activities.

**2754 Board #148 May 29 3:30 PM - 5:00 PM**

**Challenge And Motivation In Introductory And Advanced Triathlon Events: A Pilot Study**

Anna M. Willard, W. Matthew Silvers. *Eastern Washington University, Cheney, WA.* (Sponsor: Wendy Repovich, FACSM)

Email: annagirl520@aol.com

(No relationships reported)

**PURPOSE:** Participants of introductory and advanced triathlon events were surveyed to determine the role of challenge as it relates to motivation for participation.

**METHODS:** Two events were selected for survey analysis. The introductory event was the Ironman Challenge (IMC), a three-week long triathlon event designed to encourage physical activity and triathlon participation among university staff and students. The advanced event was the 2008 Ironman Coeur d'Alene triathlon (CDA). Survey information was solicited from convenience samples of participants at both events (IMC:  $n = 38$ ; CDA:  $n = 59$ ). The dependent variable of interest was motivation type. Chi squared tests were employed to identify significant trends in motivation within each group.

**RESULTS:** For IMC, there were significantly fewer ( $p < 0.05$ ) individuals who marked "Challenge" ( $n=14$ ) compared to "Other" ( $n=24$ ). Also there was a small, yet statistically significant difference ( $p < 0.05$ ), in the responses of CDA with almost 50% of respondents indicating "Challenge" ( $n=29$ ) as a motivational factor compared to "Other" ( $n=30$ ).

**CONCLUSION:** Participants in each event cited "Challenge" as a significant source of motivation, albeit this trend was more apparent for CDA. In follow up questioning, participants in both groups cited that the motivation of participation yielded positive exercise and physical activity habits. If introductory triathlon events, such as the IMC, can encourage physical activity with motivation sources similar to advanced events, perhaps they can be used to foster healthy habits for individuals who are less active. Further research should explore the effects of other sources of participant motivation, such as a support system, and spirituality, on participation and exercise adherence.

**Psychological Characteristics Of Ultramarathon Participants**

James F. Konopack<sup>1</sup>, Eric Hall, FACSM<sup>2</sup>. <sup>1</sup>Monmouth University, West Long Branch, NJ. <sup>2</sup>Elon University, Elon, NC.

Email: jkonopac@monmouth.edu

(No relationships reported)

Despite the widely accepted notion of an exercise dose-response effect on various health outcomes, the psychological consequences of extremely long bouts of physical activity are unclear.

**PURPOSE:** To evaluate life satisfaction, exercise dependence, enjoyment, and affective changes with participation in a running event of 50, 100, or 150 miles.

**METHODS:** Male ( $n = 10$ ) and female ( $n = 10$ ) participants (Mean  $\pm$  SD age =  $40.8 \pm 10.3$  yrs) completed self-reports prior to and immediately following participation in a 50-, 100-, or 150-mile trail run. All participants supplied written informed consent and responses to the Activation-Deactivation Adjective Checklist (AD ACL; Thayer, 1989), Satisfaction with Life Scale (SWLS; Diener et al., 1985), Physical Activity Enjoyment Scale (PACES; Kendzierski & DeCarlo, 1991), and Exercise Dependence Scale (EDS; Hausenblas & Symons Downs, 2002). Baseline values of SWLS and EDS were compared with normative data, and changes in AD ACL were analyzed using repeated measures ANOVA. An independent t-test was used to compare PACES scores between those who completed their event ( $n=10$ ) and those who completed  $\geq 26.2$  mi but did not finish ( $n=10$ ).

**RESULTS:** EDS scores indicated that 80% displayed symptoms of exercise dependence, with 10% at higher dependence risk. Baseline SWLS scores were high to very high (Mean  $\pm$  SD =  $29.8 \pm 3.6$ ) at baseline and slightly, but not significantly, higher post-event (Mean  $\pm$  SD =  $30.3 \pm 3.2$ ), as expected given the global nature of the measure. Pre-post affective changes on the AD ACL were observed, including significantly reduced Energy ( $F=6.8, p < .05$ ) and increased Tiredness ( $F=13.27, p < .01$ ). Increases in Tension ( $F=4.24, p = .06$ ) and decreases in Calmness ( $F=3.98, p = .07$ ) were borderline significant. Athletes completing their planned distance had significantly higher PACES scores than non-finishers ( $t = 2.10, p = .05$ ).

**CONCLUSIONS:** AD ACL changes suggest that extremely long bouts of running negatively influence affective valence, likely due to strong interoceptive cues (Ekkekakis et al., 2008) and sleep deprivation. However, life satisfaction was high and athletes enjoyed their activity, an effect moderated by finisher status. Symptoms of exercise dependence were common, which itself may influence psychological health.

**Temporal Stability And Interrelationships Of Personality Traits And Life Satisfaction In College Athletes.**

David A. Tobar, Tyler J. Masters, Bonnie G. Berger. *Bowling Green State University, Bowling Green, OH.* (Sponsor: Amy L. Morgan, FACSM)

Email: dtobar@bgsu.edu

(No relationships reported)

Personality traits are considered stable across time, but individual characteristics may influence this stability. However, there is a paucity of research examining the test-retest reliability of personality traits and the influence of individual characteristics in college athletes.

**PURPOSE:** To determine the role of gender and changes in life satisfaction in test-retest reliability of personality traits in college athletes.

**METHODS:** College athletes ( $N = 65$ ; Age = 20.1 yrs) were sampled from men (Baseball:  $n = 27$ ; Hockey:  $n = 10$ ) and women sport teams (Softball:  $n = 14$ ; Swimming:  $n = 14$ ). Each athlete completed the Eysenck Personality Questionnaire-Revised (EPQ-R) and the Satisfaction with Life Scale (SWLS) in early January (Time 1) and late April (Time 2). The EPQ-R measured the traits of Psychoticism (P), Extraversion (E), and Neuroticism (N), and the SWLS assessed global life satisfaction (LS). Data were analyzed using Pearson correlation coefficients between personality traits as well as life satisfaction at both time points in men and women, separately. Correlations were also calculated between changes in life satisfaction and changes in personality.

**RESULTS:** Test-retest reliability coefficients were significant for P (Men:  $r = .50, p < .005$ ; Women:  $r = .73, p < .001$ ), E (Men:  $r = .55, p < .001$ ; Women:  $r = .85, p < .001$ ), N (Men:  $r = .44, p < .01$ ; Women:  $r = .59, p < .005$ ), and LS (Men:  $r = .59, p < .001$ ; Women:  $r = .56, p < .005$ ). Personality traits were not correlated ( $p > .05$ ) with each other at either time point. N was significantly correlated with LS at time 1 (Men:  $r = -.49, p < .005$ ; Women:  $r = -.39, p < .05$ ) and time 2 (Men only:  $r = -.41, p < .05$ ). Changes in LS were correlated with changes in N (Men only:  $r = -.38, p < .05$ ), and no other correlations between difference scores were significant ( $p > .05$ ).

**CONCLUSION:** Personality traits and life satisfaction were stable over a 4-month period in college athletes, especially for women. As expected, low scores on Neuroticism were associated with life satisfaction. However, Neuroticism in male athletes was more closely related to global life satisfaction than in female athletes. Monitoring factors that potentially affect life satisfaction or Neuroticism would be prudent for college athletes, particularly men, as mental health (or well-being) can influence academic and sport performance.

**The Comparison Of Elite Disabled Athletes, Former Athletes And Non-athletes On Annual Income, And Highest Level Of Formal Education Attained**

Paul D. House, Mark Faries. *University of Central Oklahoma, Edmond, OK.*

Email: phouse@uco.edu

(No relationships reported)

The Comparison of Elite Disabled Athletes, Former Athletes and Non-Athletes on Annual Income, and Highest Level of Formal Education Attained

**PURPOSE:** The purpose of this study was to compare annual income, employment status, and highest level of formal education attained between current and former elite disabled athletes and disabled non-athletes.

**METHODS:** To obtain subjects from our athletic population 200 surveys with letters of informed consent were mailed-out to Paralympic athletes as well as 200 to the U.S. Association of Blind Athletes. For our non-athletic population 200 surveys with letters of informed consent were mailed-out to each of the following organizations: United Cerebral Palsy, American Council of the Blind, United Spinal Association, and the Amputee Coalition of America. Three groups were formed for comparisons: current athletes (CA) (mean  $\pm$  SD: 32.81  $\pm$  10.38 yrs; n=71), former athletes (FA) (mean  $\pm$  SD: 41.47  $\pm$  12.37 yrs; n=19), and non-athletes (NA) (mean  $\pm$  SD: 51.25  $\pm$  15.1 yrs; n=122). Surveys included straight forward questions on age, athletic status, annual income, and continuous years of employment. A Oneway ANOVA with a Tukey's HSD Post Hoc was used to detect differences between groups.

**RESULTS:** There were no significant differences in annual income between all three groups. Although FA had a higher mean annual income compared to NA (mean  $\pm$  SD: 4.79  $\pm$  3.2; 3.23  $\pm$  2.9 respectively), it did not reach significance ( $p=.111$ ). CA had non-significantly higher levels of formal education compared to NA ( $p = 0.118$ ). Finally, NA reported significantly greater numbers of years of continuous employment compared to CA ( $p \leq 0.05$ ).

**CONCLUSIONS:** Although not significant, an interesting finding was that CA had completed, on average, a higher level of formal education compared to NA. Furthermore, FA demonstrated a non-significantly higher annual income compared to NA. Had we controlled for age, income and education might have shown significant differences between groups. Additionally, the great age discrepancy between groups is probably the reason for the significantly greater continuous years of employment seen in NA compared to CA. Future research should investigate incomes and education levels while controlling for age.

**Effects Of Music And Watching Television During Exercise On Times Of Volitional Fatigue And Rates Of Perceived Exertion**

Hari Kasi<sup>1</sup>, Kelly Brooks<sup>2</sup>. <sup>1</sup>University of Louisiana at Monroe, Monroe, LA. <sup>2</sup>Louisiana Tech University, Ruston, LA. (Sponsor: Jeff Chandler, FACSM)

Email: kasihari@gmail.com

(No relationships reported)

**INTRODUCTION:** Hearing music or watching television during exercise motivates people to maintain the sustained effort and a dissociation of the exertion tolerance.

**PURPOSE:** The objective of the study is to investigate the effects of music and watching TV on times of volitional fatigue and Borg's rate of perceived exertion.

**METHODS:** Fifteen (n=15) college students (Mean 24 $\pm$ 2.3 years of age) participated in the study. Subjects signed an informed consent form and a parent/guardian signed for minor participants. Testing was performed in the Human Performance Laboratory at the University of Louisiana at Monroe. Participants returned to the lab on three separate occasions. In a random order each participant performed a controlled run on the treadmill use Bruce protocol. All the runs were to volitional fatigue. Heart rate (HR) and Borg's rate of perceived exertion (RPE) were measured at one minute intervals during runs. Time to volitional fatigue was measure at the end of the test. Subjects are allowed to choose their favorite music and shows while exercising. The levels of significance  $p$  being  $< 0.05$ .

**RESULTS:** Paired samples T - tests were conducted using SPSS 14.0 Significance was present at .05 level . The mean times of volitional fatigue for the control , music and watching television are 13min 21 sec  $\pm$  1 min 48sec, 13min 51sec  $\pm$  2min 7sec and 14min 01  $\pm$  1min 53 sec respectively. There is a significant difference ( $p=0.037$ ) in the times of volitional fatigue between the control and music. A significant difference ( $p=0.003$ ) is also noted in the times of volitional fatigue between controls and watching television .There isn't any significant increase in the times of volitional fatigue between the music and watching television.

**CONCLUSIONS:** Hearing music and watching television is significantly increasing the total time of exercise when compared to the control. However, this is a preliminary investigation and further investigation with a larger sample size may provide more information.

**Difference In Wingate Power Output In Response To Music As Motivation**

Kristal Brooks<sup>1</sup>, Kelly Brooks<sup>2</sup>, William D. Brooks<sup>1</sup>. <sup>1</sup>University of West Georgia, Carrollton, GA. <sup>2</sup>Louisiana Tech University, Ruston, LA. (Sponsor: Jeff Chandler, FACSM)

Email: kbrooks32@hotmail.com

(No relationships reported)

**INTRODUCTION:** Wingate testing while using music to enhance performance has produced mixed results in past studies. The effect of motivational music on anaerobic power is unclear.

**PURPOSE:** The purpose of this study was to test Wingate performance with the presence of music as a motivational tool, and without the presence of music. The study aimed to identify if music played a significant role in performance enhancement.

**METHODS:** Subjects were randomized into two groups. The two groups were composed of a "music first" trial group and a "music last" trial group, as the testing order was counterbalanced between groups. Subjects were tested with or without music, according to randomized groups. Music was deemed motivational by the Brunel Music Rating Inventory.

**RESULTS:** Results indicated a significant difference in anaerobic performance when using motivational music. Peak power, average power, overall anaerobic power, and the drop in power over time were all significantly different ( $p<.01$ ) than when music was not used. Performance was significantly better in all categories when motivational music was present ( $p<.01$ ). The order in which the music was played (during the first trial or the second trial) did not have a significant difference on performance.

**CONCLUSIONS:** It was concluded that motivational music has a positive impact on anaerobic performance during a Wingate test. This can translate into a possible increase in anaerobic sports performance. Future studies may look at unmotivational music and performance, or at the application of using music during anaerobic conditioning.

**The Influence Of Music On A Supramaximal Exercise Bout**

Jasmin Hutchinson<sup>1</sup>, Todd Sherman<sup>1</sup>, Lyndsey Davis<sup>1</sup>, Dusty Cawthon<sup>1</sup>, Nathan Reeder<sup>1</sup>, Gershon Tenenbaum<sup>2</sup>. <sup>1</sup>Oxford College of Emory University, Oxford, GA. <sup>2</sup>Florida State University, Tallahassee, FL.

Email: jhutch3@emory.edu

(No relationships reported)

**PURPOSE:** To evaluate the influence of music on anaerobic performance using a maximal effort Wingate anaerobic test.

**METHODS:** Physically active male and female participants (N = 25) completed a 30-second Wingate anaerobic test under two different conditions: music and no music. The volume of the music was standardized at 75dB. The musical selection was the same for each participant, and was selected based upon a survey of musical preferences of undergraduate students using the BMRI-2. During the task physiological and psychological data were collected. Monark anaerobic testing software was used to obtain measures of peak power, mean power, and % power drop, while a scale questionnaire was administered immediately after the trial to gauge the subject's level of motivation, exertion, and affect. Data analysis was conducted using a series of paired-sample t-tests in SPSS.

**RESULTS:** Peak power and mean power were significantly higher with music than without. In addition, participants reported increased motivation and more positive affect in the music condition as opposed to the non-music condition.

**CONCLUSIONS:** The results of this study suggest that music can have a positive influence over anaerobic performance. This supports previous research that has suggested music can be a valuable tool during physically strenuous activities, and extends these findings to include supramaximal exercise.

#### **Evaluation Isokinetic Swimming Propellants Muscles: Comparative Study Between Styles. Pilot Study**

Leonardo Luiz B. Secchi, Mavi Diehl Muratt, Emmanuel Gomes Ciolac, Júlia Maria D'andrea Greve. *School of Medicine, University of São Paulo, São Paulo, Brazil.*

Email: leob\_fisioterapia@yahoo.com.br

(No relationships reported)

Swimming is characterized as a sport of pitch, where the internal rotators (IR) are one of the primary muscles involved in the movement. There is no evidence about the isokinetic parameters of the upper muscles as the thrusters (internal rotators and adductors) comparing the different styles, where these are the main means of displacement in the water.

**PURPOSE:** To compare the muscle function, using isokinetic evaluation in butterfly and breaststroke (symmetric styles) and freestyle and backstroke (asymmetric styles) based on the hypothesis that symmetric styles have a higher torque (kinetic synchronous movement) when compared to asymmetric styles.

**METHODS:** 21 subject male and female, elite swim level, age: 16 - 33 years old, height: 161 - 190 m, weight: 54 - 88 kg and mean week 18.000 - 80.000 m. 10 athletes are specialized in symmetric swim and 11 athletes in asymmetric. They were evaluated on isokinetic dynamometer (Biodex Medical Systems 3 Inc, USA). They performed 5 (60°/s) and 20 repetitions (300°/s). The peak torque (PT) and work fatigue (WF) were evaluated.

**RESULTS:** One way analysis of variance found no differences between the groups for the initial tests ( $p > 0.05$ ).

**CONCLUSION:** The peak torque and fatigue are not affected by the styles in elite swimmer with high level of training.

#### **The Effect Of Back Exercises On Drawing Arms In Archers**

İpek Eroglu Kolayis<sup>1</sup>, Hayri Ertan<sup>2</sup>, Hakan Kolayis<sup>1</sup>. <sup>1</sup>*Sakarya University, Sakarya, Turkey.* <sup>2</sup>*Anadolu University, Eskisehir, Turkey.*

Email: ikolayis@sakarya.edu.tr

(No relationships reported)

According to some studies, elite archers develop a specific forearm and pull finger muscle activation strategy by active contraction of the forearm extensors with the fall of the clicker. On the other hand, the back muscles play the major role in drawing and releasing phases of the bow. Besides, properly working back muscles help to maintain forearm muscle activation strategy. This strategy may require a relatively long training period.

**PURPOSE:** to investigate the effect of back and shoulder-girdle strength training program on muscular activities during release phase and performance in beginner archers.

**METHODS:** Six male and two female beginner archers (age: 16,38±0,38 ; years of training 1,94±1,04; FITA scores 1083±71,2) were involved in the study. Each subject participated in double test session. Eight weeks of back and shoulder-girdle strength training program (Lateral Pull Down, Rowing, Dumbell Lateral Rise, Dumbell Front Rise, Dumbell Behind Rise, Dumbell Shrug, Upright Rowing, Back Extension, Sit up) were applied in %40-60 of max. between two test session. Forearm extensors and flexors, deltoid posterior, deltoid middle, trapezius middle and trapezius lower muscle's activities belonging both of drawing and bow arms were measured in each test session by using EMG. Besides, the scores on the target was also recorded. Subjects have made a total of twentyfour successive shots at the each experimental part of the study.

**RESULTS:** EMG recordings 2 s prior and 1 s after the fall of clicker has been rectified, integrated and normalized. Differences between two test sessions were analysed in Wilcoxon statistical tests. According to the results of the study, there were significant differences in forearm flexors and extensors, deltoid posterior, deltoid middle, trapez middle and lower in drawing arm, and forearm extensors, deltoid middle and lower in bow arm and the performance between two test session ( $p < 0,05$ ).

**CONCLUSIONS:** A positive development was observed with the effect of back shoulder-girdle strength training in beginner archers. So that the archery coaches may involve strength training program in their training cycle in addition to technical training to gain more performance and time.

Email: filefyle@portugalmail.pt

(No relationships reported)

**PURPOSE:** The aim of the present study was to compare two approaches for a 2D kinematical image's reconstruction in Breaststroke swimming: dual media recording vs. separated recording plans.

**METHODS:** The sample comprised seven male breaststrokers (19.1 ± 4.3 years of age; 1.78 ± 0.62 m of height; 70.4 ± 8.0 kg of body mass; 69.10 ± 4.16 s of personal best in the 100 m

Breaststroke event). The subjects performed a 100 m maximal Breaststroke bout on a 50 m swimming pool. Two video cameras ( $f = 50$  Hz) were placed in sagittal plane at 25 m of the head wall to record swimmer's images underwater camera (GR-SXM25 SVHS, JVC, Yokohama, Japan) and above water (GR-SX1 SVHS, JVC, Yokohama, Japan). The images were subsequently reconstructed (Panasonic, AG 7355, Japan) using two different procedures: dual media (DM) and separated recording plans (SP). A full stroke cycle was then analyzed twice for each subject with Ariel Performance Analysis System (Ariel Dynamics Inc., California, USA). Digitalization of the subjects considered the modified anthropometric model of Zatsiorsky (Leva, 1996). Data were filtered using a 5 Hz cutting frequency (Winter, 1990). Reliability of digitalization was very high ( $R = 0.97$ ;  $IC_R = 0.87$ ;  $0.95$ ). The following kinematic variables were compared with Wilcoxon tests: stroke cycle period (SCP), stroke frequency (SF), stroke length (SL), mean swimming velocity ( $v$ ), stroking index (SI), intra-cycle variation of the horizontal velocity of the centre of mass ( $dv$ ) and vertical displacement of the center of mass (VD).

**RESULTS:** The kinematic variables did not differ when the two procedures of reconstruction were compared; with an exception for the VD ( $DM = 0.17 \pm 0.05$  cm,  $SP = 0.14 \pm 0.06$  cm,  $p = .018$ ). Indeed, VD assessment using SP digitalization procedure may be influenced by different factors such as the light refraction phenomena, non-steady flow of the water around the swimmer's body, higher difficulty to clearly determine the air-water interface plan and be unable to observe the head, trunk and limbs actions above the water.

**CONCLUSIONS:** The DM procedure seems to slightly underestimate the water depth when compared with SP. On the other hand, DM seems more suitable to digitalize anatomic points especially when the air-water interface is determinant for the analysis.

Supported by FCT grant: POCI/DES/58362/2004.

**Expressions Of Strength And Average Rate Of Dynamic Force Development: Are These Measures Related?**

Lawrence W. Weiss, FACSM<sup>1</sup>, Brian K. Schilling<sup>1</sup>, Andrew C. Fry<sup>2</sup>, Loren Z. F. Chiu<sup>3</sup>, Christopher A. Moore<sup>1</sup>. <sup>1</sup>The Univ. of Memphis, Memphis, TN.

<sup>2</sup>The Univ. of Kansas, Lawrence, KS. <sup>3</sup>Univ. of Alberta, Edmonton, AB, Canada.

Email: lweiss@memphis.edu

(No relationships reported)

Average rate of force development (RFD) may be calculated as  $DF / DT$ . The elapsed time for force is based upon operationally-defined starting and ending points. Specific time segments of RFD have been proposed as being unique for each individual with implications for both performance and training. These segments consist of the first and second halves of the total elapsed time for RFD. The first half is referred to as the "start gradient" (SG), and the second half, the "acceleration gradient" (AG). It has been reported that RFD and SG have little association with peak force (P<sub>KF</sub>). Although often associated with isometric force, RFD might also be considered for dynamic performance (DRFD). Dynamometers exist that measure only dynamic actions, so associations between the analogous segments of DRFD may be examined.

**PURPOSE:** To determine the association between various aspects of strength and DRFD for two "explosive" lifts to ascertain if they represent unique characteristics.

**METHODS:** Subjects were 48 men, 22.9 yrs ( $s = 4.17$ ) of age, weighing 83.3 kg ( $s = 14.55$ ), who had been engaged in systematic wt training for at least 3 months and could perform a 1RM parallel back squat with  $\geq$  body wt and a 1RM hang power clean with  $\geq 70\%$  body wt. Subsequent to three practice sessions, testing took place during two identical sessions in which 30% 1RM parallel jump squats and 90% 1RM hang power cleans were performed in duplicate. Data were obtained using a linear velocity transducer. Velocity was sampled at 100 Hz and smoothed using a five-point rolling average. The direct measure of velocity and known lifting loads were used to calculate force and power via inverse dynamics with no further smoothing. Variables analyzed for this report were average DRFD, SG, AG, P<sub>KF</sub>, P<sub>KP</sub>, 1RM, and relative 1RM (adjusted for body wt.). Associations were calculated via Pearson Product-moment correlations.

**RESULTS:** For the squat, DRFD was associated ( $p < .01$ ) with SG (.73), AG (1.00), P<sub>KF</sub> (.66), P<sub>KP</sub> (.82), 1RM (.44), and Rel1RM (.44). For the hang power clean, DRFD was associated ( $p < .01$ ) with SG (.98), AG (1.00), P<sub>KF</sub> (.88), P<sub>KP</sub> (.82), 1RM (.61), and Rel1RM (.59).

**CONCLUSION:** For squats and hang power cleans, DRFD appears to be directly related to AG, highly related to SG, P<sub>KF</sub>, P<sub>KP</sub>, and moderately related to 1RM and Rel1RM, indicating that they have a tendency to covary with each other.

**An Optimal Isotet Rest Period For Strength Recovery During A Common Isokinetic Test**

Ivan N. Blazquez<sup>1</sup>, Barbara L. Warren, FACSM<sup>2</sup>, Ann M. O'Hanlon<sup>1</sup>, Lynette R. Silvestri<sup>1</sup>. <sup>1</sup>University of New Orleans, New Orleans, LA. <sup>2</sup>University of Puget Sound, Tacoma, WA.

Email: clinicaltrainer@hotmail.com

(No relationships reported)

Isokinetic testing has been used in rehabilitation settings on a regular basis, yet there is a lack of consistency in rest period usage among protocols.

**PURPOSE:** The purpose of this study was to establish an optimal rest period that would allow reproducibility of strength during a common isokinetic strength-test.

**METHOD:** Twenty-seven healthy college-aged males ( $23 \pm 3.8$  yrs and body weight  $79.61 \pm 11.11$  kg) underwent isokinetic strength testing (Cybex NORM) of the knee flexors and extensors, to determine peak torque at 60, 180 and 300 deg/sec, respectively. Work:rest ratios of 1:3, 1:8 and 1:12 were counterbalanced between sets. Subjects were tested on five separate occasions; two familiarization sessions and three experimental sessions. A 3 X 3 repeated measures ANOVA was used to analyze the data with  $\alpha < .05$ .

**RESULTS:** There was no significant interaction of rest and velocity for either knee extension or knee flexion peak torque. Secondly, there was no significant difference in either knee extension or knee flexion peak torque when comparing work:rest ratios. However, there was a significant difference in peak torque between velocities: knee extension peak torque ( $F = 498.238$ ,  $p < .05$ ), knee flexion peak torque ( $F = 1048.166$ ,  $p < .05$ ).

**CONCLUSION:** These findings suggest that a 1:3 work:rest ratio is sufficient during a common isokinetic strength test. Furthermore, the lack of significant differences among work:rest ratios suggests the need for more research in this area to better understand the impact of rest duration on strength performance.

**Effect Of Variable Repetitions On Peak Torque In Male And Female Athletes**

Barbara L. Warren, FACSM, Sarah Moody, Deanna Malikie. University of Puget Sound, Tacoma, WA.

Email: blwarren@ups.edu

(No relationships reported)

Isokinetic testing is often used to assess strength in various muscle groups. It was determined that a number of protocols have used several different repetition sets to assess peak torque. This study measured peak torque in both males and females when using five different velocities and four different repetition sets.

**PURPOSE:** To examine the effects of using variable repetitions on peak torque production in male and female athletes.

**METHODS:** Fifteen male (mean age=20.2 years, height = 199 cm, weight= 84.85 kg) and fifteen female (mean age= 20.5 years, height = 171.9 cm, weight = 77.15 kg) university athletes with no known knee injuries were tested on a Cybex NORM isokinetic machine performing maximal knee extensions with knee flexions held constant at 300 deg/sec. Each subject was tested five or six times, one or two familiarization and four experimental sessions, at velocities of 60, 120, 180, 240, and 300 deg/sec. The variable repetitions of four, six, eight or ten were randomly assigned. A 2 X 4 X 5 repeated measures ANOVA ( $\alpha < 0.05$ ) was used to analyze the data, with gender, repetitions, and velocities as independent variables and peak torque as the dependent variable.

**RESULTS:** There were no significant differences in peak torque in either male or female athletes when using a variable number of repetitions. Interestingly enough, when

assessing the means of the males and females, the females were much more consistent in peak torque production at each velocity than their male counterparts, regardless of number of repetitions. Additionally, the males in four of the five velocities produced the greatest peak torque when performing four repetitions. Females tended to produce greater peak torques when they executed eight or ten repetitions. As expected there were significant differences in peak torque based on velocity ( $F=742.95$ ,  $p<0.05$ ). Additionally, there were significant differences in peak torque by gender ( $130.774$ ,  $p<0.05$ ).

**CONCLUSIONS:** When assessing peak torque it appears that females need more repetitions while males need fewer repetitions. This would seem to be an important consideration in rehabilitation protocols and research investigations.

**Kinematic Differences In Youth Baseball Pitchers: An Investigation Into The Cocking And Acceleration Phases**

David W. Keeley, Gretchen D. Oliver. *University of Arkansas, Fayetteville, AR.* (Sponsor: Dr. Charles Riggs, FACSM)  
 Email: dwk0611@msn.com  
 (No relationships reported)

The use of studies incorporating mature pitchers as the basis for defining proper throwing mechanics across all ages does not take into account the unique differences between pitchers of different ages.

**PURPOSE:** The purpose of this study was to examine kinematic differences between youth pitchers of different ages.

**METHODS:** Reflective markers were attached to 18 pitchers before a series of fastballs were thrown the age regulated distance. Each pitch was recorded by three synchronized video cameras (120 Hz). Marker locations were calculated using DLT and standard techniques were used to calculate pitching motion kinematics. Student t-test analyses were conducted at maximum shoulder external rotation (MER) and ball release (BR) to identify differences between groups.

Table 1. Results of t-tests analysis.

	MER		BR	
	Prepubescent Pitchers	Pubescent Pitchers	Prepubescent Pitchers	Pubescent Pitchers
Trunk rotational velocity (°/s)	701.9 ± 440.7	926.4 ± 364.2	850.2 ± 512.1	1043.2 ± 408.6 *
Horizontal adduction (°)	4.7 ± 7.4	13.7 ± 6.1	2.01 ± 5.28	3.9 ± 4.6
Elbow extension (°)	125.0 ± 36.6	138.6 ± 27.2	156.45 ± 16.41	164.2 ± 12.9

\*  $p < 0.01$

**RESULTS:** Results of t-test analyses are shown in Table 1. At MER, the rate of forward trunk rotation and the angles of horizontal shoulder adduction and elbow extension were significantly higher in older pitchers. At BR, the rate of forward trunk rotation was the only variable that remained significantly higher in the older group.

**CONCLUSION:** Increased core muscular strength accompanying pubescence may result in the torso being rotated at higher rates in older pitchers. This increase in torso rotational velocity may play a role in increasing the angles of horizontal adduction and elbow extension at MER by increasing centrifugal forces transferred down the throwing arm. At BR, although the rate of forward trunk rotation remained higher in older pitchers, strength increases in the musculature of the throwing arm may compensate for the higher torso rotation velocities, allowing the shoulder and elbow to reach a position that is similar to that observed in younger pitchers.

**2768 Board #162 May 29 2:00 PM - 3:30 PM**  
**Comparison Of On-horse And Postflight Techniques Used By Elite Gymnasts In Performing Two Handspring Category Vaults**

Yoshiaki Takei, FACSM, Ravi Viswanathan, Brandon Male. *Northern Illinois University, DeKalb, IL.*  
 Email: ytakei@niu.edu  
 (No relationships reported)

The handspring and salto (somersault) forward tucked vault forms the basis for learning the advanced handspring and double salto forward tucked (Roche) vault. On-horse and postflight (second flight) mechanical variables have important "causal influence" on postflight performance, landing on the mat, and overall score of a vault.

**PURPOSE:** To identify the differences of on-horse and postflight techniques in performing the handspring and salto forward tucked vault and the Roche vault.

**METHODS:** The subjects were 51 gymnasts performing the handspring and salto forward tucked vault at the 1988 Olympic Games and 23 gymnasts performing the Roche vault at the 2000 Olympic Games. The vaults were filmed by a 16-mm camera operating at 100 Hz. Approximately 80 frames were digitized for each vault. A theoretical model was developed to identify the mechanical variables that determine the linear and angular motions of the vaults.

**RESULTS:** The results of t tests applied to the data indicated that the Roche vault, compared to the handspring and salto forward tucked vault, had significantly ( $P < .005$ ): (1) greater resultant and vertical velocities of body center of mass (CM) at horse touchdown (TD); (2) shorter time of arm support on horse; (3) greater resultant and vertical velocities at horse takeoff (TO); (4) greater maximum height attained by CM, greater horizontal distance traveled by CM, and longer duration of time in postflight; (5) greater somersaulting angular distance, smaller average somersaulting moment of inertia, and greater average somersaulting angular velocity of postflight; and (6) greater resultant and vertical velocities at mat TD.

**CONCLUSION:** Successful progression from the handspring and salto forward tucked vault to the Roche vault is likely when the focus is on achieving: (1) large vertical velocity at horse TD by reaching toward the far end of the horse with the hands and arms as quickly as possible upon the board TO; (2) large vertical velocity at horse TO by pushing off the horse quickly and forcefully downward and forward with the hands and shoulders (flexion of the humerus and elevation of the scapulae); and (3) great maximum height, large horizontal distance, and long time of postflight to enable additional salto forward required for the Roche and simultaneously prepare for controlled landing on the mat.

**2769 Board #163 May 29 2:00 PM - 3:30 PM**  
**Place Kicking Kinematics Following Static And Dynamic Stretching Warm-ups In Young Female Soccer Players**

Rodney Pius, Roger L. White, Qin Lai, Hermann J. Engels, FACSM. *Wayne State University, Detroit, MI.*  
 (No relationships reported)

**PURPOSE:** This study compared the effects of a standardized static and dynamic stretching warm-up on performance of a maximal instep type soccer place kick.

**METHODS:** Sixteen female high school varsity soccer players (age:  $15.9 \pm 0.9$  yrs) completed two randomly assigned experimental sessions that consisted of either a 10-min standardized static (S) or dynamic (D) warm-up (Faigenbaum et al., 2005), each followed immediately by 3 consecutive trials of a maximal effort instep place kick with the preferred leg. Testing was performed using a ball of standard size and inflation (FIFA, 2008) under controlled indoor athletic field conditions. Kicking performance motion was obtained using a video camera (Panasonic PV-GS55), and then digitized and measured from the start of the kicking leg's forward swing to the toe contact on ball at 60Hz using video-based, 2-D motion analysis software (Peak Motus, Peak Performance, Inc.). The primary dependent variables were mean and maximal linear velocities on the toe of the kicking foot, as the index for kicking performance. In addition, mean angular velocities on the ankle, knee, and hip of the kicking leg were measured to allow for a more in-depth interpretation of the kinematic characteristics of the place kick.

**RESULTS:** Paired t-tests revealed no significant differences between the static and dynamic warm-up conditions on mean linear velocity (S:  $10.50 \pm 1.85$  m/s; D:  $10.63 \pm 1.75$  m/s) and maximal linear velocity (S:  $18.06 \pm 3.12$  m/s; D:  $18.23 \pm 2.77$  m/s) on the toe ( $p>0.05$ ). Similarly, no differences for the warm-up conditions were observed on any of the

angular velocity variables ( $p>0.05$ ).

**CONCLUSION:** The present data in young female soccer players demonstrate no differences in soccer place kicking performance with the instep of the preferred leg following completion of either a static or dynamic warm-up. Recent clinical recommendations to avoid pre-event static stretches and to use a dynamic pre-event warm-up to optimize exercise performances in tasks that require a high power output need further evidence-based refinements that should include sport-specific tasks.

**Kinematic And Kinetic Differences Among Three Landing Tasks: Drop-jump, Sidestep, And Pivot**

Nelson Cortes<sup>1</sup>, James Onate<sup>1</sup>, Jay Hertel, FACSM<sup>2</sup>, Brent Arnold<sup>3</sup>, Stephen Marshall<sup>4</sup>, Scott Ross<sup>3</sup>, Lauren Kramer<sup>5</sup>, Bonnie Van Lunen<sup>1</sup>. <sup>1</sup>Old Dominion University, Norfolk, VA. <sup>2</sup>University of Virginia, Charlottesville, VA. <sup>3</sup>Virginia Commonwealth University, Richmond, VA. <sup>4</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC. <sup>5</sup>Pennsylvania State University, State College, PA.  
(No relationships reported)

Several tasks have been utilized to identify potential risk factors for Anterior Cruciate Ligament (ACL) injuries. Each task may place different demands on the joints; therefore it is relevant to understand the kinematic and kinetic differences among these tasks.

**PURPOSE:** The purpose of this study was to determine kinematic and kinetic differences between a drop-jump (DJ), sidestep (SS), and pivot (PI) task.

**METHODS:** 19 female collegiate soccer athletes ( $19.58 \pm 0.84$  years;  $1.67 \pm 0.05$  m;  $63.66 \pm 10.11$  kg) from a Division I institution participated in this study. 3D Motion analysis data were captured with a VICON system and Bertec force plates sampling at 500Hz. Three trials were collected for the DJ task, while 10 unanticipated trials were collected for the SS and PI, with a custom visualization software creating the unanticipated factor. Separate repeated measures analyses of variance were conducted for each dependent variable. Alpha level set at  $p<0.05$ . Kinematic measured in degrees, and kinetic measured in multiples of body weight.

**RESULTS:** There was a significant difference in ankle flexion (AF) at initial contact (IC) between tasks ( $SS=13 \pm 14 > PI=2 \pm 13$ ,  $SI > DJ=-8 \pm 13$ ,  $PI > DJ$ ,  $pPI=16 \pm 8$ ,  $SS > DJ=17 \pm 6$ ,  $pSI=-3 \pm 8$ ,  $PI > DJ=-0.6 \pm 4$ ,  $pDJ=38 \pm 10$ ,  $p=.003$ ). There was also a significant difference in maximum knee flexion (MKF) ( $DJ=83 \pm 10 > SI=52 \pm 6$ ,  $DJ > PI=50 \pm 15$ ,  $pSI=57 \pm 16$ ,  $DJ > PI=53 \pm 9$ ,  $pSI=1.42 \pm 27$ ,  $DJ > PI=1.08 \pm 48$ , and  $SS > PI$ ,  $p<0.001$ ).

**CONCLUSIONS:** The three tasks appear to have distinct kinematic and kinetic characteristics. DJ task had higher VGRF than the other two tasks, as well as higher MKF and MHF that may help in attenuating the increased landing forces. When conducting biomechanical studies to understand ACL injuries the tasks chosen should be sport specific.

**2771 Board #165 May 29 2:00 PM - 3:30 PM**

**Effect Of Footwear On Lower Extremity Secondary Plane Movements During A Soccer Specific Jumping Task**

Alicia N. Abbey<sup>1</sup>, Robert J. Butler<sup>2</sup>, Robin M. Queen<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC. <sup>2</sup>University of Evansville, Evansville, IN. (Sponsor: Donald Kirkendall, FACSM)  
R. Queen presenting  
(No relationships reported)

**PURPOSE:** The purpose of the study was to examine the effect of different types of footwear (running, turf, and bladed cleat) on lower extremity landing mechanics in the secondary planes of motion. Due to the increased rigidity of the bladed cleat, it was hypothesized that the bladed cleat condition would result in increased joint moments and increased peak joint angles compared to the running and turf shoe conditions.

**METHODS:** Fourteen male and fourteen female recreational soccer players were selected for the study. Subjects underwent a movement analysis while performing a controlled jump heading activity in the three different footwear conditions. The jump heading activity consisted of the subject jumping forward from a standing position half of their body height behind the 2 force plates, landing on the force plates covered with artificial turf with both feet and then jumping up to head a ball that was suspended at half the subject's maximum jump height above the front of force plates, and landing back on the force plates. The footwear testing order was randomized for each subject. Peak knee and hip joint moments and angles in the frontal and transverse plane were examined from initial contact with the force plates until the subject left the force plates to head the ball. Due to suggested differences in male and female landing mechanics, a two-way ANOVA (gender x footwear) was utilized to analyze the data with a critical p-value established at 0.05.

**RESULTS:** No interactions were observed for any variables. Independent of shoe condition, females exhibited a greater peak knee external rotation angle and a greater peak hip adduction angle compared to the male subjects, while males exhibited a greater peak ankle inversion moment than the females. Independent of gender, wearing the turf shoe resulted in a significantly greater ankle inversion moment compared to the running shoe.

**CONCLUSIONS:** Contrary to the hypothesis, the rigid bladed shoe did not increase moments or angles when compared to the turf or running shoe conditions. Therefore, footwear does not appear to effect landing mechanics in preparation for a jump heading task. However, it may be appropriate to assess changes in landing mechanics during different landing conditions to thoroughly examine the role that footwear may play in altering injury risk during jump landings.

**Joint-specific Power Production And Fatigue During Maximal Cycling**

Jim C. Martin, FACSM<sup>1</sup>, Nicholas A. T. Brown<sup>2</sup>. <sup>1</sup>The University of Utah, Salt Lake City, UT. <sup>2</sup>Australian Institute of Sport, Canberra, Australia.  
Email: jim.martin@utah.edu  
(No relationships reported)

Cycling power decreases substantially during a maximal 30 s cycling trial. It is not known whether powers produced at each joint decrease to a similar extent or if each joint exhibits an individual fatigue profile. Changes in movement patterns and/or relative joint powers with fatigue could arise from several different mechanisms or from a complex interplay of mechanisms.

**PURPOSE:** The purposes of this investigation were to determine the changes in movement and power at each joint during a fatiguing cycling trial.

**METHODS:** Thirteen trained cyclists performed a 30s maximal isokinetic cycling trial at 120 rpm. Pedal forces and limb kinematics were recorded. Joint powers were calculated using a sagittal plane inverse dynamics model, averaged for the initial, middle, and final 3s intervals of the trial, and normalized to initial values.

**RESULTS:** Relative ankle plantar flexion power was significantly less than all other joint actions at the middle interval ( $51 \pm 5\%$  of initial power;  $p=0.013$ ). Relative ankle plantar flexion power for the final interval ( $37 \pm 3\%$ ) was significantly less than the relative knee flexion and hip extension power ( $p=0.010$ ). Relative knee extension power ( $41 \pm 5\%$ ) was significantly less than relative hip extension power ( $55 \pm 4\%$ ) during the final three second interval ( $p=0.045$ ). Knee flexion power ( $47 \pm 5\%$ ) did not differ from relative hip extension power ( $p=0.06$ ).

**CONCLUSION:** These changes in power were accompanied by a decrease in time spent extending by each joint with fatigue (i.e., decreased duty cycle,  $p < 0.03$ ). Because the ankle fatigues more than the hip and knee joints, either peripheral muscle fatigue or changes in motor control strategies were identified as the potential mechanisms for joint-specific fatigue.

---

**2773 Board #167 May 29 2:00 PM - 3:30 PM**  
**Muscle Onset Timing In Subjects Trained To Reduce Tibial Shock**

Allison R. Altman, H. Philip Crowell, Irene S. Davis, FACSM. *University of Delaware, Newark, DE.*  
Email: aaltman@udel.edu  
(No relationships reported)

Stress fractures are one of the most serious overuse injuries in runners. High tibial shock, or peak positive tibial acceleration (PPA), is correlated to high loading rates and tibial stress fracture incidence. Runners are able to reduce their PPA by altering their footstrike pattern. This change may be associated with earlier onset times of the ankle musculature.

**PURPOSE:** To compare the onset times of the ankle dorsiflexors and plantarflexors, before and after a gait retraining protocol.

**METHODS:** 9 subjects with high PPA have been studied to date. Following a baseline instrumented gait analysis, all subjects underwent a gait retraining protocol aimed at reducing their PPA. Along with kinematics, electromyographic (EMG) data were collected from the medial and lateral gastrocnemius, soleus, and tibialis anterior muscles. Data were sampled at 1200 Hz. Onset was determined when the linear envelope exceeded 2.5 standard deviations above the resting mean. Onsets were extracted from the period from 125 ms before footstrike through the end of stance. These times were compared between baseline and post-gait retraining.

Figure 1. Mean EMG onset time expressed in milliseconds prior to footstrike, error bars are mean  $\pm$  SEM.

**RESULTS:** Subjects reduced their PPA by 39%, 6/10 increased, and 2/10 decreased their dorsiflexion at footstrike. Mean EMG onset times were similar before and after the retraining (Figure 1). However, the between-subject variability for these times was extremely high for all four muscles tested. The individual differences were largest in the soleus and tibialis anterior. For example, one subject activated the soleus as much as 22 ms later while another 27 ms prior to the pre-retraining onset time.

**CONCLUSION:** While all subjects reduced their tibial shock significantly, there were no consistent changes in ankle muscle onset times.

**Comparing EMG Data On Upper And Lower Regions Of Rectus Abdominis During Exercise To Fatigue**

Ray F. Moss, Anthony Caterisano, FACSM, Tim Patrick, Jaimie Grossnickle. *Furman University, Greenville, SC.*  
Email: ray.moss@furman.edu  
(No relationships reported)

A long standing debate in Exercise Science concerns the anatomy and physiology of the rectus abdominis muscle. The debate centers around whether the rectus abdominis (RA) may be parsed into upper (URA) and lower (LRA) functional units even though anatomically it is one unified muscle with tendinous inscriptions which compartmentalize the muscle into the famous "six pack" configuration.

**PURPOSE:** To determine if there were differences in the electromyographical (EMG) signatures of the upper and lower regions of the rectus abdominis during two conditions of the crunch exercise performed by each subject to volitional fatigue.

**METHODS:** Ten male volunteer collegian athletes (mean age = 20.8 yrs.) performed 2 sets of crunch exercises, randomly assigned, on 2 separate days, 48 hours apart. Data were collected using the BIOPAC<sup>TM</sup> bipolar EMG system, normalizing the data to the maximal EMG signatures of the URA and LRA during a resisted crunch maneuver. Two conditions of the crunch exercise were used. Condition 1 (C1) consisted a crunch cycle of 2 seconds; one second up and one second down. Condition 2 (C2) consisted of a crunch cycle of 4 seconds; two seconds up and 2 seconds down. EMG data were collected continuously throughout testing with the initial and final 8 seconds deleted prior to statistical analysis. Data were analyzed using a Student's t test for paired means, initial vs. fatigue EMG C1 and C2 for the URA and LRA, with a  $P \leq .05$  accepted for significance.

**RESULTS:** The mean EMG data during the initial phase of activities for the URA and LRA, respectively, were, C1:  $9.7 \pm 2.6$  mVsec. and  $8.4 \pm 2.5$  mVsec. C2:  $7.6 \pm 2.8$  mVsec. and  $6.5 \pm 2.7$  mVsec. The mean EMG data during the fatigue phase of activities for the URA and LRA were C1:  $10.6 \pm 4.4$  mVsec and  $11.8 \pm 4.2$  mVsec; C2:  $8.0 \pm 1.8$  mVsec. and  $8.6 \pm 2.2$  mVsec. The changes in EMG data between initial and fatigue components of the exercises were significant for the LRA under both conditions,  $P \leq .031$  (C1) and  $P \leq .007$  (C2) respectively, with no differences found in the URA.

**CONCLUSION:** The RA may be parsed into an URA and LRA for the physiologic purposes of core strength training.

**The Relationship Of Arm Span To Maximum Voluntary Isometric Contraction And 1rm Bench Press Performance.**

Megan Williamson<sup>1</sup>, David Bellar<sup>1</sup>, Matt Muller<sup>1</sup>, Tiffany J. Patrick<sup>2</sup>, Jacob Barkley<sup>1</sup>, Ellen L. Glickman, FACSM<sup>1</sup>. <sup>1</sup>Kent State University, Kent, OH.  
<sup>2</sup>Notre Dame College, South Euclid, OH.  
Email: mwilli93@kent.edu  
(No relationships reported)

In previous studies, isometric lifting has produced varied results. These studies have examined both the acute and training effects of isometric contraction on the bench press. To date there have been no published studies that account for arm length on the acute affects of isometric contraction on the bench press exercise.

**PURPOSE:** The purpose of this study was to determine what the relationship between arm span and the acute effects of Maximum Voluntary Isometric Contraction on one repetition maximum performance in the bench press.

**METHODS:** The participants involved in this study were eight female college track and field athletes (Height  $1.72 \pm 0.9$ , BMI  $32.1 \pm 9.2$ ) who compete in the throwing event (Hammer, Shot Put, Discus, Javelin). The average 1RM bench press for the participants was  $59.5 \pm 19.8$  kilograms. A counterbalanced, within subjects design was chosen for this study. Participants were asked to report to the weight room on two separate occasions. Both days began with a standard warm-up of the bench press exercise consisting of 70% 1RM for a set of five repetitions and 80% 1RM for 3 repetitions. After the warm-up both trial days consisted of three separate, single maximal attempts to set a new 1RM in the bench press. The two treatments that were counterbalanced were Standard (STAND) and MVIC. The STAND treatment consisted only of the three maximal lifts in the bench press exercise. The MVIC treatment consisted of a 30 second maximal voluntary isometric contraction against a stationary bar at 90 degrees of elbow flexion immediately prior to each single maximal bench press lift to induce fatigue. A 72 hour washout period was incorporated between treatments.

**RESULTS:** A significant bivariate correlation ( $r=-0.855$ ,  $p=.007$ ) was found between arm span and change between previously determined 1RM and performance during MVIC. No significant relationship was found between arm span and performance change in the STAND condition ( $r=-.344$ ,  $p=0.404$ ).

**CONCLUSION:** The significant negative correlation suggests that those individuals with longer arm spans were not able to lift as much weight post-MVIC. Thus the fatigue associated with MVIC produced a greater affect in those who displaced the weight the farthest past 90 degrees of elbow flexion.

Goel<sup>1</sup>, Timothy E. Hewett, FACSM<sup>2</sup>. <sup>1</sup>University of Toledo, Toledo, OH. <sup>2</sup>Cincinnati Children's Hospital Sports Medicine Biodynamics Center, Cincinnati, OH.

<sup>3</sup>University of Cincinnati, Cincinnati, OH. <sup>4</sup>William Beaumont Hospital, Royal Oaks, MI.

Email: carmen.quatman@utoledo.edu

(No relationships reported)

Mechanisms of non-contact ACL injuries include evidence supporting two loading patterns: injury via anterior tibial (AT) shear or via knee abduction (AB) collapse. While the ACL appears to be susceptible to AT loads, AB collapse is a commonly reported ACL injury mechanism. Intuitively, if an AB mechanism predominated, concomitant injury to the MCL would be expected, as it may provide primary restraint against AB stress. However, combined ACL/MCL injuries are rarer than isolated ACL injury.

**PURPOSE:** Analyze stresses ( $S$ ) and strains ( $E$ ) in ACL and superficial MCL (sMCL) during landing and injury simulations in a female athlete at high risk for ACL injury. The hypotheses were that combined AT/AB loads would have higher ACL  $S$  and  $E$  compared to AB loads and AT/AB loads would have higher ACL  $S$  and  $E$  relative to the sMCL.

**METHODS:** A validated finite element knee model developed from CT and MRI images of this at risk athlete was employed to analyze  $S$  and  $E$ . Kinematic and kinetic data from the same athlete were used as input for the model (ABAQUS 6.8 software). ACL and sMCL  $S$  and  $E$  were analyzed at the peak AB moment during landing from multiple drop vertical jumps (5 trials). The trial with the highest peak AB moment ( $HAB_m$ ) was used for control and injury simulations. The control was simulated with AB angle neutralized to static posture position. Injury simulations included AB injury via 4° increase in AB angle and AT/AB injury via combined 6mm AT translation and 4° AB angle increases.

**RESULTS:**  $HAB_m$  had higher ACL  $S$  and  $E$  than the control. AB injury had higher ACL  $S$  and  $E$  compared to  $HAB_m$  and control. However, AB injury had 40% higher  $S$  and  $E$  in sMCL compared to the ACL. In contrast, AT/AB injury had 7-fold higher ACL  $S$  and  $E$  compared to AB injury loads and AT/AB loads had 55% higher ACL  $S$  and  $E$  relative to the sMCL.

**CONCLUSIONS:** These findings indicate combined AT/AB loads may increase the likelihood for ACL injury compared to AB loads alone during high abduction moments. Interestingly, the sMCL appeared to be a secondary restraint to combined AT/AB loads relative to the ACL. These results help to explain the high prevalence of reported isolated non-contact ACL injuries in the absence of MCL injury, which likely result from combined anterior tibial shear and knee abduction collapse.

Email: yuc24@pitt.edu

(No relationships reported)

Landing tasks commonly result in non-contact knee ligament injuries and are widely performed in military training and operations. Previous civilian research has demonstrated mixed results on the effects of visual input availability on landing performance. Soldiers are frequently required to perform landings without sufficient visual input and although data are not available for fast-roping exercises performed by air assault soldiers, night time tactical maneuvers increase the risk of injury two fold.

**PURPOSE:** To determine the differences in knee landing kinematics and vertical ground reaction forces (VGRF) of air assault soldiers with and without visual input.

**METHODS:** A total of 110 male air assault soldiers ( $28.7 \pm 7.1$  yrs,  $177.2 \pm 7.2$  cm,  $83.6 \pm 12.8$  kg) participated. Subjects performed a two-legged drop landing task from a 50 cm platform onto two force plates. Six high-speed infrared cameras tracked the trajectories of the reflective markers attached to subjects' lower extremities. Subjects performed three trials each with visual input and blindfolded. Knee flexion angle, knee valgus angle, and VGRFs (normalized to body weight) were compared between conditions with dependent t-tests.

**RESULTS:** No significant differences in knee flexion and valgus angles were detected at initial foot contact. When blindfolded, maximum knee flexion was less (right:  $89 \pm 20^\circ$  vs.  $85 \pm 20^\circ$ ,  $p < 0.001$ ; left:  $89 \pm 19^\circ$  vs.  $86 \pm 20^\circ$ ,  $p < 0.001$ ), maximum VGRF of the left foot was greater ( $333.9 \pm 88.9\%$  BW vs.  $351.5 \pm 83.3\%$  BW,  $p = 0.001$ ), and time elapsed from initial foot contact to maximum VGRF of the left foot was longer ( $0.374 \pm 0.10$  vs.  $0.394 \pm 0.09$  s,  $p = 0.022$ ).

**CONCLUSIONS:** Diminished visual acuity caused the subjects to alter their landing strategy for the two-legged drop landing task. While the greater VGRF of the left foot may pose greater risk of injury, soldiers are able to dissipate the force by prolonging the time from initial foot contact to peak VGRF. Significant differences found only with the left leg raises the question whether landing strategies change based on the availability of visual input, perhaps increasing asymmetrical or preferable joint loads.

**Differences In Impact Force Attenuation And Knee Kinematics During Drop Jump And Drop Landing**

Songning Zhang, FACSM, Jeremy A. Steeves. *The University of Tennessee, Knoxville, TN.*

Email: szhang@utk.edu

(No relationships reported)

Few studies have compared impact attenuation during a pure landing task when impact attenuation is the main goal to a drop jump task where impact attenuation is immediately followed by energy generation.

**PURPOSE:** To examine differences of impact force attenuation between drop landing and the landing phase of a drop jump activity.

**METHODS:** Seven NCAA football athletes (TRAINED) and 7 recreationally active students (REC) with limited sports training and prior experience in jumping sports, performed 5 drop landing trials from each of 3 landing heights: 40 cm, 60 cm and 100% of each individual's maximum jump height (100%MJH) and 5 drop jump trials from each of the 3 drop heights. Simultaneous recording of 3D kinematics and ground reaction force (GRF) were conducted at 240 Hz and 1200 Hz, respectively. Selected peak GRF and kinematic variables were evaluated using a mixed design  $2 \times 2$  (group  $\times$  height) repeated measures analysis of variance (ANOVA,  $p < 0.05$ ) for the 40 and 60 cm conditions for the two activities separately. The group differences at the 100%MJH were evaluated with an independent-samples t-test.

**RESULTS:** The results showed that the TRAINED participants had significantly smaller peak GRF (1.7 and 2.2 BW for 40 and 60 cm) and longer time to the peak (0.057 and 0.053 s for 40 and 60 cm) compared to the REC participants (2.0 and 2.7 BW, 0.050 and 0.048 s for 40 and 60 cm) in the landing phase of drop jump. However, the TRAINED participants had greater peak GRFs (2.7 and 3.5 BW for 40 and 60 cm) and significantly shorter times to the peak (0.048 and 0.043 s for 40 and 60 cm) compared to the REC participants (2.0 and 2.7 BW, 0.060 and 0.053 s for 40 and 60 cm) in drop landing. The TRAINED athletes also showed similar knee ranges of motion (ROM) in the landing phase during drop jump but smaller and non-significant knee ROMs ( $p = 0.051$ ) in drop landing compared to the REC counterparts.

**CONCLUSIONS:** The TRAINED athletes exhibited greater impact attenuation during the landing phase of drop jump but less impact attenuation during drop landing. This difference is related to the differences in the knee ROMs during the two different landing activities. The TRAINED athletes are able to tolerate greater impact force in the regular landing and absorb greater impact force during the landing phase to facilitate energy generation during the takeoff phase in drop jump.

**Ability Of Competitive Swimmers To Modify Start Depth Is Not Dependent Upon Age**

Andrew C. Cornett, Josh C. White, Joel M. Stager, FACSM, Brian V. Wright. *Indiana University, Bloomington, IN.*  
(No relationships reported)

**PURPOSE:** There is a distinct paucity of research relating to safety concerns in competitive swimming starts. The purpose of this study was to expand upon the existing literature by examining the ability of competitive swimmers of different ages to modify on request the maximum head depth achieved during a competitive swimming start.

**METHODS:** Fourteen swimmers aged 10 years and under (age =  $7.9 \pm 1.3$  years, height =  $1.29 \pm 0.10$  m, mass =  $30.94 \pm 6.6$  kg), ten 11-12 year old swimmers (age =  $11.3 \pm 0.5$ , height =  $1.48 \pm 0.06$  m, mass =  $42.9 \pm 6.1$  kg), and eighteen 13-14 year old swimmers (age =  $13.5 \pm 0.5$ , height =  $1.62 \pm .06$  m, mass =  $54.0 \pm 6.3$  kg) were filmed underwater during execution of two competitive starts. All subjects were members of a USA Swimming sanctioned swim club. Swimmers completed one start and a subsequent freestyle sprint without instruction. Prior to the second start the swimmers were asked to make the start as shallow as possible while still completing the sprint. For each start, the maximum depth of the center of the head was determined using 2D DLT analysis.

**RESULTS:** A two-way mixed design ANOVA for maximum depth of the center of the head yielded no interaction between instruction and age group, but significant main effects for both instruction ( $F_{1,39} = 16.6$ ;  $p < 0.01$ ) and age group ( $F_{2,39} = 5.4$ ;  $p = 0.08$ ). As there was no significant interaction between instruction and age group, the 10&U, 11-12, and 13-14 groups were combined in an analysis of the ability to modify depth. When instructed to dive shallowly, the maximum head depth decreased significantly ( $p < 0.01$ ) from  $0.56 \pm 0.03$  m to  $0.45 \pm 0.02$  m. Similarly, the uninstructed and instructed groups were combined in an analysis of the age groups. The maximum head depth was significantly greater ( $p = .006$ ) for 13-14 year olds ( $.58 \pm .03$  m) than for 10&U swimmers ( $.42 \pm .04$ ), but neither group was different with respect to maximum head depth from 11-12 year olds.

**CONCLUSIONS:** Swimmers 14 years of age and younger possess the ability to modify competitive start depth on command. However, from a safety perspective, it is important to note that not all swimmers successfully modified their competitive start depth.

**Retention Of A One-session Injury Prevention Intervention After Training Abstinence**

Daniel Herman<sup>1</sup>, James Oñate<sup>2</sup>, Paul Weinhold<sup>3</sup>, Kevin Guskiewicz<sup>3</sup>, William Garrett, Jr., FACSM<sup>4</sup>, Bing Yu<sup>3</sup>, Darin Padua<sup>3</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA. <sup>2</sup>Old Dominion University, Norfolk, VA. <sup>3</sup>University of North Carolina, Chapel Hill, NC. <sup>4</sup>Duke University, Durham, NC.  
(No relationships reported)

**PURPOSE:** To examine the level of retention of technique feedback instruction for ACL injury prevention on the lower extremity kinematics and kinetics of a stop-jump task in strength-trained female athletes after a 9-week period of training abstinence.

**METHODS:** 10 recreational female athletes ( $n=10$ , age= $22.5 \pm 2.3$  yrs, ht= $1.67 \pm 0.07$  m, wt= $64.1 \pm 9.1$  kg) completed a strength training program focusing on the quadriceps, gluteus medius, gluteus maximus, and hamstrings. Lower extremity kinetic and kinematic data were collected during 5 stop-jump trials both before (PRE-FB) and after (PST-FB) participation in a feedback protocol. Data was also collected after a period of 9 weeks during which subjects refrained from strength or feedback training (RET). Statistical analyses were performed using dependent samples t-tests ( $\alpha < .05$ ).

**RESULTS:** The subjects demonstrated significantly improved kinetics and kinematics at PST-FB compared to PRE-FB, including decreased knee anterior shear force ( $.44 \pm .14$  BW vs  $.61 \pm .24$  BW,  $p=.011$ ), vertical ground reaction force ( $1.43 \pm .47$  BW vs  $2.10 \pm .85$  BW,  $p=.024$ ), knee valgus moment ( $.08 \pm .04$  BW\*BH vs  $.14 \pm .09$  BW\*BH,  $p=.033$ ), knee extension moment ( $.18 \pm .05$  BW\*BH vs  $.23 \pm .06$  BW\*BH,  $p=.020$ ), and hip adduction moment ( $.08 \pm .04$  BW vs  $.16 \pm .08$  BW,  $p=.011$ ), as well as increased hip flexion angles ( $37.1 \pm 7.8^\circ$  vs  $31.9 \pm 8.1^\circ$ ,  $p=.003$ ). Subjects demonstrated significantly decreased strength in all muscle groups after refraining from strength training for 9 weeks (RET) compared to PST-FB. No significant differences were observed in the subjects' kinetic or kinematic data at RET compared to PST-FB.

**CONCLUSIONS:** The results indicate that strength-trained subjects who underwent a one-time feedback intervention on stop-jump technique were able to improve their performance during a stop-jump task. Furthermore, these subjects were able to retain those improvements over a period of 9 weeks, even though the subjects' strength had significantly decreased. These results suggest that athletes who undergo pre-season injury prevention programs may be able to retain the effects during the course of a season.

**Systematic Review Of Biomechanical Analysis Of Male 100 Meter Sprint**

Ming Long, Jun Zhang. *Jinan University, Guangzhou, China.* (Sponsor: Yong Tai Wang, FACSM)  
Email: ytwang88@hotmail.com  
(No relationships reported)

In track and field, 100 meter (m) sprint is one of the most exciting events. Improved technology has facilitated sport skills and performance enhancement. However, the research in 100m sprint is not well documented.

**PURPOSE:** To analyze key elements in different phases of male 100m sprint and to compare skill characters among Chinese and American elite sprinters to help the 100m sprinters in China to improve their performances.

**METHODS:** Systematic views and secondary data analysis to compare biomechanical characters in elite 100m sprinters in China and America.

**RESULTS:** In sprint start, no difference was found on the forces exerted against the blocks and on reaction time among the sprinters. Through the analysis of leg movement, the sprinters should flex their knees properly ( $90^\circ$  for front leg &  $120^\circ$  for rear leg) in order to produce the maximum impulse so that they can leave the blocks with the greatest possible velocity in the sprint start. Acceleration phase was the most important phase in sprint since it made up the maximum velocity and accounted for 64% of performance. Maximum velocity (MV) was found highly related to the sprint performance ( $r = 0.78$ ). Chinese sprinters had less MV ( $11.11 - 11.30$  m/s) compared to American elite sprinters ( $11.76 - 12.05$  m/s). Maintaining MV was found to be crucial to keep high performance ( $r = 0.99$  for  $MV > 11.5$  m/s). At initial foot contact, the vertical velocity and landing angle were  $1.15$  m/s and  $85.7^\circ$  for American sprinters, and  $1.35$  m/s (17% higher) and  $81.5^\circ$  for Chinese sprinter. Compared to American sprinters with  $144.4^\circ$  of initial knee flexion and  $10.2^\circ$  range of motion during landing, Chinese sprinters had disadvantages in lifting leg ( $152.1^\circ$  of initial knee flexion and  $3.2^\circ$  of range of motion). Increasing the horizontal distance between supporting leg and the project of center of gravity (.67m for American and .53m for Chinese sprinters) was related to increased stride length and velocity.

**CONCLUSIONS:** Sprint training and performance improving should emphasize on increasing stride frequency and length, high center of gravity with less fluctuation, as well as smooth movement rhythm. It is crucial to increase duration and distance for acceleration phase in order to optimize the maximum velocity in sprint.

**2782 Board #176 May 29 3:30 PM - 5:00 PM****Age And Experience Differences In Work Intensity During Soccer Matches**

Morris Levy<sup>1</sup>, Michael S. Orendurff<sup>2</sup>, Jason D. Walker<sup>3</sup>, David Hoffman<sup>4</sup>. <sup>1</sup>University of Minnesota, Duluth, MN. <sup>2</sup>Texas Scottish Rite Hospital for Children, Dallas, TX. <sup>3</sup>University of Southern California, Los Angeles, CA. <sup>4</sup>University of Dallas, Duluth, TX.  
Email: mlevy@d.umn.edu

*(No relationships reported)*

**PURPOSE:** The purpose of this project was to compare the distribution of movement intensity for a men's under-20 (U-20) and a boy's under-12 (U-12) team.

**METHODS:** Step rate data were recorded on 5 players from each team during competitive matches using

StepWatch Activity Monitors. Step rates were categorized into 7 levels of intensity: Walk, Slow Jog, Fast Jog, Run, Fast Run, Sprint, and Max as a percentage of the total samples. Each level was compared between the two teams using ANOVAs. First Referees' step rates were also recorded.

**RESULTS:** For U-12 players the step rate data showed much more time spent in recovery at low levels of intensity (Walk, Slow Jog, Fast Jog), less time spent in Run, Fast Run, and Sprint intensities, but more time at Max intensity compared to the U-20 team. The First Referees' distributions mimicked the players they were officiating.

**CONCLUSIONS:** Data confirm that younger players are apt to run more often at maximum intensity, with more frequent low-level recovery periods. The U-20 players were able to compress their step rates to maintain a moderate to high level of activity more often but spent less time at either the slowest or fastest rates. U-20 players rarely hit top speed unless a critical play was forming that might result in a scoring opportunity in either goal. So, these more experienced players were also more likely to avoid frequent rest periods necessary after bouts of maximum speed. This is likely due to reduced fitness and ball control skills by U-12 players, and not an inability to read the development of a critical play. Coaches may want to encourage younger teams to focus more on ball control skills as it would allow these younger players to better modulate work intensity to manageable levels during soccer matches.

**2783 Board #177 May 29 3:30 PM - 5:00 PM****Lean Tissue Index: An Excellent Predictor Of Bone Mineral Density Of Adolescent Female Cross-country Runners**

Marc P. Bonis, Ph.D.<sup>1</sup>, J. Mark Loftin, Ph.D., FACSM<sup>2</sup>. <sup>1</sup>University of New Orleans, New Orleans, LA. <sup>2</sup>University of Mississippi, Oxford, MS.  
Email: mpbonis@bellsouth.net

*(No relationships reported)*

**PURPOSE:** Determine the best body-composition variable for predicting bone mineral density (BMD) in the sub-population, which included body weight (WGT), lean tissue (LT), body mass index (BMI), body fat (BF), lean tissue index (LTI = LT/Height<sup>2</sup>), and body fat index (BFI = BF/Height<sup>2</sup>). Subjects: 28 female runners (Mean Age + SD = 14.9 + 1.6 yrs).

**METHODS:** Measure BMD using DXA and estimate skeletal maturity (SM) using questionnaire data.

**RESULTS:** Partial correlations indicated LTI was the variable most highly associated ( $p = .712$ ) with BMD. Multiple linear regression indicated LTI was the predictor variable with the best fit. Predictions of the dependent criterion variables, BMDleg and BMD, were calculated using the independent predictor variables, LTI and SM. Significant regression equations were found. The subjects' BMDleg was found to be equal to  $(-2.486) + (2.912)SM + (5.540E-02)LTI$ ,  $[F(2,23) = 20.161, SEE = .0634]$  with an  $R^2 = .637$ ; and the subjects' BMD was found to be equal to  $(-1.645) + (2.209)SM + (4.068E-02)LTI$ ,  $[F(2,23) = 18.828, SEE = .0487]$  with an  $R^2 = .621$ .

**CONCLUSION:** LTI was the body composition variable most highly associated with BMD ( $p = .712$ ). LTI was also the best body-composition component to predict BMD ( $r = .788$ ).

---

**2784 Board #178 May 29 3:30 PM - 5:00 PM****Influence Of Body Fat Percentage On Agility, Strength, And Endurance Performance**

Katie J. Bouley, Mary C. Pieklo, Tracey D. Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*  
Email: kbouley@spfldcol.edu

*(No relationships reported)*

Individuals carry different levels of body fat, and the degree of fatness can impact overall performance, including strength, agility, and endurance. A low relative body fat and a high ratio of lean muscle mass to body fat are two characteristics observed in most athletes. Some athletes may display body fat percentages that are too high or too low for optimal performance.

**PURPOSE:** The purpose of the investigation was to examine the relationship between body fat percentage and athletic performance in moderately active females.

**METHODS:** Fifteen moderately active females currently taking a form of estrogen based chemical contraceptive performed a series of performance tests to measure overall endurance, relative muscular strength, muscular endurance, and agility performance. Percent body fat was estimated using hydrostatic weighing techniques. Endurance was measured by performing a VO<sub>2</sub>peak test following the Modified McConnell Running Protocol. Relative muscular strength was measured using a handgrip dynamometer to determine maximum grip strength. Muscular endurance was measured using a handgrip dynamometer to determine the strength decrement index (SDI). Agility performance was measured using the SEMO Agility Test. The Pearson Product Moment Correlation Coefficient was used to determine the relationship between percent body fat and athletic performance.

**RESULTS:** Significant linear relationships were found between endurance performance and percent body fat ( $r = -0.88, p < 0.01$ ) and between muscular endurance and percent body fat ( $r = 0.64, p < 0.05$ ). No significant linear relationships were found between percent body fat and relative muscular strength ( $r = -0.43, p > 0.05$ ) and agility performance ( $r = 0.25, p > 0.05$ ).

**CONCLUSION:** Body fat percentage is highly related to cardiovascular endurance and muscular endurance performance in moderately active females.

(No relationships reported)

The relation between body fatness (%Fat) and body mass index (BMI) has been studied in athletes using estimates of %Fat from densitometry, which are less valid than estimates from a 4-component model for athletes in certain sports.

**PURPOSE:** To evaluate the relation between %Fat and BMI and to estimate the validity of BMI standards for overweight/obesity (O/O) in athletes using a 4-component (4C) model to assess %Fat.

**METHODS:** Height and weight were measured in young (21.0±2.5 yrs) female athletes (FA, n=54, 165.6±7.5 cm, 59.3±7.8 kg, 21.6±2.1 kg·m<sup>-2</sup>), male athletes (MA, n=38, 181.4±8.5 cm, 78.0±15.0 kg, 23.5±3.0 kg·m<sup>-2</sup>), football players (FP, n=40, 186.4±6.5 cm, 107.5±16.4 kg, 30.8±3.6 kg·m<sup>-2</sup>), female sedentary controls (FC, n=45, 164.5±4.9 cm, 58.2±8.6 kg, 21.5±3.3 kg·m<sup>-2</sup>), and male sedentary controls (MC, n=36, 177.9±4.9 cm, 71.1±7.6 kg, 22.5±2.3 kg·m<sup>-2</sup>). Measures of body density by underwater weighing, total body water via deuterium dilution, and total body mineral from DXA were used to assess body composition using a 4C model.

**RESULTS:** FA did not differ from FC in height, weight or BMI (p=0.381-0.887) but FA were leaner (18.7±5.3% vs. 26.4±5.2%, p<0.001). Similarly, MA did not differ from MC in BMI (p=0.091) but were taller (p=0.036), heavier (p=0.015), and leaner (10.1±54.1% vs. 15.1±4.8%, p<0.001). In contrast, FP were taller, heavier, and had greater BMI (all p<0.001) than MC, but did not differ in %Fat (13.2±6.6%, p=0.146). BMI was curvilinearly related to %Fat among FA and that relation was moderated by race (%Fat = 128.905 - 10.874\*BMI + 0.267\*BMI<sup>2</sup> - 4.463\*Race (0=white, 1=black), R=0.53, SEE=4.6%, p=0.001). The relation was similar in the combined group of MA and FP (%Fat = 39.362 - 2.785\*BMI + 0.064\*BMI<sup>2</sup> - 2.417\*Race, R=0.69, SEE=4.2%, p<0.001). Low rates of overfatness were found in FA (3.7%), MA (10.5%), FC (11.1%), and MC (13.9%) but many (42.5%) FP were classified as overfat. Using BMI >25 kg·m<sup>-2</sup> for O/O, sensitivity was low (FA = 0.50), medium (MA = 0.75), and high (FP = 1.00), whereas the opposite was found for specificity (0.94, 0.74, 0.09). BMI cutpoints maximizing sensitivity and specificity were 23.4, 25.4, and 31.7 in FA, MA, and FP, respectively.

**CONCLUSION:** BMI and %Fat are not strongly related in athletes and BMI should not be used to classify overweight/obesity in this group, especially not among FA and FP.

---

**2786 Board #180 May 29 3:30 PM - 5:00 PM**  
**Subcutaneous Fat Distribution Of Wheelchair Basketball Players**

Kenya Kumagai<sup>1</sup>, Matthew D. Beekley, FACSM<sup>2</sup>, Takashi Abe<sup>3</sup>. <sup>1</sup>Nagasaki International University, Nagasaki, Japan. <sup>2</sup>University of Indianapolis, Indianapolis, IN. <sup>3</sup>University of Tokyo, Tokyo, Japan. (Sponsor: M.D. Beekley, FACSM)

Email: kumagai@niu.ac.jp

(No relationships reported)

Exercise and caloric restriction can lead to a reduction in total body fat mass. However, it is not clear whether local changes in the amount of the subcutaneous fat happen during activity and inactivity.

**PURPOSE:** Evaluate the subcutaneous fat distribution of wheelchair basketball players.

**METHODS:** Subcutaneous fat thickness (FTH) at 11 places was measured using B-mode ultrasound in wheelchair basketball players (WB, n=13), inactive wheelchair users (SW, n=12), and able-bodied persons (AB, n=11). Subcutaneous fat cross-sectional area (F-CSA) was presumed using a cross-sectional model and the cross-section was modeled by a double circle. The outside circle represents the whole outline of the modeled part and the inside circle represents the outline of the musculoskeletal system. The area between inside circle and outside circle represents F-CSA, which was calculated by subtracting the area of musculoskeletal cross-section (MS-CSA) from the area of whole organization cross-section (W-CSA). MS-CSA and W-CSA were calculated by using FTH (f) and circumference (l), measured at the modeled part [(W-CSA)=p(l/2p)(l/2p), (MS-CSA)=p(l/2p-f)(l/2p-f)].

**RESULTS:** As for FTH of the upper limb and the trunk, a significant difference was not found in either area among the three groups. Within the lower thigh, FTH of WB and SW were thicker than that of AB (p<0.05). However, WB and SW had smaller W-CSA and MS-CSA in the lower limb than AB (p<0.01). In addition, W-CSA and MS-CSA in the upper limb of WB were larger than that of the others (p<0.05). Finally, while F-CSA in most parts of the body of WB tended to be smaller compared with SW, there was no significant difference of F-CSA in any areas of the three groups.

**CONCLUSIONS:** The thicker subcutaneous fat measured in the paraplegic person's lower limbs does not mean that a localized increase of subcutaneous fat at the paralyzed part occurred. It is expected that atrophy of the muscle had occurred at the paralyzed part, and the place where muscle had existed was occupied by subcutaneous fat, which led to thicker subcutaneous fat. On the other hand, it is suggested that the activity of the upper limb during the wheelchair basketball has caused muscle hypertrophy at the activated part and a decrease of subcutaneous fat in the whole body.

Email: eimear.dolan3@mail.dcu.ie

(No relationships reported)

Weight category sports are classified as those for which athletes must weigh in at a designated weight prior to competition. Due to the weight restrictive nature of such sports, body mass must take precedence over many other factors for these athletes. Accurate assessment of body composition for athletes competing in weight category sports is essential, to ensure that the most efficient use of body mass is made in order to optimise performance.

**PURPOSE:** The purpose of this study was to compare skinfold assessment and DEXA as methods of estimating body composition in a group of weight category athletes.

**METHODS:** 41 weight category athletes were recruited to take part in this study (29 horse racing jockeys and 12 boxers). The subjects (age: 24 ± 6yrs) anthropometric characteristics were, stature: 1.71 ± 0.08m, mass: 61.8 ± 11.38 kg and BMI: 21.01 ± 2.52. Body composition values were extrapolated from a dual energy x-ray absorptiometry (DEXA) total body scan. Subcutaneous fat was measured using the skinfold calliper technique from 7 sites: bicep, tricep, subscapular, supraspinale, abdominal, front thigh, and medial calf. Body density was estimated using a 7 site regression equation, and converted to percentage body fat using a standard equation.

**RESULTS:** Mean ± SD for DEXA and skinfold estimates were 11.05 ± 5.36 and 9.13 ± 2.81 respectively. Significant differences were shown between the two estimates of body composition (p = 0.000). A strong positive correlation was found between both types of assessment (r = 0.920, r<sup>2</sup> = 0.85). Mean percentage difference between both types of assessment was 2.37 ± 2.26 %, though this varied from 0.10 - 12.3 %. Variations in body composition assessments appeared to become more pronounced as DEXA total body scan estimates increased.

**CONCLUSIONS:** Though skinfold assessment is a useful and practical tool for estimation of body composition, results differed significantly from those achieved using DEXA, which has been described as a level two measure of body composition assessment. Weight category athletes are a unique population, with specialised requirements in relation to management of body composition. Population specific regression equations for estimation of body density may be required, in order to provide a more accurate assessment of body composition in this population.

**A Skinfold Regression Equation For Predicting Body Fat Percentage In Elite Female Distance Runners**

Dan Benardot, FACSM, David E. Martin, FACSM. Georgia State University, Atlanta, GA.

Email: dbenardot@gsu.edu

(No relationships reported)

**PURPOSE:** Elite female distance runners have a rational concern for sustaining relatively low body fat mass to maintain a low air-resistance profile and a high strength-to-weight ratio. However, the current criterion measure for body composition assessment, dual-energy x-ray absorptiometry (DEXA), is expensive and requires that athletes visit labs to monitor changes in soft tissue. So as to create a field technique with a relatively low standard error, we investigated the potential of creating a regression equation that would use either skinfolds (SF-BF%) or bioelectrical impedance (BIA-BF%) for predicting DEXA-derived body fat percent (DEXA-BF%).

**METHODS:** Long-distance female runners (N=77) were assessed in the Laboratory for Elite Athlete Performance at Georgia State University over a 5-year period using IRB-approved protocols. Body composition was predicted for all athletes using DEXA (Lunar DPXL) and 9 skinfolds (triceps, biceps, pectoral, midaxillary, subscapular, suprailiac, abdomen, thigh, and calf) using a Harpenden caliper. A sub-portion (N=23) of these athletes were also assessed using BIA (Tanita BF-350) set to 'athlete' mode.

**RESULTS:** Athletes ranged in age from 18 to 39 (mean=25.4 yr;  $\pm 5.07$ ), and had a mean weight of 56.6kg ( $\pm 4.58$ ) and a mean height of 168.47cm ( $\pm 6.16$ ). The DEXA-BF% was more highly correlated with SF-BF% ( $R=.864$ ;  $p<.001$ ) than with BIA-BF% ( $R=.417$ ;  $p<.05$ ). As a result, a regression analysis using age, 9 skinfolds, height, and weight was used to predict DEXA-BF%. The variables explaining a significant portion of the variance in DEXA-BF% included weight and the midaxillary, suprailiac, mid-thigh, and calf skinfolds. These variables were included in a linear regression analysis to predict DEXA-BF% that resulted in an equation with an  $R^2$  of .909, and a SEE of  $\pm 1.77\%$ .  $[DEXA_{BF\%} = WT_{kg} (.124) + MIDAXILLARY_{mm} (.826) + SUPRAILAC_{mm} (.475) + THIGH_{mm} (.237) + CALF_{mm} (.512) - 8.063]$

**CONCLUSIONS:** Skinfolds are predisposed to wide error when used by inexperienced anthropometrists, and also produce large intrameasurer error. However, when used by an experienced single measurer on the same individual, the high  $R^2$  and relatively low SEE of this equation may provide female endurance athletes with a satisfactory field assessment technique for monitoring changes in body fat percent.

**The Effects Of Hypoxic Manipulation On  $VO_{2max}$  And Sea-level Performance: A Meta-analysis**

Roy M. Salgado, Daryl L. Parker, Roberto Quintana. *CSU Sacramento, Sacramento, CA.*

(No relationships reported)

In the past decades there has been an increased interest in hypoxic manipulation (HM) (i.e. altitude training, live high + train low (LH+TL) etc.) for improvement in sea-level performance. The efficacy and mechanism of HM has been conflicting. A method of resolving the equivocal nature of HM data is through the use of meta-analysis.

**PURPOSE:** The purpose of this meta-analysis was to identify the effects of HM versus normoxic training on  $VO_{2max}$  and sea-level performance.

**METHODS:** An online database and the reference lists of peer-reviewed journal articles were used to find pertinent journal articles. A total of 74 journal articles were found, of which 32 met the inclusion criteria and 16 of the 32 were reviewed for this preliminary study. The journal articles included in the meta-analysis had to meet the following 1) used a control group in their design and 2) reported means and standard deviations with their results. The dependent variables were  $VO_{2max}$  and exercise performance. Exercise performance was defined as time trial performance, peak power during a GXT, or total work capacity. The independent variable was HM and included traditional altitude training, LH+TL, live low + train high and intermittent hypoxic exposure. There were a total of 43 extracted data points:  $VO_{2max}$  (n = 19 control and n = 24 HM) and performance (n = 20 control and n = 23 HM). Effect size (ES) was calculated using Cohen's d:  $ES = (\text{posttest mean} - \text{pretest mean}) / \text{pretest SD}$ . A t-test was used to determine the difference between the mean ES for the control and the HM.

**RESULTS:** The mean ES for control and HM were .28 and .33 for  $VO_{2max}$  and .29 and .50 for performance, respectively. There were no difference in ES for  $VO_{2max}$  but a statistically higher ES was observed for performance in HM group.

**CONCLUSION:** In summary our data indicates a statistically higher ES for performance in HM versus normoxic training but no differences were observed between ES's of  $VO_{2max}$ .

**Influence Of Body Mass, Body Composition, And Performance State On Total Hemoglobin Mass**

Walter F. Schmidt<sup>1</sup>, Carolin Doerfler<sup>1</sup>, Nadine Wachsmuth<sup>1</sup>, Christian Voelzke<sup>1</sup>, Gunnar Treff<sup>2</sup>, Stefanie Thoma<sup>3</sup>, Juergen Steinacker, FACSM<sup>2</sup>, Andreas Niess<sup>3</sup>, Nicole Prommer<sup>1</sup>. <sup>1</sup>University of Bayreuth, Bayreuth, Germany. <sup>2</sup>University of Ulm, Ulm, Germany. <sup>3</sup>University of Tübingen, Tübingen, Germany.

Email: walter.schmidt@uni-bayreuth.de

(No relationships reported)

**PURPOSE:** To define the separate impact of lean body mass and of endurance performance state on total haemoglobin mass and to evaluate its influence on  $VO_{2max}$ .

**METHODS:** In total, 114 male subjects categorized into 7 performance groups which were characterized by extremely different inter-group body dimensions and endurance performance participated at the study (I. German elite rowers (R, n=15,  $VO_{2max}$  65.7 $\pm$ 6.3 ml/kg/min), II. German elite runners (GR, n=13, 69.0 $\pm$ 3.0ml/kg/min), III. Kenyan elite runners (KR, n=10, 71.5 $\pm$ 5.0ml/kg/min), IV. Body Builders (BB, n=20, 48.2 $\pm$ 7.7ml/kg/min), V. leisure athletes (LA, n=14, 59.5 $\pm$ 6.0ml/kg/min), VI. fit but untrained subjects (UTr, n=10, 51.1 $\pm$ 6.0ml/kg/min), and VII 10.4  $\pm$ 2.4 yrs old fit boys (Y, n=32, 56.6 $\pm$ 6.2ml/kg/min)). tHb-mass was determined using the optimized CO-rebreathing method and  $VO_{2max}$  was measured on a discipline-specific ergometer and calculated to treadmill conditions. Lean body mass was determined using skin fold measurement and was calculated by age-adjusted formulas.

**RESULTS:** Absolute  $VO_{2max}$  ranged from 1010 to 6320 ml/min and tHb-mass from 242g to 1453g showing a very close relationship. Except BB all groups fit well in this relationship (regression analysis without BB:  $r = 0.973$ , BB included:  $r = 0.92$ ). tHb-mass was best related to lean body mass (LBM,  $r = 0.964$ ) and less to body surface area (BSA,  $r = 0.935$ ) and body mass ( $r = 0.919$ ). At identical body mass those groups characterized by high performance state (R, GR, KR) showed ~25% higher tHb-mass than those with low performance (LA, UTr, Y). Comparing both subgroups at identical lean body mass the difference in tHb-mass was reduced to 11.5%.

**CONCLUSION:** In athletes and fit sedentary subjects  $VO_{2max}$  is closely related to tHb-mass over the whole physiological range indicating that the change in 1g haemoglobin is associated with a change in  $VO_{2max}$  by 4.4 ml. tHb-mass mostly depends on lean body mass (16.8g haemoglobin per 1kg LBM), whereas endurance performance has only minor impact. BBs, however, differ from all other groups. Although their tHb-mass is very high due to high LBM, this beneficial precondition can not be converted into high aerobic performance. It is concluded that although high tHb-mass is a prerequisite metabolic adaptations are necessary for high  $VO_{2max}$ .

**Laboratory Performance Evaluations, Time Trial Performance, And Training Intensity Distribution In Elite Masters Cyclists**

Adam D. StPierre, Neal A. Henderson. *Boulder Center for Sports Medicine, Boulder, CO.*

Email: stpierre.adam.d@gmail.com

(No relationships reported)

**PURPOSE:** This study looked at the relationship between laboratory performance evaluations (Lactate Threshold (LT) Power and  $VO_{2max}$ ), simulated time trial (TT) performance, and training intensity distribution in a group of elite masters cyclists.

**METHODS:** On two occasions separated by 7 weeks, 5 males [54.0 $\pm$ 10.0 yr, 73.0 $\pm$ 7.0 kg, 52.02 $\pm$ 3.61 ml·kg<sup>-1</sup>·min<sup>-1</sup>] volunteered to perform an incremental lactate profile and

VO2max test on a cycle ergometer. After a sufficient warm-up, workload started at 100W and increased by 25W every 4 minutes until exhaustion. Two days later the subjects performed a 38km simulated TT using their own bicycles on a computer controlled stationary trainer. The course was programmed to mimic the altitude and distance profile of a local TT course. No training modifications were made; subjects were asked to maintain their normal training and racing patterns for the duration and were asked to record all training using a commercially available power measuring device. All training data were downloaded via commercially available software for analysis.

**RESULTS:** Subjects' body mass was 2.6% lower ( $73.0 \pm 7.0$  kg vs.  $71.2 \pm 7.3$ ;  $p > 0.05$ ) following 7 weeks of training. Subjects completed the 38km TT 4.1% faster ( $1:07:47 \pm 4:20$  vs.  $1:05:00 \pm 3:51$ ;  $p = 0.05$ ) at 8% higher power ( $232 \pm 32$  W vs.  $251 \pm 36$  W;  $p > 0.05$ ). This performance improvement was despite no statistically significant difference in power at LT ( $240 \pm 31$  W vs.  $246 \pm 36$  W;  $p > 0.05$ ) or in absolute VO2max ( $3.84 \pm 0.44$  L/min vs.  $3.97 \pm 0.37$  L/min,  $p > 0.05$ ). Subjects spent  $33.9 \pm 3.0\%$  of their training time at less than 50% of their initial sustained TT power,  $26.4 \pm 8.6\%$  between 50 and 75% of TT power,  $16.9 \pm 1.9\%$  between 75 and 95%,  $3.4 \pm 0.7\%$  from 95-100%,  $6.4 \pm 2.1\%$  from 100-110%,  $9.4 \pm 3.0\%$  from 110-140% of TT power, and  $3.7 \pm 1.9\%$  above 140% of TT power. Subjects trained an average of  $7.6 \pm 3.1$  hours per week (range 12.2 to 3.7).

**CONCLUSIONS:** We conclude that performance improvements may occur without improvement in laboratory variables typically associated with increased performance, namely LT power and VO2max. We also conclude that the training distribution and/or total training time undertaken by our subjects was sufficient to improve TT performance and relative VO2max but insufficient to improve power at LT as defined by our protocol.

**Comparison Of RPE To Blood Lactate Levels In Cyclists Based On Mileage Per Year**

Ryan M. Broxterman, Paul G. Wagner, Patti A. Bender. *Washburn University, Topeka, KS.*

Email: ryan.broxterman@washburn.edu

(No relationships reported)

**PURPOSE:** To examine the effect of number of miles cycled per year on use of the BORG-RPE (6-20) scale to predict blood lactate accumulation while cycling.

**METHODS:** Thirty male cyclists (Age 30-60, mean = 47 years) were grouped according to number of miles ridden per year (group 1 < 100, group 2 = 1000-2000, group 3  $\geq 5000$ ). Subjects completed an incremental stage cycling protocol, increasing resistance every three minutes. Rating of perceived exertion (RPE), revolutions per minute (RPM) and heart rate (HR) were recorded every minute. Blood lactate concentration was collected every 3-min and an additional sample was taken when the subject reported an RPE = 13. Lactate threshold (LT1) was defined as an RPE of 13 on the BORG-RPE scale and by a one millimole (mM) increase in blood lactate accumulation. Onset of blood lactate accumulation (LT2) was defined as a blood lactate concentration of 4.0 mM.

**RESULTS:** There was a significant difference in the RPE reported at LT1,  $p < .042$ . Groups 1 & 2 reported an RPE of 13 (mode) and group 3 reported a mode RPE of 16. However, there was no significant difference between the RPE reported at 4 mM (LT2) of lactic acid accumulation between the three groups. There was a significant difference in heart rate at 175 watts,  $p < .043$ . The mean HR for groups 1, 2, & 3 were 150, 144, & 126 bpm respectively. There was a significant difference in power output between groups 1, 2, & 3 for both LT1 (125W, 150W, 275W) & LT2 (150W, 200W, 325W),  $p < .000$ .

**CONCLUSION:** Training higher than 5000 miles per year is associated with an over estimation of LT1 using RPE. All three groups were able to predict LT2 using RPE. Lactate level coincides with RPE at LT1 and LT2, but it may not be the feedback signal which determines RPE. Subjects may attend to muscular effort rather than metabolic signaling to assess their perceived exertion.

**2793 Board #187 May 29 3:30 PM - 5:00 PM**  
**Energy Expenditure And Comfort During Nordic Walking And Ordinary Walking**

Ernst A. Hansen, Gerald Smith, FACSM. *Norwegian School of Sport Sciences, Oslo, Norway.*

Email: ernst.albin.hansen@nih.no

(No relationships reported)

It is a characteristic of Nordic Walking that energy expenditure is greater during this fitness activity than during ordinary walking. As much as 23% greater energy expenditure has been reported. The amount of extra energy expenditure during Nordic Walking most likely depends on how vigorously the Nordic Walking is performed. However for another important characteristic of fitness exercise, it is unknown how comfort compares for Nordic Walking and ordinary walking.

**PURPOSE:** To compare energy expenditure and comfort during Nordic Walking and ordinary walking.

**METHODS:** Twelve participants (mean  $\pm$  SEM: 171.5  $\pm$  1.5 cm, 67.0  $\pm$  2.7 kg, 50.6  $\pm$  2.4 years, maximal oxygen uptake of  $43.4 \pm 2.8$  ml  $\text{kg}^{-1} \text{min}^{-1}$ ) performed 6-min bouts of uphill ( $12^\circ$ ), downhill ( $12^\circ$ ), and horizontal Nordic Walking as well as ordinary walking on a motorized treadmill with their preferred pole length of  $67.6 \pm 0.6\%$  of body height. Energy expenditure was calculated from measured oxygen uptake while comfort was self-rated on a 1- to 10-point scale where 1 and 10 corresponded to "very, very uncomfortable" and "very, very comfortable", respectively.

**RESULTS:** Nordic Walking required as much as  $65 \pm 12\%$  greater energy expenditure ( $p < 0.05$ ) than ordinary walking with the greatest difference observed for the horizontal condition. During uphill and downhill conditions, energy expenditure for Nordic Walking was  $8 \pm 2\%$  and  $55 \pm 12\%$  higher, respectively ( $p < 0.05$ ). Nevertheless, comfort was similar for the two types of locomotion for each slope ( $p > 0.05$ ). Illustrating the peculiarity of Nordic Walking, comfort was  $7.3 \pm 0.6$  at the same time as participants exercised at more than 85% of their maximal oxygen uptake during uphill Nordic Walking.

**CONCLUSION:** Comfort responses were generally high and at the same time similar for Nordic Walking and ordinary walking for each slope condition despite greater energy expenditure during Nordic Walking. The substantially larger energy expenditure of Nordic Walking compared to previous studies reflects the particularly vigorous Nordic Walking technique used here. From a physical activity and public health perspective it is noteworthy that Nordic Walking (vs. other forms of physical activity, e.g. running) is comfortable and apparently gentle on the body for many people, even when performed at a considerable cardiovascular load.

---

**2794 Board #188 May 29 3:30 PM - 5:00 PM**  
**The Onset And Magnitude Of Cardiovascular Drift Depend On Exercise Intensity In Recreational Runners.**

Jena Winger, Kristi Murphy, Stasinios Stavrianeas. *Willamette University, Salem, OR.*

(No relationships reported)

Cardiovascular drift (CVD) is a gradual increase in heart rate (HR) during prolonged steady-state exercise. Despite considerable research on the etiology of this complex phenomenon, little is known as to the effects of CVD on energy consumption.

**PURPOSE:** To examine the potential effects of CVD on aerobic and anaerobic metabolism. **METHOD:** Recreational runners ( $n=10$ , age  $40.3 \pm 8.3$  years, height  $176 \pm 7$  cm, weight  $71.29 \pm 10.76$  kg,  $\text{VO}_{2\text{max}}$   $57.29 \pm 5.96$  ml  $\cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) volunteered for this study and signed informed consent forms. Each participant performed 5 running tests 2-4 days apart: a maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ) test (2-min stages to exhaustion), a Maximal Lactate Steady State test (MLSS), and 3 prolonged submaximal bouts (45 min duration each) at intensities corresponding to 95%, 100%, and 105% of the MLSS velocity (1% grade). HR and  $\text{VO}_2$  were recorded continuously throughout all tests; blood lactate was measured at the end of each stage during the first 2 tests, and every 10 minutes for the 3 prolonged bouts. All protocols were approved by the IRB.

**RESULTS:** Only 3 runners were able to complete the 105% MLSS bout. Onset of CVD was different for every participant, often with no HR plateau in the 105% MLSS bout. Small differences in exercise intensity ( $0.22 \text{ m} \cdot \text{sec}^{-1}$ ) yielded statistically significant ( $p < 0.05$ ) differences across the three intensities in the amplitude of CVD (increases of 7 BPM, 14 BPM, and 18 BPM for the 95%, 100%, and 105% respectively),  $\text{VO}_2$  ( $1.42 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ,  $1.8 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , and  $1.39 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  respectively), and blood lactate ( $0.25 \text{ mmol} \cdot \text{L}^{-1}$ ,  $0.88 \text{ mmol} \cdot \text{L}^{-1}$ , and  $1.08 \text{ mmol} \cdot \text{L}^{-1}$  respectively) between steady state and minute 40.

**CONCLUSION:** We successfully measured the small changes associated with the metabolic cost of exercise during CVD. Our data conclusively indicate that the onset of CVD is affected by the intensity of exercise and the amplitude of CVD is greater as exercise intensity increases.

**A Test For Determining Critical Heart Rate Using The Critical Power Model**

Michelle Mielke<sup>1</sup>, Terry J. Housh, FACSM<sup>1</sup>, Moh H. Malek<sup>2</sup>, Travis W. Beck<sup>3</sup>, C. R. Hendrix<sup>1</sup>, Jorge M. Zuniga<sup>1</sup>, Clayton L. Camic<sup>1</sup>, Richard J. Schmidt<sup>1</sup>, Glen O. Johnson, FACSM<sup>1</sup>. <sup>1</sup>University of Nebraska-Lincoln, Lincoln, NE. <sup>2</sup>University of California-San Diego, LaJolla, CA. <sup>3</sup>University of Oklahoma, Norman, OK.

Email: mmielke@unlserve.unl.edu

(No relationships reported)

The critical power (CP) test relates the amount of work accomplished at exhaustion ( $W_{lim}$ ) and the time to exhaustion ( $T_{lim}$ ) and, theoretically, estimates the maximum power output (P) that can be maintained for an extended period of time without fatigue. The CP test, however, overestimates the exercise intensity that can be sustained over time and a significant, progressive increase in the metabolic intensity is observed until exhaustion.

**PURPOSE:** The purpose of this study was to apply the CP model to heart rate (HR) data to propose a HR based analog of the CP test called the critical heart rate (CHR) test. The CHR was compared to the HR values at CP ( $CP_{HR}$ ), ventilatory threshold ( $VT_{HR}$ ), and respiratory compensation point ( $RCP_{HR}$ ).

**METHODS:** Ten adults (mean age  $\pm$  SD =  $23 \pm 1$  years) performed an incremental (30W increase every 2 minutes) test to exhaustion on an electronically braked ergometer for the determination of  $VO_{2peak}$ , VT, and RCP. The subjects also performed four randomly ordered workouts to exhaustion at different power outputs (ranging from 100 to 246W) for the determination of CP and CHR. For each power output, the total number of heart beats that occurred were calculated as the product of the average 5-second HR (bpm) and total time to exhaustion (min). The total number of heart beats and work (kgm) for each of the four power outputs were plotted as a function of the  $T_{lim}$  at each power output. The CHR and CP were defined as the slope coefficients of the regression lines between total number of beats or  $W_{lim}$  and  $T_{lim}$ , respectively. The HR values from the incremental test were plotted against power output or  $VO_2$  values and the regression equations derived were used to determine the HR that corresponded to CP, VT, and RCP.

**RESULTS:** A one-way repeated measure ANOVA indicated that CHR ( $165 \pm 11$  bpm,  $91.7 \pm 3.1\%$   $HR_{max}$ ) was not significantly different from  $RCP_{HR}$  ( $169 \pm 10$  bpm,  $91.9 \pm 5.5\%$   $HR_{max}$ ), but was significantly higher than  $CP_{HR}$  ( $149 \pm 13$  bpm,  $82.6 \pm 5.5\%$   $HR_{max}$ ) and  $VT_{HR}$  ( $153 \pm 15$  bpm,  $83.2 \pm 6.3\%$   $HR_{max}$ ).

**CONCLUSIONS:** The relationship between HR and  $T_{lim}$  from the CHR test can be described by the CP model. The CHR test may be a practical method for estimating RCP. Furthermore, the use of a constant HR instead of P may provide an exercise intensity that prevents the progressive increase in metabolic intensity observed until exhaustion during the CP test.

---

**2796 Board #190 May 29 3:30 PM - 5:00 PM**  
**Age, Gender, And Run Time As Determinants Of Pacing In The Marathon**

Mackenzie L. Hoops, Paul M. Vanderburgh, FACSM, Daniel S. March. University of Dayton, Dayton, OH. (Sponsor: Paul M. Vanderburgh, FACSM)

(No relationships reported)

**PURPOSE:** To determine the independent influences of age, gender, and run time on marathon pacing. Pacing was defined as the mean velocity (min/mile) of the first 20.2 miles (32.5 km) divided by that of the last six miles (9.7 km), expressed as a percentage.

**METHODS:** Subjects were 186 men and 133 women marathoners from the 2005, 2006, and 2007 races of a midwest US marathon. The course was a one-mile (1.6 km) loop with pace markers throughout, thus facilitating pacing strategy. Split times were measured electronically via shoe chip for each mile. The February event ensured that ambient temperature (never above 5 deg C), was not a factor in hyperthermia, a condition known to substantially slow marathon times and affect pacing.

**RESULTS:** Multiple regression analysis revealed that female, older or faster runners demonstrated more consistent pacing than male, younger or slower marathoners ( $p < 0.01$  for each predictor and overall explained variance was 18%). No two- or three-way interactions were statistically significant. These effects are quantified in the table below.

**CONCLUSIONS:** This is the first study, to our knowledge, that has examined and quantified the independent effects of age, gender, and run time on marathon pacing. Future studies should examine the influence of other factors and/or confounders such as effort or body composition.

Sample Effects of Predictors	
Predictor	Change in Pacing (%)
Gender: F vs. M	+4.06
Age: 55 vs. 25 yr	+7.30
Run Time: 3:00 vs. 4:30	+10.71

**2797 Board #191 May 29 3:30 PM - 5:00 PM**  
**Hydration Monitoring Of Elite Mountain Bike Riders During Preparation For The 2008 Beijing Olympic Games**

Nigel Mitchell, Kevin Currell. English Institute of Sport, South Yorkshire, United Kingdom.

Email: nigel.mitchell@eis2win.co.uk

(No relationships reported)

The Olympic mountain bike cross country event takes approximately 2 hours to complete, it is one of the longest endurance events of the Olympic Games. The riders can be susceptible to dehydration which may not only influence performance but be detrimental to health.

**PURPOSE:** The aim of the study was to assess hydration status of elite mountain bike riders during a training camp and to compare two different methods of assessing hydration status. This data was used to inform individualised hydration strategies for riders preparing for the 2008 Beijing Olympic Games.

**METHODS:** Eleven international (8M, 3F, Mean Age:  $19 \pm 4$  y) mountain bikers were assessed. Measures of urine osmolality (UO) (Osmocheck, Vitech Scientific Ltd) and urine specific gravity (USG) using urine analysis dip sticks (Healchex, Q-Tech Medical LTD UK) were taken from three consecutive mornings and two consecutive evenings during a training camp as part of the preparation of the 2007 World Championships. Self reported fluid intake was also measured on day one and day two. Hypohydration was set at a UO of greater than 700 mOsmols/kgH<sub>2</sub>O and a USG of 0.020. Measures of UO and USG were compared using Pearsons correlation coefficient. Change in UO and USG over the camp was analysed using a one way ANOVA. Post hoc analysis was undertaken with Tukeys HSD.

**RESULTS:** There was a significant correlation between UO and USG ( $r = 0.71$ ,  $p < 0.05$ ). There was no significant difference between morning UO on all three days (Day 1 AM mean = 521,  $s = 156$  mOsmols/kgH<sub>2</sub>O, Day 2 AM mean 550,  $s = 107$  mOsmols/kgH<sub>2</sub>O, Day 3 AM mean 588,  $s = 115$  mOsmols/kgH<sub>2</sub>O). No significant difference was shown between morning USG throughout all three days (Day 1 AM  $1.012 \pm 0.005$ , Day 2 AM mean 1.012,  $s = 0.003$ , Day 3 AM mean 1.012,  $s = 0.003$ ). Measurement of UO and USG both showed two individuals to be hypohydrated on Day 1 AM, and one person to be hypohydrated on both Day 2 AM and Day 3 AM. There was no significant

difference between total drink volume consumed between day one (mean 4.2 L, s = 0.7 L) and day two (mean 4.6 L, s = 1.7 L).

**CONCLUSION:** Athletes maintained hydration status throughout the camp. The use of a urine analysis dip stick was a convenient way to monitor hydration status through USG and can be easily used in the field. These data influenced hydration strategies in preparation of the 2008 Beijing Olympic Games.

**Variation Between Repeated Time-To-Exhaustion Trials Reduced With Utilization Of An Objective Exclusion Criteria.**

Rebecca W. Moore<sup>1</sup>, Bryan M. Ausink<sup>2</sup>, Michael J. Saunders, FACSM<sup>2</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>James Madison University, Harrisonburg, VA.

(No relationships reported)

**PURPOSE:** Time to exhaustion (TTE) protocols are widely used to assess endurance performance. However, the subjective endpoint of this method can contribute to increased variance between trials. Our purpose was to determine if an objective criteria for determining successful TTE completion reduced error variance between repeated trials.

**METHODS:** Ten recreational exercisers (age = 24±5 yrs;  $\dot{V}O_{2max}$  = 53.6±9.9 mL·kg<sup>-1</sup>·min<sup>-1</sup>) completed a TTE protocol consisting of a 75 minute cycle at 70%  $\dot{V}O_{2max}$  followed by a treadmill run to exhaustion at 80%  $\dot{V}O_{2max}$ . Subjects completed two TTE trials. In trial 1, all subjects were instructed to run until volitional exhaustion. In Trial 2, five subjects were similarly instructed to provide a maximal effort until exhaustion (ME). The other 5 subjects received instructions to cease running when they estimated they could complete only 10 additional minutes of exercise (SME). Peak isometric force (MVC) of the leg extensors was assessed pre-exercise and immediately post-exercise. An objective MVC criteria was used to exclude subjects who did not successfully complete the TTE trials. Subjects TTE data was excluded if their MVC declined <10% from pre-exercise levels, and their lowest MVC decline occurred in their shortest TTE trial.

**RESULTS:** Prior to application of the exclusion criteria, there was a relatively low correlation (r=0.31) and high variation (CV=34.2%) between repeated trials, partially due to the inconsistent efforts of the SME group. The exclusion criteria eliminated three subjects from the analysis, which improved the correlation (r=0.61) and CV (24.3%) between trials.

**DISCUSSION:** The MVC criteria correctly eliminated the two subjects with the greatest variance between TTE trials, and significantly reduced the total error variance between trials. Thus, using % MVC decline as an objective TTE completion criteria may reduce error variance by identifying subjects who are unable to provide consistent efforts between trials. Refinement of the existing criteria may result in further improvement in consistency between trials, as not all SME trials were identified by the present criteria.

**Effects Of Inspiratory Muscle Training On Arterial Oxygen-hemoglobin Saturation In Female Collegiate Endurance Runners**

L. R. Brilla, FACSM, K. L. Schwerdtfeger, K. M. Knutzen, FACSM, B. S. Row. Western Washington University, Bellingham, WA.

Email: Lorrie.Brilla@wwu.edu

(No relationships reported)

**PURPOSE:** The current exploratory study was conducted to determine if inspiratory muscle training [IMT] can enhance arterial oxygen-hemoglobin saturation during exercise. Such enhancement may alleviate exercise induced arterial hypoxia, if present, in runners.

**METHODS:** Seven female collegiate endurance runners performed 5 weeks of daily IMT, while five subjects served as controls for comparison. Training was 5 sets of 12 repetitions per set. To assess the effectiveness of the training program, two treadmill endurance tests were performed pre and post IMT training. Oxygen-hemoglobin saturation [SaO<sub>2</sub>] and minute ventilation [V<sub>E</sub>] were measured during the endurance tests. Resting maximal inspiratory pressure [MIP] was also measured pre and post IMT. A two-way analysis of variance with one repeated factor was used to determine whether inspiratory muscle training affected respiratory function as measured through MIP, V<sub>E</sub>, and SaO<sub>2</sub>.

**RESULTS:** MIP improved from 91.89 ± 42.54 to 113.20 ± 39.54 cm H<sub>2</sub>O (p<0.05) in the trained subjects, with no significant difference in controls, 71.36±18.0 and 65.44±21.81 cm H<sub>2</sub>O. The treatment group's SaO<sub>2</sub> pre test 91.51 ± 4.73% and post test 90.29 ± 6.29% were similar to control subjects, 92.7±3.02% and 93.21±2.75, respectively. V<sub>E</sub> pre test and post test for the treatment group were 74.06 ± 8.52 L/min and 77.73 ± 6.72 L/min, compared to 67.53±15.05 and 71.71. Three of the treatment subjects did demonstrate improved SaO<sub>2</sub>. Two of these subjects also improved V<sub>E</sub>. The control group remained unchanged from pre to post testing.

**CONCLUSION:** While there were individual responses to IMT there were no statistically significant improvements seen in SaO<sub>2</sub> and V<sub>E</sub> following 5 weeks of daily IMT in female collegiate endurance runners.

**2801 Board #195 May 29 3:30 PM - 5:00 PM**

**Activity Does Not Explain The Greater Skeletal Muscle Mass In Masters Swimmers**

Colleen M. McCracken, Louisa D. Raisbeck, Sandy Tecklenburg-Lund, Jonathon L. Stickford, Joel M. Stager, FACSM. Indiana University, Bloomington, IN.

(No relationships reported)

**INTRODUCTION:** Previous research has shown Master Swimmers to have greater muscle mass when compared to members of the general population (GP) regardless of age. However, it is an assumption that all Masters swimmers are necessarily more physically active than the GP. Masters swimmers were thus sought out in an effort to characterize the impact of a highly active lifestyle skeletal muscle mass.

**METHODS:** Three hundred and sixty-two masters swimmers completed questionnaires to assess recent self-reported physical activity status. Subjects were stratified by low and high activity levels with the resulting 35 respondents compared separately by sex and activity (low n = 9, n = 6, high n = 10, n = 10 for men and women, respectively). Muscle mass was tested through bioelectric impedance analysis using an eight-lead segmental analyzer. Data was analyzed using SPSS with one sample, independent sample t-tests and ANCOVAs.

**RESULTS:** Statistical analysis from independent samples t-tests of activity indicated differences between those performing the lowest (women, 265.0 ± 39.87 min/wk; men, 223.3 ± 33.91 min/wk) and highest (women, 1182.0 ± 176.75 min/wk; men, 1071.0 ± 152.34 min/wk) weekly activity. Additionally, one-sample t-test for the lowest reported activity for both sexes and the data that obtained for the general population yielded no differences between the groups (p > 0.05). However, ANCOVA showed muscle mass did not differ between any groups even when body surface area, age, or height is co-varied.

**CONCLUSIONS:** It can be concluded that simply being a registered member of United States Masters Swimming does not necessarily assure that an individual is highly active. Additionally, muscle mass in those who are highly active does not appear to be solely dependent upon recent activity level even when accounting for body surface area, age and height. This may indicate other factors, perhaps more long term in nature, influencing muscle mass with advancing age.

Email: iizuka.taro@jiss.naash.go.jp  
(No relationships reported)

International-class speed skaters continue travelling around the world to participate in international and national competitions during a competition season. Although such tight schedule might induce tiredness, they are required to maintain their physical and mental conditions in good states to achieve good performance throughout the season. It is not well known, however, whether their physical and mental conditions are actually being maintained throughout a competition season.

**PURPOSE:** To estimate and compare the physical and mental conditions at the beginning and at the end of a competition season in international-class speed skaters.

**METHODS:** Six international-class speed skaters (23.2±1.7 yrs) participated in the study. Data were collected every morning during the first (Japan Single Distances Championships: JSDC, Oct, 2007) and the last (World Single Distances Championships: WSDC, Mar, 2008) competition in their 2007/2008 season, both held in Nagano. Beat-to-beat heart rate (HR) were recorded for five minutes under the controlled breathing of 15 breaths per minute. Frequency domain heart rate variability (HRV) indices were obtained using spectral analysis by fast Fourier transform. The spectral power in the low-frequency (LF: 0.04-0.15Hz) and the high-frequency (HF: 0.15-0.40Hz) bands were calculated. In addition, normalized units (LFnu and HFnu) and the ratio of LF/HF index were obtained. HF and HFnu represent parasympathetic activity and the ratio of LF/HF represents an evaluation of the autonomic nervous system balance. The subjects were also asked to fill a questionnaire in which they estimated their subjective mood states on a visual analog scale.

**RESULTS:** HFnu were significantly lower in WSDC than those in JSDC (27.1±3.5 vs. 47.3±4.9,  $p<0.01$ ). Moreover, the LF/HF ratio and the mean HR were tended to be higher in WSDC than those in JSDC (3.66±0.84 vs. 1.66±0.53,  $p=0.08$  and 59.3±2.2 vs. 54.4±2.1 beats/min,  $p=0.06$ , respectively). As for the subjective mood states, there was a tendency of lower subjective feeling of vigor in WSDC than those in JSDC (33.5±7.9 vs. 43.8±8.7,  $p=0.06$ ).

**CONCLUSION:** These results suggest that the physical and mental conditions in the international-class speed skaters might be altered in the course of the competition season.

**Effect Of Prior Warm-up On Oxygen Uptake Kinetics During An 800-m Performance Trial**

Stephen A. Ingham<sup>1</sup>, Barry W. Fudge<sup>1</sup>, Jamie S. Pringle<sup>1</sup>, Andrew M. Jones, FACSM<sup>2</sup>. <sup>1</sup>English Institute of Sport, Loughborough, United Kingdom.  
<sup>2</sup>University of Exeter, Exeter, United Kingdom.  
Email: steve.ingham@eis2win.co.uk  
(No relationships reported)

**PURPOSE:** This study investigated the effect of two different warm-up regimes on pulmonary V[dot]O<sub>2</sub> kinetics during an 800-m running time trial.

**METHODS:** Eleven well-trained middle distance runners undertook a laboratory-based progressive exercise test to determine V[dot]O<sub>2</sub>max, and on two further occasions, an indoor 800-m performance trial. Performance trials were preceded by a 10-min self-paced jog and standardised mobility drills followed by either 6x50m 'strides' (control, CON) or 2x50m strides and a continuous high-intensity 200m run (WU). All warm-up runs were performed at race-pace. Blood lactate was measured before and after the warm-up and performance trial. Oxygen uptake was measured breath-by-breath during all performance trials and subsequently modelled using non-linear regression techniques. The perceived race 'readiness' of the subjects was assessed by questionnaire.

**RESULTS:** Prior to the performance trial, baseline blood [lactate] was (mean ± SD) 1.8 ± 0.3 mM greater after WU compared to CON control ( $P<0.001$ ). Participants reported significantly greater readiness in WU vs. CON, ( $P<0.05$ ). The mean response time for the V[dot]O<sub>2</sub> response was no different between groups (27.4 ± 6.4 vs 28.0 ± 7.1 s,  $P = 0.73$ ). Peak V[dot]O<sub>2</sub> attained (WU, 4214 ± 848 vs CON, 3913 ± 633 ml.min<sup>-1</sup>;  $P=0.156$ ) and total O<sub>2</sub> consumed (WU, 119.1 ± 18.2 vs CON, 108.7 ± 27.8 ml.min<sup>-1</sup>.kg<sup>-1</sup>,  $P=0.11$ ) showed tendencies towards a greater response for WU.

**CONCLUSIONS:** These data suggest that a longer duration warm-up promotes readiness for time trial performance. Whilst the mean response time was unaffected by warm-up method, the data suggest a greater contribution from oxidative processes during the performance trial following WU, as indicated by the ~ 8% greater peak V[dot]O<sub>2</sub> attained and total O<sub>2</sub> used.

**Stability Of Running Economy In Men And Women Division I Collegiate Basketball Players**

Rebecca A. Rudey<sup>1</sup>, Karissa Peyer<sup>1</sup>, Joshua J. Ode<sup>2</sup>, Jeremy L. Knous<sup>2</sup>, James M. Pivarnik, FACSM<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI.  
<sup>2</sup>Saginaw Valley State University, University Center, MI.  
Email: rudeyreb@msu.edu  
(No relationships reported)

Previous running economy studies have focused on individual, rather than team sports, and have not examined the stability of this variable as athletes mature.

**PURPOSE:** The purpose of our study was to compare running economy of NCAA Division I basketball players between their first and second years of college. **METHOD:** Anthropometrics (height, weight, % fat) were obtained on 38 (13 women, 25 men) NCAA Division I basketball players. Following these measures, all participants completed a discontinuous maximal treadmill protocol that featured alternating 3 min run and 90 sec rest stages. Expired respiratory gases (SensorMedics 2900) and heart rate (EKG) were measured continuously throughout, and finger stick blood samples (for blood lactate) were obtained during rest stages. Oxygen consumption (VO<sub>2</sub>) at the third min of stages 1 (VO<sub>2</sub>-1; 6 mph, 0% grade) and 2 (VO<sub>2</sub>-2; 6 mph, 5% grade) was used as an index of running economy. Changes in VO<sub>2</sub>-1, VO<sub>2</sub>-2, VO<sub>2</sub>max, % fat, and lactatemax were calculated by subtracting year one from year two values. Differences in running economy between years were evaluated using ANOVA. Pearson correlations were run (using absolute values and change scores) between VO<sub>2</sub>-1 and VO<sub>2</sub>-2 (dependent variables) and VO<sub>2</sub>max, % fat, and lactatemax (independent variables).

**RESULTS:** Running economy did not differ between freshman and sophomore years in either women (freshman VO<sub>2</sub>-1=34.7±0.8, sophomore VO<sub>2</sub>-1=33.4±0.8; freshman VO<sub>2</sub>-2=40.8±2.3, sophomore VO<sub>2</sub>-2=40.9±3.4) or men (freshman VO<sub>2</sub>-1=35.8±3.1, sophomore VO<sub>2</sub>-1=34.7±3.3; freshman VO<sub>2</sub>-2=42.4±3.1, sophomore VO<sub>2</sub>-2=42.9±2.7). Running economy was most strongly associated with VO<sub>2</sub>max and change in VO<sub>2</sub>max. This relationship was found to be stronger in women ( $R^2=0.31-0.64$ ) than in men ( $R^2=0.16-0.50$ ). Although, on average, running economy is stable from freshman to sophomore year, individual changes ranged from -6.3 to 4.6 ml.kg<sup>-1</sup>.min<sup>-1</sup> in VO<sub>2</sub>-1 and -7.3 to 9.1 ml.kg<sup>-1</sup>.min<sup>-1</sup> in VO<sub>2</sub>-2, and were significantly related to changes in VO<sub>2</sub>max.

**CONCLUSIONS:** On average, running economy remains stable over the first year of a varsity basketball player's collegiate career. Despite this, wide variability in change existed on an individual basis. Additional research is needed to determine the factors that may help a player improve his or her running economy.

**2805 Board #199 May 29 3:30 PM - 5:00 PM**  
**Effect During A Short Distance Duathlon Laboratory Simulation On Fat And Carbohydrate Oxidation Rate**

Mauro Ronconi<sup>1</sup>, Carlos González-Haro<sup>2</sup>, José Ramón Alvero-Cruz<sup>1</sup>, Margarita Carrillo<sup>1</sup>, Jerónimo García-Romero<sup>1</sup>, Angel Mario Diego Acosta<sup>1</sup>, Marisol Soria<sup>3</sup>, Jesús Escanero<sup>3</sup>, Iñigo San Millán<sup>4</sup>. <sup>1</sup>School of Sports Medicine (University of Málaga), Málaga, Spain. <sup>2</sup>School of Medicine (University of Zaragoza), Barcelona, Spain. <sup>3</sup>School of Medicine (University of Zaragoza), Zaragoza, Spain. <sup>4</sup>University of Colorado Sports Medicine Center and University of Colorado Hospital, Denver, CO.  
(No relationships reported)

**PURPOSE:** To assess the effects of a sprint distance duathlon laboratory simulation on FAT<sub>ox</sub> and CHO<sub>ox</sub>.

**METHODS:** 8 national level duathletes performed two incremental laboratory tests until exhaustion on a cycle ergometer (Initial workload: 60 W, stages: 30 W·min<sup>-1</sup>) and on a treadmill (Initial workload: 5 km·h<sup>-1</sup>, stages: 1 km·h<sup>-1</sup>) respectively to determine exercise intensities. Further on, subjects performed a laboratory simulation competition of a sprint distance duathlon (S<sub>1</sub>: 20 min running, S<sub>2</sub>: 45 min cycling, and S<sub>3</sub>: 12 min running) at a fixed exercise intensity of 90 %HR<sub>max</sub>. All subjects drank an amount of 475 ± 35 mL of water during the test. VO<sub>2</sub>, VCO<sub>2</sub>, and heart rate (HR) were measured and averaged for each sector. CHO<sub>oxr</sub> and FAT<sub>oxr</sub> were estimated by estequiometric equations. Physiological variables throughout the test were analyzed using repeated measurements ANOVA.

**RESULTS:** Exercise intensity expressed as %FC<sub>max</sub> was maintained throughout the test (S<sub>1</sub>: 91.0 ± 2.8 %, S<sub>2</sub>: 89.8 ± 3.8 %, and S<sub>3</sub>: 89.7 ± 4.3 %). A significant reduction in VO<sub>2</sub> (47.1 ± 6.9 vs. 43.1 ± 5.6 mL·kg<sup>-1</sup>·min<sup>-1</sup>, p<0.01), and running speed (15.6 ± 0.6 vs. 14.9 ± 1.0 km·h<sup>-1</sup>, p<0.001) was observed between S<sub>1</sub> and S<sub>3</sub>. A progressive reduction in CHO<sub>oxr</sub> and a progressive increase in FAT<sub>oxr</sub> were observed during the whole laboratory simulation test.

		S1	S2	S3
FAT <sub>oxr</sub>	(g·min <sup>-1</sup> )	0.38 ± 0.32 <sup>a, b</sup>	0.56 ± 0.23 <sup>a, c</sup>	0.74 ± 0.33 <sup>b, c</sup>
%FAT <sub>oxr</sub>	(%)	41.8 ± 34.0 <sup>d, e</sup>	65.5 ± 17.3 <sup>d, f</sup>	83.6 ± 14.6 <sup>e, f</sup>
CHO <sub>oxr</sub>	(g·min <sup>-1</sup> )	3.23 ± 1.65 <sup>g, h</sup>	1.64 ± 0.80 <sup>g, i</sup>	1.48 ± 1.01 <sup>h, i</sup>
%CHO <sub>oxr</sub>	(%)	77.4 ± 13.6 <sup>j, k</sup>	41.5 ± 11.3 <sup>j, l</sup>	33.5 ± 15.8 <sup>k, l</sup>

a, b, c, d, e, f, g, h, i, j p<0.001

**CONCLUSION:** Despite exercise intensity expressed as %FC<sub>max</sub> was controlled, running speed and VO<sub>2</sub> diminished between S<sub>1</sub> and S<sub>3</sub> as a possible effect of cardiovascular drift. Short distance duathlon laboratory simulation elicited an important limitation on CHO<sub>oxr</sub> as a possible effect of CHO stores depletion, and an increase of FAT<sub>oxr</sub> as a possible compensatory mechanism to maintain the intensity of exercise.

**2806 Board #200 May 29 3:30 PM - 5:00 PM**  
**Heart Rate, Blood Lactate And Time-motion Analysis Of Female Basketball Players During Competition**

anne delextrat. *London Metropolitan University, London, United Kingdom.*

Email: a.delextrat@londonmet.ac.uk

(No relationships reported)

Previous studies show average heart rate (HR) from 169 to 183 beats·min<sup>-1</sup> (89% of HR<sub>max</sub>) and an average number of 26.7 jumps and 13.6 sprints per game in female basketball players. However, in May 2000, basketball rules changed. The new rules have led to an increase in the game intensity and a higher cardiac work in male players.

**PURPOSE:** to investigate the physiological demands and movement patterns of female basketball players competing under the new rules of the game.

**METHODS:** 9 female university basketball players (25.8±2.5 years old, 172.8±4.7 cm, 63.2±4.5 kg, 19.9±3.4% of body fat) were studied during 9 games in the premiership league. During each game, HR was measured at 15-s intervals using Polar S810 heart rate monitors (Polar, Kempele, Finland), blood samples were taken to analyse [La]<sup>-</sup> between quarters, during timeouts, or during player substitution (Analox LM5, Analox Instruments Ltd., London, UK). In addition, video recordings of matches (JVC-x400 Hong Kong, China) were used to determine the frequencies of the main movements performed by the players. Differences in physiological parameters between the quarters and halves of the game were analysed by a one-way ANOVA and a student T-test for paired samples, respectively. Statistical significance was set at p<0.05.

**RESULTS:** The mean HR was 165.0±9.0 beats·min<sup>-1</sup> (89.8% of HR<sub>max</sub>) and the mean [La]<sup>-</sup> was 5.2±2.7 mmol·L<sup>-1</sup> (55.9% of [La]<sup>-</sup>max). In addition, HR was significantly higher in the first half compared to the second half (166.3±9.4 vs. 163.3±9.0 beats·min<sup>-1</sup>, P<0.01), whereas no significant effect of time was observed on [La]<sup>-</sup> (P>0.05). Video analysis showed that players performed on average 67±17 jogs, 52±19 runs, 49±17 sprints, 117±14 low-intensity shuffles, 123±45 medium-intensity shuffles, 58±19 high-intensity shuffles and 35±11 jumps.

**CONCLUSION:** These results indicated first, that the changes in the rules of the game have increased the intensity of the game, and second that less movements are performed during a game by female compared to male players.

**2807 Board #201 May 29 3:30 PM - 5:00 PM**  
**Stability Of Power Output Before And After Training In Beginner Rowers**

Karissa Peyer<sup>1</sup>, Rebecca A. Battista<sup>2</sup>, Carl Foster, FACSM<sup>2</sup>, James M. Pivamik, FACSM<sup>1</sup>, Chris Dodge<sup>2</sup>. <sup>1</sup>*Michigan State University, East Lansing, MI.*

<sup>2</sup>*University of Wisconsin - La Crosse, La Crosse, WI.*

(No relationships reported)

Repeated exposure to a novel rowing time trial task, as well as training may enhance pacing strategy development and improve performance.

**PURPOSE:** Our purpose was to evaluate time and power output (PO) during repeated rowing time trials before and after training.

**METHODS:** Ten participants with no previous rowing experience (7 women, 3 men) completed two 2000-meter time trials (T1 and T2) on a Concept II rowing ergometer with instructions to finish as quickly as possible. Time trials were performed 2-4 days apart. 500m pace, PO (watts) and stroke rate (strokes/min) (SR) were recorded every 100m. All participants then completed four weeks of ergometer training, using both variable and constant pacing strategies. After training, participants completed two additional 2000-meter time trials (T3 and T4). Finally, a graded maximal exercise test to fatigue was completed on the ergometer to estimate aerobic fitness (VO<sub>2max</sub>). Time, PO, and SR across trials were analyzed using repeated measures ANOVA. Pearson correlations were used to compare changes after training (T2 to T3) in these three outcome variables with VO<sub>2max</sub>.

**RESULTS:** Average time to completion was (T1=616 ± 147, T2=590 ± 123, T3=563 ± 93, T4=559 ± 93 sec) average PO was (T1=125 ± 78, T2=137 ± 82, T3=146 ± 75, T4=149±75 watts) and average SR was (T1=34±4, T2=33±4, T3=35±3, T4=35±3 strokes/min). Although time and PO improved from T1 to T2, only changes in PO achieved statistical significance (P<0.05). Significant improvements were seen in time and PO from T1 to T3 and T4. We found a weak relationship between participants' VO<sub>2max</sub> and change in time (r = 0.33) and power (r = -0.25) but a significant association between VO<sub>2max</sub> and change in stroke rate (r=0.65; P<0.05).

**CONCLUSION:** Based on these findings, beginning rowers become faster and produce greater PO through both repeat performance and training. Fitter participants were more likely to increase stroke rate with training. Results suggest a rapid learning of technique with minimal exposure to the task. Decrease in time between T1 and T3 suggest a training effect occurred and more than one trial may be needed to accurately gauge performance in this novel task. Smaller differences in time and PO between T3 and T4 suggest progress may occur in smaller increments once basics of the task are learned.

**Validation Of A 1-day Maximal Lactate Steady-state Protocol For Running**

Naroa Etxebarria. *English Institute of Sport/Loughborough University, Loughborough, United Kingdom.* (Sponsor: Susan Shirreffs, FACSM)

Email: Naroa.etxebarria@eis2win.co.uk

(No relationships reported)

Laboratory assessment of maximal lactate steady state (MLSS) has traditionally involved a time-consuming series of submaximal tests over multiple days.

**PURPOSE:** To validate a modified (1-day) protocol for determining the MLSS running velocity (MLSSv).

**METHODS:** Six endurance-trained athletes (age  $26 \pm 5$  y; height  $1.72 \pm 0.03$  m; body mass  $65.0 \pm 5.4$  kg;  $\text{O}_2$  peak  $60.0 \pm 7.1$  ml·kg<sup>-1</sup>·min<sup>-1</sup>; mean  $\pm$  SD) participated in this study. Each participant completed an initial progressive incremental treadmill test to determine submaximal and maximal  $\text{VO}_2$ , and lactate threshold (LT) velocity. LT was determined as the velocity before a  $>1$  mM increase in lactate concentration. After a 7-day break participants performed the modified single day (MLSS-1-d) to estimate the MLSSv. The new MLSS-1-d involved an initial 15-min bout at the LT velocity followed by a series of 10-min bouts increasing by  $0.5$  km·h<sup>-1</sup> until steady state conditions were lost. After a further 7-day break participants then performed the traditional multi-day (MLSS-multi) protocol involving at least three 30-min tests on different days as the criterion measure of MLSSv. Data were log-transformed and validity of the new method established in both raw units and % error (with 90% confidence limits) using linear regression.

**RESULTS:** The mean ( $\pm$  SD) values for MLSSv were  $13.9 \pm 1.4$  km·h<sup>-1</sup> for MLSS-1-d and  $14.0 \pm 1.5$  km·h<sup>-1</sup> for MLSS-multi, and  $2.7 \pm 0.6$  mM and  $2.9 \pm 0.8$  mM for the LT, respectively. The standard error of estimate (90% confidence limits) for MLSSv using MLSS-1-d was  $0.18$  ( $0.12$ - $0.43$ ) km·h<sup>-1</sup> and  $1.2$  ( $0.7$ - $2.8$ )%. The corresponding estimates for LT were  $0.45$  ( $0.29$ - $1.07$ ) mM and  $19.4$  ( $12.2$ - $52.2$ )%. Correlations between the two methods were  $r=0.99$  ( $0.96$ - $1.00$ ) for the MLSSv and  $r=0.75$  ( $0.02$ - $0.97$ ) for the LT.

**CONCLUSION:** The MLSS-1-d is a viable practical alternative to the traditional multi-day protocol for estimating the MLSSv in distance runners. However, the substantial noise in the estimate of the LT precludes use of this measure until further refinements are made to the protocol.

(No relationships reported)

**PURPOSE:** The aim of the study was to compare the physiological characteristics and performance measures between elite adolescent soccer players that are retained or rejected by professional soccer clubs.

**METHODS:** Fifteen, highly-trained adolescent soccer players (English Premier League) (Mean  $\pm$  SD,  $14.6 \pm 0.9$  years, peak:  $54.7 \pm 6.5$  mL·kg<sup>-1</sup>·min<sup>-1</sup>, Self-assessed Tanner stage range 2 - 4) were divided into two groups, successful (retained by the club for future development) and unsuccessful (rejected by the club). All subjects completed laboratory tests to measure  $\text{VO}_2$  peak, body composition and resting cardiac structure and function. Tests included a cycle ergometer test to exhaustion pedaling at 60 rpm with 3-minute stages of 35 W load increments; standard gas exchange variables were measured. Body fat percentage was assessed using a Bod Pod, and Cardiac dimensions at rest were measured by M-mode echocardiography. Stroke volume was estimated by Doppler interrogation, of aortic flow velocity. Following laboratory testing, all subjects' running sprint performance was assessed over 10 (Spr10) and 20 (Spr20) meters, electronic timing gates were used for accurate measurement.

**RESULTS:** The successful players were significantly older ( $14.9 \pm 0.9$  versus  $13.9 \pm 0.2$  yrs,  $p=0.03$ ), taller ( $170.2 \pm 6.6$  versus  $160.8 \pm 4.1$  cm,  $p=0.01$ ), heavier ( $60.2 \pm 8.5$  versus  $49.2 \pm 6.5$  kg,  $p=0.03$ ), and had a lower body fat percentage ( $8.5 \pm 4.1$  versus  $16.2 \pm 4.7$  %,  $p=0.02$ ). The successful players were significantly faster (Spr10:  $1.9 \pm 0.1$  versus  $2.0 \pm 0.1$  sec,  $p=0.03$ , Spr20:  $3.2 \pm 0.2$  versus  $3.5 \pm 0.1$  sec,  $p=0.02$ ), and had greater absolute  $\text{VO}_2$  peak values ( $3.4 \pm 0.5$  versus  $2.5 \pm 0.4$  L·min<sup>-1</sup>,  $p=0.01$ ). Left ventricular end diastolic dimension (LVED) was significantly larger in the successful players ( $51.8 \pm 3.1$  versus  $47.9 \pm 2.1$  mm BSA<sup>-0.5</sup>,  $p=0.03$ ). There were no significant differences between groups for relative  $\text{VO}_2$  peak, left ventricular end systolic dimension (LVES), cardiac output at rest, and stroke volume at rest.

**CONCLUSIONS:** The present data indicate that successful adolescent soccer players are physically more mature and consequently have greater performance capacity. This suggests that early maturing adolescents are at an advantage when competing in age group soccer.

**2810 Board #204 May 29 3:30 PM - 5:00 PM**  
**A Comparison Of The Physiological Demands Of Two Commercially Available Cycle Ergometers In Trained Cyclists**

Gregory C. May, Eimear Dolan, Paula A. Fitzpatrick, Giles Warrington, FACSM. Dublin City University, Dublin, Ireland.

(No relationships reported)

Cycling ergometers are routinely used in a laboratory setting to evaluate physiological function and monitor changes in training status. One limitation of many cycle ergometers, in relation to the performance testing, is their inability to replicate the cyclist own specific cycling position thereby bringing the validity of the ergometer used into question.

**PURPOSE:** The purpose of this study was to compare the aerobic and anaerobic energy demands of two commercially available cycle ergometers in trained cyclists. The first ergometer allowed full adjustment of cycling position and was electromagnetically braked (EB). The second ergometer allowed for saddle height adjustment only and was resistance braked (RB).

**METHODS:** Ten trained male cyclists were tested on 2 separate occasions within a 14 day period under the same conditions. Subjects performed a 30 second Wingate maximal sprint test followed 60 minutes later by a continuous maximal incremental step test on either the EB or RB cycle ergometer, in a random order. The Wingate test was performed at 9% of body mass and for 30 seconds with a 5 second speed up period. The incremental test started at 100W and increased in resistance by 50W every 3 minutes until volitional exhaustion. Heart rate,  $\text{VO}_2$ , power output and blood lactate were measured during the maximal test.

**RESULTS:** The results showed a significant difference ( $p<0.01$ ) for the Wingate test between the RB and EB both in terms of peak power output ( $W_{\text{max}}$ ) and mean power output ( $W_{\text{mean}}$ ) with subjects generating greater power outputs on the EB. During the maximal incremental test, significant differences ( $p<0.01$ ) were found between EB and RB for submaximal power output, heart rate, and  $\text{VO}_2$  at both lactate threshold 1 (1mmol rise above baseline, LT1) and onset of blood lactate accumulation (4mmol blood lactate reading, OBLA), as well as peak power output at  $\text{VO}_{2\text{max}}$  ( $\text{PMAX}$ ).

**CONCLUSIONS:** Overall it was shown that significant differences in physiological demands were present between the two ergometers under both anaerobic and aerobic conditions. This is may in part be explained by the different positions that the cyclists adopted on either ergometer. Further research is required to compare the findings of the current study with actual cycling performance.

**Effect Of Altering Tempo Of The Pre-match Warm-up On Skills In Youth Soccer**

Viswanath B. Unnithan, FACSM, Matthew Pook. Liverpool Hope University, Liverpool, United Kingdom.

Email: unnithv@hope.ac.uk

(No relationships reported)

The physiological consequences of a pre-match warm-up before a soccer match has been hypothesized to increase muscle temperature and range of joint movement, with a view to lowering the risk of injury during exercise. It is believed, however, that the warm-up can affect the soccer player's technical performance during competition and, therefore, the result of a match may rely on how effective the warm-up routine is.

**PURPOSE:** The aim of the study was to compare a high (HT)-and low-tempo (LT) pre-match warm-up on soccer-specific skills in a group of youth soccer players.

**METHODS:** 19 male, youth soccer players volunteered to participate in the study (Age:  $16.9 \pm 0.9$  years, Stature:  $1.73 \pm 0.05$  m and Body Mass:  $64.7 \pm 10.7$  kg). The players taking part in this study were highly trained (Number of years playing competitive soccer:  $8.6 \pm 3.1$ ; Hours per week training:  $13.7 \pm 4.8$ ). All players participated in a HT

(Heart rate:  $160 \pm 6$  beats·min<sup>-1</sup>) and a LT (Heart rate:  $132 \pm 6$  beats·min<sup>-1</sup>) warm-up lasting ten minutes. The tempo was modified by altering the dimension of the warm-up area and altering the speed of ball movement between players. Following each warm-up, the subjects carried out five skills test (Ball Control, Dribbling with a Pass, Dribbling Speed, Passing, and Shooting).

**RESULTS:** Significant differences ( $p < 0.05$ ) were identified between LT and HT for Ball Control (HT:  $35 \pm 2$  vs. LT:  $28.0 \pm 3.0$ , number of touches in 90 s) and approached significance for Shooting Skills (HT:  $16.1 \pm 4.2$  vs. LT:  $13.9 \pm 3.9$  points,  $p = 0.08$ ). No significant difference between HT and LT were identified for: Dribbling with a Pass (HT:  $7.34 \pm 1.00$  vs. LT:  $7.49 \pm 0.88$ ), Dribbling Speed (HT:  $13.11 \pm 1.55$  vs. LT:  $13.73 \pm 1.27$  s) and Passing (HT:  $2.4 \pm 1.6$  vs. LT:  $2.6 \pm 1.6$  successful passes).

**CONCLUSION:** A high-tempo warm-up can enhance certain technical skills of youth soccer players. It is possible to speculate that this can be achieved through improved proprioception and preactivation mechanisms.

**2812 Board #206 May 29 3:30 PM - 5:00 PM**  
**Time Of Day Does Not Affect Measures Of Performance While Cycling**

Erin Wilfong, Mindy Frederick, Kenneth Krings, Don Hoover. *Rockhurst University, Kansas City, MO.*

Email: don.hoover@rockhurst.edu

(No relationships reported)

**PURPOSE:** Studies have investigated a number of physiological and biomechanical variables which can impact cycling training and performance. Time of day (TOD) is a factor believed by many to influence the quality of training and performance, yet this topic has received little attention as it relates to cycling. Understanding the impact of TOD may help scientists better understand factors which influence physiological processes and help coaches develop training programs which improve performance and reduce risk of injury or overtraining. This study investigated the influence of TOD on measures physiology, perceived exertion, or gross motor performance.

**METHODS:** Fourteen avid recreational cyclists ( $47.20 \pm 11.93$  yr,  $181.40 \pm 5.85$  cm,  $80.58 \pm 7.67$  kg) volunteered for this study. Each completed three submaximal exercise bouts during two separate sessions, one session starting at 6:00am and the other at 6:00pm. The trials were performed at workload (Watts) to bodyweight (kg) ratios of 1.5:1, 2.0:1, and 2.5:1. The order of the two sessions and three workloads were randomized. Potential confounding variables such as caffeine use were controlled. Dependent measures of heart rate (HR), perceived exertion (RPE and OMNI), and gross motor performance (SpinScan™ and average torque angle) were collected throughout each trial.

**RESULTS:** A two-way within-subjects analysis of covariance ( $2 \times 3$ ) was conducted to evaluate the effect of TOD on dependent variables. No significant differences ( $p < .05$ ) were found for TOD in all dependent measures of HR, perceived effort (RPE and OMNI), or gross motor performance while cycling (SpinScan™ and average torque angle). There also were no significant differences ( $p < 0.05$ ) found related to the covariate of usual training time (AM vs. PM).

**CONCLUSIONS:** Based on the results of this study, TOD did not significantly affect performance measures during steady state cycling. Thus, the findings did not support the common observation that some individuals are "not morning people" (or vice versa) as it relates to the quality of performance during physical activities such as cycling. Additional study is needed on factors which may influence perceptions relating to TOD and exercise.

**Effect Of Conjugated Linoleic Acid And Exercise On Body Composition In Mice**

Carolina Amâncio Sasaki<sup>1</sup>, Cesar Marra<sup>2</sup>, Ricardo Jacó Oliveira<sup>1</sup>. <sup>1</sup>UCB, Brasília, Brazil. <sup>2</sup>IPCFEx, Rio de Janeiro, Brazil.

Email: carolnutri81@hotmail.com

(No relationships reported)

The effects of Conjugated Linoleic Acid (CLA) on body composition were investigated.

**PURPOSE:** Evaluate the effects of CLA supplementation associate to the Physical Exercise on Mice Wistar Body Composition.

**METHODS:** 24 healthy males Wistar mice, age 87 days. After a period 7 day of adaptation where the mice consumed water and diet *ad libitum*. Temperature and humidity of air were controlled in the range of 22°C and 60% to 70%, respectively. The mice were randomized into 3 groups (control and experimental) and supplemented by 60 days. The supplemented groups received CLA in the concentrations of 1% about the daily consumption of diet. The control group received corn oil to 1% of the daily consumption of the diet. The feed was supplied *ad libitum* daily and always was weighed the offer of the day. The next day, the remainder was analyzed the total amount of food ingestion. The animals of the exercise group accomplished a program of physical activity in a tank with water, 30 minute of swimming in a frequency of 3 times/week, supporting equivalent overload to 5% of the body weight of each coupled animal to the thorax. The animals were divided into next groups:- (PLA) group without physical activity and without CLA (1% of corn oil); - (CLA) group without physical activity and with CLA (1% of CLA); - (CLAEX) group with physical activity and with CLA (1% of CLA). For the statistical analysis was accomplished ANOVA TWO WAY for repeated measures and test "t" of student to verify the differences of % Body Fat (%BF) ( $p > 0.05$ ).

**RESULTS:** The average of %BF after are showed in table. There was significant difference between PLA and CLA and CLAEX ( $p < 0.001$ ).

Effect of CLA and Physical Exercise on Body Fat (%) in Mice			
	PLA n = 8	CLA n = 8	CLAEX n = 8
Body Fat (%)	$51.52 \pm 0.03$	$42.26 \pm 0.007 *$	$34.14 \pm 0.01 *$

**CONCLUSIONS:** The results suggest that CLA supplementation and exercise show significant effect on Body Fat (%) in Mice.

( I. Cheng, USD4000, Salary; NO, Royalty; NO, Intellectual Property; NO, Consulting Fee; NO, Honoraria; USD45000, Contracted Research; NO, Ownership Interest.)

**PURPOSE:**The present study was designed to examine the effects of coingestion of HCA with post-exercise carbohydrate supplementation on human skeletal muscle glycogen resynthesis.

**METHODS:** Six healthy active male volunteers (age,  $22.00 \pm 0.27$  years) completed two experimental trials. Subjects performed a 60-min cycling exercise at 70-75% Vo<sub>2</sub> max separated 7 days. After exercise, subjects consumed either a high carbohydrate meal (control group) or coingestion of HCA with high carbohydrate meal (HCA group). Postprandial blood samples were obtained at 30 min intervals for 3 h during exercise recovery. Muscle samples were obtained on vastus lateralis immediately after the exercise and 3 h after post-exercise.

**RESULTS:** There were significant increase in muscle glycogen resynthesis in HCA group compared to control group ( $P < .05$ ). Following exercise, the HCA group produced a significant lower insulin secretion level ( $P < .05$ ) and no different blood glucose response, respiratory exchange ration, and carbohydrate oxidation compared to control group ( $P > .05$ ). During post-exercise recovery, the HCA groups showed significant higher in total fat oxidation compared to control group ( $P < .05$ ). Both diets resulted in a rapid reduction in NEFA and glycerol after post-exercise carbohydrate supplementation with the presence or absence of HCA coingestion and no significant difference between these two groups.

**CONCLUSIONS:** the present study suggested that coingestion of HCA with carbohydrate supplementation during post-exercise recovery could be an effective way to enhance muscle glycogen resynthesis.

Email: g926077@ms3.ctust.edu.tw

( Y. Chu, USD300, Salary; STUDENT, Royalty; 0, Intellectual Property; 0, Consulting Fee; MASTER, Honoraria; 0, Contracted Research; 0, Ownership Interest.)

**PURPOSE:** The aim of the present study was designed to examine the influences of coingestion of hydroxycitrate (HCA) with post-exercise supplementation on substrate transporters in human skeletal muscle.

**METHODS:** Six healthy active male volunteers (age,  $22.00 \pm 0.27$  years) completed two experimental trials. Subjects performed a 60-min cycling exercise at 70-75% VO<sub>2</sub> max separated 7 days. After exercise, subjects consumed either a high carbohydrate meal (control group) or coingestion of HCA with high carbohydrate meal (HCA group).

**RESULTS:** Muscle samples were obtained on vastus lateralis immediately after the exercise and 3 h after post-exercise. There were increase of FAT/CD36 mRNA and FAT/CD36 protein expressions in the this study. No difference on GLUT4 mRNA levels and protein expressions between the presence or absence of coingestion of HCA after post-exercise carbohydrate supplementation. In the carbohydrate utilization viewpoint, coingestion of HCA does not affect the glucose transporting into muscular cells after post-exercise carbohydrate supplementation.

**CONCLUSIONS:**The suggestion of the present study was that coingestion of HCA with post-exercise carbohydrate supplementation up-regulation of FAT/CD36 mRNA and increased FAT/CD36 protein expressions and it means that fat utilization was increased in skeletal muscle during post-exercise recovery.

**Effect Of Rhodiola Crenulata And Cordyceps Sinensis-based Oral Supplementation On Exercise Stress Test In Altitude**

Lu-Ling Cheng<sup>1</sup>, Chiu-Chou Chen<sup>1</sup>, Hsien Chin Yu<sup>1</sup>, Li Yen Tsao<sup>2</sup>, Chia Hua Kuo<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Taipei College of Business, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: iris8888@ms22.hinet.net

(No relationships reported)

**PURPOSE:** To determine the effect to Rhodiola Crenulata and Cordyceps Sinensis-Based Oral Supplementation on muscle oxygenation after exercise at sea-level and altitude.

**METHODS:** Eighteen male subjects were weight-matched and evenly divided into 2 groups: Oral *Rhodiola Crenulata* and *Cordyceps Sinensis* (RC) supplementation and Placebo groups. A standardized 3-min step test was performed at sea-level and altitude (2200 meters). Arterial oxygen saturation (SaO<sub>2</sub>) and muscle tissue oxygenation (StO<sub>2</sub>) were measured before and after exercise. Running performance was determined by graded Bruce's protocol.

**RESULTS:** RC supplementation did not alter maximal oxygen consumption and heart rate recovery on 3-min step test. Blood lactate recoveries following both step test and all-out running was not altered by RC treatment. However, SaO<sub>2</sub> was lower in the RC group than that in placebo group. Conversely, total hemoglobin concentration and percent oxygen saturation in muscle tissue were significantly greater in the RC group than those in the placebo group.

**CONCLUSIONS:** Despites RC supplementation has no significant acute effect on exercise performance, this supplementation resulted in a greater oxygen delivery to skeletal muscle.

**Factors Related To The Status Of b-carotene**

Chien Jung Chu<sup>1</sup>, Wen Yu Chan<sup>2</sup>, Jin Jong Chen<sup>2</sup>, Wei Fong Kao<sup>2</sup>, Shun Ping Lin<sup>2</sup>, Kai Yang Tseng<sup>2</sup>. <sup>1</sup>Soochow University, Taipei, Taiwan. <sup>2</sup>National Yang-ming University, Taipei, Taiwan.

Email: c239750@scu.edu.tw

(No relationships reported)

Significant reactive oxygen species (ROS) generation after prolong and heavy exercises have been well documented. It has been suggested that carotenoids from antioxidant supplements may be an effective tool for measuring body antioxidant capacity which would protect subjects from exercise-induced oxidative damages.

**PURPOSE:** to investigate the relationship among the b-carotene status, antioxidant supplementation and exercise training.

**METHODS:** Seventy-four healthy subjects including 36 marathon runners (MR) and 38 sedentary individuals (age:  $47.67 \pm 1.98$  years, body weight:  $62.83 \pm 1.37$  kg; mean $\pm$ SEM) participated in this study. Antioxidant b-carotene counts of all 74 subjects' palms were examined using a non-invasive Raman spectroscopy. This method had been proved to be a valid evaluation of the human carotenoids status. A questionnaire including items of the fruit quantity and antioxidant supplementation frequency in recent two weeks was filled to investigate the antioxidant intake of subjects.

**RESULTS:** (1) MR had significant higher b-carotene level than sedentary subjects ( $31361 \pm 1800.9$  VS  $23342.1 \pm 1418.4$ ,  $p < .05$ ; mean $\pm$ SEM). (2) Sedentary individuals with supplements had significant higher b-carotene level than without supplementation group ( $29166.7 \pm 3323.1$  VS  $20653.8 \pm 1092.6$ ,  $p < .05$ ; mean $\pm$ SEM). (3) b-carotene level of MR with supplements is similar to MR without supplementation group ( $32666.7 \pm 3306.1$  VS  $30428.6 \pm 2040.1$ ,  $p < .05$ ; mean $\pm$ SEM).

**CONCLUSION:** (1) MR had significant higher b-carotene status than sedentary subjects majorly due to regular exercise training effects. (2) Antioxidant supplements might be important for sedentary individuals to improve their antioxidant capacity.

**2818 Board #212 May 29 2:00 PM - 3:30 PM**

**Prophylactic Supplementation Of A Nano-sized Silica Mineral Antioxidant Complex On Changes In Clinical Safety**

## Parameters And Body Water.

Scott E. Hassell, Chad M. Kerkisick, Michael D. Roberts, Vincent J. Dalbo, Jordan R. Moon. *University of Oklahoma, Norman, OK.*

(No relationships reported)

A nano-sized silica mineral antioxidant complex (MIC) is purported to alter cellular chemistry kinetics by delivering reduced hydrogen ions to the cell and reducing blood lactate levels. Further, the chemical structure of MIC supports osmotic traits that may impact levels of body water.

**PURPOSE:** This study examined the effects of 7 days of prophylactic MIC supplementation on changes in clinical safety parameters and body water.

**METHODS:** On three occasions, fifteen males (23.6  $\pm$  3.7 yrs, 180  $\pm$  8 cm, 85  $\pm$  11 kg, 16  $\pm$  5 %) were tested using identical procedures under a control (CON), rice flour placebo (PLA) and microhydrin (MIC) condition. PLA and MIC supplementation was done in a prophylactic fashion over a seven day period (4 x 250 mg capsules/day). After controlling for diet and exercise habits, participants arrived fasted and donated a blood sample before and after supplementation for determination of serum and whole blood clinical safety markers. Total body (TBW), extracellular (ECW) and intracellular (ICW) water measurements using bioelectrical impedance spectroscopy were taken before and after supplementation and before and after a peak  $\text{VO}_2$  test. Repeated measures (2 x 3) ANOVA were completed on all variables using a p-value of 0.05.

**RESULTS:** No significant changes ( $p > 0.05$ ) were found for any component of the lipid and metabolic panels, kidney/liver enzymes, markers of protein breakdown and complete blood counts. Supplementation resulted in no change in TBW ( $p = 0.43$ ), ECW ( $p = 0.65$ ) and ICW ( $p = 0.38$ ) after each condition. Similarly, no significant group x time interactions were found for ECW ( $p = 0.19$ ), although TBW ( $p = 0.09$ ) and ICW ( $p = 0.052$ ) tended to change. Significant time effects for TBW ( $p < 0.01$ ) and ICW ( $p < 0.001$ ) were found. Within-group analysis of post-exercise body water revealed significant increases in ICW in PLA (+0.51 L;  $p < 0.005$ ) and MIC (+0.43 L;  $p < 0.01$ ) along with a significant increase in TBW for MIC (+0.59 L;  $p < 0.01$ ).

**CONCLUSION:** Clinical safety markers did not change after seven days of prophylactic MIC supplementation and was well tolerated. MIC supplementation did not stimulate any changes in body water compartments, while immediate increases in TBW and ICW after maximal exercise were found. Post-exercise ICW levels increased in PLA and MIC while TBW only increased in MIC.

#### Effects Of Various Sodium Bicarbonate Loading Protocols On Blood Buffering And Perceived Readiness For Exercise

Adrian W. Midgley<sup>1</sup>, Jason C. Siegler<sup>1</sup>, Remco C.J. Polman<sup>2</sup>, Lars R. McNaughton, FACSM<sup>1</sup>. <sup>1</sup>University of Hull, Hull, United Kingdom. <sup>2</sup>University of Central Lancashire, Preston, United Kingdom.

(No relationships reported)

The performance-enhancing effects of sodium bicarbonate ( $\text{NaHCO}_3$ ) are associated largely with the degree of metabolic alkalosis, which is altered by the dosage and timing of ingestion.

**PURPOSE:** To investigate the effects of various  $\text{NaHCO}_3$  loading protocols on the time-dependent buffering profile and the perceived physical and mental readiness for intense exercise.

**METHODS:** Eight male volunteers (age,  $22.4 \pm 5.7$  yrs; height,  $179.8 \pm 9.6$  cm, body mass,  $76.3 \pm 14.1$  kg) completed: *Part A*) measures of alkalosis and perceived readiness for intense exercise throughout 120 min following ingestion of various single  $\text{NaHCO}_3$  dosages ( $0.3 \text{ g} \cdot \text{kg}^{-1}$ ,  $0.2 \text{ g} \cdot \text{kg}^{-1}$ ,  $0.1 \text{ g} \cdot \text{kg}^{-1}$  and placebo); and *Part B*) similar profiles following alternative  $\text{NaHCO}_3$  loading protocols [single morning dosage (SMD), single evening dosage (SED) and dosages ingested on three consecutive evenings (CED)].

**RESULTS:** *Part A*) Although the blood buffering was relatively constant in the 0.1 and 0.2 conditions, it was significantly higher at 60 min than at 100 min and 120 min in the  $0.3 \text{ g} \cdot \text{kg}^{-1}$  condition ( $p < 0.05$ ). Subjects exhibited greater perceived readiness for exercise at 120 min than at 30 min ( $p = 0.015$ ) and 60 min ( $p = 0.037$ ). *Part B*) Blood buffering for SMD was higher than for SED and CED ( $p < 0.05$ ), yet at 11:00 hrs mental readiness was significantly lower in the SMD condition.

**CONCLUSION:** The single 0.2 and  $0.3 \text{ g} \cdot \text{kg}^{-1}$   $\text{NaHCO}_3$  dosages appeared to be the most effective for increasing blood buffering capacity and best ingested 90 min before exercise, as sooner will reduce perceived readiness towards exercise.

---

### 2820 Board #214 May 29 2:00 PM - 3:30 PM

#### Effects Of L-arginine Supplementation On Pre And Post Maximal Exercise Inflammatory Response

Brian Kennell, Matthew R. Feeback, Eric Corbett, Jon B. Naylor, Ronald Ottestetter. *The University of Akron, Akron, OH.* (Sponsor: Gary Kami Mori, FACSM)

Email: kennell@uakron.edu

(No relationships reported)

**PURPOSE:** To determine if varying acute doses of l-arginine supplementation pre-exercise has an immediate effect on pre-exercise and post-exercise inflammatory response.

**METHODS:** Twenty five male subjects were given oral supplementation of the amino acid l-arginine 30 minutes prior to performing a maximal exercise test. Blood draws were taken pre-supplementation, post-supplementation/pre-exercise, and post exercise. Treatments included a 3 g dose (LD), a 6 g dose (HD) of l-arginine, and a placebo (PLA) for the control trial. A complete blood count was performed, using white blood cells (WBC) as a marker of inflammatory response. Linear regression was tested to determine if acute treatment accounted for a significant proportion of unique variance in WBC.

**RESULTS:** The results showed an overall significant difference between treatments ( $p = 0.031$ ). LD began at a higher WBC count but had a smaller increase in WBC count over time. HD and the PLA started near the same baseline level with a near identical slope and increase of time. The linear regression of the treatment shows time interaction to account for significant proportion of unique variance in WBC count. When taken as unique significance factors the LD treatment and time interaction was found to be significant ( $p = 0.048$ ). PLA and HD treatment were not found to be significant over time. Regardless of supplementation amount or usage, WBC count increased post-exercise. WBC count decreased following supplementation, but before exercise. A maximal dose response was also observed, as the best result was seen with the LD while the HD and PLA were similar.

**CONCLUSIONS:** For the subjects tested, an acute low dose supplementation of l-arginine decreased inflammatory response. A higher dose did not augment the decrease. Future studies might investigate chronic supplementation or the optimal acute supplementation.

---

Email: fatouros@otenet.gr

(No relationships reported)

Hemodialyzed patients (HD) demonstrate elevated oxidative stress and reduced functional status. Although exercise induces health benefits, acute exertion upregulates oxidative stress responses in HD patients. Carnitine has been postulated to have antioxidant properties.

**PURPOSE:** To investigate the effects of L-carnitine (LCAR) supplementation on performance and oxidative stress responses of HD patients.

**METHODS:** Twelve male HD patients (53.1±2.5 yrs) received either LCAR (intravenous infusion following each dialysis session, 20 mg/kg) or placebo (P, saline of equal dose) in a counterbalanced, double-blinded design, for eight weeks. Participants performed an exercise test to exhaustion before and post-supplementation. During the test,  $\dot{V}O_2$ , respiratory exchange ratio (RER), heart rate, and time-to-exhaustion were monitored. Blood samples, collected before and post-exercise, were analyzed for lactate, thiobarbituric acid-reactive substances (TBARS), protein carbonyls (PC), reduced (GSH) and oxidized glutathione (GSGG), antioxidant capacity (TAC), catalase, and glutathione peroxidase (GPX) activity.

**RESULTS:** Blood carnitine increased only in LCAR post-supplementation proportionately at rest and post-exercise. LCAR increased endurance (22%), decreased lactate (37%), RER, and submaximal heart rate but did not affect  $\dot{V}O_{2peak}$ . LCAR ingestion reduced TBARS by 19% and 10%, PC by 40% and 27%, and increased GSH/GSSG by 2.7-fold and 4-fold, at rest and post-exercise respectively, while increased GPX activity post-exercise by 10%.

**CONCLUSIONS:** The results of the present investigation suggest that LCAR intravenous infusion for two months may be effective in attenuating oxidative stress responses, enhancing antioxidant status, and improving performance of patients undergoing chronic haemodialysis treatment.

**Impact Of Silica Hydride Supplementation On Aerobic Exercise Parameters In College-Aged Males**

Vincent J. Dalbo, Michael D. Roberts, Scott E. Hassell, Jordan R. Moon, Patrick S. Tucker, Jeffrey R. Stout, FACSM, Chad M. Kerksick. *University of Oklahoma, Norman, OK.*

Email: vinnyjames@ou.edu

(No relationships reported)

A mineral based supplement purported to contain silica hydride (SH) has been suggested to bind reduced hydrogen ions which may serve to buffer hydrogen ion concentrations during aerobic exercise.

**PURPOSE:** The purpose of this study was to examine the effects of seven days of SH supplementation on physical and cognitive markers of aerobic exercise performance.

**METHODS:** Male participants (N = 15, 23.1 ± 0.8 yrs, 180.0 ± 2.1 cm, 83.4 ± 2.8 kg, 16.4 ± 1.3%) were tested on three occasions using identical testing procedures under a control (CON), rice flour placebo (PLA) and SH. PLA and SH supplementation consisted of seven-day periods in which participants consumed 4 x 250 mg capsules/day. Following the 7-day supplementation period participants arrived at the laboratory in a fasted state and completed a  $\dot{V}O_2$  peak test on a cycle ergometer. Blood lactate levels and ratings of perceived exertion (RPE) were assessed immediately pre-exercise, at 1.5 minute intervals starting 5 minutes following the initiation of exercise, and 5 minutes post-exercise. Separate one-way ANOVAs were performed for the assessment of time to exhaustion (TTE), time to ventilatory threshold (VT), time to respiratory quotient (RQ) of 1.0,  $\dot{V}O_2$  peak, peak power (PP), power at VT, heart rate at PP, TTE after VT and TTE after reaching a RQ of 1.0. Separate 3 x 8 RM ANOVAs with Tukey post hoc comparisons were used to examine blood lactate and RPE responses during testing. For each statistic a p-value of < 0.05 was used to determine significance.

**RESULTS:** A significant time effect was found for RPE and blood lactate, as the exercise protocol became more difficult and resulted in a significant increase in blood lactate over time. No significant differences between conditions were found for any of the examined performance variables.

**CONCLUSIONS:** SH supplementation had no buffering effect on blood lactate concentrations and presented no performance enhancing benefits. As a result, future research should examine if increasing the dosage and/or supplementation period affects blood lactate and/or performance outcomes.

**Effect Of Co-enzyme Q<sub>10</sub> Supplementation On Muscle Blood Flow And Metabolism In Type 2 Diabetics With Peripheral Artery Disease**

Joohee Im<sup>1</sup>, Sinclair A. Smith<sup>2</sup>, Guqiang Yu<sup>3</sup>, Gwen Lech<sup>3</sup>, Britton Chance<sup>3</sup>. <sup>1</sup>Shippensburg University, Shippensburg, PA. <sup>2</sup>Drexel University, Philadelphia, PA. <sup>3</sup>University of Pennsylvania, Philadelphia, PA. (Sponsor: William A. Braun, FACSM, FACSM)

Email: jisanders@ship.edu

(No relationships reported)

The dietary supplement co-enzyme Q<sub>10</sub> (CoQ<sub>10</sub>) is a potent antioxidant and a component of the electron transport chain which has been shown to improve muscle metabolism and blood flow.

**PURPOSE:** The purpose of this study was to determine the impact of CoQ<sub>10</sub> supplementation on muscle metabolism and blood flow in type II diabetes (T2D) patients with mild peripheral artery disease (PAD) compared to a non-diabetic control group.

**METHODS:** Seven T2D patients (69.9±5.1 years) and 7 matched controls (67.0±8.9) were tested 2 weeks post placebo (week 2) and 2 weeks post CoQ<sub>10</sub> supplementation (week 4). During each testing session the participants performed a 12 s dynamic plantar flexion exercise during which medial gastrocnemius muscle PCr and pH were measured using <sup>31</sup>P magnetic resonance spectroscopy. Muscle oxygen saturation and blood flow were simultaneously measured using near infrared spectroscopy. The placebo and CoQ<sub>10</sub> dosage was 200 mg/day. Two-way ANOVA and Newman-Keuls post-hoc tests were used to determine differences.

**RESULTS:** Comparing the T2D patients to the controls in the placebo trial, there were no differences in resting PCr (37.8±3.2 vs. 41.1±2.1 mM), end exercise PCr (17.2±6.5 vs. 20.6±5.8 mM), or resting pH (7.02±0.02 vs. 7.01±0.04). However, end exercise pH (6.98±0.07 vs. 7.00±0.04), PCr recovery rate after exercise (22.3±13.4 vs. 49.4±36.6 mM/kg/min), and blood flow index (5.3±2.9 vs. 9.7±2.9 %/s) were lower for the T2D patients (p<0.03). The time for muscle oxygen saturation recovery to 50% (70.9±52.1 vs. 31.8±8.4 s) was longer for the T2D patients (p<0.01). Comparing the placebo trial to the CoQ<sub>10</sub> trial, there were no differences (p=0.96 to 0.47) between any of the variables measured for either the T2D patients or the control group.

**CONCLUSIONS:** Our results show that there are significant muscle metabolic and hemodynamic differences between T2D patients and controls as expected. Two weeks of CoQ<sub>10</sub> supplementation at 200 mg/day however, did not significantly impact these metabolic or hemodynamic measures in either group. The lack of significance may be due to the relatively short supplementation period and low dosage. When blood flow is severely compromised, studies suggest that a higher CoQ<sub>10</sub> dose and/or a longer dosing period may be needed to elicit a significant impact on physiology.

**2824 Board #218 May 29 2:00 PM - 3:30 PM**  
**b-alanine Supplementation Fails To Increase Peak Aerobic Power Or Ventilatory Threshold In Trained Males**

Beau K. Greer<sup>1</sup>, Matthew E. Katalinas<sup>1</sup>, Danielle M. Scarmozza<sup>1</sup>, Paul M. Gallo<sup>2</sup>. <sup>1</sup>Sacred Heart University, Fairfield, CT. <sup>2</sup>Norwalk Community College, Norwalk, CT.

Email: beaugreer@hotmail.com

(No relationships reported)

Previous research reports an increase in aerobic performance and ventilatory threshold (VT) following b-alanine supplementation. However, these studies have not included highly trained subject pools.

**PURPOSE:** To determine the effect of 30 days of b-alanine supplementation (CarnageTM) on VT and peak aerobic power ( $\dot{V}O_2$  peak) in highly fit aerobic athletes.

**METHODS:** Fourteen male runners and triathletes ( $28.8 \pm 9.8$  yrs) were assigned into a b-alanine or Placebo (PL) group. Groups were matched for numbers of runners and triathletes, as well as for VT as a percentage of VO<sub>2</sub> peak. b-alanine supplementation consisted of 3000 mg/day for 7 days, and 6000 mg/day for the remaining 23 days. Before and after the supplementation period, subjects performed a continuous, graded cycle ergometry test to determine VO<sub>2</sub> peak and VT. VT was determined by the intersection of regression lines drawn to fit the upper and lower portions of the Ventilation vs. VO<sub>2</sub> curve. Data was analyzed using a 2 x 2 ANOVA with repeated measures.

**RESULTS:** 30 days of b-alanine supplementation did not increase VO<sub>2</sub> peak ( $4.05 \pm 0.6$  vs.  $4.14 \pm 0.6$  L/min) as compared to the PL group ( $3.88 \pm 0.2$  vs.  $3.97 \pm 0.2$  L/min) ( $p > 0.05$ ). VT did not significantly improve in either the b-alanine ( $3.47 \pm 0.6$  vs.  $3.49 \pm 0.6$  L/min) or PL ( $3.36 \pm 0.2$  vs.  $3.46 \pm 0.1$  L/min) group ( $p > 0.05$ ).

**CONCLUSIONS:** 30 days of b-alanine supplementation had no effect on VO<sub>2</sub> peak or VT in highly trained aerobic athletes. The potential efficacy of b-alanine supplementation need to be further investigated in both trained and untrained populations.

**Muscle Strength And Power Before And After Sublingual Administration Of L-lysine, Co-enzyme Q<sub>10</sub>, And Vitamins And Minerals**

Bert H. Jacobson, FACSM, Doug Smith, Aric Warren, Rob Glass, Crishel Kline, Joanna Fedick, John Stemm. *oklahoma state university, Stillwater, OK.*

Email: bert.jacobson@okstate.edu

(No relationships reported)

When a substance comes in contact with the buccal mucosa on the underside of the tongue it diffuses through the dense capillarized membrane of the area. Most substances may be suitable to sublingual administration if they dissolve readily in saliva and many drugs are much more potent taken sublingually. Factors such as pH, molecular weight, and lipid solubility, determine the rate and strength of absorption. Nutrients, chemicals, and drugs may be administered this manner to provide faster absorption and response.

**PURPOSE:** To determine the effectiveness of a sublingual, ergogenic spray containing vitamins, minerals, an amino acid, and a co-enzyme on muscle performance in highly trained college football players.

**METHODS:** Twenty-three Division I, NCAA offensive and defensive football linemen voluntarily participated in the study after signing a consent form. On day one, all participants were completed a questionnaire, were measured, warmed up, stretched, and were tested on number of maximum bench press repetitions (102kg, [225 lb]), the vertical jump, and grip strength. One week later participants were randomly given the placebo ( $p=11$ ) or the treatment ( $p=12$ ) spray and retested. Administration was double blind and spray containers were marked A and B.

**RESULTS:** Subjects ( $20.11 \pm 1.45$  yrs;  $132.1 \pm 9.85$  kg;  $191.19 \pm 3.85$  cm). Results of repeated measures ANOVAs yielded a significant ( $p=.047$ ) improvement for the experimental group in the bench press. The experimental groups demonstrated greater but not significant improvement in both the vertical jump ( $p=.65$ ) and grip strength ( $p=.74$ ).

**CONCLUSIONS:** While a significant improvement was found for the maximum repetition bench press and positive trends in both the vertical jump and grip strength for the experimental group, it is possible that a standardized dose (4 sprays) is too limiting for individuals averaging over 132 kg (290 lbs) and should be administered based on body weight. The tests used in this study were field-tests and may not be sensitive enough to elicit subtle responses. Additional research should focus on computerized strength testing for greater data discrimination.

**Oxethazaine As The Source Of Mephentermine And Phentermine In Athlete'S Urine**

Mei-Chieh Hsu<sup>1</sup>, Su-Fan Lin<sup>2</sup>, Cheng-Ping Kuan<sup>3</sup>, Wei-Lan Chu<sup>4</sup>, Kuei-Hui Chan<sup>1</sup>, Guo-Ping Chang-Chien<sup>2</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>2</sup>Chengshiu University, Kaohsiung, Taiwan. <sup>3</sup>Agricultural Research Institute, Taichung, Taiwan. <sup>4</sup>Taipei Veterans General Hospital, Taipei, Taiwan.

Email: meichieh1224@mail2000.com.tw

(No relationships reported)

Under the Anti-Doping program, athletes' urine samples were collected and analyzed in-competition and out-of-competition. Samples collected from athletes during the period October 2005 to October 2006 led to ten positive results, revealing the presence of mephentermine in the samples of ten different athletes. These test results were unprecedented. However, one athlete claimed that she only ingested a locally manufactured prescription oxethazaine tablet for relieving gastritis and stomachache.

**PURPOSE:** To understand if ingesting oxethazaine will produce mephentermine.

**METHODS:** Three volunteers (A, B, C) orally ingested 5, 10, 20 mg of oxethazaine, respectively. Urine samples were collected ad lib in polyethylene bottles and stored at -20 °C until analysis. The urine was analyzed for the phentermine and mephentermine by liquid chromatography-tandem mass spectrometry (LC-MS-MS) method.

**RESULTS:** Subjects A and B provided samples for the 1-6 hrs periods. Subject C provided samples for the 1-16 hrs periods. Phentermine was not detected (lower than LOD) in urine samples from subject A; it was probably due to the low amount of oxethazaine (5 mg) ingested. Both mephentermine and phentermine were detected in samples from subjects B and C. Moreover, we found out that 48 brands of gastric medicines containing oxethazaine were legally imported or locally manufactured in Taiwan.

**CONCLUSION:** Oxethazaine was the source of mephentermine and phentermine. This information is useful for the prevention athletes misusing oxethazaine. The data suggested that the sports associations should warn the athletes about the risks for taking oxethazaine.

**The Urine Metabolic Enantiomeric Differences On Famprofazone Ingestor And Methamphetamine Abuser**

Kuei-Hui Chan<sup>1</sup>, Chen-Yu Tseng<sup>1</sup>, Wei-Lan Chu<sup>1</sup>, Daphne Chen<sup>2</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>2</sup>University of California, San Diego, San Diego, CA.

Email: quenhuen@ty.ntsuo.edu.tw

(No relationships reported)

Famprofazone is an antipyretic and analgesic that also has some slight sympathomimetic properties. It is a component of the multi-ingredient medication used for pain relief. This drug has been demonstrated to be metabolized to methamphetamine (MA) and amphetamine (AM) following administration and has been shown to produce a positive urinary test result.

**PURPOSE:** To distinguish the differences of enantiomeric composition of MA and AM in urine following famprofazone administration or MA abuser.

**METHODS:** Six healthy volunteers, with a mean age ( $\pm$ standard deviation, SD) of  $25.2 \pm 1.9$  yrs, weight of  $79.0 \pm 14.1$  kg, height of  $174.5 \pm 7.7$  cm, participated in the experiment. One Gewolent tablet (25 mg of famprofazone) was administered orally to the subjects. After administration, urine samples were collected in the intervals of 0-1, 1-2, 2-3, 3-4, 4-5, 5-6, 6-7, 7-8, 8-9, 9-12, 12-15, 15-22, 22-28, 28-34, 34-40, 40-48, and 48-60 hrs. The concentrations of MA and AM for all urine samples were analyzed by gas chromatography-mass spectrometry (GC-MS). In addition, 12 urine samples from MA abuser which had been confirmed to MA positive testing result were collected. All urine samples were derivatized by N-trifluoroacetyl-L-prolyl chloride (L-TPC) and analyzed the enantiomers of the MA metabolites by GC-MS.

**RESULTS:** Thirty four percent of the urine samples from famprofazone ingestor showed MA positive (the concentrations of AM and MA higher than 100 and 500 ng/mL). The d-enantiomers of AM and MA in the urine of famprofazone ingestor were  $43.8 \pm 3.0\%$  and  $28.5 \pm 2.5\%$ . However, the d-enantiomers of AM and MA in the urine of AM abusers were  $98.6 \pm 2.1\%$  and  $97.5 \pm 1.7\%$ .

**CONCLUSIONS:** The enantiomers of urinary amphetamines metabolites from MA abuser urine differ from famprofazone ingester. Extra analysis of enantiomers can help the laboratory to avoid the interpretation of typical laboratory results of MA positive drug tests.

**Ingestion Of Capsiate Induces Increased Energy Expenditure And Increased Fat Oxidation At Rest, But Not During Exercise In Young Men**

Andrea R. Josse, Scott S. Sherriffs, Andrew M. Holwerda, Richard Andrews, Aaron W. Staples, Stuart M. Phillips. *McMaster University, Hamilton, ON, Canada.*

*(No relationships reported)*

**PURPOSE:** To examine how ingestion of capsiate, an extract from the CH-19 sweet pepper, affects energy expenditure and blood metabolites at rest and during exercise. Unlike capsaicin, a related more pungent (spicy) compound, capsiate acts through gastric vanilloid receptors before being broken down to vanillyl alcohol and a fatty acid. The thermogenic properties of capsiate remain understudied and no data exist on its interaction with exercise.

**METHODS:** Twelve healthy young men (age=24.3±3 yr, BMI=25.5±1.7 kg/m<sup>2</sup>) were studied on two occasions in a double-blind design following ingestion of either placebo (PLA) or 10mg of capsiate (CAP) at rest (60min), after 90min of cycling at 55% peak VO<sub>2</sub> and 30min into recovery. We measured energy expenditure throughout the protocol and took blood samples to determine concentrations of: lactate, glucose, glycerol, free fatty acids (FFA), and catecholamines. Subjects ingested the capsules 30min prior to exercise.

**RESULTS:** We observed increases in resting VO<sub>2</sub>, and serum norepinephrine, and decreases in serum FFA and respiratory exchange ratio with CAP vs. PLA (all p<0.05). At exercise onset, while lactate accumulation was relatively low, we did observe a reduced blood lactate concentration 30min into exercise with CAP vs. PLA (p<0.05). There were no other significant differences between CAP and PLA during or post-exercise.

**CONCLUSION:** Ingestion of 10mg of capsiate increased adrenergic activity, energy consumption, and shifted substrate utilization toward lipid at rest. Capsiate had little effect during exercise or recovery. The thermogenic changes indicate a potential role for capsiate in aiding with fat loss while dieting.

**2829      Board #223      May 29      2:00 PM - 3:30 PM**  
**Improvement Of Inflammatory And Immune Response Of Athletes At Intense Endurance Exercise By Cystine/theanine Supplementation**

Masaru Otani<sup>1</sup>, Shigeki Murakami<sup>2</sup>, Hiroshi Yoshigi<sup>2</sup>, Keisuke Sawaki<sup>2</sup>, Shuzo Kamei<sup>3</sup>, Shigekazu Kurihara<sup>4</sup>, Charles A. Titchenal<sup>5</sup>. <sup>1</sup>*The University of Tokyo, Tokyo, Japan.* <sup>2</sup>*Juntendo University, Tokyo, Japan.* <sup>3</sup>*Takaoka University of Law, Takaoka, Japan.* <sup>4</sup>*Ajinomoto Co., Inc., Tokyo, Japan.*

<sup>5</sup>*University of Hawaii at Manoa, Honolulu, HI.*

*(No relationships reported)*

Prolonged periods of intense endurance exercise training are often accompanied by an increased inflammatory response and immunosuppression. This effect has been reported to increase susceptibility to respiratory system viral infections. A recent trial in mice and elderly humans indicated that oral administration of the amino acids, cystine and theanine (CT), reinforces humoral immune response after antigen stimulation. However, the actions and effects of CT on athletes have not been reported previously.

**PURPOSE:** To determine the effects of CT supplementation on the inflammatory response and immune state in long-distance runners at a training camp.

**METHODS:** Sixteen distance runners were allocated to consume CT supplements (700 mg cystine + 280 mg theanine daily) or placebo (8 in each group) for 7 days prior to a training camp and during the 9-day camp. Daily run training averaged 19.9 km/day prior to the camp and 28.6 km/day during the camp. On the initial day and final day of the training camp, blood samples were collected before and after 15 km morning interval running workouts (1000 m 15 times) and analyzed for neutrophil and lymphocyte counts and myoglobin.

**RESULTS:** The relative change in exercise-induced blood neutrophil count (% of pre-exercise values) was significantly lower in the CT group than in the placebo group (163.3 ± 43.2 % vs. 200.4 ± 19.6 %, p = 0.044) on the initial day of training camp, but not on the last day of camp. The decline in lymphocyte count (% of pre-exercise values) was significantly less in the CT group compared with the placebo group (60.2 ± 19.2 % vs. 36.2 ± 12.0 %, p = 0.010) on the initial day of camp, but not on the last day. Post-exercise myoglobin levels were significantly lower in the CT group (p = 0.038) on the initial day of camp and there was a trend toward lower % of pre-exercise values in the CT group (p<0.09) on both measurement days.

**CONCLUSIONS:** Combined cystine and theanine supplementation significantly inhibited the increase in neutrophil count and the reduction in lymphocyte count induced by intense endurance exercise. These results suggest that combined cystine and theanine supplementation may suppress the exercise-induced inflammatory response and possibly help to reduce immunosuppression and inflammatory-derived muscle damage.

**2830      Board #224      May 29      2:00 PM - 3:30 PM**  
**Benefits Of Quercetin On Intestinal Polyp Multiplicity In Apc<sup>Min/+</sup> Mice**

Jamie L. McClellan, J Mark Davis, FACSM, E Angela Murphy, Traci L. Barrilleaux. *University of South Carolina, Columbia, SC.*

*(No relationships reported)*

Quercetin is one of a broad group of natural polyphenolic flavonoid substances, present in a wide variety of food plants, which are being investigated for their widespread health benefits. Quercetin has a diverse range of biological properties among which include anti-inflammatory and anti-carcinogenic properties. The anti-carcinogenic effects of quercetin have been well established in cell culture models; however its effects on tumorigenesis in vivo are largely unknown.

**PURPOSE:** To determine the potential benefits of quercetin on intestinal polyp multiplicity, including polyp number, size, and distribution in Apc<sup>Min/+</sup> mice. The Apc<sup>Min/+</sup> mouse model is the most widely used genetically engineered mouse model for cancer studies that involve the gastro-intestinal tract. It has been shown to have a mutated Apc gene, similar to that in patients with familial adenomatous polyposis, and in many sporadic cancers.

**METHODS:** Male and female Apc<sup>Min/+</sup> mice were randomly assigned to placebo or quercetin treatment (n=10/group). Mice were given a placebo (standard diet) or a 0.2% quercetin (QU995) diet from 4 to 20 weeks of age. Tissues were collected at 20 weeks of age and intestines were analyzed for polyp number, size and distribution in the small and large intestines.

**RESULTS:** Quercetin decreased total intestinal polyps by 60% (p<0.05), the effects were seen in sections 2 (65%), 3 (70%), and 4 (80%) of the small intestine (P2mm) (50%) and medium (1mm) (75%) polyps (p<0.05), without increasing the number of small (<1mm) polyps.

**CONCLUSION:** These data suggest that the dietary supplement quercetin may be an important nutritional strategy to prevent the incidence or delay progression of colon cancer.

**2831      Board #225      May 29      2:00 PM - 3:30 PM**  
**Effects Of Ammonium Chloride Ingestion On Phosphocreatine Recovery Following Heavy-intensity Plantar Flexion**

## Exercise

Tyler A. Churchward - Venne<sup>1</sup>, John M. Kowalchuk<sup>1</sup>, Greg D. Marsh<sup>2</sup>. <sup>1</sup>The University of Western Ontario, London, ON, Canada. <sup>2</sup>The Lawson Health Research Institute, St. Joseph's Health Care, London, ON, Canada. (Sponsor: Donald H. Paterson, FACSM)

Email: tchurchw@uwo.ca

(No relationships reported)

Intracellular acidosis has been shown to increase the time constant and/or rate constant of the phosphocreatine (PCr) kinetic response during recovery from exercise, supporting the notion that mitochondrial respiration is reduced under low pH conditions. The slowed PCr recovery in the presence of intracellular acidosis has also been attributed to an increased ATP consumption by cellular ion pumps, and/or to a pH-induced shift in the creatine kinase (CK) equilibrium. However, during this recovery period, [PCr] often rises transiently above resting values before returning to pre-exercise values. This phenomenon has been named the PCr recovery overshoot, and the mechanisms responsible for it remain unknown.

**PURPOSE:** To examine the effects of ammonium chloride (NH<sub>4</sub>Cl) ingestion on PCr recovery and the magnitude of PCr overshoot following heavy-intensity plantar flexion (PF) exercise.

**METHODS:** Eight untrained male subjects performed isotonic PF exercise in a control (CON) and NH<sub>4</sub>Cl ingestion (ACID) trial (0.3g/kg oral dose of NH<sub>4</sub>Cl, over 3 hrs prior to exercise). PF exercise (contraction rate, 0.5 Hz) was performed for 9 min each during moderate- (MOD: 75% of intracellular pH threshold, TpHi) and heavy-intensity exercise (HVY: 125% TpHi), and was followed immediately by 15 min resting recovery. <sup>31</sup>P magnetic resonance spectroscopy was used to non-invasively monitor changes in intracellular pH (pHi), [PCr], and [ATP].

**RESULTS:** End HVY exercise pHi was lower (P<0.05) in ACID (6.61 (0.07); mean (SD)) than CON (6.69 (0.06)). During recovery the PCr time constant (tPCr) was greater (P<0.05) in ACID (45 s (16)) than CON (33 s (10)). The magnitude of [PCr] recovery overshoot, as a percentage of the pre-exercise resting value, was greater (P<0.05) in ACID than CON during the following recovery periods: 3-6 min (ACID, 110% (3); CON, 107% (3)); 6-9 min (ACID, 110% (3); CON, 106% (4)); 9-12 min (ACID, 108% (3); CON, 105% (3)); and 12-15 min (ACID, 108% (3); CON, 105% (4)).

**CONCLUSION:** A greater intracellular acidosis at the end of HVY was seen in ACID vs. CON. This was associated with a longer time constant describing PCr recovery kinetics and a greater magnitude of [PCr] overshoot above baseline values.

---

## F-35 Free Communication/Poster - Training with Blood Flow Restriction

#### Skeletal Muscle Size And Strength Are Increased Following Walk Training With Restricted Leg Muscle Blood Flow: Effect Of Training Frequency

Takashi Abe<sup>1</sup>, Charles F. Kearns<sup>1</sup>, Satoshi Fujita<sup>1</sup>, Mikako Sakamaki<sup>1</sup>, Yoshiaki Sato<sup>1</sup>, William F. Brechue, FACSM<sup>2</sup>. <sup>1</sup>University of Tokyo, Kashiwa, Japan. <sup>2</sup>United States Military Academy, West Point, NY.

Email: abe@k.u-tokyo.ac.jp

(No relationships reported)

Three weeks of twice-daily walk training with restricted leg muscle arterial inflow and venous outflow (KAATSU-walk) produced substantial muscle hypertrophy (4-7% increase in muscle volume) and increased strength (increase in 1-repetition maximum (1-RM) and maximal isometric torque (MVC) 8-10%) in the thigh muscles (J Appl Physiol 100:1460-1466, 2006) and a hypertrophic potential (% change in muscle mass/# training sessions; 0.19) approximating that of high intensity resistance training. However, the impact of lower frequency KAATSU-walk training on muscle size and strength is unknown. **PURPOSE:** To investigate once-daily KAATSU-walk training on thigh muscle size and strength.

**METHODS:** Twelve young men performed walk training: KAATSU-walk training (n=6) and control (no KAATSU; n=6). Training was conducted once daily, 6 days/wk, for 3 wk. Treadmill walking (50 m/min) was performed for five sets of 2-min bouts interspersed with 1-min rest periods. The KAATSU-walk group wore pressure cuff belts (5 cm wide) on both legs during training with incremental external compression; 160-230 mmHg. Thigh muscle cross-sectional area and volume (MRI), MVC and 1-RM were measured before and 3 days following final training.

**RESULTS:** In the KAATSU-walk group, quadriceps and hamstrings muscle volume increased (both p<0.05) 1.7% (pre, 1738 cm<sup>3</sup>; post, 1768 cm<sup>3</sup>) and 2.4% (622 cm<sup>3</sup> vs. 638 cm<sup>3</sup>), respectively, following training with a hypertrophic potential of 0.09. 1-RM leg press (pre, 85 kg; post, 93 kg) and leg curl (57 kg vs. 63 kg) increased 9% and 10% (both p<0.01), respectively, following KAATSU-walk training. Also, MVC knee extension strength (4.4%; p<0.01), but not knee flexion strength (1.7%) increased following KAATSU-walk training. There were no changes in muscle volume or strength in the Control-walk group. These results confirm previous work showing that the combination of slow walk training and leg muscle blood flow restriction induces muscle hypertrophy and strength gain. However, the magnitude of change in muscle mass and strength following once-daily KAATSU-walk training is approximately one-half that reported for twice-daily KAATSU-walk training over a three week period.

**CONCLUSIONS:** There is a frequency dose-dependency to the impact of KAATSU-walk training on hypertrophic potential and muscular strength.

---

(No relationships reported)

**BACKGROUND:** By-products (H<sup>+</sup>, Pi, H<sub>2</sub>PO<sub>4</sub><sup>-</sup>) of skeletal muscle activation are not only contributed to fatigue but also to muscular adaptation (muscle hypertrophy and strength gain). Resistance training with blood flow restriction (BFR) effectively increases muscle bulk and strength despite using small workload and is presumed to provide accelerated fatigue with high levels of intramuscular by-products due to hypoxia. Recent studies have shown that women have greater resistance to fatigue than men during submaximal contractions with the same relative force. It is suggested that higher absolute force in men vs. women may produce greater mechanical compression of the vascular bed and reduce the availability of oxygen. There is no clear information as to whether gender affects the muscular responses to resistance exercise even applying BFR.

**PURPOSE:** The purpose of this study was to examine the sex differences in intramuscular by-products during low-intensity resistance exercise with BFR and during conventional high-intensity resistance exercise.

**METHOD:** Twenty-six healthy subjects (22±4 yr, age-matched 13 men and 13 women) performed unilateral plantar-flexion for 2-min (30 repetitions/min) with various conditions. Protocols were randomly performed with low-intensity (L: 20% 1RM), L with BFR (LB) and high-intensity (H: 65% 1RM). Intramuscular pH,

phosphocreatine (PCr),  $\text{H}_2\text{PO}_4^-$  during exercise were measured every 30 sec by  $^{31}\text{P}$ -magnetic resonance spectroscopy.

**RESULT:** Resting systolic blood pressure (men:  $124.2 \pm 11.7$  vs. women:  $106.5 \pm 6.3^*$  mmHg), applying pressure for BFR (men:  $161.5 \pm 15.2$  vs. women:  $138 \pm 8.1^*$  mmHg) and 1RM (men:  $50.7 \pm 6.6$  vs. women:  $31.8 \pm 8.3^*$  kg) were significantly smaller in women than in men ( $^*p < 0.001$ ). PCr depletion (men:  $19.9 \pm 4.7$  vs. women:  $22.1 \pm 4.8$  mM), intramuscular pH decrease (men:  $6.90 \pm 0.08$  vs. women:  $6.92 \pm 0.05$ ) and  $\text{H}_2\text{PO}_4^-$  increase (men:  $9.6 \pm 2.7$  vs. women:  $8.2 \pm 1.8$  mM) at the end of LB did not show statistical difference between both genders. Those during H were very similar to LB.

**CONCLUSION:** Although women showed relatively smaller muscular stress during low-intensity resistance exercise with blood flow restriction and also during high-intensity resistance exercise compared with men, there is no statistical difference between genders.

(No relationships reported)

**PURPOSE:** Skeletal muscle bulk and strength are now becoming important therapeutic targets in cardiovascular rehabilitation. However, usual resistance training needs to load muscles intensively and is hard for cardiac and elder subjects. Resistance training with blood flow restriction (BFR) is a new method to effectively increase muscle bulk and strength despite using lower workload, whereas we reported that usual low-intensity resistance exercise with BFR protocol could not result in energetically sufficient stimulus. The purpose of this study was to examine the optimal low-intensity resistance exercise with 2 difference BFR protocols composed of multiple sets in terms of muscle energy metabolism.

**METHODS:** Twelve healthy subjects ( $22 \pm 1$  yr, mean  $\pm$  SE) performed 3 sets of 1-min unilateral plantar-flexion (30 repetitions) with 1-min rest intervals. Protocols were randomly performed with low-intensity exercise by using 20% 1RM (L) and high-intensity exercise by using 65% 1RM (H) without BFR, L with intermittent (only during exercise) BFR (L-IBFR) and L with continuous BFR (L-CBFR). Phosphocreatine (PCr) and intramuscular pH were measured using  $^{31}\text{P}$ -Magnetic resonance spectroscopy.

**RESULTS:** The changes of PCr and intramuscular pH during all-sets among low-intensity conditions were significantly increased by applying BFR (L vs. L-IBFR and L-CBFR,  $p < 0.05$ ). In the PCr depletion (L-CBFR:  $15.5 \pm 1.5$ , L-IBFR:  $25.0 \pm 1.3$ , H:  $15.9 \pm 1.3$  mM) and intramuscular pH decrease (L-CBFR:  $6.84 \pm 0.02$ , L-IBFR:  $6.96 \pm 0.02$ , H:  $6.87 \pm 0.02$ ) at the end of final set, L-CBFR was significantly greater than those in L-IBFR ( $p < 0.05$ ) and similar to those in L-IBFR. Moreover, integrated PCr depletion during exercise session with rest intervals was equal level to that in H (L-CBFR:  $3952 \pm 315$  vs. H:  $4126 \pm 335$  sec $\times$ mM, ns).

**CONCLUSIONS:** Effects of low-intensity resistance exercise with BFR might be sufficiently enhanced by continuous BFR with multiple sets.

Email: m076787@h.k.u-tokyo.ac.jp

(No relationships reported)

Heat-stress has been shown to prevent muscle atrophy and facilitate exercise-induced muscle hypertrophy due partly to the expression of proteins such as HSP 72. Low-intensity resistance exercise with blood flow restriction (BFR) has been shown to increase muscle size and strength comparable to that of high-intensity exercise. Furthermore, acute bout of exercise with BFR triggers a fatigue induced heat sensation, and it may elevate muscle temperature as compared to non-restricted exercise.

**PURPOSE:** To investigate the effect of low-intensity resistance exercise combined with BFR on skin temperature ( $T_{sk}$ ) over exercising muscle.

**METHODS:** 8 healthy males (age:  $25.4 \pm 5.2$  yrs) performed 4 sets (30, 15, 15, and 15 reps with 30-s rest between sets) of low-intensity (20% 1RM) unilateral arm curl exercise with (BFR-20) and without (CON-20) blood flow restriction, and 3 sets (10 reps with 90-s rest between sets) of moderate-intensity (60% 1RM) exercise without BFR (CON-60).  $T_{sk}$ , reflective of muscle temperature beneath the skin, was measured from skin above biceps brachii (BB) muscle of both arms during exercise and 10 minutes post-exercise. Surface EMG of the BB was recorded, and mean integrated EMG (iEMG) was analyzed. Blood lactate was assessed before and 1 minute post-exercise.

**RESULTS:** iEMG and blood lactate for BFR-20 (iEMG:  $280 \pm 82\%$ , Lactate:  $180 \pm 14\%$ ) was significantly increased ( $p < 0.01$ ) as compared with CON-20 (iEMG:  $180 \pm 14\%$ , Lactate:  $143 \pm 29\%$ ). During exercise,  $T_{sk}$  was increased similarly (CON-20: from  $33.0 \pm 0.6$  to  $34.1 \pm 0.8^\circ\text{C}$ , BFR-20: from  $32.9 \pm 0.8$  to  $33.8 \pm 0.8^\circ\text{C}$ ). However, peak  $T_{sk}$  appeared after exercise in both groups, and the peak  $T_{sk}$  for BFR-20 was higher ( $p < 0.01$ ) than that of CON-20 (CON-20:  $34.6 \pm 0.7$ , BFR-20:  $34.9 \pm 0.8^\circ\text{C}$ ). Hence, the increase in  $T_{sk}$  for BFR-20 was significantly higher ( $p < 0.01$ ) as compared with CON-20 (CON-20:  $1.6 \pm 0.4$ , BFR-20:  $2.0 \pm 0.5^\circ\text{C}$ ). The increase in  $T_{sk}$  for CON-60 trial was  $1.9 \pm 0.5^\circ\text{C}$ , which was similar to the change observed in BFR-20.

**CONCLUSION:** The results suggest that low-intensity resistance exercise with BFR may increase active muscle temperature more than that of non-restricted control exercise. However, further study is necessary to clarify whether the increase in muscle temperature by low-intensity resistance exercise with BFR contributes to muscular hypertrophy.

2836 Board #230 May 29 3:30 PM - 5:00 PM

**Effects Of Walk Training With Restricted Blood Flow On Cardiovascular And Muscle Functions In Elderly**

Hayao Ozaki, Satoshi Fujita, Mikako Sakamaki, Masato Sugaya, Yoshiaki Sato, Takashi Abe. University of Tokyo, Kashiwa, Japan. (Sponsor: Michael G. Bemben, FACSM)

Email: m086693@h.k.u-tokyo.ac.jp

(No relationships reported)

Slow walk training combined with restricted leg muscular blood flow (KAATSU-walk) produces substantial muscle hypertrophy and strength gains in young men. However, the impact of KAATSU-walk in middle-aged and older population on cardiovascular and muscle functions is unknown.

**PURPOSE:** To investigate the effects of KAATSU-walk on muscle size and function, as well as aerobic capacity, in elderly subjects.

**METHODS:** Sixteen elderly men and women, aged 60-78 years were randomized into either a KAATSU-walk (2 men, 9 women;  $n=11$ ) or a non-exercising control group (1 man, 4 women;  $n=5$ , CTRL). The KAATSU-walk group performed 20 min treadmill walking (67 m/min), five days/wk for 6 wk. Subjects in the KAATSU-walk group wore pressure belts on proximal part of both legs during training with restrictive pressure at 140-200 mmHg. The following were assessed prior to and following the training program; (1) maximum isometric knee extension and isokinetic knee extension and flexion strength, (2) muscle mass (MM), (3) functional fitness and (4) maximum oxygen uptake ( $\text{VO}_{2\text{peak}}$ ). MM was estimated from ultrasound-measured muscle thickness using the prediction equations. Functional fitness was assessed by Timed Up and Go Test (time to walk both ways from the chair to 2.4m marker) and Chair stand Test (repeated chair stand in 30 seconds).  $\text{VO}_{2\text{peak}}$  was extrapolated from the relationship between heart rate response and oxygen uptake measured during exercise.

**RESULTS:** In the KAATSU-walk group, maximum isometric and isokinetic strength (for example, 11.8% for isometric knee extension strength) and ultrasound-estimated skeletal muscle mass (6.0% and 10.7% for total and thigh, respectively) increased ( $P < 0.05$ ), but not in the CTRL group. Functional fitness also improved significantly only in

the KAATSU-walk group ( $P < 0.05$ ); however, there was no change in estimated  $\dot{V}O_{2peak}$  (absolute [pre:  $1.76 \pm 0.56$  l/min, post:  $1.70 \pm 0.55$  l/min]; relative [pre:  $31.8 \pm 6.3$  ml/kg/min, post:  $31.2 \pm 6.2$  ml/kg/min]) in either group ( $P > 0.1$ ).

**CONCLUSION:** Slow walk training combined with restricted leg muscular blood flow increased muscle strength and size improved functional fitness in elderly. However, aerobic capacity remained unchanged following the 6-week training period in either group.

#### **Effects Of Exercise And Low Caloric Diet With Varying Density On Body Weight And Satiety**

Sae Won Song<sup>1</sup>, Yoon Jung Bae<sup>1</sup>, Kwang Hun Park<sup>2</sup>, Joohyung Lee<sup>2</sup>. <sup>1</sup>Dongduk Women's University, Seoul, Republic of Korea. <sup>2</sup>Kookmin University, Seoul, Republic of Korea.

Email: dreamerjung@hotmail.com

(No relationships reported)

**PURPOSE:** This study examined the combined effects of low caloric diet with either high or low energy density and aerobic exercise on body composition, blood lipids profiles, and satiety in overweighted young women.

**METHODS:** Twenty three women were recruited and randomly assigned to either high energy density diet plus exercise group (HDE;  $n=12$ ,  $22 \pm 1$  yrs,  $65 \pm 7$  kg,  $163 \pm 5$  cm,  $25.8 \pm 1.9$  kg/m<sup>2</sup>,  $34 \pm 4$  %fat) or low energy density diet plus exercise group (LDE;  $n=11$ ,  $22 \pm 2$  yrs,  $67 \pm 7$  kg,  $161 \pm 7$  cm,  $24.2 \pm 3.0$  kg/m<sup>2</sup>,  $35 \pm 4$  %fat) to participate a 4-week weight management program. All subjects were educated to maintain a low caloric diet ([Unsupported Character - &#8786;]1,500 kcal/d) throughout the study and record their daily dietary intake. During the study, their lunch, which was isocaloric ( $483 \pm 26$  for HDE,  $487 \pm 27$  kcal for LDE) but different weight of food ( $365 \pm 68$  for HDE,  $814 \pm 202$  g for LDE) was provided for each group. The food composition and volume of one group was not informed to other group. The hunger level was evaluated by a scale (1: extremely starving, 9: extremely full) at 17:30 hour of each day. Two hours after each lunch, they exercised on a stationary bike at approximately 60% of their maximal heart rate for 45 min. Prior to and at the completion of study, their physical characteristics were measured and resting blood samples were drawn for analyses of blood lipid profiles.

**RESULTS:** Average daily energy intake was  $1,551 \pm 259$  for HDE and  $1,404 \pm 150$  kcal for LDE ( $P > 0.05$ ). Body weight ( $-1.9$  kg) and %fat ( $-1.4$ %) were significantly reduced in LDE ( $P < 0.05$ ), but not in HDE ( $-0.9$  kg,  $-1.0$ %, respectively). Waist circumference was reduced from  $79 \pm 9$  to  $74 \pm 9$  cm in LDE ( $P < 0.05$ ), but not in HDE (from  $80 \pm 7$  to  $77 \pm 6$  cm). No changes were noticed before and after study between groups in total cholesterol, triglycerides, and glucose. The hunger level was significantly higher in HDE ( $2.46 \pm 0.28$ ) than in LDE ( $3.10 \pm 0.26$ ) ( $P < 0.05$ ).

**CONCLUSIONS:** Low caloric diet in LDE appeared to be more effective in controlling body weight compared to HDE. It appeared that weight control program with low caloric diet in combination with exercise should include the density of diet.

#### **Acute Weight Loss Patterns By Professional Horse Racing Jockeys In Preparation For Racing**

Giles David Warrington, FACSM<sup>1</sup>, Eimear Dolan<sup>1</sup>, Adrian McGoldrick<sup>2</sup>, Gregory May<sup>1</sup>, Paula Fitzpatrick<sup>1</sup>. <sup>1</sup>Dublin City University, Dublin 9, Ireland.

<sup>2</sup>The Turf Club, Co. Kildare, Ireland.

Email: giles.warrington@dcu.ie

(No relationships reported)

Horse racing is a weight category sport, for which jockeys must weigh in at a designated weight prior to, and immediately after each race. Current weight standards in Irish horse racing, range from 52.7 - 64 kg and 62 - 76 kg for Flat and National Hunt racing respectively. Weight allocations are based solely on the ability of the horse, requiring jockeys to constantly cycle their body mass at a specified weight allowance in order to compete. Strict and potentially dangerous weight loss practices have been previously reported to be used by jockeys in order to comply with the stipulated weight standards. The magnitude of acute weight loss typically attained by jockeys in preparation for competition would appear however, to be largely unknown.

**PURPOSE:** The purpose of this study was to examine typical weight loss patterns in professional horse racing jockeys.

**METHODS:** A structured self-report questionnaire was distributed to 24 jockeys (10 Flat, 14 National Hunt) who volunteered to participate in the study. This questionnaire provided a subjective evaluation of typical body mass on racing and non racing days. Mean percentage body mass loss was extrapolated from the results. Participants also provided information as to the typical amount of time given to achieve the stipulated weight.

**RESULTS:** Mean reported typical riding weight was shown to be  $3.8 \pm 2.2$  % below the subjects self reported non riding weight (range: 0 - 7.9%). The largest reported mean weight loss for a race was  $3 \pm 1.4$  kg (range: 1.4 - 7.3kg), equating to a mean percentage body mass loss of  $5 \pm 2$  % (range: 2.3 - 10.5%). Subjects were typically given 24 - 48 hours notification of the required weight they had to attain for a particular race.

**CONCLUSIONS:** Results from this study would appear to indicate that current weight standards are set below a level which is easily attainable for this group of subjects. Furthermore extreme acute weight loss practices appeared to be evident in a number of cases. Further research is required to specifically examine the impact of typical weight loss practices used by jockeys on their physiological and cognitive function as well as health and well-being.

#### **Epicardial and Abdominal Fat Responses To Weight Loss In Obese Men**

Maeng-Kyu Kim<sup>1</sup>, Kiyoji Tanaka, FACSM<sup>1</sup>, Takayuki Endo<sup>1</sup>, Mi-Ji Kim<sup>1</sup>, Tomoaki Matsuo<sup>1</sup>, Tsugio Tomita<sup>2</sup>, Seiji Maeda<sup>1</sup>, Ryuichi Ajisaka<sup>1</sup>.

<sup>1</sup>University of Tsukuba, Tsukuba, Japan. <sup>2</sup>Higashi Toride Hospital, Toride, Japan.

Email: kimmk@stat.taiiku.tsukuba.ac.jp

(No relationships reported)

In cross-sectional studies, echocardiographic epicardial fat measurement seems to be a reliable and diagnostic marker of visceral fat. However, a comparative study of the changes in epicardial fat as well as those in the visceral or truncal depot in response to weight loss has yet to be investigated.

**PURPOSE:** To compare the changes of epicardial, abdominal, and regional fat compartments following a low calorie diet intervention in obese men.

**METHODS:** We evaluated 27 moderately obese men (age:  $45.8 \pm 1.7$  years; body mass index:  $30.5 \pm 0.7$  kg/m<sup>2</sup>, mean  $\pm$  SE) and conducted a 12-week clinical weight-loss intervention with a daily low calorie diet presented through weekly lectures. Immediately before and after the intervention, the epicardial fat thickness was measured by transthoracic echocardiography, and abdominal fat tissues were determined by computed tomography scans. Whole and regional fat compartments were measured by dual X-ray absorptiometry.

**RESULTS:** Subjects experienced a 27% decrease of the initial estimated daily calorie intake, on average, and had 11% and 17% loss of body weight and body fat, respectively, accompanied by a 15% decrease in epicardial fat thickness (from  $8.2 \pm 0.3$  to  $7.0 \pm 0.3$  mm,  $P < 0.001$ ) and a 30% decrease in abdominal fat compartments after the program. The percentage change in visceral adipose tissue in response to weight loss was twice as high as the change in epicardial fat tissue ( $P < 0.001$ ). Stepwise multiple regression analysis revealed that the change in abdominal fat compartments and initial visceral fat tissue were independent determinants of the change in epicardial fat thickness ( $P < 0.05$ ).

**CONCLUSION:** It appears that during low calorie diet-induced weight loss that the proportionally highest reduction is abdominal fat compartments in men with obesity. Whereas, when compared to other fat compartments, reduction in epicardial fat tissue in response to weight loss seems to be low.

**2840 Board #234 May 29 3:30 PM - 5:00 PM**  
**The Effect Of Weight Loss And Physical Activity On Bone Mineral Density In Overweight Women**

Krista L. Rempolski, John M. Jakicic, FACSM, Amy D. Otto, Kelli A. Davis, Jessica L. Unick, Christine A. Dutton, David O. Garcia. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M. Jakicic, FACSM)  
 Email: klompolski@gmail.com  
 (No relationships reported)

It is known that weight loss can cause reductions in Bone Mineral Density (BMD); however, few studies have reported on the effect of weight loss combined with physical activity across long-term prospective studies.

**PURPOSE:** To examine the effect of weight loss, fat loss and physical activity on changes in BMD in overweight women across a 24 month weight loss intervention.

**METHODS:** Data from 90 overweight women (BMI =  $32.6 \pm 4.3$  kg/m<sup>2</sup>; age =  $38.6 \pm 5.5$  years) participated in a 24 month behavioral weight loss intervention. Participants were instructed to reduce energy intake to 1200-1500 kcal/d, and physical activity was prescribed at 1000-2000 kcal/wk at a moderate-to-vigorous intensity. Assessments of weight, physical activity, body composition, and BMD measured at the hip were completed at 0, 6, and 24 months. BMD of the femoral neck, greater trochanter, intertrochanter, and Ward's was assessed using DXA.

**RESULTS:** Weight change from baseline at 6 and 24 months was  $-8.8 \pm 4.5$  kg and  $-6.9 \pm 7.4$  kg, ( $p < 0.05$ ). The change in physical activity from baseline at 6 and 24 months was  $1265 \pm 1256$  kcal/wk and  $1236 \pm 1345$  kcal/wk. BMD decreased significantly at 6 and 24 months for total BMD ( $-0.0024 \pm 0.0184$ ,  $-0.0096 \pm 0.0283$  gms/cm<sup>2</sup>), femoral neck ( $-0.0101 \pm 0.0242$ ,  $-0.0129 \pm 0.0391$  gms/cm<sup>2</sup>), greater trochanter ( $-0.0018 \pm 0.0215$ ,  $-0.0090 \pm 0.0308$  gms/cm<sup>2</sup>), and Ward's ( $-0.0011 \pm 0.0420$ ,  $-0.0161 \pm 0.0481$  gms/cm<sup>2</sup>), ( $p < 0.05$ ). Weight change at 6 months was correlated with 6 month measures of BMD (total BMD,  $r = .28$ ; femoral neck,  $r = .34$ ; greater trochanter,  $r = .26$ ). Change in weight at 24 months was correlated with 24 month measures of BMD (total BMD,  $r = .53$ ; femoral neck,  $r = .58$ ; greater trochanter,  $r = .47$ ; intertrochanter,  $r = .33$ ), ( $p < .01$ ). Change in physical activity was not significantly correlated with change in BMD at 6 or 24 months.

**CONCLUSIONS:** Bone Mineral Density significantly decreased with weight loss resulting from decreased energy intake and increased physical activity. However, the clinical significance of this decrease in overweight or obese women is unclear. Physical activity did not appear to influence changes in BMD. However, walking was the primary form of activity. Whether a different dose or mode of activity or might result in different findings warrants further investigation.

**Residential Weight Loss Programmes For Children: Consistent Favourable Responses Irrespective Of Baseline Fitness And Fatness**

Carlton B. Cooke<sup>1</sup>, Michael C. Cooke<sup>2</sup>, Duncan Radley<sup>1</sup>, Paul J. Gately<sup>1</sup>. <sup>1</sup>Leeds Metropolitan University, Leeds, United Kingdom. <sup>2</sup>University of Leeds, Leeds, United Kingdom.  
 Email: c.cooke@leedsnet.ac.uk  
 (No relationships reported)

**PURPOSE:** Assess variation of responses to a residential weight loss programme involving physical activities and dietary restriction.

**METHODS:** Repeated measures design pre and post the 8 week intervention. The daily schedule included six 1-hour, skill based, fun, physical activities, moderate dietary restriction and lifestyle education. BMI defined as overweight was required for inclusion. Tertiles were derived from baseline fatness and fitness. Analysis of covariance was used to evaluate the intervention across tertiles. 203 overweight and obese children (mean age 14.02 years) attended the camp for between 6 to 53 days. Children were assessed for height, weight, body composition, other anthropometrics and aerobic fitness pre and post intervention. Blood pressure and various biochemical markers of cardiovascular disease risk were also recorded for varying proportions of campers.

**RESULTS:** Campers, who stayed for a mean of 30 days, reduced their weight and standardised BMI scores by 6.35kg and 0.3 units respectively. Increases in VO<sub>2</sub> at 85% HR max of 0.2L.min<sup>-1</sup> and 3.89ml.kg<sup>-1</sup>.min<sup>-1</sup> were also observed. Significant ( $P < 0.003$  -  $P < 0.000$ ) improvements were consistently seen across all tertiles of campers, based on a comparison of pre and post values. Variability of change data are shown in table 1.

VARIABLE	ALL CAMPERS	FATNESS TERTILES	FITNESS TERTILES
(post-pre)	Mean	Range of means	Range of means
% Body fat	-3.3	-3.18 to -3.52	-2.67 to -3.87
Waist Circumference (cm)	-6.2	-5.41 to -6.70	-5.64 to -6.85
BP Systolic (mmHg)	-6.63	-5.98 to -7.6	-4.79 to -7.61
BP Diastolic (mmHg)	-7.41	-6.67 to -8.51	-6.36 to -9.31
TC (mmol.L-1)	-0.76	-0.06 to -0.89	-0.67 to -0.94
TG (mmol.L-1)	-0.22	-0.07 to -0.31	-0.18 to -0.68
LDL (mmol.L-1)	-0.70	-0.44 to -0.92	-0.58 to -0.79
TC/HDL	-0.68	-0.19 to -1.16	-0.45 to -0.76
Leptin (ng.ml-1)	-60.90	-53.64 to -75.19	-41.34 to -75.39

Longer duration of stay was associated with greater improvements in outcomes, but the effect of the camp remained consistently significant when controlling for duration of stay for body fat, waist circumference and blood pressure.

**CONCLUSIONS:** The 8 week residential intervention was consistently effective for overweight and obese children across several key variables, when controlling for baseline

**Characteristics Of Responders And Non-responders To A 12-week Fat Loss Intervention**

Sarah L. Dunn, Stephen H. Boutcher, FACSM. *University of New South Wales, Sydney, Australia.*  
(No relationships reported)

Metabolic and autonomic factors may influence the ability of overweight women to lose fat undergoing an exercise-based fat loss intervention.

**PURPOSE:** Characteristics of responders and non-responders to a 12-week lifestyle intervention consisting of high intensity interval exercise (HIIE), fish oil supplementation, and Mediterranean diet in sedentary overweight women were examined.

**METHODS:** Subjects were assigned to an intervention consisting of fish oil consumption, HIIE, and Mediterranean diet. Thirty-four females (BMI  $27.0 \pm 0.5$  kg/m<sup>2</sup>; age  $23.5 \pm 0.7$  yrs) underwent pre- and posttraining testing including a VO<sub>2peak</sub> test, resting metabolic rate assessment for respiratory exchange ratio (RER), heart rate (HR), systolic blood pressure (SBP), and a dual energy x-ray absorptiometry (DEXA) scan to measure body composition. The women undertook 36 supervised exercise sessions that involved 8 s of sprinting on a cycle ergometer followed by 12 s of relative rest, repeated for a total of 20 min. Dietary intake was regularly monitored through food diaries. Fish oil consumption consisted of 1.8 g of eicosapentaenoic and docosahexaenoic acid daily. The women were grouped into responders (RES; n=21) or non-responders (NRES; n=13) based on body weight loss. RES lost ( $\geq 0.05\%$ ) of their initial body weight while NRES did not. All values are expressed as mean  $\pm$  standard error.

**RESULTS:** There were significant differences ( $p < 0.05$ ), at baseline for HR ( $70.1 \pm 1.9$ ;  $64.2 \pm 1.4$  bpm), SBP ( $116 \pm 2$ ;  $109 \pm 3$  mmHg), and RER ( $0.87 \pm 0.01$ ;  $0.93 \pm 0.02$ ). In the RES women there was a significant decrease in fat mass ( $-2.7 \pm 0.4$ ;  $0.6 \pm 0.4$  kg) and overall body weight ( $-2.8 \pm 0.4$ ;  $1.2 \pm 0.3$  kg) compared to the NRES women. Both RES and NRES increased VO<sub>2peak</sub> ( $0.28 \pm 0.03$ ;  $0.29 \pm 0.03$  L/min) with no significant difference between groups. Diets were similar in composition and total kilojoules.

**CONCLUSION:** Thirty-six, 20-min bouts of HIIE, plus fish oil, and a Mediterranean diet led to significant fat loss in most but not all women. NRES possessed a higher RER and lower HR and SBP. The higher respiratory exchange ratio suggests impaired fat oxidation, whereas the lower heart rate and blood pressure suggest reduced sympathetic tone.

**Effectiveness Of A Culturally Tailored Commercial Weight Loss Program Among UK South Asian Women.**

Sunita Procter, Janice L. Thompson, FACSM. *University of Bristol, Bristol, United Kingdom.*  
Email: sunita.procter@bristol.ac.uk  
(No relationships reported)

South Asian women have higher rates of central obesity, type 2 diabetes and heart disease than the general population. Based on limited published data, South Asian women are less physically active and eat diets higher in fat and energy compared to non-South Asian counterparts. There is little evidence on the effectiveness of weight-loss interventions targeted at and developed for this group.

**PURPOSE:** To determine the effect of a culturally-tailored commercial weight loss program on weight loss and adoption of healthy eating and physical activity behaviors in South Asian women.

**METHODS:** 41 overweight/obese South Asian women (BMI  $29.0 \pm 5.2$  kg/m<sup>2</sup>, weight  $71.9 \pm 14.9$  kg, Age  $38.5 \pm 10.0$  years, mean  $\pm$  SD) were recruited from two community-based locations. Culturally-tailored supplemental materials were developed prior to initiation of the intervention with input and approval from the target community; these materials were given in addition to standard program materials during intervention implementation. A non-South Asian program leader coached participants on culturally appropriate strategies to change diet and physical activity behaviors over the 11-week program. Weekly food diaries were kept and daily steps were recorded using a pedometer. Weight was measured weekly. Height, waist circumference and %body fat were measured at baseline and the end of the program. Focus groups and individual interviews were conducted post intervention to collect qualitative data on satisfaction with the program, views on culturally-enhanced materials and barriers and enablers of making diet and activity changes.

**RESULTS:** Reduction in weight and BMI of the 31 women who attended two or more meetings were statistically significant (weight  $-2.3 \pm 2.1$  kg,  $p < 0.001$ , BMI  $-0.9 \pm 0.9$  kg/m<sup>2</sup>,  $p < 0.001$ ). %body fat ( $-1.6 \pm 1.2\%$ ,  $p < 0.001$ ) and waist circumference ( $-1.3 \pm 2.1$  cm,  $p = 0.003$ ) also decreased significantly. Food diary and qualitative data indicated that women maintained their traditional dietary choices while reducing serving sizes which contributed to weight loss.

**CONCLUSIONS:** A culturally-tailored commercial weight loss program resulted in significant weight loss and other obesity indicators among South Asian women.

*Supported by Weight Watchers UK Ltd and University of Bristol Vice Chancellor's Scholarship.*

**2844 Board #238 May 29 3:30 PM - 5:00 PM**  
**Determining The Efficacy Of The Bodybugg Armband When Implemented Into The Lifestyle Of Sedentary Individuals**

Jean Luc Leiba<sup>1</sup>, Jessica Hendrikson<sup>1</sup>, Frank Clarizio<sup>1</sup>, Emily Payne<sup>2</sup>, Ryan Lown<sup>1</sup>, Ed Roble<sup>1</sup>, Laurie Schubert<sup>1</sup>, Rebekah Smith<sup>1</sup>, Catlin Plank<sup>1</sup>, Catherine Arnold<sup>1</sup>, Craig E. Broeder, FACSM. <sup>1</sup>*Benedictine University, Lisle, IL* <sup>2</sup>*Benedictine University, Lisle, IL.*  
Email: jluc725@yahoo.com  
(No relationships reported)

**PURPOSE:** Fourteen sedentary individuals (4 males, 10 females, Age  $7.7 \pm 11.2$ ) were selected for a 12-week weight loss pilot study to determine the monitoring effectiveness of the bodybugg armband system. **METHOD:** Subjects worked out with a personal trainer at least three times a week performing both aerobic and resistance training, attended weekly educational sessions, wore the bodybugg monitor 24 hrs/day (except when showering or swimming), participated in team challenges, and download bodybugg data every 2-3 days. The subjects' exercise intensity and goals gradually increased weekly based on an individual's progress and initial testing.

**RESULTS:** Data showed a 9% weight loss and 8.6% BMI decrease with the greatest absolute fat losses occurring in the most active individuals (Low activity = -2.4%; High Activity = -8.2%). Over the entire 12-weeks, all contestants took 14,889,060 steps and expended 3,897,450. The strongest stepwise regression correlations were observed between weight loss and % kcal expenditure change from baseline (CFB): ( $r = 0.69$ ,  $p < 0.005$ ), % VO<sub>2</sub> max CFB ( $r = 0.65$ ,  $p < 0.01$ ), and % steps/day CFB ( $r = 0.65$ ,  $p < 0.01$ ). Declines in body weight or % body fat were not correlated with improvements in total and segmental body strength (i.e., bicep curl or chest press). Finally, using the median of daily kcal expenditure, subjects were divided into low versus high daily energy expenditure groups (LDEE versus HDEE), fitness improvements were not different between the groups (VO<sub>2</sub> max,  $p = 0.16$  and total 1-RM strength,  $p = 0.71$ ). Yet, weight loss was 2.3 times greater in the group that had the greatest pre-to-post gain in total daily energy expenditure ( $p = 0.004$ ). Thus, the bodybugg system was able to distinguish if a lack of or increase in daily lifestyle physical activity level, independent of fitness changes, played a significant role in a person's weight loss success in the program.

**CONCLUSION:** In conclusion, the bodybugg monitoring system can play a very important role in determining both fitness and non-fitness related physical activity levels during a free-living monitored weight loss program. However, follow up research is needed to determine if the bodybugg system can facilitate continued weight loss success after a person completes a supervised program.

## Influences Of Weight Gain And Macronutrient Source On Monocyte TLR4 And Cytokine Expression In Mice

Kelley Strohacker, Richard J. Simpson, Katie C. Carpenter, Whitney Tharpe, Brian K. McFarlin. *University of Houston, Houston, TX.*

Email: kstrohacker@mail.coe.uh.edu

(No relationships reported)

Excessive weight gain increases systemic inflammation, which is implicated in the development of most secondary diseases associated with obesity. Toll-like receptor 4 (TLR4) has been purported to mediate weight gain induced increases in systemic inflammation; to our knowledge, its role has not been fully evaluated. Excess calorie consumption is the most common cause of excessive weight gain, but the influence of macronutrient content on weight gain and TLR4 is unknown.

**PURPOSE:** The purpose of this study was to determine the effect of dietary macronutrient content on weight gain and markers of systemic inflammation in blood monocytes following 12-weeks of feeding.

**METHODS:** Male CD-1 mice were randomly assigned to high fat (HF, n = 12, 60% fat) or high carbohydrate (HC, n = 13, 60% CHO) groups. Mice were allowed ad libitum access to food and water. Venous blood was collected at 0, 4, 8 and 12 weeks from a peripheral saphenous vein. Three-color flow cytometry was used to measure monocyte TLR4 expression and intracellular LPS-stimulated monocyte IL-6 and TNF- $\alpha$  production. Data were analyzed with a repeated measure ANOVA, significance was set at  $P \leq 0.05$ .

**RESULTS:** Body weight at week 12 was 20% greater in HF than HC ( $P < 0.05$ ). Similar effects were found for percentage of weight gained. TLR4 MFI at week 12 was 30% greater in HC than HF ( $P < 0.05$ ). Percent increase in body weight at week 12 was positively correlated with the concentration of monocytes producing IL-6 ( $r = 0.34$ ,  $P < 0.05$ ) and TNF- $\alpha$  ( $r = 0.38$ ,  $P < 0.05$ ) but negatively correlated with IL-6 MFI ( $r = -0.38$ ,  $P < 0.05$ ) and TNF- $\alpha$  MFI ( $r = -0.41$ ,  $P < 0.05$ ).

**CONCLUSIONS:** Our findings are contrary to our hypothesis that weight gain due to high-fat feeding would lead to greater inflammatory responses. TLR4 expression appears to follow the same pattern during weight gain regardless of macronutrient content until week 8 (when HF gained ~50% of body weight and HC gained ~30%); at this point monocytes concentration appears to decrease and MFI increases relative to HF values. More research is needed to determine how changes in the blood relate to changes in peripheral adipose tissue compartments.

### 2846 Board #240 May 29 3:30 PM - 5:00 PM Prevention Of Weight Gain In College Freshmen Through Environmental Change

Stella L. Volpe, FACSM<sup>1</sup>, John M. Jakicic, FACSM<sup>2</sup>, Jean A. Anliker<sup>3</sup>, Peggy Policastro<sup>4</sup>, May May Leung<sup>5</sup>. <sup>1</sup>University of Pennsylvania, Philadelphia, PA. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA. <sup>3</sup>University of Massachusetts, Amherst, MA. <sup>4</sup>Rutgers, The State University of New Jersey, New Brunswick, NJ. <sup>5</sup>University of North Carolina, Chapel Hill, NC.

Email: svolpe@nursing.upenn.edu

(No relationships reported)

A university dining hall would be an ideal community in which to study the effects of an environmental change on the prevention of weight gain, since it will allow for tracking of the impact of an environmental manipulation over an extended period of time in the same participants, because freshmen are required to consume their meals in the dining hall. If the environment of the dining halls is altered to decrease the amount of food available, weight gain during the college years may be prevented.

**PURPOSE:** To determine the effectiveness of altering the environment to prevent weight gain in college students.

**METHODS:** College freshmen and transfer students were recruited. Two dining halls served as the research sites: one was the intervention dining hall, the other served as the control. In the intervention dining hall, portion sizes and serving utensils in self-service areas were decreased. Body weight and body mass index (BMI) were the primary outcome variables.

**RESULTS:** There was a clinically significant reduction in BMI of about 0.8% in the experimental group (initial n=57), while the control group had a 2% increase in BMI (initial n=61) (baseline to post-intervention). Similar patterns occurred with body weight: the intervention group lost about 0.8 kg, while the control group had a weight gain of about 0.9 kg (baseline to post-intervention).

**CONCLUSIONS:** Though not statistically significant, these results are clinically significant, because it has been reported that for every 1% above desirable BMI, the risk for coronary heart disease (CHD) increases by 3.3% for women and 3.5% for men. Moreover, for every kilogram of weight loss, there are significant reductions in risk factors for CHD and diabetes mellitus. For every kilogram weight gain after high school, the CHD risks increase by 5.7% for women and 3.1% for men.

### 2847 Board #241 May 29 3:30 PM - 5:00 PM Pomegranate Seed Oil Supplementation During High-Fat Feeding May Reduce Weight Gain And Type 2 Diabetes Risk In Mice

Brian K. McFarlin, Kelley A. Strohacker, Michael L. Kueht. *University of Houston, Houston, TX.*

Email: bmcfarlin@uh.edu

(No relationships reported)

The health benefits of pomegranate consumption have recently received considerable scientific focus, with most studies examining fruit and/or juice consumption. Pomegranate seed oil (POMo) is a rich source of 9-cis, 11-trans conjugated linolenic acid (CLA), which may offset the side effects associated with weight gain.

**PURPOSE:** The purpose of this study was to evaluate the effects of POMo consumption during 14-weeks of high-fat feeding (60% calories from fat) in mice.

**METHODS:** Male, wild-type CD-1 mice were divided into one of three groups (N=20 per group): High-Fat (HF), HF + Seed Oil (HF+POMo), or lean control (LN). In HF and HF+POMo, mice were provided ad libitum access to a high-fat chow (60% of joules (calories) from fat). HF+POMo was supplemented with 61.79 mg of POMo/day. LN consumed a restricted low-fat (10% of joules (calories) from fat) chow to maintain body weight within 5% of initial weight. Plasma was analyzed for biomarkers associated with cholesterol profile (total cholesterol, HDL, and triglycerides), glucose sensitivity (glucose and insulin), adipose tissue accumulation (leptin and adiponectin), and systemic low-grade inflammation (CRP and haptoglobin). Data were analyzed for significance using a one-way ANOVA, with significance set at  $P < 0.05$ .

**RESULTS:** Weight gain (HF and HF+POMo) was associated with an increase in biomarkers of cholesterol profile, insulin insensitivity, adipose tissue accumulation, and systemic low-grade inflammation ( $P < 0.05$ ). POMo supplementation only altered selected aspects of weight gain. HF+POMo mice gained 20% less weight than HF, despite similar level of caloric intake ( $P = 0.002$ ). HF+POMo mice had a 100% lower plasma leptin concentration ( $P < 0.001$ ) and 80% greater adiponectin concentration ( $P = 0.019$ ), than HF mice. Plasma insulin concentration was 26% lower in HF+POMo, compared to HF ( $P = 0.003$ ).

**CONCLUSIONS:** POMo intake was associated with an improvement in insulin sensitivity, suggesting that risk of developing type II diabetes may have been reduced; however, cardiovascular disease risk did not appear change. More research is needed to determine the mechanism by which POMo exerts its action.

---

### 2848 Board #242 May 29 3:30 PM - 5:00 PM Relationship Between Sedentary Behaviors And Markers Of Insulin Sensitivity In Young Women

Kathleen Woolf, Shauna Salvesen, Brandy-Joe Milliron, Mark Johnson, Mallory Adams. *Arizona State University, Mesa, AZ.*

Email: kathleen.woolf@asu.edu

(No relationships reported)

Sedentary lifestyles may be associated with the rising prevalence of obesity and chronic disease in the US.

**PURPOSE:** The purpose of this study was to examine the relationship between accelerometer-determined sedentary behaviors and markers of insulin sensitivity.

**METHODS:** Young (25-40 y) normal weight (BMI  $22.2 \pm 1.9$  kg/m<sup>2</sup>; n=26), overweight (BMI  $27.2 \pm 1.4$  kg/m<sup>2</sup>; n=22), and obese (BMI  $34.4 \pm 2.7$  kg/m<sup>2</sup>; n=27) women were recruited for the study. Height, weight, and waist circumference were determined for each participant. Fasting blood samples were measured for serum insulin and plasma glucose concentrations. Insulin sensitivity was calculated according to the Quantitative Insulin Sensitivity Check Index (QUICKI) method. Participants wore an accelerometer (Kenz Lifecorder) and reported time to sleep and time awake for 7-days. Time (minutes/day) spent in four activity levels (inactive, light, moderate, vigorous) was determined. Sleep time (minutes/day) was subtracted from the inactive category. Sedentary behaviors (inactive - sleep minutes/day) was determined for each participant. One-way analysis of variance examined differences in markers of insulin resistance across the weight groups. Partial correlations (controlling for age) examined the relationship between sedentary behaviors (minutes/day) and markers of insulin sensitivity.

**RESULTS:** Waist circumference and serum insulin increased significantly across BMI categories (waist circumference [cm]: normal weight  $77 \pm 8$ , overweight  $92 \pm 6$ , obese  $105 \pm 9$  [p<0.01]; insulin [ $\mu$ U/mL]: normal weight  $6 \pm 3$ , overweight  $8 \pm 4$ , obese  $13 \pm 7$  [p<0.01]). QUICKI decreased significantly across BMI categories (normal weight  $0.389 \pm 0.041$ , overweight  $0.360 \pm 0.036$ , obese  $0.334 \pm 0.021$  [p<0.01]). No differences were seen between BMI categories for plasma glucose. The normal weight, overweight, and obese women participated in  $618 \pm 82$ ,  $631 \pm 137$ , and  $659 \pm 95$  minutes/day of sedentary behaviors, respectively [p=0.36]. Using partial correlations (controlling for age), time (minutes/day) spent in sedentary behaviors was positively associated with insulin (r=0.31; p<0.01) and negatively associated with QUICKI (r=-0.29; p=0.01).

**CONCLUSIONS:** In this study, more time spent in sedentary behaviors was associated with unfavorable markers of insulin sensitivity.

---

**2849 Board #243 May 29 3:30 PM - 5:00 PM**  
**Body Composition and Hormonal Adaptations Associated With Forskolin Consumption In Overweight And Obese Women**

Michael P. Godard, FACSM, Beth A. Ewing. *Western Illinois University, Macomb, IL.*

Email: MP-Godard@wiu.edu

(No relationships reported)

**PURPOSE:** This study examined the effect of forskolin on body composition, testosterone, sex hormone binding globulin (SHBG), and blood pressure in overweight and obese (BMI  $\geq 26$  kg/m<sup>2</sup>) women.

**METHODS:** Twenty-two subjects (forskolin, n=10; placebo, n=12) were studied in a randomized, double-blind, placebo-controlled study for 12 weeks.

**RESULTS:** Forskolin was not shown to elicit favorable changes in body composition as determined by the Bod Pod compared with the placebo group (p>.05) in women. There was no significant change for fat-free mass in the forskolin group ( $-0.06 \pm 3.66$  kg) compared with the placebo group ( $1.86 \pm 4.10$  kg). There was no significant change for fat mass in the forskolin group ( $0.39 \pm 2.72$  kg) compared with the placebo group ( $1.55 \pm 5.51$  kg). Serum free testosterone levels showed no significant change in the forskolin group ( $3.38 \pm 4.29$  pg/ml) compared with the placebo group ( $-2.05 \pm 3.88$  pg/ml). There was no significant change for serum total testosterone concentration in the forskolin group ( $3.38 \pm 4.29$  ng/ml) compared with the placebo group ( $-2.05 \pm 3.88$  ng/ml). There was no significant change for SHBG in the forskolin group ( $0.01 \pm 0.78$  nmol/L) compared with the placebo group ( $-1.15 \pm 2.39$  nmol/L).

**CONCLUSIONS:** Oral ingestion of forskolin (250 mg of 10% forskolin extract twice a day) for a 12-week period was not shown to alter body composition. The results indicate that forskolin is not a therapeutic agent for the management and treatment of obesity in women. A previous study conducted in our lab (*Obesity Research*, 13(8): 1335-1343, 2005) on overweight and obese men showed that forskolin did elicit favorable changes in body composition by significantly decreasing body fat percentage and fat mass and significantly increasing serum free testosterone compared with the placebo group (p $\leq$ 0.05). We conclude that the differences in women and men are likely attributed to the dissimilarity of basal testosterone levels.

**2850 Board #244 May 29 3:30 PM - 5:00 PM**  
**Obesity In Elderly Women Is Associated With Insulin Resistance Of Glucose And Protein Metabolism**

Eric DB Goulet, Stéphanie Chevalier, Réjeanne Gougeon, José A. Morais. *McGill University, Montréal, QC, Canada.*

Email: eric.goulet@mcgill.ca

(No relationships reported)

We have previously shown that normal aging is associated with insulin resistance of glucose metabolism that also extends to that of protein. Obesity creates particular metabolic changes that contribute in further decreasing insulin sensitivity of glucose metabolism. How obesity affects insulin sensitivity of protein metabolism in the elderly remains unknown.

**PURPOSE:** To compare insulin sensitivity of whole-body glucose and protein metabolism between obese (O) and non-obese (NO) elderly women.

**METHODS:** [<sup>13</sup>C] leucine kinetics were measured in 10 healthy NO and 8 healthy O elderly women in the postabsorptive state and during a hyperinsulinemic ( $40 \mu\text{U} \cdot \text{m}^{-2} \cdot \text{min}^{-1}$ ), euglycemic ( $5.5 \text{ mmol} \cdot \text{L}^{-1}$ ), isoaminoacidemic (amino acids maintained at individual baseline) clamp for 210 min. Body composition was measured using bioelectrical impedance analysis with validated equations. Volunteers followed a 7-day, isoenergetic formula-based diet before the clamp comprising  $1.8 \text{ g protein} \cdot \text{kg fat-free mass (FFM)}^{-1} \cdot \text{day}^{-1}$ .

**RESULTS:** Age did not differ (O:  $72 \pm 4$  vs. NO:  $70 \pm 6$  yrs), and body mass ( $77 \pm 9$  vs.  $57 \pm 7$  kg), body mass index ( $31 \pm 3$  vs.  $23 \pm 2$  kg  $\cdot \text{m}^{-2}$ ), FFM ( $40 \pm 3$  vs.  $36 \pm 3$  kg) and fat mass (FM) ( $37 \pm 6$  vs.  $22 \pm 5$  kg) were significantly higher in O than NO (all P < 0.02). In the postabsorptive state, leucine rate of appearance (Ra, protein breakdown) was 12% higher (P < 0.01) and disappearance (Rd, synthesis) 10% higher (P < 0.01) in O than NO, but leucine oxidation and net balance did not differ between groups. With hyperinsulinemia, insulin sensitivity (glucose infusion rate  $\cdot \text{FFM}^{-1}$ /mean plateau insulin) was 56% less (P = 0.02) in O than NO, with no difference in the rate of amino acid infusion between groups. The percent change in leucine flux, Ra and Rd was not different between groups, but that of leucine oxidation was 26% higher (P = 0.02) in O than NO. FM (kg) correlated (r = 0.70, P < 0.01) with the % change in leucine oxidation.

**CONCLUSION:** In addition to demonstrating a reduced insulin sensitivity of glucose metabolism, our results suggest that obese elderly women also have a blunted protein anabolic response to hyperinsulinemia due to increased losses through oxidation.

**2851 Board #245 May 29 3:30 PM - 5:00 PM**  
**Effects Of Exercise On Appetite And Whole Saliva in Humans**

Nami Someya<sup>1</sup>, Masumi Kamei<sup>1</sup>, Yoshiyuki Fukuba, FACSM<sup>2</sup>, Naoyuki Hayashi<sup>1</sup>. <sup>1</sup>Kyushu University, Kasuga, Japan. <sup>2</sup>Prefectural University of Hiroshima, Hiroshima, Japan.

(No relationships reported)

We previously confirmed that the sight and smell of food enhance appetite and salivary flow, and decrease salivary viscosity.

**PURPOSE AND METHODS:** To examine the effect of exercise on appetite and the characteristics of saliva, six subjects performed high-intensity exercise for 12 min [2.0 and 1.6 W/kg (weight) for males and females, respectively] and low-intensity exercise for 24 min [1.0 and 0.8 W/kg (weight) for males and females, respectively] after a 3-min baseline. Then subjects rested for 36 min as a recovery phase. Whole saliva was collected for 3 min at the baseline and every 12 min during exercise and recovery phase.

Subjects rated prospective food consumption on a 100-mm visual analog scale (Question: How much food do you think you could eat? Answer: 0 = nothing at all, 100 = a large amount). Subjects placed a nylon ball (15 mm in diameter) in their oral cavity to promote salivary flow. We then measured the flow and viscosity of saliva.

**RESULTS:** The rate of prospective food consumption increased 30 min after the end of low-intensity exercise ( $p < 0.05$ ), but did not change during and after high-intensity exercise. Compared to the resting baseline, salivary flow significantly decreased during high-intensity exercise, but not during and after low-intensity exercise. The viscosity of saliva did not significantly change in response to exercise. There was no significant correlation between the changes in appetite and saliva variables.

**CONCLUSION:** These results suggest that the effects of exercise on appetite and salivary flow depend on the intensity of the exercise, and that the change in appetite associated with exercise does not relate to the characteristics of saliva.

**The Influence Of High Intensity Running And Cycling On Plasma Acylated Ghrelin Concentrations In Males**

Lucy K. Wasse<sup>1</sup>, James A. King<sup>1</sup>, Masashi Miyashita<sup>2</sup>, Caroline Sunderland<sup>3</sup>, David J. Stensel<sup>1</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>University of Tsukuba, Tsukuba, Japan. <sup>3</sup>Nottingham Trent University, Nottingham, United Kingdom.

Email: L.K.Wasse@lboro.ac.uk

*(No relationships reported)*

Running suppresses plasma acylated ghrelin and this may be related to a well-documented transient suppression of hunger during running. The effects of cycling on acylated ghrelin may differ to those of running since body mass is supported during cycling.

**PURPOSE:** To examine the effects of cycling and running on plasma acylated ghrelin and hunger.

**METHODS:** Following University ethical approval 10 healthy males (mean  $\pm$  SEM: age  $21.6 \pm 0.5$  yrs, BMI  $23.4 \pm 0.9$  kg·m<sup>-2</sup>, VO<sub>2</sub> max  $55.7 \pm 2.6$  and  $47.4 \pm 2.4$  mL·kg<sup>-1</sup>·min<sup>-1</sup> for running and cycling respectively) completed 3, 4 h trials; control, running and cycling in a random order after a 10 h fast. During the exercise trials, subjects ran or cycled for 1 h at 70% of mode-specific VO<sub>2</sub> max for the first hour, and then rested for the remainder of the trial with a test meal consumed at 3 h. During the control trial subjects rested throughout. Hunger ratings were measured every 0.5 h using a visual analogue scale. Venous blood samples were collected at 0, 0.5, 1, 1.5, 2, 3, 3.5 and 4 h for determination of acylated ghrelin via an enzyme immunoassay (SPI BIO, France).

**RESULTS:** There was a wide variation in acylated ghrelin concentrations among subjects (mean  $\pm$  SEM: fasting value  $264 \pm 88$ , range 61-1227 pg·mL<sup>-1</sup>). There was a main effect of time (two-way ANOVA  $P < 0.05$ ) indicating suppression of acylated ghrelin and hunger after feeding but no main effect of trial and no interaction effect. Upon removal of an outlier whose mean fasting acylated ghrelin values were 795 pg·mL<sup>-1</sup> higher than the mean of the remaining 9 subjects (mean  $\pm$  SEM:  $184 \pm 42$  pg·mL<sup>-1</sup>), a trend was evident (main effect of trial  $P = 0.07$ ,  $N = 9$ ) for suppressed acylated ghrelin concentrations at 0.5 h in the running and cycling trials compared with the control trial ( $123 \pm 111$  v  $182$  pg·mL<sup>-1</sup> respectively) and at 1 h in the running and cycling trials compared with the control trial ( $105 \pm 114$  v  $178$  pg·mL<sup>-1</sup> respectively).

**CONCLUSION:** Plasma acylated ghrelin concentrations were not reduced during either running or cycling exercise although a trend was evident on removal of an outlier. These initial findings warrant further investigation with an increased subject number.

*(No relationships reported)*

Wrestlers frequently undergo periodic weight-loss in order to compete in the higher end of their weight-class and minimize the chances of conceding size to an opponent. Unsurprisingly, such "weight-making" practices can impair performance. Starvation and overtraining elevate levels of inflammatory mediators and decrease levels of anabolic compared to catabolic hormones, causing muscle-wasting. Recent advances have been made in treating inflammatory illnesses, such as exercise-induced asthma, with fish-oils.

**PURPOSE:** We aimed to examine the inflammatory response to weight-making and to ascertain the potential for fish-oil supplementation as a ergogenic aid in this context.

**METHODS:** A 2-way mixed-measures design was executed over a four week period prior to competition, during which, wrestlers lost weight. Circulating levels of cytokines, anabolic and catabolic hormones were compared between wrestlers assigned to either fish-oil supplementation or placebo at -28days, -7days and +3days relative to competition.

**RESULTS:** No significant differences in the ratio of growth hormone to cortisol (GH/C) existed, with individual wrestlers showing a contrasting array of responses to weight-making. Our data did suggest, however, that fish-oils may exert a female-specific regulatory effect on decreases in GH/C. Although none of the cytokine-profiles showed a significant difference from supplementation, a consistent trend was revealed towards lower levels in the fish-oil group. Fish-oil profiles for Interleukins 2/4/5/6/8/10/12p70/1b/ as well as TNF- $\beta$ , and TNF- $\alpha$  show lower concentrations than the controls at either -7days, +3days or at both time-points. The pro-inflammatory cytokines IL4, IL-8 and TNF- $\alpha$ , frequently associated with inflammatory disease, showed the most pronounced response to supplementation.

**CONCLUSIONS:** Our desire to work in elite sport limited our sample size and underpowered the study. Yet, consistent trends in the attenuation of cytokine levels, as well as an observed amelioration in the catabolic environment in females, would support the need for further research.

**Gender Comparison Of Vastus Lateralis Basal Myogenic, Proteolytic, Myostatin And Myokine Mrna Levels**

Emily Louis, Nick Luden, Erik Hayes, Ulrika Raue, Bozena Jemiolo, Scott Trappe, FACSM. Ball State University, Muncie, IN.

*(No relationships reported)*

It is well established that males generally have greater muscle mass compared to females. Additionally, it has been shown that in response to prolonged bed rest, females appear to experience unloading-induced atrophy more quickly and to a greater extent than males. These findings suggest that males and females may have differences in basal molecular regulation of muscle mass.

**PURPOSE:** The aim of this study was to compare basal levels of myogenic, proteolytic, myostatin, and myokine mRNA between the male and female vastus lateralis (VL) muscle.

**METHODS:** Biopsies from the VL of seven males ( $26 \pm 3$  yr,  $75 \pm 8$  kg) and seven females ( $25 \pm 3$  yr,  $59 \pm 5$  kg) were obtained 10-12 hours following a standardized meal. All

subjects were recreationally active, healthy, and had refrained from all non-essential physical activity during the 48 hours prior to the biopsies. Using RT-PCR, the mRNA levels of select myogenic (MyoD, myogenin, MRF4), proteolytic (MuRF-1, atrogin-1), myostatin, and myokine (IL-6, -8, and -15) genes were analyzed and normalized to GAPDH.

**RESULTS:** *Myogenic:* MRF4 gene expression was 1.8-fold higher in males ( $p<0.05$ ) than females. *Proteolytic:* Males had higher atrogin-1 (2.4-fold) and MuRF-1 (1.6-fold) gene expression compared to females ( $p<0.05$ ). *Myostatin:* Basal levels of myostatin mRNA was 12.5-fold higher in males compared to females ( $p<0.05$ ). *Interleukins:* Males had higher basal IL-6 (2.0-fold) and IL-15 (5.9-fold) mRNA ( $p<0.05$ ).

**CONCLUSION:** *In general, the male VL had higher basal levels of myogenic, proteolytic, myostatin and myokine mRNA as compared to females. These findings substantiate gender-specific differences in the molecular regulation of muscle mass at rest. However, direct factors responsible for, and as a result of these differences have yet to be elucidated. Supported by NASA grant NNJ06HF59G*

**Isokinetic Strength And Anaerobic Performance In African-American And Caucasian Males**

Stacy D. Hunter, David R. Bassett, FACSM, Eugene Fitzhugh, Dinesh John. *University of Tennessee, Knoxville, TN.*  
(No relationships reported)

African-Americans outperform their Caucasian counterparts in anaerobic activities like sprinting and jumping. However, the mechanism explaining their superior performance in these activities remains unclear. The force-velocity characteristics of the muscles, as determined by isokinetic testing, are related to muscle fiber type, and may partially explain racial differences in anaerobic performance.

**PURPOSE:** To compare vertical jump (VJ) height and power (VJP), sprint time, and isokinetic strength in African-American and Caucasian college-aged males, and to examine correlations between these variables.

**METHODS:** The participants were 23 African-American and 27 Caucasian recreationally active, college-aged males. Anthropometric measures (height, weight, percent body fat, and thigh circumference) were taken and physical activity (PA) was assessed by questionnaire. Subjects were tested for VJ, 100-m run time, and isokinetic peak torque (PT). Isokinetic knee extension and flexion were performed on a Biodex System 3 at angular velocities of 60, 120, 210, 300, and 400 degrees  $\cdot$  s<sup>-1</sup>. Peak torques and relative torques (RT), using torque generated at 60 degrees  $\cdot$  s<sup>-1</sup> as the reference, were analyzed.

**RESULTS:** There were no significant differences between African-Americans and Caucasians in anthropometric variables, PA, PT, or RT. African-Americans exhibited greater VJ height ( $p<0.01$ ) and VJP ( $p<0.05$ ). African-Americans were also faster in the 100-m dash when controlling for body fat percentage and wind velocity ( $p<0.05$ ). Vertical jump height significantly correlated with 100-m sprint time ( $r = -0.769$ ,  $p<0.001$ ). Vertical jump power significantly correlated with isokinetic knee extension PT at all angular velocities and with knee flexion PT at 120, 300 and 400 degrees  $\cdot$  s<sup>-1</sup>.

**CONCLUSION:** African-Americans demonstrated superior performance in the VJ and 100-m dash, but not in isokinetic strength. However, African-Americans showed a trend towards greater PT and RT at high angular velocities which may give them a slight performance advantage in tasks requiring fast speeds of muscle contraction.

Email: bradley.nindl@amedd.army.mil  
(No relationships reported)

Growth hormone (GH) exists as a family of molecular weight (MW) variants with different biological activities and whose response patterns to exercise are poorly understood. Whereas the pulsatile release of GH is known to be sexually dimorphic, no data are available that directly compare GH MW variant exercise responses in men and women. Such information may be important in understanding sex-related differences in exercise and metabolic adaptations.

**PURPOSE:** To compare GH MW variant responses to acute resistance exercise in men and women.

**METHODS:** 10 men and 10 women performed an acute exercise test (AET; 6 sets of 10 RM squats), and had blood drawn pre, mid, and post (0, +15, and +30 min post) of the AET. Serum samples were fractionated using high pressure liquid chromatography into 3 MW pools (A: >60 kDa; B: 30-60 kDa; C: <30 kDa) which correspond to GH oligomers, GH dimers and GH monomers, respectively. GH concentrations were determined using a commercially-available immunoassay. Data were analyzed with repeated measures ANOVA.

**RESULTS:** Across all time points and sex, Fraction C (GH monomer) was the highest MW variant collected (C:  $14.3 \pm 1.8 > A: 9.6 \pm 1.7 > B: 5.2 \pm 0.7$  ng;  $p<0.05$ ). Interactions with fraction, time, and sex ( $p<0.01$ ) indicated that women experienced GH increases in all 3 MW variants examined from pre to mid exercise (A: pre:  $7.7 \pm 7.1$  vs mid:  $14.9 \pm 12.4$ ; B: pre:  $4.1 \pm 3.1$  vs. mid:  $6.8 \pm 5.3$ ; C: pre:  $8.9 \pm 7.2$  vs. mid:  $19.7 \pm 15.8$ ), while men did not increase until post-exercise (A: pre:  $2.1 \pm 2.5$  vs. +15 post:  $11.0 \pm 8.5$ ; B: pre:  $0.9 \pm 1.1$  vs. post:  $5.7 \pm 3.7$ ; C: pre:  $2.7 \pm 2.3$  vs. post:  $17.1 \pm 8.9$ ). In recovery, men maintained elevations of the B (pre:  $0.9 \pm 1.1$  vs. +30 post:  $5.5 \pm 3.9$ ) and C fractions (pre:  $2.7 \pm 2.3$  vs. +30 post:  $14.9 \pm 10.7$ ) for at least 30 min ( $p<0.05$ ), while all fractions in women returned to baseline within 15 min ( $p>0.05$ ).

**CONCLUSIONS:** Women experienced earlier increases in all GH variants during exercise whereas men demonstrated more sustained increases in GH monomers and dimers in the post-exercise milieu. Temporal GH molecular variant responses to exercise differ in men and women.

**2857 Board #4 May 30 9:30 AM - 11:00 AM**  
**Age-related Changes In Number Of Nucleus Around Neuromuscular Junction In Rat Diaphragms**

Akane Yamaguchi, Minako Kawai, Hirofumi Miyata. *Yamaguchi Univ, Yamaguchi, Japan.*  
Email: miyalab@yamaguchi-u.ac.jp  
(No relationships reported)

**PURPOSE:** Previous studies demonstrated a decrease in neuromuscular activity with aging and the extent of decrease could influence neuromuscular junction morphology and function. In this study, we compared number of nucleus around neuromuscular junction (NMJ nucleus) and 3-dimensional (3D) morphological properties of motor endplate in diaphragm muscle between young and old rats.

**METHODS:** Young (2-5 months old,  $n=7$ ) and old (over 2 years old,  $n=7$ ) male Wistar rats were used. Mid-costal diaphragm muscle segments were removed and endplates were labeled with a-bungarotoxin conjugated tetramethylrhodamine. A number of single muscle fiber with labeled endplate was isolated from the segments under fluorescent microscope, and myonuclei including NMJ nucleus were stained with DAPI (4', 6-diamino-2-phenylindole) to examine the space distribution of these nuclei.

**RESULTS:** In 54 single fibers from young diaphragm, the mean values (+ standard deviation) of endplate surface area and volume were  $1428 \pm 613$   $\mu$ m<sup>2</sup> and  $2019 \pm 972$   $\mu$ m<sup>3</sup>, respectively. In 58 single fibers from old diaphragm, the mean value of endplate surface area and volume were  $2531 \pm 1190$   $\mu$ m<sup>2</sup> and  $2440 \pm 1684$   $\mu$ m<sup>3</sup>, respectively. Large variations were found in endplate surface area and volume in old diaphragm, as compared to these values in young diaphragm. Decreased endplate density (endplate area / outer surrounding area) in the old diaphragm indicated fragmentation of the endplate (from  $71.5\% \pm 7.3\%$  to  $55.2 \pm 7.3\%$ ). The number of NMJ nucleus was significantly higher in

old ( $16.1 \pm 6.6$ ) than young ( $9.7 \pm 5.2$ ) diaphragm muscles. There were almost same significant relationships between the number of nuclei and endplate volume in both young ( $r=0.52$ ) and old ( $r=0.53$ ) diaphragms. Therefore, the endplate volume / number of NMJ nucleus were identical in both age groups.

**CONCLUSIONS:** The identical rate of endplate volume to number of NMJ nuclei of diaphragm muscle between two age groups suggest that the nuclear domain in NMJ area is also constant, as shown in myonuclei domain of muscle fiber with aging in previous study.

**Dexa-determined Body Composition Differences Between Young And Old Rats Are Not Sensitive Enough To Predict Age-related Strength And Sensorimotor Function Decrements**

Sang-rok Lee, Edward C. Archer, Jacob M. Wilson, Ken P. Leonard, Carlos Ugrinowitsch, Young-min Park, Paul C. Henning, Shirin Hooshmand, Neema Bakhshalian, Jeong-su Kim. *Florida State University, Tallahassee, FL*

(No relationships reported)

DEXA-determined Body Composition Differences between Young and Old Rats Are Not Sensitive Enough to Predict Age-related Strength and Sensorimotor Function Decrements

Sarcopenia defined as the age-related decline in muscle mass and resultant decrements in strength, and motor function that follow, is increasingly being studied with the use of animal models. Recently, dual-energy x-ray absorptiometry (DEXA) has been used to determine body composition in animals. Nevertheless, its ability to detect differences in age-related indices of lean body mass and to use these indices to predict changes in functionality and strength has not yet been investigated.

**PURPOSE:** To investigate the ability of DEXA to determine differences in age-related changes in body composition, and to investigate whether these measures were sensitive enough to predict changes in strength and motor function with age in young (10 months) and old (21 months) rats.

**METHODS:** Young ( $n=16$ ) and old ( $n=14$ ) Fisher 344 male rats were tested using DEXA to assess total body mass (TBM), lean body mass (LBM), and bone mineral content (BMC). A murine-specific digital force gauge was used to assess forelimb grip strength, while an inclined plane was used to evaluate sensorimotor function.

**RESULTS:** Young animals had significantly greater ( $p<0.05$ ) TBM ( $426 \pm 19$  vs.  $402 \pm 22$  g), LBM ( $271 \pm 22$  vs.  $239 \pm 29$  g), and BMC ( $14 \pm 7$  vs.  $12 \pm 4$  g). Similarly, grip strength ( $1394 \pm 180$  vs.  $1547 \pm 125$ ) and motor function, as determined by angle of inclined plane ( $44 \pm 5$  vs.  $38 \pm 5^\circ$ ), were higher ( $p<0.05$ ) in young as compared to old animals. Multiple regression analyses did not reveal any significant relationships between body composition measures and indices of strength or motor function ( $p>0.05$ ).

**CONCLUSIONS:** DEXA was able to detect differences in TBM, LBM, and BMC between young and old animals. However, these variables do not appear to be sensitive enough measures to explain the variance in strength and sensorimotor function. Future research should incorporate longitudinal models using more sensitive measurements to predict age-related differences in strength and motor function.

**Hindlimb Muscle Quality And Ambulation In Old Rats**

David W. Russ<sup>1</sup>, Angela Horner<sup>1</sup>, Audrone Biknėvicius<sup>2</sup>, Christopher W. Ward<sup>3</sup>. <sup>1</sup>Ohio University, Athens, OH. <sup>2</sup>Ohio University College of Osteopathic Medicine, Athens, OH. <sup>3</sup>University of Maryland School of Nursing, Baltimore, MD. (Sponsor: Randall Keyser, FACSM)  
Email: russd@ohio.edu

(No relationships reported)

**PURPOSE:** To assess age-related declines in muscle contractile function and locomotion in an animal model.

**METHODS:** *In situ* force frequency data and *in vitro* sarcoplasmic reticulum (SR)  $Ca^{2+}$  release and reuptake rates were collected from the plantarflexor muscles of 5 young (6-8 months) and 5 old (24-26 months) F344/BN rats. Videographic and ground reaction force measurements were used to assess gait biomechanics in a subset of these animals ( $n = 3/\text{group}$ ).

**RESULTS:** The plantarflexors of old rats produced significantly less force ( $\sim 20\%$ ) than those of the young rats ( $P=0.046$ ), but age-related atrophy was minimal. Only the medial gastrocnemius showed a trend ( $P=0.10$ ) for age-related loss of mass. When muscle force was expressed relative to muscle mass (muscle quality) the effect of age disappeared, but a significant age X frequency interaction ( $P=0.036$ ) persisted, such that the muscle quality was reduced in old muscles only in response to higher frequencies ( $> 50$  Hz). When contractile forces were expressed relative to body mass however, marked reductions ( $>50\%$ ) were observed for all frequencies (all  $P < 0.01$ ). SR release was impaired in old vs. young muscles ( $\sim 20\%$ ,  $P = 0.036$ ), but SR reuptake was surprisingly enhanced ( $\sim 25\%$ ,  $P = 0.42$ ). Locomotor analyses revealed that old rats moved significantly more slowly than young rats ( $0.41 \pm 0.12$  vs.  $0.80 \pm 0.18$  m/s). Qualitatively, old rats exhibited greater gait asymmetry and spinal flexion than young rats during all stride phases. Additionally, while the gaits of young rats tended to exhibit either spring-like or pendular center-of-mass mechanics, those of old rats were extremely variable, falling within the domain of "intermediate mechanics."

**CONCLUSIONS:** Older animals exhibit a frequency-specific reduction in muscle quality, even in instances where muscle atrophy is minimal. This impairment may be related to SR calcium release, but not reuptake. These losses in muscular performance are magnified when expressed relative to body mass, and may contribute to marked locomotor dysfunction with aging.

Email: wolfgang@imp.uni-erlangen.de

(No relationships reported)

**PURPOSE:** To determine the effect of a multipurpose exercise program on sarcopenia and functional ability of females 65 years and older living in the community.

**METHODS:** 246 women (69 $\pm$ 4 years) living independently in the area of Erlangen-Nürnberg (Germany) were randomly assigned into an exercise (EG:  $n=123$ ) or a control group (CG:  $n=123$ ). Subjects of the EG performed a multipurpose exercise program (2x60 min/w.) with special emphasis on exercise intensity, while subjects of the (wellness-)control group performed a program that primarily focused on well being.

**RESULTS:** After 18 months significant exercise effects were observed for Lean Body Mass (changes: EG:  $518 \pm 1357$  g vs. CG:  $8 \pm 1527$  g,  $p=.008$ , Effect size (ES): .35) and Appendicular Skeletal Muscle Mass (EG:  $20 \pm 760$  g vs. CG:  $-278 \pm 901$  g,  $p=.007$ , ES: .36). Significant group-differences were further detected for isometric maximum strength and power changes (leg-press strength:  $95 \pm 121$  N vs.  $-34 \pm 121$  N,  $p<.001$ , ES: .50; leg-press power:  $12.0 \pm 109$  W vs.  $-47 \pm 114$  W,  $p=.008$ , ES: .53). Changes of balance as assessed by static posturography did not significantly differ between the groups ( $p=.109$ , ES: .24). Significant exercise effects were also observed for changes of the Timed Up and Go-test ( $-.37 \pm .88$  vs.  $.09 \pm .93$  s,  $p<.001$ , ES: .51), complex reaction time ( $-7.5 \pm 10.5$  vs.  $-3.0 \pm 13.0$  s,  $p=.01$ , ES: .38) and time under load during treadmill test to voluntary maximum ( $1:07 \pm 2:46$  vs.  $0:15 \pm 2:06$  min,  $p=.04$ , ES: .35).

**CONCLUSIONS:** Low volume multipurpose exercise programs that focus on a high intensity philosophy relevantly affect sarcopenia and functional ability in the elderly.

**Relative Expansion Of Extracellular Water May Mask Actual Relationship Between Muscle Volume And Strength During Aging**

Yosuke Yamada<sup>1</sup>, Shingo Oda, PhD<sup>1</sup>, Yasuko Okayama, PhD<sup>2</sup>, Misaka Kimura, PhD<sup>2</sup>. <sup>1</sup>Kyoto University, Kyoto, Japan. <sup>2</sup>Kyoto Prefectural University of Medicine, Kyoto, Japan.

Email: you-taro@human.mbox.media.kyoto-u.ac.jp

(No relationships reported)

**PURPOSE:** Skeletal muscle tissue holds a large volume of water partitioned into extracellular water (ECW) and intracellular water (ICW) fractions. We hypothesized that age-related decreases in specific force (muscle strength per muscle size) are partly caused by the relative expansion of ECW.

**METHODS:** A total of 119 healthy men aged 20-88 years old participated in this study. Knee isometric extension strength, vertical jump, and chair standing were measured as indices of muscle strength and power in the lower extremities. The regional lean mass (LM), total body water (TBW), ICW, and ECW in the lower leg were estimated by anthropometry (skinfold and circumference measurements) and segmental multifrequency bioelectrical impedance spectroscopy (S-BIS). Furthermore, in 22 elderly, knee extension strength was measured, and muscle thicknesses of quadriceps were assessed by ultrasonography. The index of the ratio of ICW to ECW in the thigh was measured by segmental multi-frequency impedance analysis.

**RESULTS:** Although ICW and the LM index decreased significantly with aging ( $P < 0.001$ ), no significant changes in ECW were observed ( $P = 0.134$ ). Thus the ECW/TBW ratio was significantly ( $P < 0.001$ ) increased with age (young adult,  $27.0 \pm 2.9\%$ ; elderly,  $34.3 \pm 4.9\%$ ; advanced elderly,  $37.2 \pm 7.0\%$ ). Adjusting for this by including the ICW/TBW ratio in our models significantly improved the correlation between the LM index and strength-related measurements and correlated with strength-related variables independently of the LM index ( $P < 0.001$ ). The index of the ratio of ICW to ECW in the thigh was also correlated with knee strength independently from muscle thickness of quadriceps.

**CONCLUSIONS:** The ECW/TBW ratio increases in the lower leg with aging. The results of this study suggest that the expansion of ECW relative to ICW masked actual muscle cell atrophy during aging. Moreover, S-BIS may be useful to assess the physical function of the lower extremities.

**Relationship Of Body Composition And Physical Activity To Muscle Performance In Women Across The Lifespan**

Mark M. Mistic<sup>1</sup>, Kyle T. Ebersole, FACSM<sup>2</sup>, Ellen M. Evans, FACSM<sup>3</sup>. <sup>1</sup>Northern Illinois University, DeKalb, IL. <sup>2</sup>University of Wisconsin-Milwaukee, Milwaukee, WI. <sup>3</sup>University of Illinois, Urbana, IL.

Email: mistic@niu.edu

(No relationships reported)

The relationship between body composition and physical function is an emerging area of research within the aging literature. In particular, changes with aging are poorly understood with respect to the relationship of muscle performance, body composition, and physical activity.

**PURPOSE:** The primary aim of this study was to investigate the relationship between body composition and physical activity to leg strength and fatigue in women across the lifespan.

**METHODS:** Seventy-two women were grouped into one of two age groups: Young (20-30 years;  $n=37$ ) or Old (61-84 years;  $n=35$ ). Each participant performed 25, maximal leg extensions (EXT) and flexions (FLX) at  $180^\circ \text{ sec}^{-1}$ . For each leg, a fatigue index (FI%) was determined from the peak and ending torque. Peak torque (TQ) was subsequently normalized to leg mineral free lean mass (MFLM) and used for age and limb comparisons of maximal strength. Body fat (BF%) and MFLM were measured using DXA and physical activity (STEPS) was assessed for 7 days using a step counter.

**RESULTS:** The Young had significantly ( $p < 0.05$ ) lower BF% and greater STEPS,  $\text{MFLM}_{\text{TOTAL}}$ , and  $\text{MFLM}_{\text{LEG}}$  compared to Old. Repeated measures ANOVA indicated that although there was no difference in FI% and TQ between limbs (dominant vs. non-dominant), there was a significant main effect for age (collapsed across limb) where the Young group had lower EXT-FI%, FLX-FI%, and greater EXT-TQ, FLX-TQ than the Old. Correlation analysis suggested that EXT-TQ and EXT-FI% had the highest correlation to AGE ( $r = -0.61$  and  $0.34$ ) while FLX-TQ had highest correlation with STEPS ( $r = 0.33$ ). EXT-TQ was also correlated to BF% ( $r = -0.39$ ),  $\text{MFLM}_{\text{LEGS}}$  ( $r = 0.39$ ), and STEPS ( $r = 0.27$ ). FLX-TQ was also correlated to AGE ( $r = -0.31$  and BF% ( $r = -0.24$ ), and EXT-FI% was also correlated to %BF ( $r = 0.30$ ). When controlling for AGE, no significant correlations were found.

**CONCLUSIONS:** The results indicate significant age-related differences in body composition, strength, and physical activity. However, once AGE is accounted for, body composition and physical activity can not fully explain the age-related changes in muscle function. Thus, it is possible that other factors such as muscle activation and/or muscle composition may contribute to the age-related changes in function observed.

**High-intensity Fatigue In The Soleus Of Young And Old Men**

Brian H. Dalton, Andrew W. Davidson, Brad Harwood, Charles L. Rice. *The University of Western Ontario, London, ON, Canada.* (Sponsor: Anthony A Vandervoort, FACSM)

Email: bdalton@uwo.ca

(No relationships reported)

In the soleus, the inherent low maximal motor unit firing rates (MUFRs) are unchanged with age, despite an age-related slowing in the contractile properties of the triceps surae. High intensity fatigue typically induces contractile slowing and lower MUFRs. The question here is in the aged soleus will high intensity fatigue induce further slowing and changes in MUFRs? **PURPOSE:** Thus, the effects of high-intensity sustained isometric fatigue on the MUFRs and contractile properties of the soleus were compared in 6 young (~24 years) and 6 old (~75 years) men.

**METHODS:** Various measures of the contractile function of the soleus and triceps surae were tested during 2-6 sessions via maximal voluntary isometric contractions (MVCs) and tibial nerve stimulation. Populations of MUFR trains were recorded from the soleus with tungsten microelectrodes during a high-intensity (75-100% MVC) sustained isometric fatiguing contraction task, and during MVCs prior to the fatigue task and at 1, 2, 5, and 10 minutes post task failure.

**RESULTS:** Old men had greater fatigue resistance than the young with a time to task failure of ~138 seconds and ~100 seconds, respectively. Voluntary activation of the triceps surae, as assessed by the interpolated twitch technique, was near maximal ( $> 99\%$ ) for all subjects. At task failure, voluntary activation decreased to ~89% for both age groups. Maximal MUFRs in both groups were reduced ~44% and contraction duration slowed by ~30% following the fatigue task. Contraction duration recovered equally in both groups within 2 minutes of recovery, but maximal MUFRs did not recover until 5 minutes in the old men compared with one minute for the young.

**CONCLUSION:** There is no relative age-related difference in the reduction of maximal MUFRs in response to high-intensity fatigue. However, recovery of maximal MUFRS was impaired in the old despite the recovery of contractile properties.

(No relationships reported)

Aging affects muscle mass and strength, which affects ADL performance, but it remains unknown if the tendon properties also deteriorate with aging. Cross-linking (x-link) of collagen molecules provides structural integrity to the fibrils in tendons, and it is known to change with age in animal models, but has never been examined in humans.

**PURPOSE:** To examine the mechanical properties of the patellar tendon, *in vivo*, and x-link properties in elderly (OM) and young males (YM).

**METHODS:** Seven OM (67±1yrs, 86±4 kg) and 11 YM (27±1yrs, 81±2 kg) with the same activity level (YM 5±2 hrs/wk, OM 6±1 hrs/wk) were included. MRI was used to assess the tendon structural properties. Patellar tendon mechanical properties were assessed using simultaneous force and ultrasonography samplings. Tendon biopsies were obtained and analyzed for x-link content: Collagen concentration (Coll), Hydroxylysyl-pyridinoline (HP), Lysyl-pyridinoline (LP), Pentosidine (Pent). Results are reported as Mean±SEM.

**RESULTS:** Tendon structural properties did not differ between OM and YM. Similarly, the tendon mechanical properties did not differ between OM and YM.

Collagen and Crosslinks properties

	Coll (mg/mg dry wt)	HP (mmol/mol coll)	LP (mmol/mol coll)	HP/LP	Pent (mmol/mol coll)
OM	0.49±0.10*	898±65*	49±14**	26±5	73±0.5**
YM	0.73±0.04	645±55	16±2	49±9	11±0.1

Significantly different from YM. p<0.05. \*\*p<0.01.

**CONCLUSION:** These data show that the structural and mechanical properties of the human patellar tendon, *in vivo*, do not differ in OM and YM. At the same time, these are the first data on humans that show an age-related difference in tendon x-link properties to our knowledge. OM displayed lower collagen content, but greater pentosidine x-links compared to YM. This age related increase in pentosidine x-link may serve to maintain the mechanical properties with aging.

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effects of complex training and n-3 polyunsaturated fatty acid (n3PUFA) supplementation on health-related physical fitness tests, serum lipoprotein profiles and inflammatory markers in college female students.

**METHODS:** Thirty college females were randomly assigned to one of three groups: Group I (placebo, 3.6g/day, n = 10); Group II [n3PUFA (2.4g/day) + placebo (1.2g/day), n = 10]; Group III (n3PUFA, 3.6g/day, n = 10) with complex training for 12 weeks. The complex training indicates the combination of muscular resistance exercise (50-70% of 1RM, 3-4d/w, 3-20s/r) and aerobic exercise (40-75% of HRmax, 3-4d/w, 15-35min/d). All subjects were measured before and after 12 week of treatment including body weight, body fat mass, percent body fat, BMI, muscular strength, muscular endurance, cardiorespiratory endurance, flexibility, total cholesterol/HDL cholesterol ratio, LDL cholesterol, triglyceride, C-reactive protein(CRP), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), leptin, red blood cell count (RBC), white blood cell count (WBC). Analysis of covariance, Duncan's post-hoc test, Pearson correlation, simple regression, and Durbin-Watson statistic were used to determine the statistical significance.

**RESULTS:** There were significant mean differences on BMI, body weight, flexibility and CRP among three groups. The group III had lower CRP, body weight, or flexibility values as compared with Place groups (I, II). (p=.05). There were significant associations between health-related fitness components and CRP (r=-.36, p=.01), triglyceride (r=.25, p=.01) and RBC (r=.30, p=.05). There were no significant mean differences in percent body fat, body fat mass, muscular strength, muscular endurance, cardiorespiratory endurance, total cholesterol/ HDL cholesterol ratio, LDL cholesterol, triglyceride, WBC, TNF- $\alpha$  and leptin values across three groups.

**CONCLUSIONS:** The combination of complex training and n-3 polyunsaturated fatty acid supplementation may be particularly important on health related physical fitness and inflammatory markers in college female students.

**2866 Board #13 May 30 9:30 AM - 11:00 AM****Effects Of Breakfast Omission And An Acute Bout Of Exercise On Serum Lipid Concentrations**

Mary C. Pieklo, Jan E. Redmond, Katie J. Bouley, Tracey D. Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*

Email: mpieklo@spfldcol.edu

(No relationships reported)

Low-fat, high- fiber breakfast consumption may help lower serum low-density lipoprotein (LDL) and total cholesterol (TC) measurements as well as help control daily energy intake and insulin sensitivity while moderate exercise is an effective method for increasing high-density lipoprotein (HDL) and decreasing triglyceride (TG) measurements. A combination of these treatments may help maintain optimal blood lipid levels and prevent heart disease.

**PURPOSE:** To observe serum lipid changes immediately and 24 hr after breakfast or no breakfast treatments prior to a 30 min bout of aerobic exercise in middle aged males

with no history of dyslipidemia.

**METHODS:** Seven male subjects participated and ranged in age from 30 to 44 years old with an average  $\text{VO}_2$  peak of  $38.66 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1} + 6.09$ . Data were collected over three testing sessions. During session 1, subjects performed a  $\text{VO}_2$  peak test and baseline measurements were collected. During sessions 2 and 3, subjects consumed either a low-fat, high-fiber breakfast or no breakfast, both of which were followed by a 30 min bout of exercise at 60% of  $\text{VO}_2$  peak. A fasting blood sample was collected prior to treatment and exercise. Samples were also collected immediately after exercise and 24 hr post exercise. Each subject also reported all dietary intake for 24 hr following both treatments.

**RESULTS:** No significant ( $p > .05$ ) differences between the breakfast and no breakfast treatments were found for TC, TG, HDL, and LDL when baseline measurements were compared to 24 hr post treatment and exercise measurements. TC, TG, and LDL values were slightly lower 24 hr post exercise than at baseline while HDL values were higher 24 hr after exercise than at baseline when breakfast was omitted. Between the two exercise sessions, no differences were found in 24 hr post exercise macronutrient or total caloric intake. No differences in exercise RER and  $\text{VO}_2$  were found between treatments.

**CONCLUSION:** A low-fat, high-fiber breakfast in conjunction with 30 min of acute exercise were not sufficient to alter lipid concentrations. Breakfast omission and 30 min of moderate intensity exercise exhibited a trend towards lower cholesterol levels 24 hr post exercise and treatment.

**Exercise Enhances Whole-body Cholesterol Turnover In Mice Via Changes In Bile Acid Metabolism**

Maxi Meissner, Rick Havinga, Renze Boverhof, Ido Kema, Folkert Kuipers. *University Medical Center Groningen, Groningen, Netherlands.*

Email: m.meissner@med.umcg.nl

(No relationships reported)

**PURPOSE:** Exercise (EX) has long been prescribed for prevention or treatment of cardiovascular and metabolic diseases. Besides improving plasma lipid profiles, it has been shown to reduce hepatic steatosis and gallstone formation. Moreover, EX has recently been reported to induce beneficial changes in expression of genes of hepatic and intestinal cholesterol metabolism. However, underlying mechanisms are yet unclear. Bile acids (BA) are synthesized from cholesterol in the liver. BA facilitate intestinal fat absorption but also act as signaling molecules. Interventions targeting BA homeostasis potentiate changes in cholesterol metabolism. EX might exert its beneficial effects on cholesterol metabolism by modulating BA homeostasis. There are indications for EX to change BA metabolism. However, the direct effects of EX on BA metabolism have not been reported so far.

**AIM:** To investigate the effects of EX on BA metabolism and markers of cholesterol turnover in healthy mice.

**METHODS:** Two groups of 10 mice exposed to a voluntary running wheel for 2 wks starting at 11 wks of age (EX AM, EX PM) and 6 sedentary (SED AM and SED PM) mice on standard chow were sacrificed either at AM (06:30-08:30 h) or PM (18:30-20:30 h) for determinations of lipid profiles and gene expression patterns. 48 h feces was collected at 2 wks of EX (collected for SED at same time). Another 10 EX and 6 SED underwent a 30min gallbladder cannulation to determine bile flow and composition.

**RESULTS:** EX had decreased plasma total plant sterol / cholesterol levels (marker of cholesterol absorption), and increased plasma lathosterol / cholesterol levels (marker of cholesterol synthesis). EX had an increased feces production ( $p < 0.0001$ ), fecal BA output ( $p = 0.0012$ ), fecal secondary BA output ( $p = 0.02$ ) and total neutral sterol output ( $p = 0.0027$ ) vs. SED. EX induces specific changes in intestinal and hepatic gene expression patterns consistent with enhanced BA turnover. EX had an increased biliary BA secretion ( $p = 0.012$ ), while bile flow, biliary phospholipid or cholesterol excretion were not different.

**CONCLUSION:** Exercise appears to increase cholesterol turnover, decrease intestinal cholesterol absorption and promote de novo BA synthesis likely related to less ligand availability to activate pathways normally suppressing de novo BA synthesis.

**Short-term Changes In Ldl Density And Lipoprotein Particle Number In Trained Men After 3 Different Modes Of Exercise**

Steven E. Martin, Shawn P. Glowacki, Wade Womack, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.*

Email: smartin@hlkn.tamu.edu

(No relationships reported)

**PURPOSE:** To determine the short-term changes in LDL density and lipoprotein particle number after three different modes of exercise in trained men.

**METHODS:** Twenty seven subjects were randomly assigned to complete either (resistance [RE], endurance [EE], or combination resistance/endurance [CE]) exercise. Fasting blood samples were obtained 24 h before (baseline) and 24 h after exercise. The average group characteristics were as follows: [RE:  $n = 9$ , age =  $22 \pm 1$  yr, weight =  $75.7 \pm 4$  kg, %fat =  $14 \pm 1$ ,  $\text{VO}_{2\text{peak}} = 3.43 \pm 0.1 \text{ L/min}$ ], [EE:  $n = 9$ , age =  $23 \pm 1$  yr, weight =  $87.7 \pm 4$  kg, %fat =  $17 \pm 3$ ,  $\text{VO}_{2\text{peak}} = 4.0 \pm 0.10 \text{ L/min}$ ], [CE:  $n = 9$ , age =  $22 \pm 1$  yr, weight =  $99.7 \pm 5$  kg, %fat =  $21 \pm 3$ ,  $\text{VO}_{2\text{peak}} = 3.94 \pm 0.10 \text{ L/min}$ ].

**RESULTS:** of a 3 (GROUP) x 2 (TIME) ANOVA (repeated for TIME) for all dependent variables were as follows: No significant GROUP x TIME interactions were determined for any of the plasma volume adjusted dependent variables. A GROUP main effect was observed for LDL density. LDL density was significantly higher in both RE and EE groups compared to the CE group. A TIME main effect was observed for LDL density and the number of  $\text{LDL}_3$  and  $\text{LDL}_4$  particles. Significant increases in LDL density ( $1.0314 \text{ g/cm}^3$  to  $1.0316 \text{ g/cm}^3$ ), and the number of  $\text{LDL}_3$  (7.8%), and  $\text{LDL}_4$  (7.1%) particles occurred 24 h after exercise compared to baseline values.

**CONCLUSION:** These data show that regardless of exercise group, LDL density and the number of  $\text{LDL}_3$  and  $\text{LDL}_4$  particles were significantly elevated 24 h after a single exercise session in trained men.

**Non-fasting Triglyceride Level In Children: Relationship With Weight Status And Screen Time**

Emily E. Hill, Joey C. Eisenmann, Karin A. Pfeiffer, FACSM, Joseph J. Carlson. *Michigan State University, East Lansing, MI.*

(No relationships reported)

Recent research suggests that non-fasting triglycerides (TG) may better reflect cardiovascular disease (CVD) risk than fasting measures. While several prospective studies have examined the relationship between non-fasting TG and CVD risk in adults, few studies have examined non-fasting TG in children.

**PURPOSE:** The purpose of the present study was to examine the relationships among weight status, screen time, and non-fasting TG in 9-11 year old children.

**METHODS:** Participants included 100 children (39 boys, 61 girls; mean age  $10.6 \pm 0.4$  yrs). Non-fasting blood samples were obtained via finger stick and analyzed for total cholesterol, HDL-cholesterol, and TG. Time since last meal was recorded prior to blood sampling. Height and weight were assessed according to standard procedures. Body mass index ( $\text{kg/m}^2$ ) was calculated and used to create weight status categories based on age- and sex-specific CDC growth percentiles (i.e., normal weight, overweight, obese). Total screen time was determined by self-reported time spent watching TV, computer use, and playing video games per day; groups were determined based on average screen time per day, with the cut off between high and low at 4 hours. Partial correlations and ANCOVA, controlling for age and sex, were used to examine the associations among weight status, screen time, and non-fasting TG.

**RESULTS:** BMI was moderately correlated with non-fasting TG ( $r = 0.35$ ,  $p < 0.001$ ). Combined overweight/obese children showed significantly elevated TG levels ( $122.1 \pm 7.8 \text{ mg/dL}$ ) compared to normal weight children ( $92.6 \pm 6.2 \text{ mg/dL}$ ;  $p < 0.05$ ). The correlation between screen time and non-fasting TG was weak ( $r = 0.06$ ), and was further reduced when controlling for BMI ( $r = 0.01$ ). Non-fasting TG levels were significantly higher among children with  $> 4$  hrs/d of screen time ( $118.5 \pm 8.6 \text{ mg/dL}$ ) compared to those with

<4 hrs/d screen time ( $95.2 \pm 6.3$  mg/dL) ( $p < 0.05$ ); however, the difference was no longer significant when controlling for BMI ( $113.5 \pm 8.4$  mg/dL vs.  $97.9 \pm 6.1$  mg/dL, respectively;  $p = 0.15$ ).

**CONCLUSION:** Overweight and obese children exhibit higher non-fasting triglycerides than normal weight children, which may negatively contribute to CVD health status. This relationship does not appear to correlate directly with screen time.

**Influence Of Caloric Expenditure On Postprandial Triglyceride And Glucose Responses Following A High-carbohydrate Meal**

James R. Rowe, Heidi Bistrup, Kelley Henry, Melinda Villarreal, Kyle D. Biggerstaff, Vic Ben-Ezra. *Texas Woman's University, Denton, TX.*  
Email: jrowe@mail.twu.edu

*(No relationships reported)*

**PURPOSE:** To examine the effects of aerobic exercise expending 350 and 700 kcal of energy on postprandial triglyceride (Tg) and glucose responses following a high carbohydrate (CHO) meal.

**METHODS:** Non-active individuals ( $n = 9$  women/4 men; age =  $22.8 \pm 3.7$  yrs; Ht =  $169 \pm 10.4$  cm; Wt =  $75.7 \pm 22.4$  kg; BMI =  $26.1 \pm 5.8$  kg/m<sup>2</sup>; VO<sub>2</sub> max =  $34.1 \pm 6.9$  ml/kg/min) completed three trials in a random order: 1) control trial, 2) single exercise session expending 350 kcal (EX350), and 3) single exercise session expending 700 kcal (EX700). Exercise consisted of treadmill walking at 60% VO<sub>2</sub> max until 350 and 700 kcal of energy had been expended. The control session consisted of seated rest. The morning after each experimental session, a fasting (12hr) blood sample was collected followed by consumption of a high-CHO liquid meal (2.44 g/kg of fat free mass (CHO), 0.33 g/kg FFM fat, and 0.56 g/kg FFM protein. Blood was collected again at 1, 2, 3, 4, 5, and 6 hrs post-meal and analyzed for (Tg) and glucose concentrations. The areas under the curve (AUC) were calculated for both (Tg) and glucose concentrations. A repeated measures ANOVA was used to determine statistical significance ( $p < 0.05$ ).

**RESULTS:** Baseline glucose concentrations were not different between trials ( $p = 0.71$ ). Postprandial AUC for glucose concentrations were not different between trials ( $p = 0.38$ ) (rest =  $592.6 \pm 96.3$  mg/dl; 350 kcal =  $626.9 \pm 118.7$  mg/dl; 700 kcal =  $602.6 \pm 70.0$  mg/dl). Baseline Tg concentrations were not altered with exercise of 350 kcal or 700 kcal when compared with rest ( $p = 0.94$ ). Postprandial Tg concentrations following rest ( $937.3 \pm 928.4$  mg/dl) were not altered ( $p = 0.37$ ) following exercise of 350 kcal ( $807.1 \pm 605.1$  mg/dl) or 700 kcal ( $867.3 \pm 672.6$ ).

**CONCLUSION:** The glucose and Tg responses following a high-CHO meal were unaffected by a prior exercise session. The postprandial Tg response to prior exercise is different from the effect of exercise on the postprandial Tg response following a high-fat meal. There was substantial inter-subject variability in the exercise-induced change in the TG response, with the exercise induced change in the Tg AUC ranging from -27.4 to +17.4%.

*This study was Supported by Texas Woman's University's Research Enhancement Program.*

**Does Baseline High Density Lipoprotein Cholesterol Influence Post-exercise Change Associated With Acute Exercise?**

Tait Lawrence, Lynn B. Pantone, FACSM, Robert J. Moffatt. *Florida State University, Tallahassee, FL.*

Email: tait\_lawrence@hotmail.com

*(No relationships reported)*

**PURPOSE:** The purpose of this study was to determine if baseline levels of high density lipoprotein cholesterol (HDL) affects the change in HDL levels associated with an acute bout of exercise of varying energy expenditure.

**METHODS:** Two groups of healthy untrained male volunteers participated in this study. Subjects were assigned to one of two groups according to their baseline HDL levels. The LOW HDL group consisted of 13 subjects with clinically low HDL ( $< 40$  mg/dl) and the NORMAL HDL group consisted of 14 subjects with normal HDL ( $\geq 45$  mg/dl). Age, diet, VO<sub>2</sub>max and anthropometric data were collected prior to initiation of the experimental protocol and were similar for both groups. Age, height, weight, BMI, VO<sub>2</sub>max and resting HDL for LOW were  $21.9 \pm 2.0$  yrs,  $1.8 \pm 0.1$  m,  $80.9 \pm 7.9$  kg,  $25.2 \pm 2.2$  kg/m<sup>2</sup>,  $45.8 \pm 5.1$  ml/kg/min and  $35.7 \pm 2.7$  mg/dl, respectively while characteristics of the NORMAL group were  $23.4 \pm 7.1$  yrs,  $1.8 \pm 0.1$  m,  $78.6 \pm 7.6$  kg,  $24.3 \pm 2.5$  kg/m<sup>2</sup>,  $47.5 \pm 4.8$  ml/kg/min and  $53.9 \pm 5.8$  mg/dl. Subjects completed two nonconsecutive exercise sessions (on separate days) expending 500 and 700 kJ while running on a treadmill at 65% of VO<sub>2</sub>max. Venous blood was collected pre-exercise, immediately post-exercise (IPE), and 24 hours post-exercise (+24) and analyzed for HDL and subfractions of HDL (HDL<sub>2</sub> and HDL<sub>3</sub>) and corrected for any shift in plasma volume.

**RESULTS:** No differences in HDL or HDL subfractions were observed between NORMAL and LOW HDL groups at any post-exercise times. With both groups pooled HDL was significantly increased ( $p < 0.05$ ) by 2.5 mg/dl (5.6%) at IPE, but not at +24 when compared to pre-exercise values. The increase in HDL post exercise was due for the most part to increased HDL<sub>3</sub> (3.5 mg/dl, 13.6%) whereas the HDL<sub>2</sub> subfraction remained statistically unchanged.

**CONCLUSIONS:** Baseline HDL status does not appear to affect the magnitude of post-exercise HDL-C alterations in untrained men. Furthermore, post-exercise increases in HDL associated with acute exercise appear due to increased HDL<sub>3</sub> and not HDL<sub>2</sub> in the subjects of this study.

**Responses Of Lipids And Lipoproteins Following Acute And Training Resistance Exercise In Obese Postmenopausal Women**

Ronique N. Pleasant<sup>1</sup>, Melinda Villarreal<sup>1</sup>, Joshua S. Wooten<sup>1</sup>, Robert M. Hein<sup>2</sup>, Robert D. Menzies<sup>2</sup>, Melody D. Phillips<sup>3</sup>. <sup>1</sup>Texas Woman's University, Denton, TX. <sup>2</sup>John Peter Smith Hospital, Forth Worth, TX. <sup>3</sup>Texas Christian University, Forth Worth, TX.

Email: ronique06@yahoo.com

*(No relationships reported)*

A single aerobic session and aerobic training can favorably modify lipids and lipoproteins in postmenopausal women, but the effects of a single resistance exercise session (RE) and resistance training (RT) remain equivocal.

**PURPOSE:** To determine the acute effects of RE and chronic effects of 12 weeks of RT on lipid and lipoprotein-cholesterol concentrations in obese, postmenopausal women.

**METHODS:** Sedentary, obese, non-smoking, postmenopausal women, not taking HRT, were divided into either an exercise group (E,  $n = 10$ ; age =  $65.7 \pm 1.8$  y; BMI =  $32.6 \pm 3.5$  kg/m<sup>2</sup>) or control group (C,  $n = 11$ ; age =  $66.1 \pm 3.0$  y; BMI =  $32.9 \pm 4.3$  kg/m<sup>2</sup>). Fasting (12 hr) blood samples were collected prior to and 24 hr after the first (BT) and last (AT) exercise session, and at the same time points for C. E performed ten upper and lower body resistance exercises (3 sets, 8 rep/set, 80% 1-RM) 3 times per week for 12 weeks; while C attended education classes twice per week for 12 weeks. Serum was assayed for total cholesterol, triglycerides, LDL-C, HDL-C, HDL<sub>2</sub>-C, and HDL<sub>3</sub>-C concentrations. A 2 x 2 x 2 (group x training period x time) MANOVA with repeated measures was used to determine changes in lipid and lipoprotein variables. A 2 x 2 (group x time) repeated measures ANOVA was used to assess body composition.

**RESULTS:** The MANOVA revealed no significant changes in serum lipids or lipoproteins following RE or RT. No changes in body composition were observed post-training ( $P > 0.05$ ).

Variable	Pre-BT	24 hr BT	Pre-AT	24 hr AT
----------	--------	----------	--------	----------

TC (mg/dl)	C	189 ± 28	205 ± 40	201 ± 48	206 ± 42
	E	217 ± 55	212 ± 49	207 ± 105	195 ± 106
Tg (mg/dl)	C	107 ± 42	96 ± 49	116 ± 49	112 ± 45
	E	114 ± 40	103 ± 25	129 ± 92	102 ± 48
LDL-C (mg/dl)	C	112 ± 26	129 ± 37	118 ± 40	124 ± 41
	E	140 ± 51	137 ± 41	127 ± 89	120 ± 88
HDL-C (mg/dl)	C	55 ± 16	57 ± 14	60 ± 13	60 ± 16
	E	55 ± 12	55 ± 16	53 ± 15	54 ± 17
HDL2-C (mg/dl)	C	36 ± 12	35 ± 10	35 ± 12	33 ± 16
	E	36 ± 10	34 ± 13	33 ± 14	35 ± 13
HDL3-C (mg/dl)	C	19 ± 9	21 ± 7	25 ± 6	26 ± 6
	E	19 ± 5	21 ± 6	20 ± 5	20 ± 7

**CONCLUSION:** These data suggest that a single RE session and a 12-week RT program have no effect on lipids and lipoproteins. Compared to the effects of aerobic training, resistance exercise related changes in body composition may be necessary to modify lipids and lipoproteins in obese, postmenopausal women.

**Trans Fatty Acid Consumption And The Effect On Lipids In Young Adults: Jayhawk Observed Eating Study (joe)**

Bruce W. Bailey<sup>1</sup>, Laura Roling<sup>2</sup>, Bryan K. Smith<sup>3</sup>, Debra K. Sullivan<sup>4</sup>, Joseph E. Donnelly, FACSM<sup>5</sup>. <sup>1</sup>Brigham Young University, Provo, UT. <sup>2</sup>University of Kansas, Lawrence, KS. <sup>3</sup>University of Kansas, Kansas, KS. <sup>4</sup>University of Kansas Medical Center, Kansas, KS. <sup>5</sup>University of Kansas, Kansas, KS.

Email: bruce.bailey@byu.edu

(No relationships reported)

**INTRODUCTION:** Nutrient intake, body weight and increased body fat percent (BF) among young adults and the relationship among lipoproteins are of interest.

**PURPOSE:** The purpose of the current study was to determine if changes in trans fatty acid intake among young adults over a 12-week period results in changes in Total, LDL, non-HDL and HDL cholesterol.

**METHODS:** Two-hundred and sixty participants (163 men and 97 women) consumed ad-libitum diets in the Kansas University cafeteria over a 12-week period. Energy and nutrient content were measured using digital picture plate waste photography, and all meals and snacks taken outside of the cafeteria were measured by dietary recall.

**RESULTS:** Trans fatty acid consumption was positively correlated with HDL, LDL and Total cholesterol. For every one gram of Trans Fatty acid consumed there was an increase of 0.69 mg/dL in HDL, 2.38 mg/dL in LDL and 2.95 mg/dL in Total Cholesterol. Increased BF predicted an increase in LDL cholesterol and a decrease in HDL cholesterol. For every percent increase in BF there was a decrease of 0.77 mg/dL in HDL cholesterol and an increase of 1.89 mg/dL in LDL cholesterol.

**CONCLUSION:** In this population of young adults increased consumption of trans fatty acids resulted in higher levels of both HDL and LDL Cholesterol. Change in body fat on the other hand was associated with detrimental changes in both HDL and LDL cholesterol.

(No relationships reported)

**PURPOSE:** The purpose of this study was to isolate and identify the bacteria, yeasts, and molds found in protective athletic mouth-guards (PAM) and to correlate these microorganisms with potential oral and systemic diseases.

**METHODS:** After obtaining informed consent, 62 Division 1 football players were divided into 4 groups with 2 groups wearing their PAM all season and the other 2 groups having their PAM changed at mid-season. All PAM were collected at the end of the season. Clinical oral examinations were performed on each subject at pre-season and at season-end. Each device was aseptically cultured for the presence of bacteria, yeasts, and molds. The PAM were cut and their surfaces and depths were touched to Blood agar (BAP) and Sabouraud dextrose agar (Sab). The BAP were incubated at 37°C for 24 hours while the Sab were incubated for 2 weeks at ambient temperature (22-23°C). Positive cultures were identified using standard laboratory methods, including molecular biological techniques.

**RESULTS:** The 84 PAM retrieved during the entire study yielded a total of 164 gram positive cocci, 158 gram positive bacilli, 13 gram negative cocci, and 23 gram negative bacilli. Of the 164 gram positive cocci, 82 were methicillin-resistant. The PAM yielded a total of 21 yeast and 108 mold isolates. These microbes have been implicated in a wide range of oral and systemic diseases, including diseases of the heart, GI tract, bones, and lungs (pneumonias and exercise induced asthma).

**CONCLUSIONS:** The results of this study confirm that PAM are contaminated with a variety of bacteria, yeasts, and molds which may act as a source for both oral and systemic infectious diseases. While the authors of this study firmly advocate the required use of such devices, PAM should be sanitized daily to reduce the number of microorganisms and replaced at least every 2 weeks or when damaged.

**Eccentric Resistance Exercise In Prostate Cancer Survivors: Does Androgen Deprivation Therapy Mitigate Training**

## Effects?

Pamela Hansen<sup>1</sup>, Paul Lastayo<sup>2</sup>, Christopher Decher<sup>2</sup>, Dutch Plante<sup>2</sup>. <sup>1</sup>University of Utah/ Utah Sports Research Network, Salt Lake City, UT.

<sup>2</sup>University of Utah, Salt Lake City, UT. (Sponsor: Liz Joy, FACSM)

Email: pamela.hansen@hsc.utah.edu

(No relationships reported)

Men with prostate cancer treated with androgen deprivation therapy (ADT) suffer skeletal muscle wasting and a decline in functional status. Resistance exercise may be beneficial, but the optimal exercise mode and whether ADT blunts training effects is not clear in this population.

**PURPOSE:** To determine: 1) the feasibility of an eccentric resistance exercise training protocol in men with prostate cancer and 2) whether it improves strength and physical function. Finally, 3) to determine whether men with prostate cancer on ADT have a blunted effect to the training as compared to men with prostate cancer who are not on ADT.

**METHODS:** Ten men (mean age 66, range 48-86) with prostate cancer were enrolled, five were currently on ADT. All men underwent a 12-week resistance exercise training protocol using a recumbent, high-force eccentric, leg cycle ergometer three times per week at a "somewhat hard" perceived exertion for 12-15 minutes. Pre- and post-exercise changes were examined within and between groups to assess: quadriceps muscle volume (MRI), isometric knee extension strength, functional mobility (Timed Up and Go Test (TUG), 6-minute walk, health-related quality of life (FACT-P) and fatigue (FACIT-fatigue scale). Data were analyzed using t-tests and mixed effects linear regression, which accounted for three repeated measurements both pre- and post-treatment.

**RESULTS:** There was 100% compliance with the 12 week exercise protocol. The ADT group demonstrated significant within group improvements in the 6-minute walk ( $p=0.01$ ). The non-ADT group demonstrated significant within group improvements in the physical subscale of the FACT-P ( $p=0.03$ ), the TUG ( $p=0.01$ ) and an increase in quadriceps muscle volume ( $p=0.04$ ). Both groups had significant improvements in isometric knee extension strength ( $p<0.01$ ) with the between group assessment revealing significantly greater improvements in strength in the ADT group ( $p=0.01$ ). No other between-group differences existed.

**CONCLUSION:** Eccentric resistance was well tolerated and both groups derived some benefits in strength and functional mobility. Men on ADT did not appear to have a blunted response to the exercise as compared to prostate cancer survivors not on ADT, though a larger study is needed to verify this.

### 2876 Board #23 May 30 8:00 AM - 9:30 AM

#### Impact Of Incentives On Dramatic Weight Loss And Cad Risk Reduction In Sedentary II/III Obese Individuals

rob huizenga. csmc, Beverly hills, CA.

(No relationships reported)

Dramatic weight loss in sedentary class II/III obese patients has been documented on reality-TV in front of hundreds of millions of viewers worldwide; critics insist these results stem from filmed boot camps with ever-present trainers and cash prizes and are therefore not generalizable.

**PURPOSE:** To evaluate the impact of live-in camps, TV exposure and financial incentives on weight loss and CAD risk factor reduction.

**METHODS:** Sixty-two unfit participants  $31.4 \pm 7.0$  years old,  $132 \pm 27$  Kg and with a body mass index (BMI) of  $43.3 \pm 5.6$  Kg/m<sup>2</sup> were recruited; fourteen subjects (BL) lived in a filmed "boot camp" for one to three months of an eight-month TV show with cash prizes. Thirty-six subjects (H) received a three-day "weight-loss" seminar and then went home with no filmed live-in boot camp, no trainers and nominal financial inducements. Twelve subjects (C) were sent home with no weight loss instructions or incentives.

**RESULTS:** At eight months the total weight loss % for BL, H and C women and men respectively was  $-31.3 \pm 9.5$  and  $-38.6 \pm 11.9$ ;  $-22.3 \pm 9.7$  and  $-27.7 \pm 10.2$ ; and  $5.2 \pm 6.8$  and  $2.3 \pm 3.9$ . One year after the shows completion, total weight loss % for BL, H and C women and men was  $-25.9 \pm 7.8$  and  $-30.7 \pm 7.8$ ;  $-19.3 \pm 12.5$  and  $-20.7 \pm 11.6$ ; and  $1.0 \pm 5.3$  and  $0.7 \pm 12.9$ . The BL and H groups respectively had resolution of HTN (9/12; 20/28 (including 6/6 contestants who had anti-hypertensive meds discontinued)), low HDL cholesterol (4/9; 12/19), hypertriglyceridemia (3/3; 6/6), elevated CRP (9/12; 10/23), elevated fasting glucose or insulin (4/4; 14/14), "high risk" waist size (9/13; 8/35) and the metabolic syndrome (7/9; 18/22). Orthopedic and medical side effects were less frequent in the H group compared to the BL group injuries did not prevent intense exercise in either group.

**CONCLUSIONS:** In this study of unfit, class II/III obese participants, a three-day weight loss seminar followed by self-monitored two-a-day exercise and moderate caloric restriction at home with nominal financial incentives resulted in dramatic weight loss and CAD risk factor reduction comparable to filmed live-in boot camp participants, with trainers and large financial incentives. Side effects were tolerable and transient.

#### Primary Antiphospholipid Syndrome: Aerobic Capacity And The Effect Of Acute Physical Exercise On Prothrombin Time

Carolina B. Garcia, Jozélio Freire Carvalho, Ana Lúcia Sá Pinto, Karin Klack, Luciana Jnaot Matos, Carlos Eduardo Negrão, Eloísa Bonfá, Fernanda Rodrigues Lima. University São Paulo, São Paulo, Brazil. (Sponsor: Fernanda R Lima, FACSM)

Email: carollgarciasp@yahoo.com.br

(No relationships reported)

The effect of acute exercise on PT is still controversial on literature. It is known that acute and exhaustive physical exercise has an increased potential for coagulation. Studies on influence of physical exercise on coagulation parameters in primary antiphospholipid syndrome (PASP) are scarce.

**PURPOSE:** The aim of this study is to evaluate the effects of acute physical exercise on prothrombin time in patients with primary antiphospholipid syndrome (PAPS) under oral anticoagulation.

**METHODS:** Nine premenopausal women PAPS patients (Sapporo criteria) with exclusive deep venous thrombosis were enrolled in the study. All individuals were undergoing chronic anticoagulation therapy and PT was stable (INR between 2-3) for 2 weeks before the test. Drugs were also stable for 2 months and patients were on their regular diet for the same period. Exclusion criteria were diabetes, systemic hypertension, arterial thrombosis, congestive heart failure, secondary antiphospholipid syndrome, body mass index (BMI)  $>30$  and stroke. Prothrombin time (PT) was assessed using the CoaguChek XS (Roche Diagnostics, Indianapolis, USA) with capillary blood during a maximum cardiopulmonary stress test (RAMP protocol). PT was measured at: baseline, anaerobic threshold (AT), immediately after the test and 1 hour after the test. Comparisons between PT at baseline, AT, immediately after the test and 1 hour after, were analyzed using the Student t- test.

**RESULTS:** PAPS patients [mean age  $33 \pm 8.6$  years, mean body mass index (BMI)  $22.28 \pm 2.64$  Kg/m<sup>2</sup>] with mean disease duration of  $5.33 \pm 4.54$  years had an aerobic capacity within the predicted value for sedentary women according to ACSM's guidelines (mean VO<sub>2</sub> peak  $32.38 \pm 4.36$  ml/Kg/min). PT was stable throughout the studied period, with no significant changes in mean PT measured at baseline and AT time ( $2.17 \pm 0.21$  vs.  $2.17 \pm 0.23$ ,  $p=1.00$ ), baseline and immediately after AT ( $2.17 \pm 0.21$  vs.  $2.15 \pm 0.19$   $P=0.44$ ) and 1 hour after the test ( $2.15 \pm 0.19$  vs.  $2.23 \pm 0.25$   $p=0.09$ ). In addition, none of the patients had thrombosis and bleeding in a month follow up.

**CONCLUSION:** This is the first study to demonstrate that PAPS patients with venous complications have normal aerobic capacity. The acute and exhaustive exercise test was safe and did not affect the PT in these patients.

### 2878 Board #25 May 30 8:00 AM - 9:30 AM

#### Acute Lymphoblastic Leukemia: Efficacy And Safety Of High-intensity Resistance Training In Children And Adolescents

Beatriz M. Perondi, Mavi D. Muratti, Guilherme Artioli, Bruno Gualano, Gabriele Z. Netto, Bruna Carvalho, Vitor Painelli, Ana Lucia S. Pinto. School of Medicine - University of São Paulo, Sao Paulo, Brazil. (Sponsor: Fernanda R. Lima, FACSM)

Email: biap@uol.com.br

(No relationships reported)

Children and adolescents with Acute Lymphoblastic Leukemia (ALL) during treatment present side effects such as anemia, infection, bleeding, muscle weakness, impaired motor coordination and fatigue. Side effects occur due to chemotherapy, lack of physical activity and the sickness itself. Studies show enhanced muscle strength and aerobic capacity in patients undergoing supervised exercise training programs. The optimal intensity of resistance training able to induce greater adaptations without adverse effects remains unknown.

**PURPOSE:** To investigate efficacy and safety of a high-intensity resistance training program in children and adolescents with ALL during the maintenance phase of treatment.

**METHODS:** Four patients (ages 6 to 16) were submitted to echocardiogram and VO<sub>2</sub>max at baseline. They underwent an intrahospital training program twice a week for 12 weeks. Training sessions consisted of 10 min treadmill warm-up followed by 30 min resistance training (4 sets of 6-10 repetition maximum [RM]), 20 min treadmill aerobic training and 5 min stretching exercises. Ten-RM tests were conducted with 4 exercises: bench press, lat pulldown, leg press and leg extension at baseline and after 12 weeks of training. Patients underwent hemogram, aspartate aminotransferase, creatine phosphokinase, aldolase, hemocrit, sedimentation rate, C-reactive protein and venous Lactate before and after training. Pediatric quality of life inventory (Peds QL) including cancer, multidimensional fatigue and generic core scale were carried out by parents and patients.

**RESULTS:** Significant 10-RM improvement in bench press (70%,  $p = 0.002$ ), lat pulldown (70%,  $p = 0.0005$ ), leg press (64%,  $p = 0.005$ ) and leg extension (57%,  $p = 0.01$ ) were observed as a result of intensive resistance training. During training none of the patients presented fatigue, pain, bleeding, infection or required hospital admittance. Patient's hemogram showed no change. Serum muscle enzymes or inflammatory markers didn't increase after training. Peds QL showed a tendency to improve in parent-answered questionnaires. The same did not happen in patient's questionnaires.

**CONCLUSIONS:** Progressive high-intensity resistance training may be an effective and safe intervention capable of improving strength and life quality in children and adolescents with ALL.

**Developing A Wireless System For Athletes' Ekg And Running Pattern Monitoring And Analyzing**

Shun-ping Lin, Kai Yang Tseng, Jin Jong Chen, Wei Fong Kao. *National Yang-ming University, Taipei, Taiwan.*

Email: shunping.lin@gmail.com

(No relationships reported)

Marathon is one of the most popular exercises in the world which attracts more than 450 thousand people per year to participate in with 1/87000 sudden death and many lower extremity injuries. EKG and running pattern monitoring and analyzing during marathon race have been suggested to reduce the injury rate and improve running performance.

**PURPOSE:** to develop a mini portable wireless system for athletes' EKG and running pattern monitoring and analyzing.

**METHODS:** One regular marathon (RM) runner and one ultramarathon (UM) runner were recruited to run on a treadmill with speed changed every 5 minutes. A 10g mini wireless device which including EKG leads, processor, 3 axis accelerometer, data processor and signal transmitter, was fixed on the lumbar-sacral joint and connected to EKG sensors on the athlete's chest wall during different running speeds (8, 9, 10, 12 and 14 km/hr). The wireless EKG was compared with traditional EKG to validate its reliability and HR was determined immediately by self-developed software. Variables computerized from 3D accelerometer data which including 3 axis acceleratory velocities, step frequency, step lengths and running stages during different speeds, were also presented immediately on the computer.

**RESULTS:** The wireless EKG had better resolution than traditional EKG, especially during higher running speed. The HR determined automatically from wireless EKG was highly corrected and matched with counts from traditional EKG ( $p < 0.05$ ). Different running patterns between the RM runner and the UM runner could be identified from variables created from 3D accelerator data. The UM runner had better L/R balance and smoother soaring period which indicated better running efficacy than the RM runner.

**CONCLUSION:** This wireless system could real time monitor and analyze the EKG and running pattern with accuracy and reliability. It could be applied to detect possible injury risks and running technology faults during competitions.

**Developing A Questionnaire For Quantifying Illness In Elite Athletes**

David B. Pyne, FACSM<sup>1</sup>, Alexander Matthews<sup>2</sup>, Philo U. Saunders<sup>1</sup>, Kieran E. Fallon<sup>1</sup>, Peter A. Fricker<sup>1</sup>. <sup>1</sup>*Australian Institute of Sport, Belconnen, Australia.* <sup>2</sup>*Australian National University, Canberra, Australia.*

Email: david.pyne@ausport.gov.au

(No relationships reported)

**PURPOSE:** To develop and evaluate a questionnaire that quantifies the self-reported frequency, duration and severity of illness in highly-trained athletes. We examined whether highly-trained runners had more frequent illness than recreationally active individuals, and whether runners more prone to illness were undertaking more strenuous training programs.

**METHODS:** A daily illness questionnaire was administered for three months to quantify the type, frequency, duration and severity of illness, and the functional impact on the ability to complete regular training or competition. A total of 35 participants (12 highly-trained national level runners living in a community setting and 23 age- and sex-matched recreationally active medical students) aged 20-40 y completed the questionnaire. Self-reported details of training or physical activity, injury and the impact of illness on athletic/exercise performance using a 3 point Likert scale (minimal, moderate or severe) were evaluated. Data were log- or root-transformed before analysis using a student's t-test for samples with unequal variance.

**RESULTS:** Runners had a similar frequency of illness ( $2.1 \pm 1.2$ ,  $1.8 \pm 2.3$  episodes, mean  $\pm$  SD) but substantially longer duration of symptoms ( $5.5 \pm 9.9$ ,  $2.8 \pm 3.1$  days, mean difference  $\pm 90\%$  confidence limits,  $49 \pm 28\%$ ) and higher illness load ( $7.7 \pm 16.2$ ,  $4.5 \pm 4.8$  units,  $42 \pm 30\%$ ) than control subjects respectively. Runners more prone to illness (three or more episodes) had similar training loads to healthier runners less prone to illness (two or fewer episodes).

**CONCLUSIONS:** Highly-trained runners experienced longer episodes of illness with a greater impact on daily activity than recreationally active individuals. The athlete illness questionnaire is useful for quantifying the pattern of self-reported symptoms of illness in field settings.

**Effect Of Comprehensive Exercise On Lymphedema In Breast Cancer Survivors: A Pilot Study**

Allison Oki<sup>1</sup>, Patrick Troumbley<sup>2</sup>, Kim Walker<sup>2</sup>, Dutch Plante<sup>1</sup>, Pam Hansen<sup>1</sup>. <sup>1</sup>*University of Utah, Salt Lake City, UT.* <sup>2</sup>*Huntsman Cancer Hospital, Salt Lake City, UT.* (Sponsor: Liz Joy, FACSM)

Email: allison.oki@hsc.utah.edu

(No relationships reported)

One in nine women are diagnosed with breast cancer. Early diagnosis and better treatments are allowing women to survive longer. With this positive trend, greater attention is being focused on survivorship issues such as lymphedema, which affects 5-30% of patients who have undergone treatment for breast cancer. Previously there was a concern that aerobic exercise and resistance training in the effected arm may cause or worsen lymphedema. Limited studies have provided preliminary evidence to suggest that exercise may be safe.

**PURPOSE:** To examine changes in strength and arm circumferences (as a measurement of lymphedema) in 32 breast cancer survivors before and after undergoing a comprehensive exercise program.

**METHODS:** This retrospective study reviewed results of 32 breast cancer survivors (mean age 51, range 26-76) who voluntarily enrolled in a comprehensive fitness program. Twenty-two percent of the women had lymphedema at baseline. Cancer treatment included a combination of mastectomy (60%), lumpectomy (40%), axillary node dissection (69%), sentinel node biopsy (28%), radiation therapy (69%) and chemotherapy (88%).

Participants completed a supervised exercise program 2-3 times per week including aerobic and resistance exercise. Arm circumference (sub-axillary, upper arm and forearm) were obtained at baseline and after an average of 22 weeks (range 12-40 weeks) of training. Pre and post exercise measurements in arm circumference and biceps curl strength were assessed for all women as a group, as well as for subgroups by treatment type, using two-tailed t-tests.

**RESULTS:** Compliance with the training program was excellent (83%). There was no significant increase in arm circumference post exercise for the entire group, nor for any treatment subgroup. Interestingly, the sub-axillary measurement showed a significant decrease in circumference ( $p=0.05$ ) for the entire group. Biceps strength increased for the entire group as well as for all subgroups ( $p<0.05$ ).

**CONCLUSION:** Participation in a comprehensive exercise program for breast cancer survivors was well tolerated. The women demonstrated a decrease in sub-axillary arm circumference with concurrent improvements in biceps strength. This study supports the limited body of literature supporting the safety and efficacy of exercise in this population.

**Different Impacts And Recovery Courses Between Ultramarathon And Regular Marathon**

Chang Hsun Chiang<sup>1</sup>, Jin Jong Chen<sup>2</sup>, Chung-Jung Chen<sup>3</sup>, Wei Fong Kao<sup>4</sup>. <sup>1</sup>National Taiwan University Hospital, Taipei, Taiwan. <sup>2</sup>National Yang-ming University, Taipei, Taiwan. <sup>3</sup>Hsing Wu College, Taipei, Taiwan. <sup>4</sup>Taipei Veterans General Hospital, Taipei, Taiwan.

Email: b90801040@ntu.edu.tw

(No relationships reported)

Exercise-associated overtraining syndrome attributed to inappropriate recovery becomes an increasing problem among marathon competitions. Few researches have been conducted to study the prolong effects of ultramarathon on cortisol and systematic damages.

**PURPOSE:** (1) To investigate the influences of marathon competitions on cortisol and other physiological biomarkers; (2) To reveal the recovery courses of cortisol and other physiological biomarkers; and (3) To compare the immediate responses and relevant recovery courses of cortisol and other physiological biomarkers among different marathon competitions.

**METHODS:** Twenty-one runners in the 2006 Taipei IAU ultramarathon competition (24-hours ultramarathon, 24 UM, n=13; 12-hours ultramarathon, 12 UM, n=8) and 20 runners in Taipei ING 42 km regular marathon (RM) were recruited in this study. Blood and saliva samples were collected about one week before each race, immediately after each race and the 3<sup>rd</sup> and the 7<sup>th</sup> (only for UM runners) day after each race to represent the baseline, immediate responses and the recovery courses of mentioned biomarkers.

**RESULTS:** Saliva cortisol levels, which increased significantly from  $17.8 \pm 2.7$  nmol/L (RM) and  $25.5 \pm 5.0$  nmol/L (24UM) in baseline to  $44.3 \pm 3.9$  nmol/L (RM) and  $43.1 \pm 5.5$  nmol/L (24 UM) immediately after competitions with similar magnitude, returned to pre-competition in 3 days. Comparing the other immediate responses with baseline values, this study significantly showed the followings: (1) lactate dehydrogenase (LDH), representing global damage, increased in 12 UM and RM, (2) creatine kinase-MB (CK-MB), representing cardiac damage, increased only in 24 UM, and (3) aspartate aminotransferase (AST), representing liver damage, increased in 12 UM and 24 UM. Most biomarkers recovered to baseline values on the 3<sup>rd</sup> day after the RM, and on the 7<sup>th</sup> day for the 12 UM and 24 UM.

**CONCLUSIONS:** The present study demonstrated that (1) saliva cortisol changes was not related to the prolong effects of UM on systematic damages, (2) different types of marathons caused inconstant physiological stresses on biomarkers, and (3) compared with RM, UM indeed caused more profound physiological stress and physical load, so that a longer recovery process is needed.

**The Body Weight Loss And Core Temperature Regulation During And After Ultramarathon Running**

Fong Chou Kuo<sup>1</sup>, Kai Yang Tseng<sup>2</sup>, Jin Jong Chen<sup>2</sup>, Shun Ping Lin<sup>2</sup>, Wei Fong Kao<sup>2</sup>, Yi Jen Huang<sup>1</sup>. <sup>1</sup>Soochow University, Taipei, Taiwan. <sup>2</sup>National Yang-ming University, Taipei, Taiwan.

Email: frank.kuo@scu.edu.tw

(No relationships reported)

The elevating core body temperature (BTc) which also called hyperthermia after ultramarathon (UM) may develop a life threatening heat disorder. Some studies examining hydration status and BTc suggest that dehydration is not associated with increases in BTc, but the others do not agree with them.

**PURPOSE:** To investigate the body weight (BW) loss and BTc regulation during and after 12-hour UM (12UM) and 24-hour UM (24UM).

**METHODS:** Thirty two experienced UM runners, 19 subjects participating in 12UM and 13 subjects participating in 24UM, were recruited as experimental group subjects. Body temperature (tympanic temperature) and total body weight (TBW) were recorded every four hours in all subjects through the competition, and the weather conditions (dry bulb temperature, wet bulb temperature, humidity and wind speed) were also recorded. The BTc and BW loss were calculated afterward.

**RESULTS:** The TBW decreased in both 12UM (TBW: -5.57%) and 24UM groups (TBW: -2.08%). TBW significantly decreased through the whole 12UM timeframe, but TBW of the 24UM group decreased only in the first eight hours and the last eight hours. There is no hyperthermia and hypothermia after 12UM (BT: -0.005°C) and 24UM (BT: -0.029°C). BTc significantly decreased only during the first eight hours in the 12UM group, and BTc of the 24UM group only decreased from 8<sup>th</sup> to 20<sup>th</sup> hours.

**CONCLUSIONS:** Significant body weight loss after UM is not associated with increases in BTc and exercise duration. The BTc reducing is mainly affected by the chilling and raining weather conditions during UM. Taking part in the UM in appropriate weather condition may not cause hyperthermia.

**Diet, Mood, Iron Status And Bone Mineral Density Of Freshman Female Collegiate Athletes**

Kimberly White<sup>1</sup>, Jeffery Stein<sup>2</sup>, Larry Leverenz<sup>2</sup>, Gregory Rowdon<sup>2</sup>. <sup>1</sup>Gatorade Sports Science Inst., Barrington, IL. <sup>2</sup>Purdue University, West Lafayette, IN. (Sponsor: Randy Eichner, FACSM)

Email: kim.white1@gatorade.com

( K. White, Pepsico, Salary; Pepsico, Ownership Interest.)

College-age women tend to have low dietary intakes of iron and nutrients related to bone health. Inadequate intakes of these nutrients may be especially problematic for female collegiate athletes due to increased risk of injury or decreased performance.

**PURPOSE:** To investigate dietary habits of female collegiate athletes that may influence bone mineral density and iron status, and to relate iron status to fatigue and depression.

**METHODS:** Female athletes entering their freshman year of competition were recruited. Blood hemoglobin (Hb) and serum ferritin, bone mineral density (BMD, by dual x-ray absorptiometry), dietary habits (Block 2005 food frequency questionnaire) and mood (Profile of Mood States survey) were assessed within their first two months in college. Data were analyzed for mean  $\pm$  standard error, and correlations investigated using the Spearman rank correlation coefficient.

**RESULTS:** For nutrients related to bone health, mean intake of calcium and vitamin K were above the RDA ( $1345.3 \pm 98.2$  mg/d and  $225.5 \pm 31.7$  mcg/d, respectively, n=33), whereas vitamin D intake was below adequate ( $141.4 \pm 12.8$  IU/d, n=33). BMD for the total body, spine, and total femur were  $1.21 \pm 0.02$ ,  $1.30 \pm 0.02$ , and  $1.21 \pm 0.02$  g/cm<sup>2</sup>, respectively (n=48), and in good agreement with literature for this population. The average Z-score for total body BMD ( $1.6 \pm 0.2$ ) was above normal. Total iron intake was above the RDA ( $37.5 \pm 5.0$  mg/d, n=33), with the majority from supplements ( $21.5 \pm 4.7$  mg/d). Intake of vitamin C, a promoter of iron absorption, was  $146.4 \pm 9.4$  mg/d

(n=33). Mean Hb was normal ( $13.3 \pm 0.1$  g/dL, n=59, range 9.3-15.8). 53% (32 of 60) had ferritin  $\leq 20$  ng/mL and classified as iron deficient. Hb was  $\leq 12.0$  g/dL, ferritin  $\leq 20$  ng/mL for 4 women. Dietary iron, from supplemental or food sources, was not correlated with ferritin level. A significant, negative correlation was found between ferritin and depression ( $\rho = -0.4$ ,  $p = 0.007$ ), fatigue ( $\rho = -0.3$ ,  $p = 0.04$ ) and total mood disturbance ( $\rho = -0.4$ ,  $p = 0.003$ ).

**CONCLUSION:** Freshman female athletes entered collegiate competition with adequate dietary habits and BMD. However, half of this population was iron deficient. Iron status was related to feelings of depression and fatigue but not to dietary iron. Interventions to improve iron status, beyond iron supplementation, should be developed.

**Prevalence Of LVH In Athletes Classified By Race And Gender**

Rahul H. Damani, Jjeoma Ananaba, J. Jason West, John P. Higgins, FACSM. *University of Texas Medical School, Houston, TX.*

Email: rahul.h.damani@uth.tmc.edu

(No relationships reported)

Evidence-based data support the role of the resting 12-lead electrocardiogram (ECG) in the pre-participation screening of young athletes, and is endorsed by the European Society of Cardiology (ESC) & International Olympic Committee (IOC) guidelines. Hypertrophic cardiomyopathy (HCM), is commonly associated with sudden cardiac arrest in young athletes. Unfortunately, it is usually not detected by history or physical examination. However, the ECG in HCM will often manifest left ventricular hypertrophy (LVH). Complicating this, physiological hypertrophy ("athletes heart") frequently manifests LVH on the ECG, as well.

**PURPOSE:** To document prevalence of LVH by 12-lead ECG in collegiate athletes and look for differences based on race and gender.

**METHODS:** We studied ECGs from a group of 365 US collegiate athletes presenting for pre-participation screening. All ECGs were evaluated and classified as either normal or abnormal according to the criteria established in the ESC guidelines. An ECG was classified as having LVH if it met one of the following three criteria. 1) S-wave in V1 or V2  $\geq 3$  mV 2) R-wave in lead V5 or V6  $\geq 3$  mV 3) R-wave or S-wave in lead I, II, III, aVR, aVL, or aVF  $\geq 2$  mV.

**RESULTS:** Among 365 subjects studied, 239 (65%) were male and 126 (35%) were female. Sixty nine percent (n=252) were Caucasian, 22% (n=79) were African-American and 5% (17) were Asian. Twenty-seven percent (n=99) of athletes demonstrated LVH on ECG; 74 (31%) were male and 25 (20%) were female (95% Confidence Interval, 2 to 20;  $p < 0.02$ ). LVH was present in 30% (n=77) of Caucasians, 19% (n=15) of African-Americans, and 23% (n=4) of Asian athletes (95% CI, 1 to 21;  $p < 0.04$ ).

**CONCLUSIONS:** Among athletes studied with 12-lead resting ECG, approximately 27% demonstrated LVH. LVH Prevalence was highest in Caucasians (30%), followed by African-American (19%) (95% CI, 1 to 21;  $p < 0.04$ ). Male athletes had higher prevalence of LVH compared to female athletes (31% v/s 20%; 95% CI, 2 to 20;  $p < 0.02$ ). Our study suggests that prevalence of LVH may be affected by race and gender.

**PURPOSE:** To determine whether a lot of sumo wrestlers suffer metabolic syndrome.

**METHODS:** Subjects were 20 severe obese sumo wrestlers of university student whose body weight was more than 100 kg, body mass index more than 30 kg/m<sup>2</sup>, waist circumference more than 90 cm, waist/height ratio more than 0.5. We took blood samples early morning, and measured HDL-cholesterol (HDL-C), triglyceride (TG), fasting blood sugar (FBS) and insulin (IRI). HOMA-R was calculated by the formula. We measured systolic and diastolic blood pressure (sBP, dBP) at the resting state early morning. Each data was evaluated as abnormal value in case of the follows: HDL-C < 40mg/dl; TG  $\geq 150$ mg/dl; FBS  $\geq 110$ mg/dl; sBP  $\geq 130$ mmHg; dBP  $\geq 85$ mmHg. We evaluated as 1) abnormal lipid metabolism in case of abnormal HDL-C and/or abnormal TG, as 2) abnormal glucose metabolism in case of abnormal FBS, and as 3) hypertensive state in case of abnormal sBP and/or dBP. In addition, we decided as metabolic syndrome when subjects possessed two in three above abnormal states with severe obesity, as metabolic syndrome reserve when they possessed one in three above abnormal states with severe obesity, as simple obesity when they did not possessed any other abnormality except obese state. We evaluated as abnormal value of IRI in case of over 12.2 micro IU/ml, and as abnormal value of HOMA-R in case of more than 2.0.

**RESULTS:** We admitted abnormal HDL-C in 3 subjects, abnormal TG in 1 subject, normal FBS in all subjects, abnormal sBP in 8 subjects, abnormal dBP in 4 subjects. And we admitted abnormal lipid metabolism in 4 subjects, hypertensive state in 11 subjects. As the result, we discovered 3 subjects with metabolic syndrome and 9 subjects of metabolic syndrome reserve and 8 subjects of simple obesity. We admitted abnormal value of IRI in 8 subjects, and abnormal value of HOMA-R in 14 subjects.

**CONCLUSIONS:** Unexpectedly sumo wrestlers with metabolic syndrome were a few even if they were severe obese, but sumo wrestlers of metabolic syndrome reserve accounted for about a half of all subjects. Because it is estimated that 70 % of all subjects possess insulin resistance, it might be important for severe obese sumo wrestlers to reduce extra body fat.

**Injury Incidence During 12 Months Of Performance Training**

Jorge E. Gomez, FACSM<sup>1</sup>, Shaylon D. Rettig<sup>2</sup>, Carlos A. Reyes<sup>2</sup>. <sup>1</sup>University of Texas Health Science Center, San Antonio, TX. <sup>2</sup>CATZ Sports San Antonio, San Antonio, TX.

Email: gomezje@uthscsa.edu

(No relationships reported)

**PURPOSE:** Increasing numbers of youth and adult athletes are enrolling in performance training institutes to improve sport performance and overall fitness. Training at a performance training institute may require an increase in total training time, with the possibility of increasing exposure for injury. CATZ™ training mimics the neuromuscular demands of sport in a controlled setting in order to improve speed, agility, flexibility, & strength, and to prevent injury. The purpose of this study was to identify the incidence of injury during CATZ™ performance training.

**METHODS:** An injury was defined as any injury resulting in a cessation of training. Injury data was recorded by coaches prospectively using a standard form. Follow-up data was obtained in person or by telephone on all injured athletes within 1 week.

**RESULTS:** During a 12 month period of continuous surveillance, CATZ™ clients logged 11,472 hours of training. Ten injuries were reported during the 12 month period for an overall injury incidence of 0.87 injuries per 1000 training hours. Of the ten injuries, 8 resulted in the client seeking medical attention or lost playing time. All injured clients were between the ages of 12 and 20. The training activity associated most commonly with injury was back pedaling (3/10).

**CONCLUSION:** Overall the injury incidence is lower than those reported for the sports our clients normally participate in, indicating that CATZ™ sports performance training is a safe adjunct to regular sports training. All but one injury occurred during the first 30 minutes of the 60 minute session, suggesting that fatigue was not a factor in most injuries.

**Massage Impairs Rather Than Enhances Lactic Acid Removal From Muscle After Strenuous Exercise**

Victoria Wiltshire, Veronica Poitras, Melissa Pak, Terence Hong, Jay Rayner, Michael E. Tschakovsky. *Queen's University, Kingston, ON, Canada.*  
Email: vicky.wiltshire@queensu.ca  
(No relationships reported)

Sports massage has been widely accepted among the athletic community as an aid to promote muscle recovery from exercise. The Canadian Sports Massage Therapists Association (CSMTA) website ([www.csmta.ca](http://www.csmta.ca)) states that it "relieves soreness and assists in the removal of lactic acid and other waste products". To date no studies have investigated the claim about lactic acid removal.

**PURPOSE:** To test the hypothesis that massage improves muscle lactic acid removal post exercise.

**METHODS:** Twelve healthy young University undergraduate male subjects lay supine and performed 2 min of isometric handgrip at 40% maximal voluntary contraction (MVC). Forearm blood flow (FBF; Doppler and Echo ultrasound of the brachial artery) and deep venous forearm blood lactate concentration (DV[La<sup>-</sup>]; StatProfile M Blood Gas Analyzer, Nova Biomedical) were measured every 30 s for 10 min post-handgrip under three conditions: Control (passive rest), Massage (effleurage and petrissage), and Active Recovery (rhythmic exercise at 10% MVC).

**RESULTS:** Data are mean ±SE. DV[La<sup>-</sup>] at 30 s post handgrip increased by a similar amount above baseline across conditions (Control 6.1 ±0.5, Massage 5.5 ±0.6, Active Recovery 5.7 ±0.6 mmol/L). From 4.5 min post handgrip onwards, it was lower in Active Recovery than Control or Massage, P<0.05. FBF was highest in Control vs. Massage and Active Recovery for the first 3.5 min post-handgrip, all P<0.05. Examination of beat by beat flow tracings revealed markedly reduced flow during limb compression with rhythmic Massage and during the contraction phase of rhythmic exercise in Active Recovery. Total FBF area under the curve (AUC; ml) for 10 min post handgrip was significantly higher in Control vs. Massage (4203 ±531 vs. 3178 ±304) but not vs. Active Recovery (3584 ±284, P=0.217). La<sup>-</sup> efflux (mmol; FBF x DV[La<sup>-</sup>]) AUC mirrored FBF AUC (Control 20.5 ±2.8 vs. Massage 14.7 ±1.6, P=0.03 vs. Active Recovery 15.4 ±1.9, P=0.064).

**CONCLUSIONS:** Massage impairs lactic acid removal from muscle following strenuous exercise by mechanically impeding blood flow.

**Cardiac Dimensions In Professional Soccer Players**

haroldo C. alexio. *Clube Atlético Mineiro, Belo horizonte - minas gerais, Brazil.*  
Email: haroldoaleixo@uol.com.br  
(No relationships reported)

Soccer training may determine some specific cardiac findings. Echocardiogram alterations can be related both to pathological conditions and physiological adaptations.

**PURPOSE:** To determine the most frequent echocardiographic patterns in 41 professional soccer players.

**METHODS:** Echocardiographic data were obtained from 41 consecutive male professional players of a Brazilian soccer team. The group characteristics were: mean ±SD, age: 23,15 ± 4,05 years; body mass index (BMI): 23,5 ± 1,19 kg/m<sup>2</sup>; body surface area (BSA): 1,93 ± 0,13m<sup>2</sup>. Echocardiographic parameters analyzed: left atrium (LA), aortic root (Ao), right ventricular end diastolic (RVEDd), left ventricular end diastolic (LVEDd), left ventricular end systolic (LVESd) diameters. Also investigated interventricular septal thickness (IVT), left ventricular posterior wall thickness (PWT), ejection fraction (EF), left ventricular mass index (LVMI) and relative wall thickness (RWT). Cardiac dimensions were defined as normal (LVMI ≤ 115g/m<sup>2</sup> and RWT ≤ 0,42); eccentric left ventricular hypertrophy (LVMI > 115 g/m<sup>2</sup> and RWT ≤ 0,42); concentric left ventricular remodeling (LVMI ≤ 115 g/m<sup>2</sup> and RWT ≥ 0,42); concentric left ventricular hypertrophy (LVMI > 115 g/m<sup>2</sup> and RWT > 0,42).

**RESULTS:** Echocardiographic parameters (mean ± SD) were observed: Ao 33,5mm (± 2,64), LA 37,5mm (± 3,54), RVEDd 20,49mm (± 4,8), LVEDd 52,46mm (± 4,83), LVESd 33,54mm (± 3,20), PWT 11,0mm (± 1,25), EF 69,83% (± 6,14). Mean LVMI observed was 142,20 g/m<sup>2</sup> (± 25,68) and mean RWT was 0,42 (± 0,07). Considering cardiac geometry, six athletes (14,6%) were classified as "normal" while "concentric remodeling" was present in one (2,4%). Seventeen (41,5%) had "eccentric left ventricular hypertrophy" and equal number were characterized as "concentric left ventricular hypertrophy".

**CONCLUSIONS:** This study establishes the variety of echocardiogram presentations found in top level athletes. Considering that heart adaptations to physical activity vary with different types of exercise one suppose that different echocardiographic patterns will also be found according to the main function of the athlete in the field (e.g., midfielder, defender, goalkeeper and so forth). Additional studies with greater number of athletes must consider this variable.

**Perceived Pain, Fear Of Falling And Physical Function In Women With Osteoporosis**

Lutz Vogt<sup>1</sup>, Markus Hübscher<sup>1</sup>, Katharina Schmidt<sup>1</sup>, Ulrich Klinkmüller<sup>1</sup>, Stephanie Keiser<sup>2</sup>, Matthias Fink<sup>2</sup>, Winfried Banzer<sup>1</sup>. <sup>1</sup>Goethe-University Frankfurt, Frankfurt/Main, Germany. <sup>2</sup>Hannover Medical School, Hannover, Germany.  
(No relationships reported)

**PURPOSE:** Spinal osteoporosis, a significant medical and socioeconomic problem, leads to loss of bone density, reduced pulmonary function, disability and pain. The present study evaluated the extent to which pain intensity affects physical function and falls-related self-efficacy in elderly women with osteoporosis.

**METHODS:** The study included a randomly recruited sample of 82 (age 73.8±8.1 years) community living postmenopausal women with diagnosed osteoporosis (T-score < -2.5 by DXA) with and without vertebral fractures. Numeric rating scale (NRS) measures (0 = no pain, 10 = unbearable) were applied to obtain actual self-perceived pain intensity and to stratify between patients with mild (0-3), moderate (4-6) and severe (7-10) pain. Activity-related fear of falling was evaluated with the Falls-Efficacy-Scale International Version (FES-I). Physical performance measures included dominant quadriceps strength, postural sway and temporal gait parameters. The highest value of three isometric voluntary contractions, recorded by a strain gauge force transducer, was considered to be representative of the maximum knee extensor strength. Center-of-pressure (COP) signals in quiet stance with eyes open were used to compute the range of postural sway (95. Percentil). For gait recordings subjects were required to walk across a computerized electronic walkway at their natural cadence.

**RESULTS:** Controlling for age and history of falls in the previous 6 month ANCOVA indicated significant (p<0.05) slower walking velocities and impaired balance capacity for patients with severe pain. Furthermore, significant (p<0.05) between-group differences could be detected for lower extremity muscle strength and fear of falling. The covariate vertebral fracture demonstrated no significant influences on all the parameters obtained. Patients with more intense pain (NRS>4) were 6.4 times (95%-CI: Odds Ratio: 1.5-26.7) more likely to score below average in fall-related self-efficacy and all physical performance tests.

**CONCLUSION:** In osteoporosis actual pain intensity seems to influence fear of falling and physical performance irrespective of vertebral fractures and history of falls. These results have implications for intervention programs designed for fall prevention and functional performance improvement.

**A Metabolic Evaluation Of A Novel Spring-loaded Crutch Design**

Ryan P. Sandberg, Matthew K. Seeley, Joshua F. Chacon, Steven D. Monson, Merrill D. Funk, Neil Nokes, Gary W. Mack, FACSM. *Brigham Young University, Provo, UT.*  
Email: ryan.sandberg@hotmail.com  
(No relationships reported)

Increased energy expenditure is one challenge for active individuals who use crutches and desire to remain mobile. A relatively novel spring-loaded crutch design is currently being marketed. One of the multiple proposed advantages of this new crutch design is decreased energy consumption during crutch ambulation, however, this idea has not yet been objectively tested.

**PURPOSE:** The primary purpose of this study was to determine if the novel spring-loaded crutch design decreases oxygen consumption during crutch ambulation, relative to traditional crutches. The secondary purpose of this study was to determine whether this hypothesized decrease in oxygen consumption is related to the spring, located within the post of the spring-loaded crutch, or the unique shape of the spring-loaded crutch.

**METHODS:** Twenty healthy subjects ambulated at a standardized speed (0.97 m/s) while using three different crutch designs: traditional, spring-loaded, and modified spring-loaded (spring-loaded shape, with no spring). Following a familiarization period, subjects ambulated for five minutes with each crutch design, in a randomized order. Oxygen consumption was measured during the fifth minute of each test and compared, between each of three crutches, using a one-way ANOVA ( $p = 0.05$ ).

**RESULTS:** Oxygen consumption during crutch ambulation was not significantly different ( $p = 0.529$ ) among the traditional ( $16.72 \pm 2.12$  ml/kg/min), spring-loaded ( $17.23 \pm 2.29$  ml/kg/min), and modified spring-loaded crutch ( $17.43 \pm 1.65$  ml/kg/min) designs.

**CONCLUSION:** The present data indicate that neither the spring within the post of the spring-loaded crutch, nor the unique shape of the spring-loaded crutch decrease oxygen consumption during crutch ambulation, relative to traditional-crutch ambulation.

**The Spectrum Of Methicillin-resistant Gram Positive Cocci Isolated From Protective Athletic Mouth-guards**

Robert S. Conrad<sup>1</sup>, R. Tom Glass<sup>1</sup>, Gifty Benson<sup>1</sup>, Robert W. Allen<sup>1</sup>, Gerwald A. Köhler<sup>1</sup>, James W. Bullard<sup>1</sup>, Aric J. Warren<sup>2</sup>, C. Rieger Wood<sup>3</sup>, Judyth M. Gulden<sup>1</sup>, John R. Miller, III<sup>1</sup>, P. Cody Buchanan<sup>1</sup>, Wilson T. Knight, III<sup>1</sup>, Anthony P. Tricinella<sup>1</sup>, Richardo Aguilar<sup>1</sup>, Dustin O. Hayes<sup>1</sup>, Christopher L. Bass<sup>1</sup>, Michael A. McClain<sup>1</sup>. <sup>1</sup>Oklahoma State University Center for Health Sciences, Tulsa, OK. <sup>2</sup>Oklahoma State University, Stillwater, OK. <sup>3</sup>Private Practice of Dentistry, Tulsa, OK. (Sponsor: Steve Edwards Ph.D., FACSM)

Email: r.stan.conrad@okstate.edu

(No relationships reported)

**PURPOSE:** The purpose of this study was to isolate and identify the gram positive cocci found in protective athletic mouth-guards and to determine their level of methicillin sensitivity/resistance.

**METHODS:** After obtaining informed consent, 62 division 1 football players were divided into 4 groups with 2 groups wearing their mouth-guards all season and the other 2 groups having their mouth-guards changed at mid-season. All mouth-guards were collected at season-end. The mouth-guards were cut aseptically and their surfaces and depths were touched to Blood agar plates. The plates were incubated at 37°C for 24 hours. Positive cultures were identified using standard laboratory methods, including molecular biological techniques. Antibiotic sensitivities were determined for all isolates of gram positive cocci using standard procedures.

**RESULTS:** The 84 mouth-guards yielded a total of 164 gram positive cocci with the most common species being *Staphylococcus* spp. and *Micrococcus* spp. Of the gram positive cocci, 82 (50%) were methicillin-resistant. Surprisingly, only 5 of the gram positive cocci were *S. aureus* with only 2 of those being MRSA. The remaining 80 methicillin-resistant cocci were divided between various *Staphylococcus* spp.(49) and *Micrococcus* spp.(31). While all of these gram positive cocci have been implicated in a wide range of oral and systemic diseases, they may either be overlooked or ignored in a clinical setting because they are not *S. aureus*.

**CONCLUSIONS:** The results of this study confirm that mouth-guards are contaminated with a wide variety of gram positive cocci which may act as a source for both oral and systemic infectious diseases. While this study supports the required use of such devices, mouth-guards should be sanitized daily to reduce the number of microorganisms and replaced at least every 2 weeks or when damaged. If disease occurs, isolation of the microorganisms and antibiotic susceptibilities should be performed so that proper treatment can be rendered immediately.

**Diagnosis Of Left Ventricular Hypertrophy By Lead Criteria In The Analysis Of ECGs Over Time In Young Athletes**

Ijeoma E. Ananaba, Rahul H. Damani, J Jason West, John P. Higgins. *University of Texas Health Sciences Center, Houston TX, Houston, TX.*

Email: ijeoma.e.ananaba@uth.tmc.edu

(No relationships reported)

Sudden cardiac death in young athletes is a subject that has been studied extensively. As a result of such studies, it has previously been determined that abnormal left ventricular hypertrophy (LVH) is the single most common cause of sudden cardiac death athletes younger than 35. This has contributed to current recommendations made by the European Society of Cardiology (ESC) and the International Olympic Committee (IOC) for pre-participation screening. Because HCM may not manifest hypertrophy until exercise volume increases, the ESC and the IOC have recommended the use of electrocardiograms (ECGs) every 1-2 years as a screening tool in active athletes. There have been no studies to determine if certain ECG criteria for LVH might be more sensitive to detect changes in the athlete's heart once training has begun.

**PURPOSE:** To document differences in the resting 12-lead ECG performed at two different times in college athletes.

**METHODS:** We studied the ECGs from a group of 155 college athletes who presented for pre-participation screening at least 1 year apart. ECGs were determined reflect changes secondary to LVH based on the following criteria. Precordial leads: 1) S-wave in V1 or V2  $\geq 3$  mV 2) R-wave in lead V5 or V6  $\geq 3$  mV; Limb leads: 3) R-wave or S-wave in lead I, II, III, aVR, aVL, or aVF  $\geq 2$  mV.

**RESULTS:** Among the 155 athletes studied, 55 patients (35%) exhibited ECG changes consistent with LVH, 28 (18%) of which were abnormal on initial presentation, and later reclassified as normal, and vice versa for the remainder (17%). On further analysis, more abnormalities were detected using criteria that focused on differences in precordial leads rather than limb lead criteria.

**CONCLUSIONS:** In studying the temporal relationship in a cohort of student athletes, 35% of athletes demonstrated changes consistent with LVH, divided equally between those classified as normal to abnormal, and classified from abnormal to normal. On further analysis, it was noted that more ECGs using precordial lead criteria were more likely to become abnormal than those using limb lead criteria, suggesting that precordial lead criteria might be more sensitive in detecting heart abnormalities than limb lead criteria. This conclusion of course requires further evaluation including correlation with echocardiographic findings which we are currently researching.

**Habitual Exercise Decreases Serum Angiopoietin-related Growth Factor Levels In Healthy Human Subjects**

In Deok Kong<sup>1</sup>, Min-Jeong Kim<sup>1</sup>, Dae Sik Kim<sup>1</sup>, Yun Bok Sim<sup>1</sup>, Na Hyun Kim<sup>2</sup>. <sup>1</sup>Wonju College of Medicine, Yonsei Univ., Wonju, Republic of Korea.

<sup>2</sup>College of Nursing, Keimyung Univ, Daegu, Republic of Korea.  
Email: kong@yonsei.ac.kr  
(No relationships reported)

It is known that angiotensin-related growth factor (AGF/Angptd6) potentially regulates lipid, glucose, and energy metabolism. Previous studies in animal subjects suggest that AGF might be a potential regulator of metabolic homeostasis by counteracting obesity. However, human studies are lacking and the effect of regular exercise in AGF levels in humans has not yet been reported.

**PURPOSE:** The objective of this study was to determine whether an association exists between AGF levels and exercise in healthy human subjects.

**METHODS:** 18 healthy subjects (age 45.33±10.43) performed 50 minutes of supervised aerobic exercise four to five times per week for 12-weeks. Pre and post-training measurements were made. Body composition and body fat were measured by BoCA X1 analyzer. The predicted VO<sub>2</sub>max was determined using a treadmill test. Enzyme-linked immunosorbent assay (ELISA) was used to measure the AGF level in human serum.

**RESULTS:** After the 12-week training program, there was a significant increase in maximal exercise capacity (VO<sub>2</sub>max=37.75±0.42) compared to before training (VO<sub>2</sub>max=33.54±0.36). Serum AGF concentrations decreased after 12 weeks training from 364.08±5.7 to 308.4±3.96 ng/ml (P=0.012). The decrease was inversely related to changes in BMI (P<0.0001), body fat (P<0.0001), waist-to-hip ratio (P<0.0007) and serum triglycerides (P<0.0029). In contrast, changes in serum AGF were positively related to serum HDL cholesterol (P<0.0012). Insulin sensitivity was also improved post training compared to before training from 4.29±0.15 to 2.25±0.09, as indicated by HOMA-IR.

**CONCLUSIONS:** There have been no previous studies on AGF levels in healthy human subjects. Our study shows that habitual exercise significantly decreases serum AGF levels in humans. This finding is contrary to many former animal studies. Further studies in human subjects are warranted to validate these findings. In the future, AGF may be used as a therapeutic target for metabolic syndrome.

**Comparison Of Anthropometric Measures For Adherers And Non-adherers Following A 24-week Walking Intervention**

Cherilyn N. Hultquist<sup>1</sup>, Dixie L. Thompson, FACSM<sup>2</sup>. <sup>1</sup>Kennesaw State University, Kennesaw, GA. <sup>2</sup>University of Tennessee, Knoxville, TN.

Email: chultqui@kennesaw.edu

(No relationships reported)

A common reason for initiating an exercise program is to improve body composition (BC). While there is great debate about the ideal amount of daily physical activity (PA) necessary to impact BC, many U.S. adults have difficulty achieving minimal PA recommendations. The 10,000 steps/day (10k/day) walking recommendation is a unique approach as it allows PA to be built into one's day without an emphasis on duration or intensity. However, the impact that a 10k/day program has on BC is currently under studied.

**PURPOSE:** To determine anthropometric changes in previously inactive women during a 24-week walking intervention utilizing the 10k/day recommendation.

**METHODS:** 55 previously sedentary women (45.6 ± 5.8 y) completed a 24-week walking intervention. At baseline and at week 24, body mass, body fat, and waist and hip circumference (WC & HC) were assessed. Those who averaged ≥ 9500 steps/day throughout the intervention were classified as adherers (n = 25). Independent t-tests were used to determine BC differences between adherers and non-adherers at week 24. Pearson correlations were used to determine relationships between average steps/day and BC variables.

**RESULTS:** There was no difference for steps/day between adherers and non-adherers at baseline (5327 ± 948 and 5435 ± 1388, respectively, p = 0.735). There was a difference for steps/day throughout the 24-week intervention with adherers averaging 9921 ± 642 steps/day, and non-adherers averaging 8339 ± 1101 steps/day (p < 0.001). There was a difference between adherers and non-adherers at week 24 for change in fat mass (kg) with adherers losing 4.3 ± 4.0 kg and non-adherers losing 1.3 ± 2.6 kg (p = 0.002) and in HC reduction with adherers losing 3.9 ± 3.1 cm and non-adherers losing 1.2 ± 2.1 cm (p = 0.001). There was a correlation between average steps/day and fat mass lost r = 0.328, p = 0.015, and average steps/day and HC reduction, r = 0.369, p = 0.006.

**CONCLUSIONS:** Overall, adherers were significantly more active and benefited from more favorable BC changes. The 10k/day recommendation may be an appropriate approach for inactive people initiating an exercise program for weight loss. Future research in this area should include examinations of what impacts adherence to an exercise program and why non-adherers regress back to sedentary lifestyles.

**2897 Board #44 May 30 9:30 AM - 11:00 AM**  
**Comparison Of Aerobic Training Methods On V02 Max, Body Composition And Anaerobic Power.**

Cliffa Foster, Chris Poole, Brandon Bushey, Colin Wilborn. University of Mary Hardin-Baylor, Belton, TX.

Email: cfoster@umhb.edu

(No relationships reported)

**PURPOSE:** To investigate the potential impact of various aerobic training methods on VO<sub>2</sub>, body composition and anaerobic power.

**METHODS:** Thirty-four healthy male & female subjects (18-30yrs) participated in an equated volume supervised running workout for six weeks utilizing two alternate training methods. Group one (N = 17, 21 ± 3 yr) participated in Interval Training Distance (ITD) and group two (N = 17, 21 ± 3 yr) participated in Long Slow Distance (LSD). All subjects participated in a familiarity session (FAM), a Pre-Test (T1) and a Post-Test (T2). Each testing session consisted of a VO<sub>2</sub> Max, a 30 second Wingate and body composition assessment. Data were analyzed by a two-way ANOVA with repeated measures. Significance was set at p < 0.05 and adopted throughout.

**RESULTS:** The ITD and LSD groups experienced significant increases (p < 0.001) in VO<sub>2</sub> max, with 9.05% (4.19 ± 4.15 ml/kg/min) and 3.18% (1.39 ± 3.67 ml/kg/min) increases respectively. A significant interaction (p < 0.05) in VO<sub>2</sub> max occurred between groups, as the ITD group displayed a 302% greater increase when compared to the LSD group. Body fat percentage significantly decreased (p < 0.01) in the ITD (1.08 ± 1.90%) and LSD (1.55 ± 3.21%) groups, while a significant reduction (p < 0.05) in total body weight was also observed. There was no change in Wingate peak or mean power at a p < 0.05 significant level.

**CONCLUSIONS:** The findings of this study suggest that the ITD training method has a greater impact on aerobic capacity than LSD training method. However, both ITD and LSD training methods had a significant impact on aerobic capacity, body weight, and body composition.

**2898 Board #45 May 30 9:30 AM - 11:00 AM**  
**Effect Of Moderate Altitude On Lactate Clearance During Active And Passive Recovery**

John E. Davis, Sara A. Swanton, Geri L. Gaskell, Kelley Walsh. Alma College, Alma, MI.

Email: davisj@alma.edu

(No relationships reported)

**PURPOSE:** To determine the effect of moderate altitude exposure on lactate clearance during active and passive recovery following maximal exercise.

**METHODS:** Six healthy, active subjects (age= 20.7 ± 1.5 yrs, weight = 80.8 ± 19.5 kg) were asked to complete two graded-exercise tests to exhaustion on a cycle ergometer at sea level (SL1), upon acute exposure to 3400 m (ALT1), two weeks following acclimatization at 3400 m (ALT2), and upon return to sea level (SL2). Workloads were increased every two minutes following a two-minute warmup until volitional fatigue. Following the exercise tests at each location, subjects participated in either an active or passive recovery trial. During the active trial, subjects exercised at 35% of their VO<sub>2</sub>max while venous blood lactate measurements were taken every two minutes until lactate levels were decreased to half of their maximum values (T 1/2). This protocol was repeated during passive recovery while a subject sat in a chair and the same measurements were performed.

**RESULTS:** T1/2 (in minutes) was significantly faster (P<.05) during the active trial vs. the passive trial in all four locations (SL1: 14.3 ± 3.2 vs. 22.3 ± 4.2, ALT1: 12.6 ± 7.3 vs. 20.6 ± 7.2, ALT2: 11.2 ± 6.3 vs. 22.3 ± 6.9, SL2: 11.1 ± 1.0 vs. 18.2 ± 6.6). However, there were no differences in the active or passive trials between locations except that

T1/2 for the active trial in SL2 (11.1 ± 1.0) was significantly faster ( $P < .05$ ) than SL1 (14.3 ± 3.2).

**CONCLUSION:** These data suggest that active recovery is beneficial for the removal of blood lactate even after acute exposure to moderate altitude and altitude acclimatization.

Physical training has been suggested to reduce oxidative stress by decreasing a generation of reactive oxygen species or increasing antioxidant capacity. However, we still need more information concerning influences of age, gender, fitness level or training modalities on the training-induced adaptation to oxidative stress.

**PURPOSE:** The purpose of this study is to examine the effects of slow speed jogging training for four months on oxidative stress and antioxidant capacity in blood in middle-aged persons.

**METHODS:** The subjects were 26 middle-aged persons (male n=7, woman n=19, 56.8 (SD 7.2) yr.) they were members of a university marathon club for the regional resident. They jogged 1-5 times a week for about 1 hour at slow speed of 7-8 minutes/km for four months. Plasma samples were collected on two occasions, one at an early stage (July), the other at maintenance stage (November) in the training period. The collected samples were analyzed for reactive oxygen metabolites-derived compounds (d-ROMs) and trolox equivalent antioxidant capacity (TEAC). In addition, the correlation between TEAC and antioxidants intake in their meals by questionnaire survey was examined.

**RESULTS:** Although slow speed jogging training for four months induced no significant change in resting plasma d-ROMs concentrations, it increased TEAC significantly ( $p < 0.05$ ). There was a positive correlation between TEAC at the early stage and that at the maintenance stage of the training period ( $r = 0.46$ ,  $p < 0.05$ ). There was a negative correlation between increased TEAC values at the maintenance stage and TEAC at the early stage ( $r = 0.61$ ,  $p < 0.01$ ). There were no significant correlations between antioxidants intake and d-ROMs or TEAC.

**CONCLUSIONS:** The present study suggested that slow speed (7-8 km/min) jogging training might improve antioxidant capacity, especially might be effective for those having low antioxidant capacity in middle-aged persons.

Email: giampiero.merati@unimi.it

(No relationships reported)

Heart rate variability (HRV) has recently been proposed to detect the autonomic adaptations to endurance training. However, the effect of training on HRV indexes remains inconclusive.

**PURPOSE:** To assess whether the morning short-term HR recording in clinostatic and orthostatic position may be useful in evaluating the training-induced autonomic changes and can predict the maximal aerobic performance.

**METHODS:** Eight high-level endurance athletes (biathlon) and 8 healthy sedentary subjects, matched for age and anthropometry, were enrolled. RR series were recorded after awakening in supine (10 min) and standing (10 min) positions. The HRV parameters considered were RMSSD, pNN50, SD<sub>1</sub>, LF and HF (Low [0.04-0.15 Hz] and High [0.15-0.40 Hz] Frequencies: absolute and normalized) powers, LF/HF ratio, and the non-linear index ApEn (Approximate Entropy, m=2, r=0.2SD, n=500). The maximal aerobic performance (VO<sub>2</sub>max) was also measured in the athletes.

**RESULTS:** HRV tended to be higher in the athletes than in sedentary subjects in clinostatic position (RMSSD: 68±32 vs 43±22 ms, respectively; pNN50: 42±24 vs 24±18%, and SD<sub>1</sub>: 48±22 vs 30±15 ms), but the statistical significance was reached in orthostatic position only. Normalized LF and HF powers did not differ between groups in both conditions. Conversely, LF absolute power was significantly increased in athletes group both at rest (1002±565 vs 387±229 ms<sup>2</sup>,  $p < 0.05$ ) and during standing (1106±697 vs 403±189 ms<sup>2</sup>,  $p < 0.05$ ), whereas HF power was significantly higher during standing only (165±137 vs 27±12 ms<sup>2</sup>,  $p < 0.05$ ). ApEn was similar at rest in athletes and sedentary subjects (1.27±0.05 vs 1.21±0.10, respectively) and was reduced similarly during standing (1.01±0.19 vs 1.13±0.13,  $p = ns$  between groups). In the athletes group, the difference between clinostatic and orthostatic values of normalized LF power positively correlated ( $r = 0.66$ ) with VO<sub>2</sub>max, whereas the clino-orthostatic transition in HF negatively correlated ( $r = -0.77$ ) to VO<sub>2</sub>max.

**CONCLUSIONS:** HRV may be useful in detecting the autonomic changes induced by endurance training. However, the autonomic system has to be slightly stimulated with standing. The clino-orthostatic adaptation of LF and HF normalized powers seems to be able to predict the maximal aerobic performances in the athletes.

**Comparison Of Vastus Lateralis And Medial Hamstring Electromyographic Activity Across Five Cardiovascular Exercises**

Judith M. Burnfield, Ryan T. Roemmich, Tyler Scherr, Thad W. Buster. *Madonna Movement and Neurosciences Center, Lincoln, NE.*

Email: jburnfield@madonna.org

(No relationships reported)

Greater emphasis on the value of incorporating cardiovascular training into rehabilitation programs has heightened the need to define normative muscle activation patterns across cardiovascular exercises. This study's findings will help guide clinical decision-making regarding selection of appropriate exercises to meet not only the cardiovascular fitness goals but also the muscle strengthening needs of clients recovering from a variety of orthopedic and neurologic disorders.

**PURPOSE:** To compare vastus lateralis (VL) and medial hamstring (MH) muscle activity patterns across five cardiovascular exercises.

**METHODS:** Six males and four females participated (mean age 25±5 yrs). Subjects engaged in three equipment familiarization sessions and then performed each of the following exercises for 5 minutes in random order: treadmill jogging (J), stair stepping (S), elliptical training (E), treadmill walking (W) and recumbent biking (B). Subjects were instructed to perform each at an intensity that could be maintained for 30-min. Kinematic (8 camera), foot-floor contact pattern (footswitches), and VL and MH surface electromyography (EMG) data were recorded simultaneously during the final minute on each device. Cycles were defined using kinematic (B, S, E) and footswitch (W, J) data. For each muscle and exercise, 10 representative cycles were used to calculate the average peak (expressed as % maximum voluntary contraction, % MVC), mean (% MVC) and duration (expressed as % cycle) of EMG activity. Separate 5x1 ANOVAs with repeated measures identified significant differences in EMG activity (peak, mean, duration) across exercises for each muscle.

**RESULTS:** All data expressed as mean ± SD. VL: Peak: J, S > E, W, B (105±52, 95±37 > 51±30, 43±34, 35±25;  $p < 0.001$ ). Mean: S, J > E, W, B (41±13, 40±15 > 26±14, 20±8, 19±9;  $p < 0.001$ ). Duration: E, S > W (61±18, 53±18 > 29±22;  $p < 0.001$ ). MH: Peak: J > B, E, S (56±46 > 15±11, 11±9, 8±5;  $p < 0.001$ ) and W > S (21±11 > 8±5;  $p < 0.001$ ).

Mean: J > B, E, S ( $25 \pm 15 > 9 \pm 6$ ,  $7 \pm 5$ ,  $5 \pm 4$ ;  $p < 0.001$ ) and W > S ( $13 \pm 6 > 5 \pm 4$ ;  $p < 0.001$ ). Duration: J > S, E ( $49 \pm 23 > 17 \pm 27$ ,  $14 \pm 14$ ;  $p < 0.001$ ).

**CONCLUSION:** When greater VL activation is warranted, consider S and J. When VL protection is needed (e.g., post-polio overuse), then B and W appear beneficial. J consistently provided the greatest MH activation, while S offered greater MH protection.

(No relationships reported)

Daily measurement of heart rate variability (HRV) is a unique tool to optimize exercise training among highly active males. However, this has not been assessed in less active males and females.

**PURPOSE:** To assess the utility of HRV in daily exercise prescription among moderately active (~2 exercises/wk) males and females.

**METHODS:** Twenty-one males (age:  $35 \pm 3$  yrs,  $VO_{2max}$ :  $49 \pm 6$  ml/kg/min) and twenty-two females (age:  $34 \pm 4$  yrs,  $VO_{2max}$ :  $37 \pm 6$  ml/kg/min) were divided into standard training (ST,  $n=7$ ), HRV guided training (HRV,  $n=7$ ) and control group ( $n=7$ ). Eight-week aerobic training period included exercises lasting 40-min each at either low or high intensity level (70% or 85% of maximal heart rate). ST-group was instructed to perform  $\geq 2$  sessions at low and  $\geq 3$  sessions at high intensity weekly. HRV-group trained based on the changes in vagally mediated HRV (SD1) measured every morning in standing position (3-min). Increase or no change in SD1, compared to previous days, resulted in high intensity training on that day. Low intensity exercise or rest was prescribed if SD1 had decreased significantly.  $VO_{2max}$  and maximal workload ( $W_{max}$ ) were measured by maximal bicycle ergometer test before and after the intervention. Training load was assessed by calculating TRIMP.

**RESULTS:** In males,  $W_{max}$  and  $VO_{2max}$  increased in both ST- (from  $275 \pm 28$  to  $294 \pm 35$  W and from  $3.96 \pm 0.52$  to  $4.14 \pm 0.53$  l/min,  $p < 0.01$  for both) and HRV-group (from  $270 \pm 29$  to  $300 \pm 25$  W and from  $4.03 \pm 0.35$  to  $4.33 \pm 0.31$  l/min,  $p < 0.01$  for both). The change in  $W_{max}$  was higher in HRV-group compared to ST-group ( $30 \pm 8$  vs.  $18 \pm 10$  W,  $p = 0.038$ ). The change in  $VO_{2max}$  did not differ between ST- and HRV-group ( $p = 0.204$ ). In females,  $W_{max}$  and  $VO_{2max}$  increased in both ST- (from  $179 \pm 32$  to  $198 \pm 35$  W and from  $2.33 \pm 0.46$  to  $2.48 \pm 0.48$  l/min,  $p < 0.05$  for both) and HRV-group (from  $174 \pm 28$  to  $189 \pm 25$  W and from  $2.28 \pm 0.43$  to  $2.46 \pm 0.38$  l/min,  $p < 0.05$  for both). No differences were found in the changes in  $W_{max}$  and  $VO_{2max}$  between ST- and HRV-group. Training load did not differ between ST- and HRV-group in males or females. No significant changes were observed in control group.

**CONCLUSIONS:** Aerobic training prescription based on daily HRV is more beneficial than standard training instruction for moderately active males. Different HRV-based training may be required for moderately active females.

**Comparison of Ankle Muscle Electromyographic Activity Across Five Cardiovascular Exercises**

Thad W. Buster, Ryan T. Roemmich, Nicholas J. Doherty, Judith M. Burnfield. *Madonna Rehabilitation Hospital, Lincoln, NE.*

Email: tbuster@madonna.org

(No relationships reported)

Expanded access to fitness equipment in rehabilitation settings has enabled clinicians to more frequently incorporate these devices therapeutically. However, a better understanding of how muscle demands vary across cardiovascular exercises is essential for optimizing therapeutic usage of the devices.

**PURPOSE:** To compare ankle muscle activity patterns during five common cardiovascular exercises.

**METHODS:** Ten healthy adults participated (6 male, 4 female;  $25 \pm 5$  yrs). After completing 3 familiarization sessions, each subject performed 5 exercises in random order: recumbent biking (B), stair stepping (S), elliptical training (E), treadmill walking (W), and treadmill jogging (J). Subjects performed each at an intensity that could be maintained for 30-min. Footswitch, kinematic, and tibialis anterior (TA) and medial gastrocnemius (MG) surface electromyography (EMG) data were recorded simultaneously during the final minute of a 5-min workout on each device. Cycles were defined using footswitch (W, J) and kinematic (B, S, E) data. EMG data were normalized to the maximum voluntary contraction (MVC) and expressed as % MVC. For each muscle, the peak (% MVC), mean (% MVC), and duration (expressed as % cycle) were calculated from the average of 10 representative cycles recorded during the respective activity. Separate ANOVAs with repeated measures identified significant differences in EMG activity (peak, mean, duration) across exercises for each muscle.

**RESULTS:** All data expressed as the mean  $\pm$  SD. TA: Peak: J > S, W, B, E ( $89 \pm 34 > 31 \pm 26$ ,  $23 \pm 6$ ,  $20 \pm 11$ ,  $17 \pm 10$ ;  $p < 0.001$ ). Mean: J, W > B, E ( $32 \pm 12$ ,  $23 \pm 6 > 11 \pm 5$ ,  $10 \pm 5$ ;  $p < 0.001$ ) and J > S ( $32 \pm 12 > 16 \pm 12$ ;  $p < 0.001$ ). Duration: J, W > B, S, E ( $78 \pm 17$ ,  $60 \pm 16 > 33 \pm 28$ ,  $32 \pm 29$ ,  $26 \pm 28$ ;  $p < 0.001$ ). MG: Peak: J > W, S, E, B ( $133 \pm 36 > 85 \pm 30$ ,  $80 \pm 50$ ,  $65 \pm 46$ ,  $54 \pm 11$ ;  $p < 0.001$ ). Mean: J > B, S, E ( $48 \pm 15 > 28 \pm 7$ ,  $27 \pm 10$ ,  $25 \pm 15$ ;  $p < 0.001$ ). Duration: B, S, J > E ( $69 \pm 15$ ,  $65 \pm 25$ ,  $57 \pm 13 > 36 \pm 26$ ;  $p < 0.001$ ) and B > W ( $69 \pm 15 > 50 \pm 14$ ;  $p < 0.001$ ).

**CONCLUSION:** Peak TA activity varied greater than 5-fold across exercises while duration varied 3-fold. If the therapeutic goal is maximizing TA activation, J should be considered. In contrast, E minimized TA demand compared to other exercises. MG peak and duration varied to a lesser extent across exercises (maximum 2-fold), with J requiring the greatest activation and E affording lesser activity.

**Effects Of Aerobic Exercise Training On The Anthropometry And Blood Biochemistry In Health Young Women**

Yu-Hua Kuo<sup>1</sup>, Hsiao-Fan Hung<sup>1</sup>, Chi-Sheng Yang<sup>2</sup>, Hui-Ju Wang<sup>1</sup>. <sup>1</sup>China Medical University, Taichung, Taiwan. <sup>2</sup>Hungkuang University, Taichung, Taiwan.

(No relationships reported)

Aerobic exercise is beneficial to health. It improves insulin-resistant status and cardiorespiratory fitness, and reduces the incidence of obesity, type 2 diabetes and cardiovascular diseases. Eotaxin is a secretory product of the adipose tissue and its expression is reversibly increased in obesity. In addition, levels of eotaxin could contribute to the signs and symptoms of asthma. However the relationship between eotaxin and anthropometry and blood biochemistry in young women has not been investigated.

**PURPOSE:** To study the effect of aerobic exercise training on anthropometry and blood biochemistry in sedentary health young women.

**METHODS:** Ten healthy young sedentary women (20-23 yr) underwent aerobic exercise training for 8 weeks. The subjects were directed to run on a treadmill at 60-70%  $VO_{2max}$ , 3 days per week. Duration of each session started from 20 min in first week, and was increased by 5 min per week until 45 min/session. After exercise training subjects returned their sedentary lifestyle for 8 weeks to wash out the training effect. The same subjects then served as their own untrained control during the next 8 weeks.  $VO_{2max}$ , weight, body fat (BF), heart rate in rest (HRr), resting blood pressure, waist circumference (WC), waist-to-hip ratios (WHR), heart rate in every level of testing ( $HR_{level}$ ), and plasma eotaxin, glucose, total cholesterol (TC), and high-density lipoprotein cholesterol (HDL-C) were measured before and after training in both groups.

**RESULTS:**  $HR_{level}$  was decreased after aerobic exercise training. Plasma eotaxin, glucose, TC, HDL-C were not changed after long-term aerobic training. Weight, BF, and  $VO_{2max}$  were increased, but HRr, systolic blood pressure (SBP), WC, and WHR were not changed when compared with control. However, there was a positive correlation between plasma eotaxin levels and WC and WHR, and eotaxin was negatively correlated to HDL-C levels. There was also a negative correlation between SBP and HDL-C.

**CONCLUSION:** Aerobic exercise training can improve cardiorespiratory fitness. In addition the positive correlation between plasma eotaxin and WC suggest that eotaxin can

(No relationships reported)

It is recognized that facilitation of fat metabolism is important for health-related aspect of exercise. Intensity at which maximal fat oxidation occurs is defined as FATmax that can be applied for exercise prescription; however, the training effects at FATmax intensity was not well established.

**PURPOSE:** To compare the training effects of 8 weeks of running at FATmax intensity and heart rate control intensity corresponding to FATmax (HRC<sub>FATmax</sub>) on maximal fat oxidation and aerobic power (VO<sub>2max</sub>).

**METHODS:** Fourteen male and nineteen female college students [age: 21.40 (4.54) yrs; height: 166.70 (10.58) cm, weight: 63.22(14.08) kg] were recruited in this study. Incremental exercise to determine FATmax intensity and VO<sub>2max</sub> were performed pre- and post- training for each participant. All participants were assigned into three groups, FATmax, HRC<sub>FATmax</sub> and control groups with comparable VO<sub>2max</sub> and FATmax intensity. Training groups underwent eight weeks (3 times/week and 30mins/time) of running program at different intensities whereas control group was asked not to engage any regular exercise during the study. Two-way split-plot ANOVA was employed to determine the difference of FATmax, FATmax intensity, and VO<sub>2max</sub> among three groups pre- and post- training.

**RESULTS:** FATmax was improved in both FATmax and HRC<sub>FATmax</sub> groups (0.47±0.19 g/min and 0.56±0.18 g/min ; 0.48±0.19 g/min and 0.58±0.22 g/min) after training ( $p<.05$ ) whereas there was no significant change (0.47±0.13 g/min and 0.43±0.11 g/min) in control group. In addition, there was no significant difference in FATmax intensity (expressed by VO<sub>2</sub> or % VO<sub>2max</sub>) between groups after training. For VO<sub>2max</sub>, FATmax and HRC<sub>FATmax</sub> group were both improved ( $p<.05$ ) after training (FATmax: 43.22±8.94 ml/kg/min to 45.77±9.11 ml/kg/min ; HRC<sub>FATmax</sub>: 42.19±6.70 ml/kg/min to 44.99±7.37 ml/kg/min) whereas there was no significant change in control group (45.40±10.24 ml/kg/min to 44.19±8.21 ml/kg/min). Moreover, there was no significant difference on VO<sub>2max</sub> between groups after training.

**CONCLUSIONS:** 8 weeks of endurance training at FATmax and HRC<sub>FATmax</sub> intensity were both improved at maximal fat oxidation rate and aerobic power, but not FATmax intensity.

---

**Effect Of Endurance Training On Cardiorespiratory And Muscle Oxygenation Responses During Ramp Exercise Testing**

Justin J. Fiutem, Haiying Zhou, Nicola Lai, Marco E. Cabrera, FACSM. Case Western Reserve University, Cleveland, OH. (Sponsor: Marco E. Cabrera, FACSM)

Email: justin.fiutem@case.edu

(No relationships reported)

Endurance training improves exercise performance, which is associated with central and peripheral adaptations that lead to enhanced delivery of oxygen (O<sub>2</sub>) to working muscle and greater oxidative capacity. To date, no comprehensive studies of oxygen transport and muscle oxygenation have been conducted to characterize training-induced adaptations combining noninvasive technologies, such as indirect calorimetry (IC), near infrared spectroscopy (NIRS) and bioimpedance cardiography (BC).

**PURPOSE:** To characterize the O<sub>2</sub> uptake (VO<sub>2</sub>), heart rate (HR), minute ventilation (VE), cardiac output (CO), and muscle oxygenation dynamic responses to ramp exercise before and after endurance training.

**METHODS:** Eight subjects (23.1±3.2 yrs., 169±10 cm, 61.6±13.1 kg) performed maximal ramp exercise tests before and after eight weeks of training (5x/wk, 1h/session). A continuous wave NIRS device was used to measure relative changes in oxy- and deoxy- Hb/Mb in the vastus lateralis of the right leg during ramp exercise. Additionally, the cardiorespiratory responses (VO<sub>2</sub>, CO, HR, and VE) were obtained using IC and BC. Muscle oxygenation during exercise was normalized to the maximal drop observed during arterial cuff occlusion. The statistical analysis used was paired t-test.

**RESULTS:** After training, peak work rate (203±66 vs. 246±71 W), peak VO<sub>2</sub> (2.5±0.8 vs. 3.0±0.9 L/min), and peak VE (93±22 vs. 101±20 L/min) improved significantly ( $p<0.05$ ). However, there were no significant changes in muscle oxygenation (26±15 vs. 27±16 %) and cardiac output (18.9±4 vs. 18.4±4 L/min) after maximal exercise. The slopes of the relationships between CO and work rate (0.065±0.01 vs. 0.05±0.01 L/min/W, and VO<sub>2</sub> and HR (0.02±0.006 vs. 0.025±0.006 L/beat) during the ramp test were also significantly different after training.

**CONCLUSIONS:** Eight weeks of endurance training improve power output with no change in CO, which suggests an enhanced O<sub>2</sub> extraction by muscle. Although changes in venous O<sub>2</sub> concentration were not measured, these results indicate that muscle oxygenation obtained via NIRS may not be a reliable index of O<sub>2</sub> extraction during maximal exercise. Other factors altered with training (e.g., mitochondrial and capillary density, O<sub>2</sub> diffusion, Mb) may affect the overall muscle oxygenation response after training.

**The Effect Of Maximal Sprint Training On Measures Of Endurance Performance**

Mary K. Thum<sup>1</sup>, Andrew R. Creer<sup>2</sup>, Emily A. Hansen<sup>1</sup>, Matthew D. Vukovich, FACSM<sup>1</sup>. <sup>1</sup>South Dakota State University, Brookings, SD. <sup>2</sup>Utah Valley University, Orem, UT.

Email: mary.thum@sdstate.edu

(No relationships reported)

**PURPOSE:** To determine the effects of two weeks of maximal sprint interval training (SITmax) on variables of endurance running performance; including peak oxygen uptake (VO<sub>2peak</sub>), the velocity associated with VO<sub>2peak</sub> (vVO<sub>2peak</sub>), progressive time to fatigue measure (TTF), and a 5km time trial (TT), in well trained runners.

**METHODS:** Twelve trained collegiate runners (4 males, 8 females) were assigned to a sprint group (SG) (n = 6; age 23 ± 2 yrs; VO<sub>2peak</sub> 67.6 ± 7.5 ml·kg<sup>-1</sup>·min<sup>-1</sup>) or endurance control group (CG) (n = 6; age 22 ± 2 yrs; VO<sub>2peak</sub> 59.4 ± 6.5 ml·kg<sup>-1</sup>·min<sup>-1</sup>). Endurance performance measures were assessed before and after two weeks of SITmax. Treadmill protocols utilizing indirect calorimetry were used to determine VO<sub>2peak</sub>, vVO<sub>2peak</sub>, and TTF. Time trials were performed on either a synthetic 200 m indoor or 400 m outdoor track, with surface and weather conditions consistent for pre and post trials. SITmax consisted of 3 sprint sessions per week for 2 wks. The number of sprints performed progressed from 4 during week 1 to 6 during week 2. Each session consisted of a 15 minute submaximal warm-up run, followed by 4-6 30 s treadmill sprints and a 15-30 minute submaximal running cool-down. The running velocity for each sprint corresponded to 120-125% of the individual's VO<sub>2peak</sub>. Control subjects were asked to maintain a normal training volume during the 14 day period.

**RESULTS:** Participants recorded training time and average HR throughout the intervention period. The SG (315±62 min-wk) performed more ( $p<0.05$ ) submaximal running throughout the study compared to the CG (250±45 min-wk). Prior to intervention, SG had higher ( $p<0.05$ ) VO<sub>2peak</sub> than CG. Following the 14 day intervention no differences in vVO<sub>2peak</sub>, TTF, or TT performance were found between the CG and SG. However, the change in VO<sub>2peak</sub> was greater ( $p<0.05$ ) in SG (3.1%; 67.6±7.5 to 69.7±7.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>) compared to CG (-3.9%; 59.4±6.5 to 57.1±6.8 ml·kg<sup>-1</sup>·min<sup>-1</sup>).

**CONCLUSION:** Although SITmax resulted in an increase in aerobic power compared to controls, there was no effect on vVO<sub>2peak</sub>, TTF or TT performance, suggesting that performance adaptations in response to SITmax may take longer than 14 d to occur in well trained runners.

**2908 Board #55 May 30 9:30 AM - 11:00 AM**  
**Effects Of Aerobic Fitness On Blood Buffering And Maximal Cycling Power During Variable Intensity Exercise.**  
 Juan Del Coso, Roberto Aguado-Jimenez, Nassim Hamouti, Ricardo Mora-Rodriguez. *University of Castilla-La Mancha, Toledo, Spain.*  
 Email: Juan.delcoso@uclm.es  
 (No relationships reported)

Variable intensity exercise (VAR = short bouts of high-intensity exercise followed by low intensity for recovery) is typically used by aerobically-trained (A<sub>E</sub>T) and untrained people (UT) to improve endurance performance. However VAR lowers blood pH which is associated with reductions in muscle force.

**PURPOSE:** To determine if acid-base regulation during VAR differs between UT and A<sub>E</sub>T and its effects on maximal cycling power.

**METHODS:** Ten A<sub>E</sub>T and ten UT ( $= 64 \pm 6$  vs  $55 \pm 6$  mL·kg<sup>-1</sup>·min<sup>-1</sup>;  $P < 0.05$ ) pedaled alternating high (1.5 min) with low (4.5 min) exercise intensity for 24 min. Exercise intensity was normalized to their ventilatory threshold (VT) resulting in 3 trials; VAR<sub>LOW</sub> = 87.5-37.5% VT; VAR<sub>MODERATE</sub>, 125-25% VT; and VAR<sub>HIGH</sub> 162.5-12.5% VT. Total work was the same for all trials ( $213 \pm 8$  and  $149 \pm 23$  kJ for A<sub>E</sub>T and UT). Arterialized-blood samples and expired gas were obtained during exercise and maximal cycling power (P<sub>MAX</sub>) was measured prior and after exercise.

**RESULTS:** Table 1 shows the mean  $\pm$  SD for blood pH (pH<sub>blood</sub>) and bicarbonate concentration ([HCO<sub>3</sub><sup>-</sup>]<sub>blood</sub>), ventilatory equivalent for CO<sub>2</sub> (VE · VCO<sub>2</sub><sup>-1</sup>) and change in P<sub>MAX</sub> at the end of each protocol. \* Different from VAR<sub>LOW</sub> at  $P < 0.05$ . † Different from VAR<sub>MODERATE</sub> at  $P < 0.05$ . ‡ Different from A<sub>E</sub>T at  $P < 0.05$

	VAR <sub>LOW</sub>		VAR <sub>MODERATE</sub>		VAR <sub>HIGH</sub>	
	A <sub>E</sub> T	UT	A <sub>E</sub> T	UT	A <sub>E</sub> T	UT
pH <sub>blood</sub>	7.43 $\pm$ 0.02	7.43 $\pm$ 0.01	7.39 $\pm$ 0.02*	7.36 $\pm$ 0.03*	7.21 $\pm$ 0.05*†	7.18 $\pm$ 0.08*†
[HCO <sub>3</sub> <sup>-</sup> ] <sub>blood</sub> (mM)	24.9 $\pm$ 1.2	24.0 $\pm$ 1.0	19.7 $\pm$ 5.1*	19.1 $\pm$ 3.0*	11.4 $\pm$ 3.2*†	10.5 $\pm$ 3.4*†
VE · VCO <sub>2</sub> <sup>-1</sup>	27.3 $\pm$ 1.5	27.7 $\pm$ 2.2	31.1 $\pm$ 2.6*	32.1 $\pm$ 3.0*	40.0 $\pm$ 5.8*†	41.2 $\pm$ 3.5*†
Δ P <sub>MAX</sub> (%)	-1.7 $\pm$ 1.5	-3.5 $\pm$ 1.2	-1.6 $\pm$ 1.3	-2.5 $\pm$ 1.3	-2.0 $\pm$ 0.8	-14.1 $\pm$ 1.4‡

**CONCLUSIONS:** To increase the exercise intensity during VAR produced similar decrease in blood pH and bicarbonate concentration and comparable increase in the respiratory compensation between A<sub>E</sub>T and UT. This suggests that blood-respiratory buffering systems are not impaired in UT people during VAR. However, despite similar low blood pH, only UT reduced the maximal cycling power after VAR<sub>HIGH</sub>. Thus, training may confer adaptations to withstand low pH without losing neuromuscular power.

**Muscle Damage Following an Ultra-marathon Downhill Running in Runners who were not Prepared for Downhill Running**  
 Ali M. Al nawaiseh, Suleiman Zboon. *The Hashemite University, Zarqa, Jordan.*  
 Email: nawaiseh\_a@yahoo.com  
 (No relationships reported)

**PURPOSE:** The purpose of this study was to examine the magnitude of Exercise-induced muscle damage (EIMD) and potential danger of Rhabdomyolysis following marathon and ultra-marathon downhill running in runners who do not prepare for the race on downhill roads.

**METHODS:** Competitive male runners ( $n = 16$ ) who finished in top 10 positions of Dead Sea annual ultra marathon (52Km) ( $n = 5$ ) and marathon (42Km) ( $n = 3$ ) were recruited to participate in the study. The road of the race starts from 800m and 700m above sea level respectively and ends at -385m below sea level. Runners from the 21&10 Km who ran on an almost level road in the second half of the race served as control group. Participants were asked to voluntarily give blood samples 24hrs after the race after signing consent form. Creatine kinase (CK) levels were measured to evaluate EIMD 24hrs after the race. Participants were asked not to take any supplements after the race and were excluded from the test if they have taken any before the race.

**RESULTS:** CK levels increased significantly after running (downhill and level running) 24 hr after the end of the race. No differences in CK levels between 10 and 21K runners. However, CK levels in downhill runners were twice the value of their counterpart level runners. CK Levels averaged 5087 u/l and 3541 24hrs after the ultra marathon and marathon respectively after excluding outlier participants.

**CONCLUSIONS:** Dead Sea ultra marathon "Run to lowest point on earth" with its 18k of downhill running increases muscle damage markers to alarming levels when participants do not practice on similar roads. Unaccustomed muscles for this kind of events have the potential of triggering some serious problems. Further investigations needed to examine the effect of preparing for the race on similar conditions and how to reduce muscle damage.

**Maintenance Of Running Economy In Highly Successful Distance Runners: A Cross-sectional Aging Study.**  
 Timothy J. Quinn, FACSM<sup>1</sup>, Michelle J. Manley<sup>1</sup>, Jason Aziz<sup>2</sup>, Jamie L. Padham<sup>3</sup>, Allison M. MacKenzie<sup>1</sup>. <sup>1</sup>University of New Hampshire, Durham, NH. <sup>2</sup>Concord Hospital, Concord, NH. <sup>3</sup>Husson School of Graduate and Professional Studies, Bangor, ME.  
 Email: tjq@unh.edu  
 (No relationships reported)

Running economy (RE) is the steady-state VO<sub>2</sub> for a given running velocity and has been shown to be strongly correlated to distance running performance. The impact of aging on RE in runners of high caliber has not been fully studied.

**PURPOSE:** To determine whether aging affects RE in a cross-sectional cohort of age-group winning runners.

**METHODS:** Subjects were recruited from large (>1,000 finishers), local road races and had to be an age group winner (1<sup>st</sup>, 2<sup>nd</sup>, or 3<sup>rd</sup> place finisher) in order to be considered for the study. Three groups were established based on age: Young (Y) (18-39 yrs,  $n=18$ ), Masters (M) (40-59 yrs,  $n=22$ ), and Old (O) (>60 yrs,  $n=11$ ). Each runner reported to the laboratory three times and completed a lactate threshold test followed by a VO<sub>2</sub> max test (Day 1) and on a separate day completed a RE test (Day 2). The RE test was conducted at four running speeds: 161, 188, 214, and 241 m/min. Each runner ran for four minutes at each speed and the steady state VO<sub>2</sub> was determined from the last minute of exercise. Complete recovery was allowed between running speeds. The VO<sub>2</sub> at each speed was plotted and a regression equation was determined and the slopes were then compared. Day 3 included body composition assessment and measurements of flexibility, muscle power, muscle strength, and muscle endurance. A 1 X 3 ANOVA was used to test for differences and significance was established at the  $p < 0.05$  level.

**RESULTS:** Upper body strength and power were significantly lower in the O group ( $p < 0.05$ ). The O group ran at a slightly lower relative VO<sub>2</sub> at each speed compared to Y

and M, however, this was accomplished at a significantly higher fraction of  $\dot{V}O_{2\max}$  ( $p < 0.05$ ). The following regression lines were calculated:  $Y = 0.1827(X) - 0.2974$ ;  $R^2 = 0.9511$  (Young);  $Y = 0.1988(X) - 1.0416$ ;  $R^2 = 0.9697$  (Master);  $Y = 0.1727(X) + 3.0252$ ;  $R^2 = 0.9618$  (Old). The slopes were not significantly different from each other.

**CONCLUSIONS:** The results from this cross-sectional study suggest that RE is maintained in age-group winning runners and that aging by itself does not limit performance-related RE. However, this maintained RE does come at a higher  $O_2$  cost.

**2911 Board #58 May 30 9:30 AM - 11:00 AM**  
**Cycling Efficiency In A Pro Tour Champion: A Case Study**

David T. Martin<sup>1</sup>, Marc J. Quod<sup>2</sup>, Hamilton Lee<sup>1</sup>, Christopher J. Gore, FACSM<sup>1</sup>. <sup>1</sup>Australian Institute of Sport, Belconnen, Australia. <sup>2</sup>Edith Cowan University, Perth, Australia.

(No relationships reported)

The hypothesis that cycling efficiency improves with years of heavy training is not Supported by cross-sectional data from recreational and elite cyclists. However, longitudinal data presented in two case studies describes improved cycling efficiency in a Tour de France champion and improved running efficiency in a marathon world record holder with maturation.

**PURPOSE:** To examine cycling efficiency over multiple years of training in a cyclist that became a UCI ProTour Champion.

**METHODS:** From 1995 - 2001, a maximal graded exercise test (GXT) was performed annually on a dynamically calibrated electromagnetic cycle ergometer (accuracy  $\pm 1.8\%$  between 100-800W). The test protocol began at 100W and increased 50W every 5min until volitional exhaustion. Expired gas analysis was performed using an automated first principles indirect calorimetry system incorporating gas analyzers calibrated against 3 alpha grade gases ( $\pm 0.03\%$  accuracy) and direct measurements of expired gas volume via a Tissot gasometer every 30s. Data from the last 2 min of 150W-400W stages ( $RER < 1.00$ ) were averaged for analysis.  $\dot{V}O_2$ , RER and Lusk equations were used to calculate Gross Efficiency (GE) and the inverse of the energy produced - energy expended regression was used to calculate Delta Efficiency (DE).

**RESULTS:** Between 18-24yrs this cyclist can be characterized as: 62-68kg; 172-173cm; 380-455 W and 6.1-7.3  $W \cdot kg^{-1}$  at  $\dot{V}O_{2pk}$ ; 4.59-5.65  $L \cdot min^{-1}$  and 73-87  $ml \cdot kg^{-1} \cdot min^{-1}$   $\dot{V}O_{2pk}$ . Economy (mean $\pm$ SD; range) was 80.2 $\pm$ 1.9; 77.5-82.5  $W \cdot (\dot{V}O_2 \cdot L \cdot min^{-1})^{-1}$  or 401 $\pm$ 10; 387-413W at 5  $L \cdot min^{-1}$   $\dot{V}O_2$ . GE was 22.6  $\pm$  0.6; 21.8-23.4% and DE was 23.6 $\pm$ 1.1; 21.9-25.4%. The correlation between GE and DE was low ( $r = 0.20$ ;  $p = 10$ ;  $n = 7$ ). Correlations between age and GE ( $r = -0.67$ ), and age and DE ( $r = 0.05$ ) did not reflect improvements in cycling efficiency with maturation.

**CONCLUSIONS:** These data do not support the hypothesis that years of heavy training improve cycling efficiency.  $\dot{V}O_{2pk}$  and corresponding power output in this champion cyclist were exceptional when expressed per kg body mass. However, measures of cycling efficiency were not unique. Accurate data describing how physiological characteristics respond to years of training in elite athletes are difficult to obtain and need to be interpreted with caution because of the challenges of maintaining calibrated equipment.

**Can Two Weeks Of Sprint Interval Training Improve Health Related Fitness In Overweight/obese Sedentary Males?**

Laura J. Whyte, John Wilson, Paul Patterson, Jason M. Gill, Andrew J. Cathcart. University of Glasgow, Glasgow, United Kingdom. (Sponsor: Yannis Pitsiladis, FACSM)

Email: l.whyte.1@research.gla.ac.uk

(No relationships reported)

Physical activity is known to be beneficial to health and many studies have investigated the efficacy of moderate and high intensity exercise to improve health related parameters (e.g. Houtard et al., J Appl Physiol 96: 101-6, 2004). However, little is known as to whether shorter duration, higher intensity exercise (e.g. "all-out" sprinting) also provides health benefits.

**PURPOSE:** To investigate whether very high intensity sprint interval training (SIT) improves health related fitness.

**METHODS:** Nine sedentary males (Age: 31.3  $\pm$  8.8 yrs, body mass index (BMI): 31.1  $\pm$  3.9  $kg/m^2$ , percentage fat: 28.7  $\pm$  5.1%) were recruited. Fasted, resting metabolic assessment, plus anthropometric and fitness measurements were made before and after subjects completed a two week SIT intervention. The SIT involved six sessions of 4-6 repeats of 30 sec Wingate Anaerobic sprints on an electromagnetically controlled ergometer, with 4.5 min of recovery between repetitions.

**RESULTS:** Two weeks of SIT improved fitness as both Wingate Anaerobic mean power (567  $\pm$  69 vs. 587  $\pm$  61 W;  $P = 0.037$ ) and  $\dot{V}O_{2\max}$  (2.95  $\pm$  0.50 vs. 3.18  $\pm$  0.44  $l/min$ ;  $P = 0.029$ ) were significantly improved from pre to post intervention. Furthermore, several health related parameters also changed: mean blood pressure (94.8  $\pm$  9.63 vs. 89.7  $\pm$  9.46 mmHg;  $P < 0.001$ ), fasted resting respiratory exchange ratio (0.77  $\pm$  0.04 vs. 0.73  $\pm$  0.04;  $P = 0.036$ ) and waist to hip ratio (0.92  $\pm$  0.07 vs. 0.90  $\pm$  0.07;  $P = 0.044$ ) were all significantly reduced. BMI, weight and the sum of 4 sites skinfold thickness did not change significantly (31.1  $\pm$  3.88 vs. 30.7  $\pm$  4.02  $kg/m^2$ ;  $P = 0.054$ , 92.9  $\pm$  13.12 vs. 91.9  $\pm$  13.63;  $P = 0.067$  and 110.4  $\pm$  21.9 vs. 105.3  $\pm$  26.8;  $P = 0.073$  respectively). In addition, the area under the curve (AUC) for blood glucose during an oral glucose tolerance test (OGTT) was unchanged (845.6  $\pm$  348.8 vs. 802.7  $\pm$  338.0 mmol/L.min;  $P = 0.59$ ). However, fasted triglyceride concentration was significantly reduced (1.35  $\pm$  0.56 vs. 1.17  $\pm$  0.31 mmol/L;  $P = 0.028$ ) and non-esterified fatty acid concentration AUC during an OGTT significantly decreased (39.68  $\pm$  26.05 vs. 16.42  $\pm$  9.63 mmol/L.min;  $P = 0.018$ ).

**CONCLUSIONS:** Two weeks of a SIT intervention substantially improves many health related parameters in overweight/obese sedentary males.

Supported in part by the Carnegie Trust and University of Glasgow, UK.

**2913 Board #60 May 30 9:30 AM - 11:00 AM**  
**Associations Between Olympic Distance Triathlon Timed Segments: Longitudinal Data From 19 World Championships**

Angel Delgado<sup>1</sup>, Edgardo Diaz<sup>1</sup>, Carlos Perez<sup>1</sup>, Cesar Gomez Ruiz<sup>1</sup>, Miguel A. Rivera, FACSM<sup>2</sup>. <sup>1</sup>University of Puerto Rico, Rio Piedras, Puerto Rico. <sup>2</sup>School of Medicine University of Puerto Rico, San Juan, Puerto Rico.

(No relationships reported)

The Olympic triathlon consists of a 1.5 km swim, 40 km bike ride, and a 10 km run. The relative importance of each segment in determining the total time in Olympic distance triathlon performance is unclear.

**PURPOSE:** This study examined the relationship between segmental times in swimming, cycling and running and the total time in the triathlon using data from 19 consecutive Olympic distance triathlon championships (1989 to 2008).

**METHODS:** Official results for world championships were gathered from the International Triathlon Union public domain database. Variables included gender (women;  $n = 815$  and men;  $n = 923$ ), swimming time (ST), cycling time (CT), running time (RT), total time (TT), and event year (EY). Pearson correlation ( $r$ ) coefficients between TT-ST, TT-CT and TT-RT were calculated after sorting the data by gender and adjusting for EY.

**RESULTS:** In women, correlations were TT-ST,  $r = 0.46$ ; TT-CT,  $r = 0.70$ ; and TT-RT,  $r = 0.69$  (TT-ST  $<$  TT-CT and TT-RT;  $P < 0.01$ ). In men, correlations were TT-ST,  $r = 0.39$ ; TT-CT,  $r = 0.55$ ; and TT-RT,  $r = 0.62$  (each  $r$  different from the others;  $P < 0.01$ ).

**CONCLUSION:** Marked gender differences existed in the contribution of swimming, cycling and running to total time in elite Olympic distance triathletes.

**2914 Board #61 May 30 9:30 AM - 11:00 AM**

## Associations Between Sprint Distance Triathlon Timed Segments In World Class Elite 16 To 19 Year-old Triathletes

Carlos Perez<sup>1</sup>, Angel Delgado<sup>1</sup>, Edgardo Diaz<sup>1</sup>, Cesar Gomez Ruiz<sup>1</sup>, Miguel A. Rivera, FACSM<sup>2</sup>. <sup>1</sup>University of Puerto Rico, Rio Piedras, Puerto Rico. <sup>2</sup>School of Medicine University of Puerto Rico, San Juan, Puerto Rico.  
(No relationships reported)

This report was part of a longitudinal study on the triathlon. The first world championship of the International Triathlon Union (ITU) for the 16 to 19 year-olds (Juniors) was held in 1995. The event, known as the sprint distance triathlon, consists of a 750m swim, 20km bike ride, and 5km run. The relative contribution of the swimming, cycling and running segments to total time in sprint distance triathlon is unclear.

**PURPOSE:** This study examined the relationship between performance in the swimming, cycling and running segments with total time in sprint distance triathlon world championships contested between 1995 and 2008.

**METHODS:** Official results for Juniors in the sprint distance triathlon world championships were collected from the International Triathlon Union public domain database. Variables included gender (women; n=566 and men; n=805), swimming time (ST), cycling time (CT), running time (RT), total time (TT), and event year (EY). Pearson correlation (*r*) coefficients were calculated between TT-ST, TT-CT and TT-RT after sorting the data by gender, and adjusting for EY.

**RESULTS:** In Junior women, correlations were TT-ST, *r* = 0.55; TT-CT, *r* = 0.84; and TT-RT, *r* = 0.74. In Junior men, correlations were *r* = 0.58, TT-ST; *r* = 0.69, TT-CT; and *r* = 0.77, TT-RT. Within each gender, the three coefficients were statistically different from the others (*P* < 0.01), and the running and swimming segments had the highest and lowest correlations with total time in the triathlon.

**CONCLUSION:** The study revealed gender differences in the contribution of swimming, cycling and running timed segments to total time in sprint distance triathlons in world-class 16 to 19 year-old triathletes.

---

### 2915 Board #62 May 30 9:30 AM - 11:00 AM Comparison Of Metabolic Responses To High Intensity Interval Training In Trained And Well-trained Males

Ken J. Hetlelid, Eva Herold, Stephen Seiler, FACSM. University of Agder, Kristiansand, Norway.  
Email: ken.j.hetlelid@uia.no  
(No relationships reported)

**PURPOSE:** During steady state exercise, well-trained endurance (WT) athletes oxidize more fat at the same relative intensity compared to recreationally trained people (RT). However, less is known about substrate oxidation during high intensity intermittent exercise. We have compared total energy expenditure (TEE) and fat oxidation during a fixed duration, high-intensity, self-paced interval training prescription in WT and RT subjects.

**METHODS:** Nine WT (VO<sub>2</sub>max 71 ± 5 ml min<sup>-1</sup> kg<sup>-1</sup>) and 9 RT (VO<sub>2</sub>max 55 ± 5 ml min<sup>-1</sup> kg<sup>-1</sup>) runners performed preliminary testing followed by a 34 min interval-training session consisting of six, 4 min work bouts separated by 2 min recovery periods on a motorized treadmill with a constant 5 % incline. The session was prescribed as a high-intensity workout with the goal being to achieve the highest possible average running speed for the work bouts. Energy expenditure and fat oxidation were calculated from continuous measurements of VO<sub>2</sub> consumption and CO<sub>2</sub> production. Due to some net CO<sub>2</sub> contribution from bicarbonate buffering during intermittent high intensity exercise, fat oxidation rates are presumably underestimated and should be considered minimum estimates.

**RESULTS:** Blood lactate (6.2 ± 2.1 vs 6.4 ± 2.5 mmol.L<sup>-1</sup>) and RPE (16.2 ± 1.4 vs 16.2 ± 1.7) responses throughout the interval session were not different between WT and RT. However, VO<sub>2</sub> during the last 3 minutes of each work bout was higher in WT (92 ± 1 vs. 87 ± 2 % VO<sub>2</sub>max, *p* < 0.01). Mean RER for the entire session was higher in RT (0.97 ± 0.03 vs 0.91 ± 0.02 *p* < 0.001). TEE in the 34 min interval session was higher in WT (641 ± 46 Kcal vs. 552 ± 75 Kcal (*p* = 0.009)). Fat oxidation during the interval session was 23.2 ± 4 g in WT vs. 9.4 ± 3 g in RT *p* < 0.001). Estimated fat oxidation accounted for 35 ± 6 % of TEE in WT vs. 17 ± 7 % in RT.

**CONCLUSIONS:** When provided a verbal and written exercise description, WT and RT perform interval training at similar perceived intensity. However, WT oxidize more fat despite higher relative oxygen consumption rates. These results suggest that the superior fat oxidation of well trained athletes seen during low intensity continuous exercise extends to high intensity intermittent exercise, accepting the limitations associated with respiratory gas exchange measurements during intermittent exercise above the lactate threshold.

---

### 2916 Board #63 May 30 9:30 AM - 11:00 AM The Cardiovascular And Metabolic Response To Arm Cranking At Three Cadences On An Upper Body Independent Crank Cycle.

Allyson Stein, Robert M. Otto, FACSM, Tara Plusch, Cortney Whitebay, Josh O'Brien, Sarah Wright, John W. Wygand. Adelphi University, Garden City, NY.  
Email: allysonstein@yahoo.com  
(No relationships reported)

Group exercise sessions seldom involve vigorous upper body exercise, but often contain a myriad of calisthenics and light resistance apparatus. In an effort to provide a substantial upper body stimulus for use in a group exercise setting, we used an arm crank exercise cycle with independent crank arms, a short (170 mm) crank arm length and a narrower crank axis, than most upper body exercise cycles. These characteristics allow for a variety of movement patterns and a faster cadence than previously observed on upper-body exercise.

**PURPOSE:** The purpose of this study was to determine the cardiovascular and metabolic response to arm cranking at cadences of 80, 100, and 120 rpm at a fixed resistance.

**METHODS:** Familiarization trials were conducted to ensure compliance to a split crank position of 180 degrees and within 2 rpm of the assigned cadence. One female and nine male subjects (age 26.2 ± 7.1 yr, body mass 92.4 ± 15.7 kg and ht. 179.5 ± 6.7 cm.) were randomly assigned to perform steady state trials of 80, 100 and 120 rpm using open circuit spirometry. Pilot testing revealed that smaller subjects (<70 kg) fail to achieve steady state at any cadence at the fixed resistance (~40% of maximal resistance).

**RESULTS:** ANOVA revealed no significant difference (*p* < .05) in BR, HR, RER and RPE among all cadences, but significant differences in Ve (64 vs 84 and 97 l/min), and VO<sub>2</sub> (26.2 vs 32.7 and 35 ml/kg/min<sup>-1</sup>) at 80 rpm versus 100 and 120 rpm, respectively. Intensity ranged from 80% to 89% of APMHR, with 120 rpm eliciting the highest intensity.

**CONCLUSION:** Arm cycle exercise can elicit substantial metabolic demand of 7.3 to 9.8 METS at cadences between 80 to 120 rpm, respectively.

---

### 2917 Board #64 May 30 9:30 AM - 11:00 AM Session RPE Following Cycling And Treadmill Exercise With Varying Intensities But Equal Caloric Expenditure

JM Green, FACSM<sup>1</sup>, CM Laurent<sup>2</sup>, NT Bacon<sup>2</sup>, EK O'Neal<sup>2</sup>, JK Davis<sup>2</sup>, PA Bishop<sup>2</sup>. <sup>1</sup>The University of North Alabama, Florence, AL. <sup>2</sup>The University of Alabama, Tuscaloosa, AL.  
Email: jmgreen@una.edu  
(No relationships reported)

**PURPOSE:** Examine session RPE (overall, [SRPE-O]; legs [SRPE-L]; breathing [SRPE-B]) following 4 exercise sessions (2 cycling, 2 treadmill) with varying intensity but equated energy expenditure (400 kcals) in a hot (~28°C) environment.

**METHODS:** Five males performed 4 (counterbalanced) trials; high-intensity cycling (HIC), low-intensity cycling (LIC), high-intensity run (HIR), low-intensity run (LIR). High and low-intensity trials were at 80% and 50% mode-specific  $\dot{V}O_{2max}$ , respectively. Prior to trials, a 5 min exercise bout was completed to determine duration needed to expend 400 kcal. Change in rectal temperature (DTrec) (start to finish) was calculated and analyzed. RPE was recorded after 5-minutes (RPE<sub>5</sub>), at the midpoint (RPE<sub>mid</sub>), and conclusion (RPE<sub>end</sub>) of exercise with overall and differentiated Session RPE estimated 20-min after each trial.

**RESULTS:** A series of one-way RM-ANOVAs revealed significant main effects for SRPE-L ( $p=0.04$ ), with SRPE-O approaching significance ( $p=0.06$ ) but no significance for SRPE-B. SRPE-L for HIC ( $8.2\pm1.3$ ) was significantly higher than LIC ( $4.6\pm0.5$ ), HIR ( $5.6\pm0.9$ ) and LIR ( $4.2\pm1.3$ ). SRPE-O was significantly higher for HIC ( $7.6\pm1.1$ ) vs. LIC ( $3.8\pm0.4$ ) and LIR ( $4.2\pm1.3$ ) while HIR ( $6.6\pm1.5$ ) was significantly higher vs. LIC and approached significance ( $p=0.06$ ) for LIR. Significant main effects were found for DTrec ( $p=0.01$ ), with post hoc analyses showing significantly higher DTrec for HIR ( $1.5\pm0.3$  °C) vs. LIC ( $0.7\pm0.2$  °C), LIR ( $1.1\pm0.4$  °C), and approaching significance for HIC ( $1.0\pm0.5$  °C) ( $p=0.06$ ). Additionally, LIR produced significantly higher DTrec vs. LIC. Significant main effects were found for RPE<sub>end</sub> ( $p=0.04$ ) but not for RPE<sub>5</sub> or RPE<sub>mid</sub>. Post-hoc analyses revealed RPE<sub>end</sub> for HIC ( $7.8\pm1.1$ ) was significantly higher vs. LIC ( $4.6\pm0.6$ ) and LIR ( $4.2\pm1.1$ ). HIR ( $6.6\pm1.5$ ) yielded significantly higher RPE<sub>end</sub> vs. LIC and approached significance for LIR ( $p=0.06$ ).

**CONCLUSION:** S-RPE was more sensitive to intensity than total caloric expenditure. Similar to RPE during exercise, Session RPE following cycling (vs. treadmill) appears to be magnified possibly due to comparatively greater localized feelings of leg strain and exertion. DTrec did not appear to have as large an influence on RPE as mode, under these conditions.

---

**2918 Board #65 May 30 9:30 AM - 11:00 AM**  
**Impact Of Swimming On Antioxidant Enzyme Status And Oxidative Markers In Old Rats**

Ming-Fen Hsu, Tsai-Wei Shen, Tsung-Hsien Lu, Hsien-Tang Lin, Chia-Chen Yang, Jo-Ping Lee, Mallikarjuna K, Chia-Hua Kuo. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L. Ivy, FACSM)  
Email: fen\_0119@hotmail.com  
(No relationships reported)

**PURPOSE:** Advancing age is associated with accumulated oxidative damage to proteins, lipids and mitochondria. In this study we tested the hypothesis that swimming exercise training could revert the age dependent oxidative damages in liver.

**METHODS:** Young (3 months) and old (12 months) Sprague-Dawley rats were divided into four groups; young control ( $n=5$ ), young exercise ( $n=5$ ), old control ( $n=5$ ) and old exercise ( $n=5$ ). 90 minutes of swimming exercise was given to the exercise group for a period of two weeks.

**RESULTS:** The estimated antioxidant enzyme activities including, superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px) and glutathione reductase (GR) were decreased with age and significantly ( $p<0.05$ ) increased with exercise training. However, elevated protein carbonyls and MDA levels were noticed in old animals, which indicate that old liver had greater accumulated oxidative damages. The significant drop in protein carbonyl content and increase in mitochondrial succinate dehydrogenase (SDH) activity was observed with response to swim training in old rats.

**CONCLUSIONS:** This data implied that swim exercise training could revert the oxidative damages in liver. This was also proven by enhanced antioxidant enzyme status with response to exercise training in old rats. From these results it is cleared that age induced detrimental effects to the liver might be reversed by regular swimming exercise training in old rats.

**2919 Board #66 May 30 9:30 AM - 11:00 AM**  
**The Energy Cost And Hemodynamic Response To Arm Crank Exercise Using Three Movement Patterns On An Independent Crank Cycle**

Josh O'Brien, Allyson B. Stein, Sarah Wright, Tara Plusch, Cortney Whitebay, Robert M. Otto, FACSM, John W. Wygand. *Adelphi University, Garden City, NY.*  
Email: joshol11@aol.com  
(No relationships reported)

The cardiovascular and metabolic stimulus derived from upper body cycling exercise is purportedly altered with different movement patterns. Asymmetrical single arm cycling (SA), double arm cycling (DA [both arms matched at identical points in the range of motion]) and split crank pattern (SP [180 degrees of separation between hands]) may require different muscle recruitment patterns, which could alter the intensity of specific muscles. This investigation used an arm crank exercise cycle with independent crank arms, a short (170 mm) crank arm length and a narrower crank axis, than most upper body exercise cycles. These cycle characteristics allow the aforementioned movement patterns.

**PURPOSE:** The purpose of this study was to determine the energy cost and hemodynamic response to arm cranking using three movement patterns at a fixed cadence of 80 rpm at a fixed resistance.

**METHODS:** Familiarization trials were conducted to ensure compliance to the different movement patterns. One female and nine male subjects (age  $26.2 \pm 7.1$  yr, body mass  $92.4 \pm 15.7$  kg and ht.  $179.5 \pm 6.7$  cm.) were randomly assigned to perform steady state trials of SA, DA and SP using open circuit spirometry. Pilot testing revealed that smaller subjects ( $<70$  kg) fail to achieve steady state at any cadence at the fixed resistance ( $\sim 40\%$  of maximal resistance).

**RESULTS:** ANOVA revealed no significant difference ( $p>.05$ ) in any variable among all trials (i.e.  $\dot{V}O_2$  2.2, 2.6, and 2.4 L/min for SA, DA, and SP trials, respectively).

**CONCLUSION:** Regardless of the arm movement pattern (SA, DA, or SP), a similar metabolic and hemodynamic response occurs at the same workload. The inclusion of a variety of movement patterns at the same resistance can provide a similar stimulus, yet keep the exercise experience novel.

**Improvements In Balance And Agility After High Intensity Water Exercise For Land-based Athletes**

John Whitehill, Jr, Nora L. Constantino, FACSM, Mary E. Sanders, FACSM, Mary E. Sanders, FACSM, Minggen Lu, Minggen Lu. *University of Nevada Reno, Reno, NV.*  
(No relationships reported)

The extent to which water training affects athletic performance on land is unclear. Agility and balance performance responses to water exercise are not well documented.

**PURPOSE:** To determine effectiveness of water-based exercise on agility and balance performance by land-based competitive athletes during off-season training.

**METHODS:** Twenty-nine healthy, competitive athletes ( $23.7 \pm 6.5$  years) were recruited to either a water exercise (WE,  $n=14$ ), or control (C,  $n=15$ ) group. The WE group trained 9 weeks, a minimum of 3 days per week, 90 minutes a session. WE exercises included: cardiovascular resistance and stretching in shallow and deep water using running, jumping, cadence and interval sets; aquatic cycling; underwater running. The control group maintained land-based, off-season training and recorded activity. Agility and balance were measured at, baseline, midway and at the end of training.

**RESULTS:** No injuries were reported for either group. For all measures the WE group significantly improved greater than the C group. Wilcoxon Rank Sums Test was used to test the difference between EX and C groups for compass clockwise, compass counter clockwise, hexagon clockwise, hexagon counter clockwise, sway and stability.

Assessment	Difference Between Post and Pre Testing (Post - Pre)		Difference Between Two Groups
	C Group	WE Group	

	n	mean $\pm$ std	n	mean $\pm$ std	Control - Ex	P - Value*
Compass Clkwise	15	-0.27 $\pm$ 0.26	14	-1.51 $\pm$ 0.52	1.24	< .0001
Compass CntrClkwise	15	-0.33 $\pm$ 0.24	14	-1.45 $\pm$ 0.49	1.12	< .0001
Hexagon Clkwise	15	-0.57 $\pm$ 0.54	14	-3.50 $\pm$ 1.03	2.93	< .0001
Hexagon CntrClkwise	15	-0.64 $\pm$ 0.39	14	-3.22 $\pm$ 1.49	2.58	< .0001
Stability	15	-0.10 $\pm$ 0.30	14	-1.02 $\pm$ 0.50	0.92	< .0001
Sway	15	1.47 $\pm$ 4.36	14	13.00 $\pm$ 6.28	-11.53	< .0001

\* Wilcoxon Rank Sums test

**CONCLUSION:** This water exercise program conducted during off-season for a variety of competitive land-based athletes resulted in greater improvements in all measures for agility and balance when compared to controls. While both groups had improvements, the WE group improved significantly more than the C group. Water exercise appears to show promise as an effective training option for healthy competitive athletes who want to improve balance and agility.

## G-16 Free Communication/Poster - *Epidemiology of Injury*

#### Risk Of Overuse Injury And Stress Fracture Among Female U.S. Army Recruits Exceeding Body Fat Limits

David N. Cowan<sup>1</sup>, Sheryl A. Bedno<sup>1</sup>, Yuanzhang Li<sup>1</sup>, Christine T. Scott<sup>2</sup>, Weiwei Han<sup>1</sup>, David W. Niebuhr<sup>1</sup>. <sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD. <sup>2</sup>Department of Defense Medical Evaluation Review Board, Colorado Springs, CO.

Email: david.cowan@amedd.army.mil

(No relationships reported)

**PURPOSE:** To compare the risk of musculoskeletal injury among female Army recruits who were over body fat (OBF) standards on accession and were able pass a pre-accession physical fitness test, to those who met body fat standards (fully qualified, FQ) and were not required to pass a fitness test. Overuse injuries (OUI) in general and stress fractures (StFx) in particular are among the most common and serious training related injuries among men and women in the military, leading to substantial morbidity, direct medical costs, and indirect personnel and administrative costs. Trainees developing OUI and StFx are more likely to receive an early discharge from the military.

**METHODS:** Each incident OUI and StFx event was identified from electronic medical records and was defined as the first outpatient encounter with an OUI or StFx diagnosis. The risk of OUI and StFx at 90 days was compared between 319 OBF subjects who passed a pre-accession physical fitness test and the population of 1656 FQ recruits. The fitness test comprised a 5-minute step test and a 1-minute push-up test, with results on each scored as pass or fail.

The association between OBF status and injury was expressed as the relative risk (RR) with the 95 percent confidence interval (95% CI).

**RESULTS:** Within the first 90 days of service, there were 172 first OUI among OBF (54%), and 836 among FQ (50%). There were 14 first StFx among OBF (4.4%), and 132 among FQ (8.0%). For OBF the OUI relative risk was 1.07 (0.95-1.20), and for StFx the relative risk was 0.55 (0.32-0.94).

**CONCLUSIONS:** In the first 90 days of military service we observed a slight but not statistically significant ( $p=0.14$ ) increase in risk of OUI, and a significantly decreased risk of StFx among OBF females. These patterns differ somewhat from those seen among men. The decrease in risk of stress fracture among OFB women may be physiologically plausible given the association of increased risk of stress fracture among individuals with low body mass index. The findings associated with OBF women and these injuries present interesting challenges for Army accession policy makers in balancing increased accessions of females with lower stress fracture risk, while controlling for costs to include possibly more overuse injuries and weight control programs.

### 2922 Board #69 May 30 8:00 AM - 9:30 AM

#### Gender-specific Incidence And Prevalence Of Anterior Knee Pain In A Military Population

Michelle C. Boling<sup>1</sup>, Darin A. Padua<sup>2</sup>, Stephen Marshall<sup>2</sup>, Kevin Guskiewicz<sup>2</sup>, Scott Pyne<sup>3</sup>, Anthony Beutler<sup>4</sup>. <sup>1</sup>University of North Florida, Jacksonville, FL. <sup>2</sup>University of North Carolina, Chapel Hill, NC. <sup>3</sup>United States Naval Academy, Annapolis, MD. <sup>4</sup>Uniformed Services University of the Health Sciences, Bethesda, MD.

Email: m.boling@unf.edu

(No relationships reported)

Anterior knee pain (AKP) is one of the most commonly diagnosed chronic knee conditions, however, there is a lack of recent epidemiologic data regarding the prevalence and incidence of this condition. Additionally, AKP is frequently reported to be more common in females compared to males, but there is scant recent epidemiologic data supporting this oft-quoted gender discrepancy.

**PURPOSE:** To determine the association between gender and the prevalence and incidence of AKP.

**METHODS:** One-thousand five-hundred and twenty-five participants from the United States Naval Academy were followed for up to 2.5 years for the development of AKP (incidence). Physicians and certified athletic trainers documented the cases of AKP. Anterior knee pain was defined as retropatellar pain during at least two of the following activities: ascending/descending stairs, hopping/jogging, prolonged sitting, kneeling, and squatting, negative findings on examination of knee ligament, menisci, bursa, and synovial plica, and pain on palpation of either the patellar facets or femoral condyles. A history of anterior knee pain (prevalence) prior to admission to the Academy was evaluated through the use of a baseline questionnaire. Poisson and logistic regressions were performed to determine the association between gender and the incidence and prevalence of AKP, respectively.

**RESULTS:** The incidence rate for AKP was 22/1000 person-years. Females were 2.23 times (95% confidence interval (CI): 1.19, 4.20) more likely to develop AKP compared to males ( $P=0.01$ ). While not statistically significant, the prevalence of AKP at study enrollment tended to be higher in females (15%) than in males (12%) ( $P=0.09$ ).

**CONCLUSIONS:** Females at the USNA were significantly more likely to develop AKP than males; however, at the time of admission to the academy, the prevalence of AKP was not significantly different between genders. Ongoing research within this cohort is being performed to examine biomechanical and anatomical characteristics as potential risk factors for AKP.

Supported by NIH grant R01 AR050461 and the National Academy of Sports Medicine.

**Longitudinal Foot Arch Height And Risk Of Injury In Us Army Basic Combat Training**

David I. Swedler<sup>1</sup>, Joseph J. Knapik, FACSM<sup>1</sup>, Tyson L. Grier<sup>1</sup>, Mark Lester<sup>2</sup>, Kelly W. Williams<sup>3</sup>, Steven H. Bullock<sup>1</sup>, Bruce H. Jones, FACSM<sup>1</sup>.

<sup>1</sup>USACHPPM, Aberdeen Proving Ground, MD. <sup>2</sup>USAISR, Ft. Sam Houston, TX. <sup>3</sup>EAE, Ft. Jackson, SC.

Email: david.swedler@us.army.mil

(No relationships reported)

A prior study (Cowan, Arch Fam Med, 2:773, 1993) suggested that high longitudinal foot arches were associated with injury incidence during military training; however, another study (Kaufman, Am J Sports Med, 27:585, 1999) using different methods showed little relationship between arch height and injury risk.

**PURPOSE:** This study examined the relationship between a direct measurement of longitudinal foot arch height and injury incidence during United States Army Basic Combat Training (BCT).

**METHODS:** Bilateral arch height was measured in 2,691 male and 1,270 female U.S. Army recruits prior to beginning BCT. Arch height was defined as the distance from the standing surface to the inferior border of the navicular tuberosity. Injuries occurring during the 9-week BCT cycle were obtained from medical records. Cox regression was used to examine injury risk among individuals with the highest 20% of arch heights (H) and individuals with the lowest 20% of arch heights (L) relative to the middle 60% of the arch height distribution (M). The M group was defined as baseline injury risk (equal to 1.00). Cox regression was used to determine hazard ratios (HRs) and 95% confidence intervals (95% CIs).

**RESULTS:** For men, the L group was at slightly higher injury risk for the left arch height (HR (L/M)=1.13, 95%CI= 0.99-1.34) but not for right arch height (HR (L/M)=1.02, 95%CI= 0.87-1.20). The male H group showed injury risk similar to the M group for both the left (HR (H/M)=1.02, 95%CI= 0.87-1.19) and right foot (HR (H/M)=0.98, 95%CI= 0.84-1.15). For women, the L group showed little increased risk of injury relative to the M group for the left (HR (L/M)=1.11, 95%CI= 0.94-1.32) or right (HR (L/M)=1.09, 95%CI= 0.92-1.29) foot. The female H group also showed little increased risk relative to the M group for either the left (HR (H/M)=1.11, 95%CI= 0.94-1.32) or right (HR (H/M)=1.09, 95%CI= 0.92-1.29) foot.

**CONCLUSION:** Direct measurement of the height of the longitudinal foot arch indicated that subjects with high and low arches were not at substantially elevated injury risk during Army BCT. These findings are in consonance with those of Kauffmann, et al. (Am J Sports Med, 27:585, 1999).

**2924 Board #71 May 30 8:00 AM - 9:30 AM**

**Risk Of Heat Illness Among Male U.S. Army Recruits Exceeding Body Fat Limits**

Sheryl A. Bedno<sup>1</sup>, David N. Cowan<sup>1</sup>, Yuanzhang Li<sup>1</sup>, Christine T. Scott<sup>2</sup>, Weiwei Han<sup>1</sup>, David W. Niebuhr<sup>1</sup>. <sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD. <sup>2</sup>Department of Defense Medical Evaluation Review Board, Colorado Springs, CO.

Email: sheryl.ann.bedno@us.army.mil

(No relationships reported)

**PURPOSE:** To compare the risk of heat illness among male Army recruits who were over body fat (OBF) standards on accession and were able pass a pre-accession physical fitness test, to those who met body fat standards (fully qualified, FQ) and were not required to pass a fitness test.

**METHODS:** Incident heat illness was identified from electronic medical records and was defined by the first outpatient encounter with a heat illness diagnosis. The risk of heat illness at 90 days of service was compared between 827 OBF subjects, who passed a pre-accession physical fitness test, and the population of 8858 FQ recruits was evaluated. The test comprised a 5-minute step test and a 1-minute push-up test, with results on each scored as pass or fail. The odds ratio (OR) (with the 95 percent confidence interval (95% CI)) was used to measure the association between OBF status and heat illness. Logistic regression was used to evaluate the adjusted OR controlling for potential confounding with other risk factors.

**RESULTS:** There were 44 first episodes of heat illness among FQ (0.5%) and 19 among OBF (2.3%). When other potential confounding factors (e.g., age, race, training site, season of year, and smoking) were controlled the adjusted OR for heat illness among OBF was 3.26 (1.82, 5.87). Most heat illnesses were minor, but all types occurred more frequently among OBF men.

**CONCLUSION:** Although there were relatively few heat illness events, there was a statistically significant three-fold greater risk among men who exceeded body fat limits. Each year thousands of men enter the Army, and a substantial number exceed body fat standards and are allowed to enter if they pass the fitness test. These findings may have implications for military accession and training policy should the level of risk identified in this study exist in the general recruit population. However, the finding of increased risk of heat illness among OBF men alone does not adequately address the situation. It may be possible to reduce the risk among OBF men by strict adherence to training and heat illness prevention guidelines. Cost benefit analyses should be conducted to determine if the benefits of allowing additional recruits to enter the Army offset the additional costs imposed by increased risks of heat illness.

Supported by US Army Accession Command.

**Risk Factors For Time-loss Injuries In The United States Army Ordnance School Advanced Individual Training**

Tyson Grier, Joseph J. Knapik, FACSM, Sara Canada, Michelle Canham-Chervak, Bruce H. Jones, FACSM. U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD. (Sponsor: Joseph Knapik, FACSM)

Email: Tyson.Grier@us.army.mil

(No relationships reported)

Only one previous study (Henderson, Milit Med 165, 9:647, 2000) has examined risk factors in Advanced Individual Training (AIT) where soldiers go to receive their specialty training after Basic Combat Training (BCT).

**PURPOSE:** This study examined risk factors for time loss injuries during United States Army Ordnance School AIT.

**METHODS:** Participants were soldiers (n= 3759 men, n=498 women) attending Ordnance AIT. Injuries were obtained from an injury surveillance system in the medical clinic serving the AIT soldiers. Potential injury risk factors included entry-level fitness, demographics, and lifestyle variables. Fitness variables included maximal effort performance on push-ups, sit-ups and a 2-mile run. A health questionnaire provided data on age, race, rank, previous injury, previous illness, and tobacco use. Fitness variables were converted to four quartiles (Q) based on the distribution of scores where Q1=high performance and Q4=low performance. AIT entry and completion dates were obtained from an Army Personnel system. Backward stepping Cox regression examined associations between time loss injury and potential injury risk factors. Multivariate hazard ratios (HR) and 95% confidence intervals (95%CI) were calculated.

**RESULTS:** For men, higher risk of injury was independently associated with race (HR (Native American/Caucasian) = 1.3, 95%CI = 1.1-1.7), previous injury (HR (yes/no) = 2.1, 95%CI = 1.8-2.6), frequent cigarette use before entering the Army (HR (yes/no) = 1.5, 95%CI = 1.3-1.7), lower push-up performance (HR (Q4/Q1) = 1.3, 95%CI = 1.1-1.5), lower sit-up performance (HR (Q3/Q1) = 1.3, 95%CI = 1.1-1.5) and slower 2-mile run time (HR (Q4/Q1) = 1.3, 95%CI = 1.1-1.6). For women, higher risk of injury was independently associated with race (HR (Asian/Caucasian) = 0.6, 95%CI = 0.5-0.9), previous injury (HR (yes/no) = 1.7, 95%CI = 1.2-2.3), and slower 2-mile run time (HR (Q4/Q1) = 2.0, 95%CI = 1.4-2.9).

**CONCLUSIONS:** Modifiable risk factors for time loss injury in Ordnance AIT include prior BCT injury, tobacco use, and aerobic fitness. Enhanced injury prevention in BCT, smoking cessation and fitness training prior to entry are potential strategies to reduce injuries.

**2926 Board #73 May 30 8:00 AM - 9:30 AM****The Prevalence Of Work-related Musculoskeletal Disorders In Certified Members Of The National Athletic Trainer's Association**

Dawn M. Hammerschmidt<sup>1</sup>, Donna J. Terbizan, FACSM<sup>2</sup>. <sup>1</sup>Minnesota State University Moorhead, Moorhead, MN. <sup>2</sup>North Dakota State University, Fargo, ND.

Email: hammerda@mnstate.edu

(No relationships reported)

**PURPOSE:** To examine the prevalence of work-related musculoskeletal disorders among certified athletic trainers (ATC) who are members of the National Athletic Trainers' Association.

**METHODS:** A random sample of 6,500 ATC representing three employment settings was sampled using the Nordic Musculoskeletal Questionnaire. A response rate of 34.4 % was achieved using an electronic survey via email.

**RESULTS:** Female ATC reported significantly ( $p<0.006$ ) more WRMD in the past 12 months than males in the neck, shoulders, wrist/hand, upper back, and hip/thigh, whereas male ATC reported significantly ( $p=0.013$ ) greater WRMD in the elbow/forearm. Female ATC reported a significant lifetime prevalence of WRMD in the neck and wrist/hand ( $p<0.016$ ). Younger ATC (20-30 year old v. 30-66+ year old) reported significantly ( $p<0.043$ ) greater WRMD in the neck, shoulder, elbow/forearm, upper back, low back, and hip/thigh regions. ATC employed for 0-5 years reported significant WRMD for the neck, shoulders, and upper back ( $p<0.044$ ), while those employed for more than 6 years reported significant WRMD for the elbow/forearm and hip/thigh ( $p<0.003$ ). No significant differences were seen between the number of hours worked per week and WRMD, nor ATC employment setting (clinical, college/university, and high school). Finally, low back had the highest prevalence rate of WRMD at 67.9%, followed by the neck 60.0%, the shoulder 46.3%, the knee 38.3%, the upper back 34.9%, the wrist/hand 31.0%, the ankle/foot 30.9%, the hip/thigh 16.5%, and finally the elbow/forearm 15.8%.

**CONCLUSIONS:** ATC do suffer a high prevalence of WRMD in several body regions. Factors such as gender, age, and the number of years employed in the profession revealed a significant relationship between ATC and WRMD. Based off this current study, the need to spread awareness of WRMD in ATC, the need to incorporate WRMD discussions into the education process of athletic training student's, and the need to incorporate education of WRMD and safety measures in the clinical setting to prevent WRMD from occurring in the workplace are suggestions for the athletic training profession.

---

**2927 Board #74 May 30 8:00 AM - 9:30 AM****Relative Isometric Shoulder Strength Norms In Young, Active Males And Females**

Michele L. Duffey<sup>1</sup>, Kenneth L. Cameron<sup>2</sup>, Christopher J. Jones<sup>3</sup>, Thomas M. DeBerardino<sup>2</sup>, Brett D. Owens<sup>4</sup>. <sup>1</sup>Penn State University, University Park, PA. <sup>2</sup>Keller Army Hospital, West Point, NY. <sup>3</sup>United States Military Academy, West Point, NY. <sup>4</sup>William Beaumont Army Medical Center, El Paso, TX.

Email: mlp127@psu.edu

(No relationships reported)

It is common clinical practice to draw strength comparisons between an injured and uninjured shoulder following acute glenohumeral instability events. This information is often used to monitor rehabilitation outcomes and determine return to activity; however, little is known about baseline isometric strength in the uninjured shoulder.

**PURPOSE:** The purpose of this study was to describe isometric shoulder strength for active college-aged men and women with no history of glenohumeral joint instability.

**METHODS:** During their initial two months at the United States Military Academy, 546 males ( $18.8\pm1.0$  yr,  $75.3\pm12.2$  kg) and 73 females ( $18.7\pm0.9$  yr,  $62.6\pm7.0$  kg) completed bilateral isometric strength tests using a hand-held dynamometer. Strength measures included internal and external rotation (IR, ER) and abduction (ABD) in the neutral position, IR and ER at 45° abduction (IR45, ER45), and flexion in the prone position (PF). Means  $\pm$ SD normalized by body mass were calculated by gender and hand dominance (table). Percentiles were calculated for all measures by gender.

**RESULTS:** All strength measures were normally distributed. Baseline measures of isometric shoulder strength indicated significant side-to-side differences ( $p\leq0.01$ ) for IR, IR45, ABD, and PF in uninjured college-aged males and in IR45 and PF for uninjured college-aged females.

	Males		Females	
	Dominant	Non-Dominant	Dominant	Non-Dominant
ER	$0.43 \pm 0.09$	$0.42 \pm 0.10$	$0.35 \pm 0.08$	$0.34 \pm 0.09$
IR	$0.60 \pm 0.13$	$0.59 \pm 0.13$	$0.47 \pm 0.11$	$0.47 \pm 0.13$
ABD	$0.78 \pm 0.17$	$0.77 \pm 0.17$	$0.64 \pm 0.19$	$0.63 \pm 0.21$
ER45	$0.48 \pm 0.10$	$0.48 \pm 0.10$	$0.39 \pm 0.09$	$0.39 \pm 0.09$
IR45	$0.58 \pm 0.12$	$0.56 \pm 0.12$	$0.47 \pm 0.11$	$0.45 \pm 0.11$
PF	$0.26 \pm 0.07$	$0.25 \pm 0.07$	$0.23 \pm 0.07$	$0.21 \pm 0.06$

**CONCLUSION:** These data may provide normative distributions for isometric shoulder strength measures which can be used by clinicians to identify strength deficiencies. Also, clinicians may use these data to monitor recovery from injury as well as functional outcomes of rehabilitation. Whether or not strength deficiencies are related to risk of glenohumeral instability warrants further study.

---

**2928 Board #75 May 30 8:00 AM - 9:30 AM****Balance, Gait, Knee Extensor Strength, And Functional Performance Among Fallers And Non-fallers With Parkinson's Disease**

Fuzhong Li<sup>1</sup>, Peter Harmer, FACSM<sup>2</sup>, Kathleen Fitzgerald<sup>3</sup>, Naruepon Vongjaturapat<sup>4</sup>. <sup>1</sup>Oregon Research Inst., Eugene, OR. <sup>2</sup>Willamette University, Salem, OR. <sup>3</sup>Oregon Medical Group, Springfield, OR. <sup>4</sup>Burapha University, Chonburi, Thailand.

Email: fuzhongli@ori.org

(No relationships reported)

Falling is a common problem for individuals with Parkinson's disease (PD). However, there is insufficient information regarding what differentiates fallers from non-fallers. Such information is important for targeted rehabilitation interventions to reduce risk of falling in individuals with PD.

**PURPOSE:** To characterize differences in balance, gait, knee strength, and functional performance between individuals with PD who are fallers or non-fallers.

**METHODS:** The study used a cross-sectional design. Twenty-seven adults with mild to moderate PD (Hoehn and Yahr [H&Y] stage I-III) (7 female, 20 male, mean age=69 years old, UPDRS Motor III=28, mean H&Y Stage=2.3) participated in this study. Outcome measures were: balance (limits of stability: maximum endpoint excursions, movement velocity, directional control), gait (velocity, stride length), knee extensor strength (isokinetic quadriceps peak torque performed at  $60^\circ\cdot s^{-1}$ ), and functional performance (50-foot walk, Up&Go).

**RESULTS:** Of the 27 participants, fourteen reported one or more falls during the previous six months. There was no significant difference in the mean H&Y stages of fallers vs. non-fallers. Analyses of mean differences in outcome measures are shown below. Fallers showed significantly lower or worse scores on limits of stability, gait, knee extensor strength, and functional performance.

**CONCLUSION:** Individuals with PD who experience falls have diminished physical capacities in balance, gait, knee extensor strength, and functional performance. Exercise interventions should target these characteristics to improve the physical abilities of individuals with PD to reduce their risk of falling.

	Fallers (n = 14)	Non-Fallers (n = 13)	
Outcome Measures	Mean (SD)	Mean (SD)	P value
Maximum endpoint excursions (%)	38.0 (12)	63.6 (13)	0.001
Movement velocity (deg/sec)	1.81 (1.4)	2.72 (1.1)	0.05
Directional control (%)	48.7 (13)	72.8 (1.0)	0.01
Knee extensor peak torque (ft-lbs)	49.37 (19)	50 (18)	0.05
Velocity (cm/sec)	97.7 (23)	113.3 (14)	0.05
Stride length (cm)	104 (23)	121 (13)	0.03
50-foot walk (sec.)	16.5 (4.1)	14.3 (2.5)	0.05
Up&Go (sec.)	10.9 (3.1)	8.5 (1.5)	0.04

Supported by NIH Grant R01 NS047130

## 2929 Board #76 May 30 8:00 AM - 9:30 AM Shoulder Pain And Gender In Manual Wheelchair Users

Jacob J. Sosnoff<sup>1</sup>, Karla Wessels<sup>1</sup>, Jennifer L. Brown<sup>1</sup>, Kyle T. Ebersole<sup>2</sup>. <sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>University of Wisconsin - Milwaukee, Milwaukee, WI.

Email: jsosnoff@uiuc.edu

(No relationships reported)

**PURPOSE:** The purpose of this investigation was to quantify the presence of shoulder pain in physically active manual wheelchair users and examine whether the presence and level of shoulder pain varied across genders.

**METHODS:** 55 manual wheelchair users (17 male, 38 female) who regularly participate in wheelchair athletics completed three separate surveys indexing the shoulder pain and difficulty performing functional activities.

**RESULTS:** 54.5% of the respondents reported shoulder pain, 36% reported taking pain medication and only 7% received some form of therapy. There were no gender differences in the incidence of shoulder pain (58.8% of males and 52.2 % of females). However, female respondents reported more severe shoulder pain and difficulty during numerous activities of daily living ( $p < .05$ ). Most of these activities required significant amounts of muscular strength and/or were composed of significant internal and external shoulder rotation.

**CONCLUSIONS:** The findings suggest that a gender disparity in shoulder pain severity, but not incidence persists in physical active wheelchair users. Further work is needed to understand the mechanisms that contribute to gender differences in shoulder pain severity.

## 2930 Board #77 May 30 8:00 AM - 9:30 AM Hyperlordosis Retraining Method Relieves Lumbar Disc And Stenosis Pain - An Unexpected Finding

Jolie Bookspan. *Neck and Back Pain Sports Medicine, Philadelphia, PA.* (Sponsor: Catherine G. R. Jackson, F.A.C.S.M. and LtCol Kelly Hill, M.D., F.A.C.S.M., FACSM)

Email: scientist@DrBookspan.com

(No relationships reported)

**PURPOSE:** Previous work has identified hyperlordotic lumbar posture as causal in lower back pain (LBP). By comparison, main source of disc lesion is identified as flexion, and stenotic pain, constriction. Patients seen for LBP with radiographically identified disc lesions and stenosis had significant pain relief using a hyperlordosis reduction technique, The Ab Revolution (AR).

The purpose of this study was to identify effectiveness of The Ab Revolution (AR), for chronic LBP with disc degeneration, herniation, or stenosis as presenting component.

**METHODS:** 47 participants (19 M, 28 F, 17 - 89) seen through the sports medicine center and University classes for LBP (pain > 6 months, orthopedic origin) with diagnosed discogenic and/or stenotic pain. All were taught AR. Control Group (N=13) was free to pursue treatment other than AR (PT, massage, surgery, Pilates, acupuncture, yoga, other) or no intervention. Participants were reassessed for LBP (better, gone, worse, same,) at day 1 and one-month follow-up. Data were analyzed using Chi-Square and non-parametric sign test.

**RESULTS:** Significant reduction of LBP using AR ( $P < .0001$ ) at each stage with no gender difference. At 1 month follow-up, 42 of 47 subjects in AR completely resolved back pain, 4 reported significant improvement, compared to 4 of 13 in the control group completely resolving pain.

**CONCLUSIONS:** AR has been previously found to reduce chronic LBP from hyperlordotic loading. A mechanism for relief from the separate problems of discogenic and stenotic pain appears to lie in direct reduction of compression through positional retraining of the space-occupying disc, and surrounding irritated and constrained nerve distributions, with crossover to daily activity where the majority of loading occurs. A second consideration is unrecognized hyperlordotic pain from hyperlordosis co-occurring with disc lesion and stenosis. Reduction of that separate source obviates or reduces total pain. Hyperlordotic posture creates foraminal narrowing, further restricting areas already compromised by stenosis LBP may also be misattributed to disc involvement or stenosis, which frequently appear radiographically, but of no clinical significance. Another hitherto unrecognized possibility is that chronic hyperlordosis mechanically contributes to disc injury.

(No relationships reported)

**$\alpha$ -Hydroxyisocaproic acid ( $\alpha$ -HICA)** is an end product of leucine metabolism in human tissues such as muscle and connective tissue. According to the clinical and experimental studies,  $\alpha$ -HICA can be considered as an anti-catabolic substance.

**PURPOSE:** To investigate the effects of  $\alpha$ -HICA supplementation on body composition, delayed onset of muscle soreness (DOMS) and physical performance of athletes during a training period.

**METHODS:** Fifteen healthy male football players (age  $22.1 \pm 3.9$  yr) volunteered for the 4-week double-blind study during an intensive training period. The subjects in the group HICA (n=8) received 583 mg of sodium salt of  $\alpha$ -HICA (corresponding 500 mg of  $\alpha$ -HICA mixed with liquid three times a day for 4 weeks, and those in the group PLACEBO (n=7) received placebo (650 mg of maltodextrin) three times a day for the same period. According to a training schedule they practiced football four times a week, strength training two times a week and had one football game a week during the study. The subjects were required to keep diaries on training, food and symptoms of DOMS. Body composition was evaluated with DEXA before and after the 4-week period. Muscle strength and running velocity were measured with field tests. Statistical comparisons were made using ANOVA.

**RESULTS:** The  $\alpha$ -HICA supplementation increased compared to placebo significantly lean whole body mass ( $p < 0.001$ ) and whole body muscle mass ( $p < 0.01$ ) while fat mass remained constant. The muscle mass of lower extremities increased by 400g in HICA but decreased by 150g in PLACEBO. The  $\alpha$ -HICA supplementation decreased significantly ( $p < 0.01$ ) the whole body DOMS symptoms in the 4<sup>th</sup> week of the treatment when compared to placebo. Muscle strength and running velocity did not differ between the groups.

**CONCLUSION:** The  $\alpha$ -HICA supplementation increases muscle mass and decreases muscle soreness during an intensive training period in athletes.

Email: gkastello@winona.edu

( G.M. Kastello, Brownwood Acres Inc., Contracted Research.)

**PURPOSE:** The purpose of this crossover, double blind study was to examine the effects of CherryFlex supplementation on eccentric exercise induced inflammation, tissue damage, oxidative stress biomarkers and delayed onset muscle soreness (DOMS).

**METHODS:** Four males and ten females (ages:  $21 \pm 0.76$  years; weight:  $72.21 \pm 3.7$  kg) performed five sets of 10 maximal eccentric contractions of the elbow flexor on a Biodex isokinetic dynamometer. The placebo and CherryFlex supplemental groups each ingested tablets 16 days prior to exercise and continued through the study. Venous blood samples were obtained at 16 and 1 day prior to exercise and 0, 2, 4, 24, 48 and 72 hours post exercise. Samples were measured for creatine kinase (CK), myoglobin, protein carbonyls (PC), thiobarbituric acid (TBARS), and C-Reactive proteins (CRP). Data for limb volume, limb girth, arm hang angle, peak torque, peak work, punctuated tenderness gauge (objective pain) and visual analog scale (subjective pain) were collected at 0, 12, 24, 48, and 72 hours post exercise. Time by treatment and treatment effects were measured using MANOVA repeated measures with Tukey's post-hoc at specific time points.

**RESULTS:** Moderately significant treatment effect were observed in TBARS ( $\pm$  SE;  $P_{24} 4.15 \pm 0.43$  vs.  $S_{24} 3.42 \pm 0.29$ ;  $p = 0.1062$ ), 12 hour objective pain at 4 cm site ( $P_{12} 1.25 \pm 0.13$  vs.  $S_{12} 1.63 \pm 0.20$ ;  $p = 0.139$ ), 12 hour relaxed arm hang angle ( $P_{12} 145.67 \pm 2.15$  vs.  $S_{12} 150.18 \pm 1.69$ ;  $p = 0.100$ ) and percent of maximum torque loss ( $S_{24} 21 \pm 4.2\%$ ,  $P_{24} 29 \pm 4.2\%$ ,  $p = 0.11$ ). Statistically significant time by treatment interactions between groups at  $p \leq 0.05$ , were observed for CRP ( $P_{24} 5.02 \pm 2.02$  vs.  $S_{24} 2.85 \pm 0.95$ ;  $p = 0.047$ ), objective pain ( $P_{12} 1.41 \pm 0.06$  vs.  $S_{12} 1.52 \pm 0.08$ ;  $p = 0.040$ ) and subjective pain ( $P_{48} 4.86 \pm 0.39$  vs.  $S_{48} 4.14 \pm 0.41$ ;  $p = 0.026$ ). The cherry supplemental group demonstrated no significant differences in protein carbonyls, creatine kinase, myoglobin, limb volume, limb girth, flexed arm hang angle, peak torque and peak work.

**CONCLUSIONS:** These findings suggest that ingestion of the CherryFlex supplement prior to and during eccentric exercise may have a protective effect on oxidative stress (TBARS), inflammation (CRP), range of motion, contractile force loss, and perceived pain.

2933 Board #80 May 30 9:30 AM - 11:00 AM

**Efficacy Of Tart Cherry Juice In Reducing Muscle Damage, Inflammation And Oxidative Stress Following Marathon Running**

Glyn Howatson<sup>1</sup>, Malachy P. McHugh, FACSM<sup>2</sup>, Jessica L. Hill<sup>1</sup>, James Brouner<sup>3</sup>, Andy P. Jewell<sup>4</sup>, Ken A. van Someren<sup>5</sup>, Rob Shave<sup>6</sup>. <sup>1</sup>St Mary's University College, Twickenham, United Kingdom. <sup>2</sup>NISMAT, New York, NY. <sup>3</sup>Kingston University, Kingston-upon-Thames, United Kingdom. <sup>4</sup>St George's Hospital Medical School, London, United Kingdom. <sup>5</sup>English Institute of Sport, Bisham Abbey, United Kingdom. <sup>6</sup>Brunel University, Uxbridge, United Kingdom.

Email: howatson@smuc.ac.uk

(No relationships reported)

**PURPOSE:** Tart cherries (*Prunus Cerasus*) are known to contain a variety of phenolic compounds and are particularly rich in anthocyanins that may help to reduce muscle damage, oxidative stress and inflammation following strenuous physical activity, and help to accelerate recovery. The purpose of this study was to determine the efficacy of a tart cherry juice blend in aiding recovery, and reducing muscle damage, inflammation and oxidative stress.

**METHODS:** Twenty recreational Marathon runners volunteered to participate. Volunteers were equally, but randomly assigned to two groups and consumed 16 fl oz of a commercially available cherry juice (CherryPharm, Geneva, NY) or placebo (PL) everyday for 5 days prior to, and for 48 h following the Marathon. Measures of muscle damage [creatine kinase (CK), delayed onset muscle soreness (DOMS) and maximum voluntary contraction (MVC)], inflammation [interleukin 6 (IL-6), C-reactive protein (CRP) and uric acid], total antioxidant status (TAS) and oxidative stress [TBARS and protein carbonyls (PC)] were taken pre-supplement, pre-race, immediately post-race, 24 h and 48 h post-race. A repeated measures ANOVA was used to ascertain differences over time and between groups.

**RESULTS:** MVC recovered significantly faster in the cherry juice group (101% versus 91% at 48h). Markers of inflammation were reduced in the cherry juice versus PL group (IL-6 post race 49% lower,  $P < 0.001$ ; CRP at 24 and 48 hr 33% lower,  $P < 0.01$ ; uric acid post race and at 24 hr 22% and 29% lower,  $P < 0.05$ ). TAS was approximately 10% greater in the cherry juice than the PL group for all post supplementation measures ( $P < 0.05$ ). TBARS at 48h post-race was 29% lower in the cherry juice than the PL at 48h ( $P < 0.05$ ). DOMS, CK and PC were not different between groups.

**CONCLUSIONS:** The cherry juice increased total anti-oxidative capacity following 5 days supplementation, and reduced inflammation, lipid peroxidation, and aided in the recovery of muscle function. This drink appears to provide athletes and exercisers with a viable means to aid recovery by increasing antioxidant capacity and reducing inflammation and oxidative stress. Perhaps more importantly, the cherry juice may have applications for the management of other clinical pathologies that incur oxidative stress and inflammation.

2934 Board #81 May 30 9:30 AM - 11:00 AM

**Effects Of Chocolate Milk Consumption On Markers Of Muscle Recovery During Intensified Soccer Training**

Stephanie F. Gilson, Michael J. Saunders, FACSM, Charles W. Moran, Dana F. Corriere, Rebecca W. Moore, Christopher J. Womack, FACSM, M Kent Todd, FACSM. *James Madison University, Harrisonburg, VA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effectiveness of chocolate milk (CM) as a post-exercise recovery beverage during intensified training in competitive soccer players.

**METHODS:** Thirteen collegiate soccer players (184±7 cm, 79±10 kg) completed two intervention periods, each consisting of one week of 'normal' training followed by four days of intensified-training (IT). Immediately following each day of IT, subjects received either a high-carbohydrate (CHO: 1.77g CHO·kgBW<sup>-1</sup>; 0.03g Fat·kgBW<sup>-1</sup>) or CM (1.2g CHO·kgBW<sup>-1</sup>; 0.4g Pro·kgBW<sup>-1</sup>; 0.1g Fat·kgBW<sup>-1</sup>) recovery beverage. Treatment beverages were isocaloric, and delivered in a randomly-counterbalanced double-blind protocol. Serum creatine kinase (CK) and myoglobin (Mb) levels, muscle soreness, mental and physical fatigue, peak isometric force of the quadriceps (MVC), and leg-extension repetitions at 70% 1-RM (Reps) were obtained prior to IT, and following 2- and 4-days of IT. Soccer-specific performance tests (t-drill, vertical jump and 1.5 mile run speed) were performed within the training sessions.

**RESULTS:** Average daily training times (85.3±5.0; 95.3±7.9 min) and HR (141.8±12.1; 145±10.9 bpm) increased significantly ( $p<0.05$ ) between baseline and IT periods, with no differences between treatment periods. Soreness, CK, Mb, MVC and Reps were all significantly altered over time during the IT period. No significant treatment\*time interactions were observed. However, serum CK levels during the CM treatment were significantly lower ( $p<0.05$ ) than CHO following two (343.5±199.8; 449.9±364.8 U/L) and four (316.9±188.3; 431.6±310.8 U/L) days of IT. Mean changes in isometric MVC values for CM (+52.7 N) tended to be greater than those for CHO (+24.6 N), although this was not statistically different between treatments. No significant differences in soccer-specific performance tests were observed between treatment beverages.

**CONCLUSIONS:** Post-exercise CM consumption provided equal or possibly superior muscle recovery responses to an isocaloric, high-carbohydrate recovery beverage following a four-day period of intensified soccer training. Performance in soccer-specific field tests were similar between beverages.

2935 Board #82 May 30 9:30 AM - 11:00 AM

**Acute Effects Of Chocolate Milk And A Commercial Recovery Beverage On Post-exercise On Muscle Damage And Endurance Cycling Performance**

Kelly L. Pritchett, PhD, RD<sup>1</sup>, Philip Bishop, EdD<sup>2</sup>, Robert Pritchett, PhD<sup>1</sup>, Matt Green, PhD, FACSM<sup>3</sup>, Charlie Katika<sup>1</sup>, Stephen Carter<sup>1</sup>. <sup>1</sup>Central Washington University, Ellensburg, WA. <sup>2</sup>University of Alabama, Tuscaloosa, AL. <sup>3</sup>University of North Alabama, Florence, AL. (Sponsor: Matt Green, FACSM)  
Email: kkerr@cwu.edu  
(No relationships reported)

**PURPOSE:** This study compared chocolate milk (CHOC) vs. a commercial recovery beverage (CRB) as a recovery aid after intense exercise regarding performance and muscle damage in trained cyclists.

**METHODS:** Ten, competitive cyclists ( $\text{VO}_{2\text{peak}}$  55.2 ± 7.3 ml/kg/min.) completed a high-intensity intermittent exercise protocol, then 15 to 18 h later performed a performance trial @ 85% of  $\text{VO}_{2\text{peak}}$  to exhaustion. Participants consumed 1.0g carbohydrate (CHO)/kg/h of a randomly assigned isocaloric beverage (CHOC, or CRB) following the first high intensity intermittent exercise session. The same protocol was repeated one week later with the other beverage.

**RESULTS:** A one-way ANOVA revealed no significant difference ( $p = .91$ ) between trials for cycling time to exhaustion at 85% of  $\text{VO}_{2\text{peak}}$  (CHOC 13 ± 10.2 min., CRB 13.5 ± 8.9 min.) A significantly higher increase ( $p < 0.05$ ) was observed from CKpre-to-post in the CRB trial compared to the CHOC trial (increase CHOC 27.9 ± 134.8 U/L<sup>-1</sup>, CRB 211.9 ± 192.5 U/L<sup>-1</sup>); with differences not significant ( $p = .35$ ) for CKpost (CHOC 394.8 ± 166.1 U/L<sup>-1</sup>, CRB 489.1 ± 264.4 U/L<sup>-1</sup>) between the two trials.

**CONCLUSIONS:** These findings indicate no difference between chocolate milk and this commercial beverage as potential recovery aids for cyclists between intense workouts. Comparatively, CHOC is more economical per serving while providing similar benefits in recovery.

2936 Board #83 May 30 9:30 AM - 11:00 AM

**The Effects Of Adding Leucine To A Carbohydrate-electrolyte Beverage On Muscle Damage, Soreness, And Performance**

Matthew S. Stock<sup>1</sup>, John C. Young, FACSM<sup>2</sup>, Lawrence A. Golding, FACSM<sup>2</sup>, Laura J. Kruskall, FACSM<sup>2</sup>, Richard D. Tandy<sup>2</sup>, Janice Conway-Klaassen<sup>2</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of Nevada, Las Vegas, Las Vegas, NV.  
(No relationships reported)

Recent studies have examined the independent and combined importance of essential amino acid and carbohydrate ingestion after resistance training. However, no studies have examined the effects of adding leucine to a commercially available sports drink on muscle damage and delayed-onset muscle soreness (DOMS). If leucine ingestion reduces muscle damage after a single training bout, athletes should be able to perform at a higher level during an ensuing training bout.

**PURPOSE:** To evaluate the efficacy of adding leucine to pre- and post-exercise carbohydrate-electrolyte beverages on blood markers of muscle damage, DOMS, and strength-endurance after a single lower-body resistance training bout.

**METHODS:** Seventeen males (age 22.9 ± 2.9 y, height 171.6 ± 28.0 cm, body mass 92.8 ± 27.2 kg) and three females (age 21.6 ± 2.6 y, height 161.7 ± 6.7 cm, body mass 61.4 ± 8.7 kg) performed 6 sets of squats to complete fatigue using 75% of their pre-determined 1-RM with 3 minutes of rest between sets. All subjects were resistance trained and familiar with the squat exercise (male 1-RM squat 151.9 ± 27.5 kg, female 1-RM squat 67.4 ± 1.3 kg). Each subject consumed carbohydrate-electrolyte beverages 30 minutes before and immediately after exercise with (LCHO) or without (CHO) the addition of leucine in randomized, double-blind fashion. Blood creatine kinase (CK), lactate dehydrogenase (LDH), and subjective surveys of DOMS were analyzed immediately before (TIME1), 24 (TIME2), 48 (TIME3), and 72 (TIME4) hours after exercise. Subjects repeated the squat protocol at TIME4 to test short-term recovery.

**RESULTS:** No differences were observed between groups for squat performance, as defined by the number of repetitions performed over 6 sets of squats to fatigue, during both TIME1 and at TIME4. The addition of leucine did not significantly decrease CK and LDH activity or subjective ratings of DOMS. Furthermore, CK values and DOMS ratings for the LCHO and CHO groups demonstrated similar patterns across all time points.

**CONCLUSIONS:** These findings suggested that adding leucine to carbohydrate-electrolyte beverages did not affect the pain associated with DOMS, blood markers of muscle damage, and squat performance during both acute testing and 3 days after the initial resistance training bout in resistance trained subjects.

---

**Carbohydrate-Protein Beverage Improves Recovery From Muscle Damage Induced By Downhill Running**

Stephen C. Chen, J Mark Davis, FACSM, Sara Mahoney, Traci Barrilleaux, Kate Hubbles, Chris Kline, Martin Carmichael, E Angela Murphy.  
*University of South Carolina, Columbia, SC.*

Email: nomorebogy@hotmail.com

(No relationships reported)

Downhill running has been shown to induce muscle fiber damage, delayed-onset muscle soreness, and various functional deficits. Consumption of carbohydrate-protein beverages during or immediately following strenuous exercise have been shown to reduce muscle damage, however its effects on performance recovery following downhill running have yet to be elucidated.

**PURPOSE:** This study examined the effects of CHO+PRO vs. CHO on multiple aspects of muscle recovery following one bout of unaccustomed novel eccentric exercise (downhill running).

**METHODS:** 20 physically active but untrained participants were randomly assigned to either CHO or CHO+PRO (n=10/group). Subjects consumed either 1.2 g·kg<sup>-1</sup> CHO (CHO) or 1.2 g·kg<sup>-1</sup> CHO + 0.3 g·kg<sup>-1</sup> protein (CHO+PRO) daily for 7 days prior to eccentric exercise, and for 2 days following exercise. For eccentric exercise, subjects performed a 30-min downhill run (DHR) at 75% of their maximal heart rate on a -18% gradient. Creatine kinase activity (CK), lower extremity muscle soreness (SOR), and maximal isometric and isokinetic torque, were all assessed prior to 24 hr post, and 48 hr post DHR. Athletic performance was also assessed including 20-m sprint time, gross motor skills, vertical jump, and multistage fitness test prior to DHR and 48 hr post DHR.

**RESULTS:** CK was increased at 24 hr and 48 hr post DHR (P<0.05) but there was no differences between the two treatments. SOR ratings from all three different lower body exercises were significantly elevated over time compared to pre exercise (PRE) and magnitude of hamstring soreness was attenuated at both 24 hr and 48 hr post exercise in the CHO+PRO group (P<0.01). CHO+PRO significantly reduced the deterioration in maximal isokinetic hamstring torque compared to CHO at 24 and 48 hr post DHR (P<0.05) but there were no treatment differences in maximal isometric torque. CHO+PRO treatment also resulted in better 20-m sprint performance 48 hr post DHR.

**CONCLUSION:** The results of this study reveal that short term consumption of CHO+PRO beverage before and after one bout of eccentric exercise can enhance multiple aspects of muscle recovery which may have important implications for athletes and military personnel.

**Attenuation Of Exertional Muscle Damage With A Nutritional Supplement**

LesLee F. Sanders<sup>1</sup>, Glen E. Duncan<sup>2</sup>, Eric Grenier<sup>3</sup>, Patricia A. Deuster<sup>3</sup>, <sup>1</sup>USARIEM, Natick, MA. <sup>2</sup>University of Washington, Seattle, WA. <sup>3</sup>USUHS, Bethesda, MD. (Sponsor: Andrew J. Young, FACSM)

Email: leslee.sanders@us.army.mil

(No relationships reported)

Previous research suggests that glutamine (GLN) administration either during or following strenuous exercise modulates post-exercise inflammatory responses and may facilitate recovery.

**PURPOSE:** This study studied the effects of GLN added to a beverage containing a carbohydrate (CHO) and an essential amino acid (EAA) mixture consumed during and after exercise on markers of EMD and performance in subjects following a strenuous physical training event.

**METHODS:** Male subjects (n = 33; mean age of 24 years ± 1) completed this blinded-crossover study. Subjects were randomized to ingest either a placebo or treatment beverage during and after two identical events (modified physical fitness test), with the alternate beverage provided at the second event. Beverages were matched for CHO and EAA content (42 grams of CHO, 6 grams of EAA per liter) providing 192 calories. The GLN containing (4 grams) treatment beverage provided 208 calories per liter.

**RESULTS:** No significant differences were noted (p ≤ 0.05) between groups with respect to muscle damage or inflammation, to include changes in creatine kinase, lactate dehydrogenase, white blood cell counts, C-reactive protein and select pro- and anti-inflammatory cytokines, as measured at baseline and after exercise. Creatine kinase, the primary variable of interest, increased after the training event in both groups indicating muscle damage had occurred. The treatment beverage did not significantly attenuate the response (p = 0.28). Plasma GLN levels remained relatively unchanged between placebo and treatment conditions, with both beverages blunting post-exercise induced decreases in GLN levels. Physical performance measures and pain scores were not significantly affected by the addition of GLN.

**CONCLUSIONS:** Our findings suggest that the addition of GLN to a CHO/EAA beverage provided during and after exercise does not confer any significant benefit over a CHO/EAA beverage alone. The intervention failed to alter circulating GLN levels or measurably affect markers of EMD and the inflammatory response, and did not improve physical performance.

(No relationships reported)

Acute Timing Effects Of B-Hydroxy B-Methylbutyrate (Hmb) Supplementation On Serum Indices Of Muscle Damage

Previous studies suggest that chronic b-hydroxy b-methylbutyrate (HMB) supplementation (>2 wk) lowers serum indices of muscle damage such as creatine kinase (CK) and lactate dehydrogenase (LDH) via a possible increase in sarcolemmal integrity. However, HMB's acute or timing effects have not yet been examined.

**PURPOSE:** Therefore, the purpose of this study was to investigate the acute timing effects of HMB on changes in serum CK and LDH after a bout of eccentric exercise.

**METHODS:** Sixteen non-resistance trained men (22±2 yrs) were assigned to HMB-Pre or HMB-Post groups. All subjects performed 55 maximal eccentric knee extension/flexion contractions on 2 occasions on either the right or left leg, in a crossover design. HMB-Pre (N=8) randomly received 3 grams of either a placebo or HMB before and a placebo after exercise. HMB-Post (N=8) received a placebo before and either 3 grams of HMB or a placebo after exercise. Blood was drawn for the determination of CK and LDH before, at 8, 24, 48, and 72 hrs post exercise.

**RESULTS:** Serum indices of damage increased, peaking at 48 hrs for CK (773%, p<0.001) and 72 hrs for LDH (180%, p<0.001). While there were no time x group effects of HMB on CK and LDH, post hoc analysis revealed that only HMB-Pre showed no significant increase in LDH levels following exercise.

**CONCLUSION:** Our findings suggest there are no acute or timing effects of HMB supplementation on indices of muscle damage. However, consuming HMB before exercise appeared to prevent increases in LDH, suggesting further research is warranted.

**The Effects Of Continuous Hiking Pole Use On Acute Static And Dynamic Balance Of Men And Women Hikers**

Julianne Abendroth<sup>1</sup>, Victoria Swigart<sup>1</sup>, Greg Dixon<sup>1</sup>, Michael Bohne<sup>2</sup>. <sup>1</sup>Willamette University, Salem, OR. <sup>2</sup>Utah Valley University, Orem, UT.  
Email: jabendro@willamette.edu  
(No relationships reported)

**PURPOSE:** Many hikers use trekking poles, which allow for an increase in overall stability and a reduction in joint forces. However, the International Mountaineering and Climbing Federation (UIAA) suggest continuous pole use has an adverse effect on acute balance. They suggest if a hiker must put the poles away, their balance may be worse than if they had not used poles at all. The purpose of this study was to examine the effects of continuous hiking pole use on acute static and dynamic balance of hikers.

**METHODS:** Eighteen hikers were recruited (9 male, 9 female; ages 21-62). University IRB approval was obtained and informed consents were signed. A foam pad was used for static balance, while the dynamic balancing task used a simulated 3.3m log. Knee angles, stride length and time, arm elevation, and m/l and vertical trunk motion were analyzed. EMG recorded the erector spinae (ES), bicep femoris (BF), vastus lateralis (VL), tibialis anterior (TA), and the gastrocnemius (GA). The hikers participated in all conditions, by first performing baseline static and dynamic balance tasks. They then walked for 15 minutes with or without trekking poles (counter-balanced) to achieve a steady state pace, before repeating the balancing tasks. The poles were set down, if in use, and the task performed as though they had come to a log on a hike. Five trials of each task were completed, while continuing to walk with or without poles between each trial. Repeated measures ANOVAs were used ( $\alpha = 0.05$ ).

**RESULTS:** Results showed fewer errors on average in the pole condition for the static balance task, though not statistically significant. No significant differences were noted for knee flexion, stride length or time, arm elevation or trunk sway. Statistically significant overall muscle activity was elicited for BF, VL, and the GA. Pairwise comparisons showed only statistical significance between baseline and the pole conditions.

**CONCLUSIONS:** The primary implication of this study was for hiker safety. UIAA suggested that trekking pole use could lead to injury while hiking. Since no statistical significance was found that trekking pole use has a negative effect on subsequent balance tasks, it is suggested that hikers should continue to use trekking poles while hiking to increase stability and lessen the forces placed on the lower extremity.

**The Relationship Of Active Ankle Stiffness With Obesity, Hormonal Replacement Therapy And Menopause**

Aur lio Faria<sup>1</sup>, Ronaldo Gabriel<sup>2</sup>, Rui Br s<sup>1</sup>, Helena Moreira<sup>3</sup>. <sup>1</sup>University of Beira Interior - CIDESD, Covilh , Portugal. <sup>2</sup>University of Tr s-os-Montes and Alto Douro - CITAB, Vila Real, Portugal. <sup>3</sup>University of Tr s-os-Montes and Alto Douro - CIDESD, Vila Real, Portugal.  
Email: afaria@ubi.pt

(No relationships reported)

Little information is available relating stiffness, obesity, hormone replacement therapy (HRT) and menopause (natural or induced). Literature suggests that higher and lower values of stiffness can lead to bone and soft tissue injuries, respectively. Once menopause is associated with biological changes in human body (e.g. bone mineral density loss), it is important to understand how some of these changes can affect stiffness.

**PURPOSE:** To investigate the relationship of active ankle stiffness (AAS) with obesity, HRT and menopause.

**METHODS:** Maximal voluntary isometric contraction (MVIC) was measured for the right leg plantar-flexion. Free oscillation data representing active ankle stiffness was obtained for 112 post menopause women ( $57.8 \pm 5.7$  years) using external pure gravitational mass equivalent to 30% of MVIC. Active ankle stiffness was computed from kinetic data recorded in response to plantar flexion/dorsiflexion perturbations, resulting from the application of a controlled impulse (100 N) that disturbs the foot-ankle angle. If individual BMI was equal or greater than 30 kg/m<sup>2</sup> they were considered obese. The data of HRT and menopause (natural or induced) was obtained through medical consultation.

**RESULTS:** Neither the group submitted to HRT ( $19391 \pm 4117$  N/m) or the group where menopause was induced ( $20469 \pm 4705$  N/m) show statistical differences for the active ankle stiffness in relation to the control group (respectively  $20676 \pm 4958$  N/m and  $19746 \pm 4378$  N/m). However, obese group show higher values ( $21529 \pm 4062$  N/m) of active ankle stiffness than non obese group ( $18906 \pm 4803$  N/m), with ( $p = 0.008$ , 95%). As greater forces are imparted to the body, greater resistance to movement is needed to produce controlled movements. Since obese have high inertia, these results could suggest that obese subjects developed some adaption's on movement control that lead to AAS higher values.

**CONCLUSION:** The data suggest that higher values in active ankle stiffness are related with obesity; however there is no evidence it happens the same either among HRT submission/non submission groups or between subjects in natural or induced menopause.

**Gait Parameters And Risk Of Falls In Patient With Fibromyalgia**

Suelen M. Goes, Ricardo M. Souza, Diogo Homann, Eduardo Paiva, Andr  L. F. Rodacki, Neiva Leite. *Federal University of Parana UFPR, Curitiba, Brazil.*

Email: su.goes@gmail.com

(No relationships reported)

Fibromyalgia includes symptoms of widespread pain (axial, upper and lower quadrant, left and right side pain), in combination with the presence of 11 out of 18 tender point sites. Patients with fibromyalgia syndrome are characterized by their chronic pain, reduced physical work capacity, muscular fatigue, difficulties with concentrating on cognitive tasks and neurological complaints, that impair the locomotion and mobility.

**PURPOSE:** To determine spatial-temporal gait parameters of patients with fibromyalgia.

**METHODS:** Ten women (age,  $55.1 \pm 5.3$  years; height,  $154.5 \pm 6.9$  cm; weight,  $76.8 \pm 8.7$  kg) were diagnosed with fibromyalgia using the American College of Rheumatology criteria volunteered to participate of the study. Kinematics were performed using an optoelectronic system (VICON, UK), sampling at 100 Hz. The right lower limb joint range of motion (hip, knee and ankle), stride length and gait velocity were determined. Subjects walked for 12 meters and the mean of three gait cycles were time-normalized and used to obtain the ensemble average.

**RESULTS:** Kinematic analysis revealed decreased mean joint range of motion of ankle, knee and hip ( $24.2^\circ \pm 3.9^\circ$ ,  $54.6^\circ \pm 4.0^\circ$ ,  $26.4^\circ \pm 6.5^\circ$ , respectively), reduced stride length ( $0.96 \pm 0.2$ m) and gait velocity ( $0.93 \pm 0.2$ m/s<sup>-1</sup>).

**CONCLUSIONS:** Subjects with fibromyalgia showed a decreased mobility which was related to pain. Patients showed reduced lower limb ROM, stride length and gait velocity. These gait patterns are similar to others studies which have analyzed the influence of muscle pain induced by training in healthy elders. The reduced ROM, stride length and gait velocity are associated with pronounced risk of falls.

**Axial Rotation Of Lumbar Spine During Treadmill Walking At Three Constant Velocities**

Ya-Ting Yang<sup>1</sup>, Yasuyuki Yoshida<sup>2</sup>, Shuji Suzuki<sup>1</sup>. <sup>1</sup>Waseda University, Tokorozawa, Japan. <sup>2</sup>Kyoto Institute of Technology, Kyoto, Japan.

Email: ya-ting@toki.waseda.jp

(No relationships reported)

Forward progression of the body during walking involves both displacement of the legs in a frontal plane and rotation of the trunk about a longitudinal axis.

**PURPOSE:** To determine the range of motion and the relative timing of displacement in transverse planes for the shoulders, lumbar spine, and pelvis during treadmill walking at three constant velocities.

**METHODS:** Three healthy young women ( $24.7 \pm 1.5$  yrs,  $1.61 \pm 0.04$  m,  $47.3 \pm 5.5$  kg) with no history of neurological or musculoskeletal disorders participated in the study. The participants were asked to walk on a treadmill (L7, LANDICE, USA) at three constant velocities (A = 0.9 m/s, B = 1.2 m/s, C = 1.5 m/s). All participants performed 2-minute walk at each velocity with a 1-minute rest in between trials. All trials were captured by an eight-camera motion capture system (MAC3D, Motion Analysis Corporation, USA), operated at 200 Hz. Ten reflective markers were placed on the bony landmarks of the shoulder, lumbar spine, and pelvis.

**RESULTS:** Stride length increased significantly (A =  $1.17 \pm 0.03$  m; B =  $1.30 \pm 0.07$  m; C =  $1.45 \pm 0.11$  m,  $p < 0.05$ ) with walking velocity. At initial contact of the right foot, the right side of the pelvis rotated forward to facilitate the placement of the foot. The angular displacement of the pelvis increased significantly with walking speed (A =  $12.1 \pm 3.6$  deg; B =  $15.6 \pm 2.4$  deg; C =  $19.8 \pm 4.0$  deg,  $p < 0.05$ ), and the timing of the peak forward rotation occurred earlier relative to foot contact as speed increased. The shoulder displacement was  $180^\circ$  out of phase with that of the pelvis. Shoulder displacement, however, did not change significantly with walking speed (A =  $10.5 \pm 2.6$  deg; B =  $7.7 \pm 1.6$  deg; C =  $10.1 \pm 2.7$  deg). Similarly, the angular displacement of the lumbar spine did not change significantly with walking speed (A =  $8.5 \pm 2.1$  deg, B =  $7.3 \pm 2.1$  deg, C =  $9.2 \pm 3.0$  deg), and the intermediate position (0 deg) occurred when both the pelvis and shoulder were at maximum angles.

**CONCLUSION:** The results indicate that only the rotation of the pelvis and not that of the shoulders or lumbar spine changed across walking speed.

**A Cross-sectional Study Of Age Related Changes In Gait In Females Aged 20-59**

Kate I. Minick, Robert J. Butler. *University of Evansville, Evansville, IN.* (Sponsor: Gregg Wilson, PhD, FACSM, FACSM)

Email: km101@evansville.edu

(No relationships reported)

Knee osteoarthritis (OA) is a leading cause of pain and disability among the elderly. Women are 2-3 times more likely than men to develop knee OA. It has been suggested that this may be associated with the finding that females with knee OA exhibit altered frontal plane gait mechanics compared to males with knee OA, who demonstrate gait mechanics closer to the asymptomatic population. However, the mechanism behind the differential disease progression in females is not well understood.

**PURPOSE:** To examine gait mechanics in females without degenerative knee OA from 20-59 years to assess potential differences in biomechanical risk factors in gait for knee OA development.

**METHODS:** Forty females between the ages of 20-59 years with no history of connective tissue knee injury volunteered to participate in the study and were divided into four age groups: 20-29, 30-39, 40-49 and 50-59. All participants completed a gait analysis at a self-selected intentional walking speed that allowed for calculation of frontal plane knee and hip joint angles and internal joint moments. The average of five trials was used to analyze the relevant variables. One way ANOVAs were performed to examine potential differences in the variables of interest ( $p < 0.05$ ).

**RESULTS:** No differences in BMI or gait velocity were observed between the age groups. Younger females exhibited higher activity levels compared to the older females as measured by the Tegner scale. No significant differences existed between the groups in peak frontal plane knee and hip abduction moments, peak knee and hip adduction angles, and peak knee and hip adduction excursion.

**CONCLUSION:** In a female population without previous knee injury and with similar BMIs, age alone is not associated with differences in gait that have been related to the development of knee OA progression. These preliminary results suggest that there is not a specific time at which to intervene with females in order to reduce their risk for knee OA progression. Other factors that occur throughout the female lifespan need to be analyzed to identify women most at risk for knee OA development.

**2945 Board #92 May 30 8:00 AM - 9:30 AM**  
**The Influence Of Running With Pain On Lower Extremity Kinematics In Runners With Patellofemoral Pain**

Tracy A. Dierks<sup>1</sup>, Matthew D. Holder<sup>1</sup>, Irene Davis, FACSM<sup>2</sup>. <sup>1</sup>Indiana University, Indianapolis, IN. <sup>2</sup>University of Delaware, Newark, DE.

Email: tdierks@iupui.edu

(No relationships reported)

Patellofemoral pain (PFP) is one of the most prevalent running overuse injuries. Abnormal kinematics, such as excessive eversion, hip internal rotation, and knee abduction (valgus) have been implicated. In most studies, the runner is in a fresh, non-exerted and pain-free state. These mechanics may not be associated with the development of pain during the run.

**PURPOSE:** To investigate the mechanics of runners with PFP as they develop knee pain over the course of a run.

**METHODS:** Twenty runners with PFP and 20 healthy controls (CON) ran on a treadmill at an average speed of 2.6 m/s ( $\pm 0.3$ ). Kinematic data were collected at 5 minute intervals. Knee pain was recorded in the PFP group at each interval using a visual analog scale (VAS). Pain onset was identified as a VAS of 3/10 (VAS3) and kinematic data were collected at this time. Peak joint angles during stance at the beginning of the run and at the time of VAS3 were compared to controls at equivalent time periods using a 2-way repeated measures ANOVA.

**RESULTS:** At the beginning, 16 of 20 runners with PFP reported a VAS of 0/10, with the rest between 0.3 and 1. The pain onset occurred at an average time of 16.5 minutes ( $\pm 8.1$ ). Overall, the PFP group displayed lower peak angles than the CON group, with only knee flexion being statistically different (Table 1). This pattern of reduction may have been a compensatory mechanism to avoid the oncoming knee pain. No interactions were observed as peak angles tended to increase in both groups over time.

**CONCLUSION:** The PFP group exhibited an overall reduction in peak angles, while both groups tended to increase peaks over time. Thus, pain onset did not appear to differentially influence the peaks in the PFP group. Greater levels of knee pain (VAS > 3/10) may be needed to elicit these changes.

**2946 Board #93 May 30 8:00 AM - 9:30 AM**  
**Comparison Of The Metabolic Cost Of Walking At Different Speeds With Stride Length In Obese And Normal Weight Adults**

James Robinson, Mark Loftin, FACSM, Dwight Waddell. *University of Mississippi, University, MS.*

Email: jhrobin1@olemiss.edu

(No relationships reported)

Comparing normal and obese energetic costs with stride length while walking at different speeds is important. We hypothesize possible coordinative shifts in gait, as revealed by changes in stride length, may occur in obese individuals while walking at non-preferred gait speeds.

**PURPOSE:** The purpose of this study was to compare stride lengths (mean and standard deviation) with metabolic costs of walking at preferred and non-preferred walking speeds in obese (O) and normal weight (NW) adults.

**METHODS:** Thirty-two adults volunteered for the study. Participants walked on the treadmill for five minutes each at preferred speed, 25% above and 25% below preferred speed. Metabolic rate (indirect caloric expenditure) was measured and the last two minutes of each condition were averaged. Net (N) values were obtained by subtracting standing ambulatory rest from gross (G) values. Body composition was determined via DXA. Stride length was determined using Vicon motion analysis. Stride length was determined over the last 30 seconds of each speed trial. Statistical analysis included a three way ANOVA (group x condition) and significance was defined as  $p < 0.05$ .

**RESULTS:** Significantly greater body composition (mass, % fat and BMI), defining subjects as Obese class I (N=14), was found for overweight subjects. No group differences were noted in preferred walking speed and net metabolic rate (W per kg). However, net  $\dot{V}O_2$  (L/min) was significantly greater for O individuals than NW individuals. There were no

significant differences in stride length regardless of weight cohort.

**CONCLUSION:** Adult stride lengths may be the same for obese and NW individuals at both preferred and non-preferred walking speeds. Treadmill walking as well as including subjects who were only mildly to moderately obese may have influenced outcome measures.

**2947      Board #94      May 30      8:00 AM - 9:30 AM**  
**Gait Adaptations To 37-kg Weight Loss Produced By Bariatric Surgery**

Patrick Rider, Cortney Herring, Jonathan Patterson, Benjamin Long, Patrick Sams, Kelly Jernigan, Walter Pories, Walter Pories, Paul DeVita, FACSM, Tibor Hortobagyi, FACSM. *East Carolina University, Greenville, NC.*  
(No relationships reported)

Many clinical conditions evoke adaptations in gait. Obese vs lean adults walk more slowly and with a more erect posture. It is unknown if such adaptations become hard-wired with obesity or there is a rapid re-adaptation of obese gait to lean gait after weight loss.

**PURPOSE:** Examine the effects of extreme weight loss on human locomotion 6 months following bariatric surgery.

**METHODS:** 3D lower limb kinematics and kinetics were assessed prior to ( $n = 5$ , BMI = 46.8) and six months after ( $n = 5$ , BMI = 32.7) bariatric surgery. Subjects walked at their self selected pace and the results of five acceptable trials were averaged.

**RESULTS:** Following surgery, subjects had significantly longer stride lengths (1.42m to 1.49m,  $p < 0.05$ ). There were also large reductions in vertical ground reaction forces (1032N to 736N,  $p < 0.05$ ), and frontal plane average knee torques (-27.3Nm to -20.9Nm,  $p < 0.05$ ). Increases in normalized (body weight x height) sagittal plane maximal ankle plantar flexor torque (7.7Nm/kg\*m to 8.5 Nm/kg\*m,  $p < 0.05$ ) and normalized (body weight) sagittal plane ankle work (0.003 J/kg to 0.049 J/kg,  $p < 0.05$ ) were observed.

**CONCLUSIONS:** The longer stride length appeared to be driven by the increased torque and work production at the ankle joint. The extreme amount of weight loss contributed to a large reduction in overall external loads placed on each individual. This resulted in large reductions in frontal plane torques at the knee joint to overcome the reduced external loads. The frontal plane knee torque result was especially significant since it is well documented that increased knee adduction torque is a predictor of knee osteoarthritis (OA), which may suggest that due to the significant weight loss, these individuals are less likely to develop knee OA. These data suggest a partial restoration of lean gait after surgery-induced large weight loss in obese adults, with disproportionately large changes in some variables.

**2948      Board #95      May 30      8:00 AM - 9:30 AM**  
**Metabolic Cost Of Altering Foot Strike Patterns In Running**

Allison H. Gruber, Elizabeth M. Russell, Joseph Hamill, FACSM. *University of Massachusetts, Amherst, MA.*  
Email: agruber@kin.umass.edu  
(No relationships reported)

Differences in kinematics of the lower extremity between a forefoot (FF) and rearfoot (RF) strike pattern may alter the metabolic demands of running. The FF strike pattern has been characterized by increased plantarflexion and inversion at touch down, greater rearfoot motion, increased knee internal rotation velocity and decreased ground contact time. It has been suggested that the kinematic profile of a FF strike pattern may reduce the metabolic cost of running as well as decrease the risk for injury. However, any deviation from preferred kinematics of gait has been shown to increase the metabolic demands of the task.

**PURPOSE:** The purpose of this study was to examine the effect of altering running strike pattern on kinematic and metabolic parameters in healthy RF strike runners.

**METHODS:** Ten natural RF strike runners (5 males, 5 females, age =  $25 \pm 5$  yrs, mass =  $64.74 \pm 9.55$  kg) participated in this study. All subjects ran  $27.2 \pm 7.1$  km per week and were free of injury for at least 1 year. Subjects were asked to run on a treadmill at their preferred running speed ( $3.01 \pm 0.50$  m/s) under two conditions: RF strike pattern and FF strike pattern. The order of conditions was counterbalanced. Oxygen consumption was measured with indirect calorimetry. Temporal-spatial parameters were collected for 60 s when the subject reached steady-state oxygen consumption. Differences between means were assessed by independent t-tests ( $\alpha = 0.05$ ).

**RESULTS:** Switching to the non-preferred gait pattern did not significantly increase the steady state oxygen consumption during running. There was no difference in stride frequency within subjects.

**CONCLUSIONS:** There was no difference in steady state oxygen consumption when switching from a preferred to a non-preferred gait pattern in running. Therefore, recommending a runner to switch strike patterns may not provide a benefit in metabolic cost.

---

**2949      Board #96      May 30      8:00 AM - 9:30 AM**  
**Long Range Correlations In Stride Time During Running To Volitional Fatigue**

Stacey Meardon, Timothy Derrick. *Iowa State University, Ames, IA.* (Sponsor: Greg Welk, FACSM)  
Email: smeardon@iastate.edu  
(No relationships reported)

Detrended fluctuation analysis (DFA) has been used to study long range correlations in running. Reduced strength of long range correlations implies a less patterned and more adaptable system. Understanding system adaptability may be important to performance enhancement and injury prevention. The effect of volitional fatigue on strength of long range correlations is unknown.

**PURPOSE:** To examine the strength of long range correlations over a prolonged run.

**METHODS:** A uni-axial low mass accelerometer was mounted to the distal anterior medial tibia of 9 runners (5 female, 4 male,  $64.3 \pm 11.1$  kg,  $171.9 \pm 14.1$  cm) to quantify impacts (1000 Hz). After warm up, subjects ran at their preferred 5K pace  $\pm 5\%$  on an indoor track to volitional fatigue. Biomechanical parameters were processed separately for three phases of the run to examine the effect of an exhaustive run; data from the first lap was omitted from analysis. The mean, standard deviation (SD), coefficient of variation (CV) and strength of long range correlations (alpha) using DFA were calculated for stride times in each phase. Cohen's d effect sizes (ES) were calculated on all variables.

**RESULTS:** Subjects ran an average of  $24.88 \pm 4.51$  min at  $3.65 \pm 0.35$  m/s. The average number of strides analyzed per phase was  $646 \pm 145$ . The mean alpha across all subjects and phases was  $.94 \pm .30$ . When compared to the beginning, alpha levels dropped in the mid portion of the run; they slightly increased at the end when compared to the middle (beginning =  $1.13 \pm .20$ , mid =  $.79 \pm .36$ , and end =  $.88 \pm .26$ ; ES beginning/mid = 1.20, ES mid/end = 1.12). Mean stride time remained consistent throughout the run ( $.70 \pm .06$ ,  $.69 \pm .06$ , and  $.69 \pm .05$ s). A small decrease in SD and CV was observed over time ( $.012 \pm .004$ ,  $.011 \pm .003$ ,  $.010 \pm .003$ s and  $1.71 \pm .61$ ,  $1.53 \pm .53$ ,  $1.48 \pm .49\%$ ).

**CONCLUSION:** A large effect of running to volitional fatigue was observed for alpha. Runners initially demonstrated persistent long range correlations consistent with a search strategy for correct running velocity and optimal stride characteristics. During the middle portion of the run, strength of long range correlations was reduced as a more adaptable running style emerged. Near the end of the run, more persistent long range correlations started to reappear as the runners' movement system became less adaptable reflecting a reduction in degrees of freedom.

**2950      Board #97      May 30      8:00 AM - 9:30 AM**

## Stride Length Influences Metabolic Cost During Walking In Obese Women

Elizabeth M. Russell, Allison H. Gruber, Barry Braun, FACSM, Joseph Hamill, FACSM. *University of Massachusetts, Amherst, MA.*

Email: erussell@kin.umass.edu

(No relationships reported)

At a given speed, humans habitually walk at the stride length (SL) and stride frequency (SF) combination that is the most economical. As the SL, and thus SF, deviates farther from the preferred, metabolic cost increases in a curvilinear fashion. However, this has only been tested across a wide range of SL's in a running gait, not walking, and in healthy populations, not obese. Biomechanical gait properties in obese persons differ from those in healthy persons and may cause a different metabolic cost profile across a range of SL's.

**PURPOSE:** To investigate how a wide range SL's, at a constant speed, influences the metabolic cost of walking in obese women.

**METHODS:** 10 obese and 10 healthy-weight women participated. Metabolic measures were recorded as subjects walked on a treadmill at a preferred pace until steady state  $\text{VO}_2$  was reached. Speed was controlled and a metronome paced SF such that subjects walked at SL's of 0%,  $\pm 5\%$ ,  $\pm 10\%$ ,  $\pm 15\%$  and  $\pm 20\%$  of their preferred length. Metabolic cost was measured as the average  $\text{VO}_2/\text{kg}$  value during the final two minutes of steady state. A mixed repeated measures ANOVA design ( $\alpha = 0.05$ ) was used to assess differences between groups and conditions.

**RESULTS:** Obese women walked slower and with shorter preferred SL's than healthy-weight women. Metabolic cost was minimized at or just above the preferred SL in healthy women and increased as SL deviated farther from the preferred. This U-shaped profile from -20% to +20% of the preferred SL was wider in the obese group. In obese women, metabolic cost was minimized across a wide range of SL's and only increased when SL deviated far from the preferred. Overall, an increase in SL from the preferred increased metabolic cost more than the same percent decrease in SL.

**CONCLUSIONS:** At a given speed, as SL deviates from the preferred SL metabolic cost increases because the limb oscillations are not operating at their natural pendular frequency, where energy inputs to the system are minimal. It is possible that the obese women did not show the same increases in metabolic cost as SL deviated from the preferred because, in an effort to control the greater inertial properties and lateral excursions of the lower limbs, the preferred SL did not match the pendular frequency of the limb.

---

### 2951 Board #98 May 30 8:00 AM - 9:30 AM Muscle Activity During Running At Reduced Body Weight.

Dana M. Forrest<sup>1</sup>, Janet S. Dufek, FACSM<sup>1</sup>, Kenji Masumoto<sup>2</sup>, John A. Mercer, FACSM<sup>1</sup>. <sup>1</sup>University of Nevada Las Vegas, Las Vegas, NV. <sup>2</sup>Kyushu University, Fukuoka, Japan.

(No relationships reported)

Running at reduced body weight (BW) may have rehabilitation advantages in that it may be possible to modulate the stress applied to the lower extremity. A unique treadmill has been designed to apply an upward directed force on the runner such that effective BW can be reduced. For example, the treadmill can be set to have the runner run at 60% of his/her BW. Recently, it has been reported that ground reaction forces (GRFs) are influenced by the variation of BW (Grabowski and Kram, JAB, 2008). The change in GRFs may be an indication that running style changes as BW is varied and we sought to understand the activity of lower extremity muscles as BW is manipulated.

**PURPOSE:** To determine if knee flexor and extensor muscle activity is influenced by 1) magnitude of effective BW and 2) intensity of exercise across BW conditions.

**METHODS:** Subjects ( $n=5$ ,  $26.4 \pm 10.6$  yrs;  $71 \pm 14.2$  kg,  $176 \pm 15.4$  cm) completed two minutes of running at 100, 90, 75 and 60% of BW at Rating of Perceived Exertion (RPE) levels of 11 (fairly light), 13 (somewhat hard) and 15 (hard). Order of conditions was RPE 11, 13 and 15 from highest (100%) to lowest (60%) BW. Prior to testing, subjects completed a familiarization period where they ran at different speeds and effective BWs. Measurement began by placing electromyography (EMG) electrodes on the belly of the rectus femoris (RF) and biceps femoris (BF). Data were collected (1000 Hz) during the final 30 seconds of each 2 minute run. EMG data were reduced by removing any zero offset, full wave rectifying, and then averaging muscle activity across 30 seconds. Dependent variables (average RF and BF muscle activity) were analyzed using a 3 (RPE: 11, 13, 15) x 4 (BW: 100, 90, 75, 60%) repeated measures analysis of variance.

**RESULTS:** Neither muscle was influenced by the interaction of BW and RPE ( $p > 0.05$ ). RF and BF muscle activity increased across RPE levels ( $p < 0.05$ ).

**CONCLUSIONS:** Muscle activity was not influenced by changes in BW when subjects were allowed to adjust treadmill speed to select a specific RPE. In general, subjects selected a faster running speed as BW was reduced and/or RPE increased. The faster running speed per reduction in effective BW offset any potential reduction of muscle demand. The treadmill used in the study was provided by Alter-G, Inc.

### 2952 Board #99 May 30 8:00 AM - 9:30 AM Foot Arch Kinematics; Differences Between Barefoot And With Footwear

Mako FUKANO, Toru Fukubayashi, Yasuharu Nagano. *Waseda University, Saitama, Japan.*

Email: mako@akane.waseda.jp

(No relationships reported)

**INTRODUCTION:** The relationship of athletes and footwear is important to sports performance. However, there is little information the effects of footwear on the foot arch kinematics which acts as a shock attenuator. The reasons include the foot is covered by sock or footwear; we cannot observe the foot motion from the outside.

**PURPOSE:** The purpose of this study was to demonstrate the footwear effects on the sagittal plane kinematics of the medial and lateral longitudinal arch during single leg landing using cineangiography.

**METHODS:** Ten healthy male and seven healthy female subjects participated in this study (males; age:  $21.7 \pm 3.4$  y.o., height:  $172.6 \pm 6.8$  cm, weight:  $61.9 \pm 6.0$  kg, females; age:  $22.3 \pm 3.8$  y.o., height:  $167.8 \pm 11.3$  cm, weight:  $58.3 \pm 14.8$  kg). IRB approved informed consent was obtained from all subjects. All subjects performed single leg landing from a height of 10cm with the knee extended under two conditions; barefoot and shod. Subjects were asked to stop and balanced after landing. All trials were recorded using cineangiography. Images were obtained at rate of 60Hz. Simultaneous vertical ground reaction force was measured using a force plate. Data were analyzed using graphic software. The sagittal plane motion of the foot arch was defined as the angular change and translational motion observed after landing. A paired t-test was performed to determine differences between barefoot and shod conditions. Significance was set at  $p < 0.05$ .

**RESULTS:** The angle variation of the lateral arch in shod condition was significantly smaller than that of barefoot (males;  $5.1 \pm 2.0^\circ$  (shod),  $7.9 \pm 3.2^\circ$  (barefoot), females;  $5.7 \pm 1.6^\circ$  (shod),  $11.5 \pm 1.9^\circ$  (barefoot)). On the other hand, the medial angle change did not have a significant difference (males;  $2.4 \pm 1.6^\circ$  (shod),  $3.5 \pm 3.3^\circ$  (barefoot), females;  $5.3 \pm 1.7^\circ$  (shod),  $7.8 \pm 2.1^\circ$  (barefoot)). The maximum vertical ground reaction force was reduced in shod condition.

**CONCLUSIONS:** This study suggests that footwear effects a change in the kinematics of the longitudinal arches during landing.

**Identification Of A Possible Genetic Risk Factor For The Fibromyalgia Syndrome**

Jonathan C. Reeser, FACSM, Catherine A. McCarty, Terrie Kitchner. *Marshfield Clinic, Marshfield, WI.*  
Email: reeser.jonathan@marshfieldclinic.org  
(No relationships reported)

The fibromyalgia syndrome (FMS) is an incompletely understood musculoskeletal pain condition that affects 2-6% of the population. Patients with FMS complain of widespread muscular pain and tenderness, in addition to fatigue, disordered sleep, headache, depression, irritable bowel and bladder, and temporomandibular joint discomfort. Clinically, FMS shares many phenotypic traits with post-concussive syndrome. FMS has been shown to have a genetic component, but does not follow simple Mendelian inheritance patterns.

**PURPOSE:** To determine whether the Apolipoprotein E4 allele may be a genetic risk factor for FMS.

**METHODS:** 150 cases of fibromyalgia were identified according to a strict phenotypic definition from among the nearly 20,000 subjects enrolled in the Marshfield Clinic Research Foundation's Personalized Medicine Research Project (PMRP) - the largest population-based biobank in the United States. Age and gender matched controls were identified from the PMRP in a 2:1 control:case ratio. The ApoE genotype for cases and controls was determined by single nucleotide polymorphism (SNP) analysis using SNPs rs7412 and rs429358. Relevant historical data were abstracted from the Clinic's electronic medical record.

**RESULTS:** Approximately one quarter of the cases and controls were found to carry at least one ApoE4 allele. However, the prevalence of the ApoE4 allele was significantly greater among those cases who had ever been in a motor vehicle accident (MVA) (28% vs 14% of controls,  $p < 0.001$ ), and among those cases who had ever smoked (41% vs 25% of controls,  $p < 0.001$ ).

**CONCLUSION:** These data strongly suggest that specific interactions between genetically susceptible individuals (e.g. those with at least one copy of the ApoE4 allele) and the environment (e.g. a history of MVA, or of ever smoking) may contribute to the risk of developing FMS.

**Effect Of Long-term Physical Activity On Health In Twins: A 30-year Longitudinal Study**

Katja Waller<sup>1</sup>, Urho M. Kujala<sup>1</sup>, Jaakko Kaprio<sup>2</sup>, Markku Koskenvuo<sup>2</sup>, Taina Rantanen<sup>1</sup>. <sup>1</sup>*University of Jyväskylä, Jyväskylä, Finland.* <sup>2</sup>*University of Helsinki, Helsinki, Finland.*  
(No relationships reported)

**PURPOSE:** Physical activity has many positive and some negative effects on health. The main aim of this study was to find out whether persistent leisure time physical activity, adjusted for genetic liability and childhood experiences, protects against chronic diseases, early signs of disability and loss of life satisfaction.

**METHODS:** From 5663 healthy adult twin pairs 146 pairs were identified who were discordant for both intensity and volume of leisure physical activity in 1975 and 1981. Of them, both members of 95 pairs were alive and participated in our follow-up study in 2005 when different chronic diseases, life-satisfaction, disability and physical activity level were assessed by a structured telephone interview. Mean age of the participants was 58 years (range from 47 to 79 years) in 2005. Paired tests were used in statistical analyses.

**RESULTS:** Active co-twins had decreased risk of different chronic diseases with active MZ twins having significantly less often two or more chronic diseases than their inactive cotwins (OR=0.14,  $p=0.031$ ). Overall, the risk of type 2 diabetes or glucose intolerance (OR= 0.09,  $p=0.022$ ) and incident elevated blood pressure (OR=0.46,  $p=0.039$ ) was decreased among active cotwins. Active cotwins were more satisfied with their life at follow-up ( $p=0.047$ ), and tended to need less hospital care during the last three years of the follow-up ( $p=0.065$ ). In contrast, active co-twins showed a tendency of having more sports-related injuries (OR=1.9,  $p=0.051$ ), but signs of disability did not differ according to activity.

**CONCLUSIONS:** Physical activity may help in maintaining health and life satisfaction. However, genetic factors may play a role in explaining some of the association between disease occurrence and physical activity as some of the findings were more clear among physical activity discordant dizygotic than monozygotic twins.

**Leisure Time Physical Activity And Body Fat: A Twin Study**

Tuija Leskinen<sup>1</sup>, Sarianna Sipilä<sup>1</sup>, Markku Alen<sup>2</sup>, Sulin Cheng<sup>1</sup>, Kirsi H. Pietiläinen<sup>3</sup>, Jussi-Pekka Usenius<sup>4</sup>, Harri Suominen<sup>1</sup>, Vuokko Kovanen<sup>1</sup>, Heikki Kainulainen<sup>1</sup>, Jaakko Kaprio<sup>3</sup>, Urho M. Kujala<sup>1</sup>. <sup>1</sup>*University of Jyväskylä, Jyväskylä, Finland.* <sup>2</sup>*University of Oulu, Oulu, Finland.* <sup>3</sup>*University of Helsinki, Helsinki, Finland.* <sup>4</sup>*Suomen Terveystalo Oyj, Jyväskylä, Finland.*  
(No relationships reported)

Exercise is thought to reduce body fat, but intervention studies are frequently limited by short follow-ups and observational studies by genetic selection. To tackle these problems, we carried out within-pair analyses in twin pairs identified on the basis of their long-term physical activity discordance. By studying both monozygotic and dizygotic twin pairs, we were able to control for childhood environment and partially for genetic liability as monozygotic co-twins share all and dizygotic co-twins on average half of their segregating genes.

**PURPOSE:** To study the effects of a physically inactive vs. active lifestyle on body fat in twin pairs discordant for physical activity for 32 years.

**METHODS:** Sixteen middle-aged (50-74 yrs) same-sex twin pairs (seven monozygotic, nine dizygotic) discordant for physical activity habits were comprehensively identified from the Finnish Twin Cohort ( $N=5663$  baseline healthy pairs). Discordance was initially defined in 1975 and the same co-twin remained significantly more active during most of the follow-up. At the end of the follow-up in 2007 a series of body composition measurements, including bioimpedance measurement of whole body fat and specific MR imaging, was carried out.

**RESULTS:** At the end of the follow-up the inactive co-twins weighed 6.5 kg more ( $P=0.12$ ) and had 6.0 kg more fat mass ( $P=0.015$ ) than their active co-twins, but no differences in fat-free masses were found. Visceral fat area was 50 % ( $P=0.010$ ), liver fat score 170 % ( $P=0.030$ ) and midhigh intramuscular fat area 48 % ( $P=0.034$ ) greater among the inactive co-twins. Similar trends were seen among both monozygotic and dizygotic pairs. The intrapair difference correlation between visceral and intramuscular fat was high ( $r=0.648$ ,  $P=0.009$ ).

**CONCLUSION:** Long-term habitual physical activity seems to protect from the accumulation of total, visceral and ectopic fat, even after partly controlling for genetic liability and childhood environment. Therefore the prevention of obesity should emphasize the role of regular leisure time activity.

(No relationships reported)

Little is known of the interactions between genetic and environmental factors that may contribute to elevate one's risk of metabolic syndrome.

**PURPOSE:** To investigate the interactive effect of adiposity-related genotypes and Body Mass Index (BMI) on markers for metabolic syndrome.

**METHODS:** Young adult Caucasians from the FMS cohort (n= 370) were measured on the following metabolic phenotypes: fasting glucose (GLU), fasting insulin (INS) and HOMA-IR, and were genotyped for the following adiposity-related gene polymorphisms: TNFa (G308A), LEPR (A150124G), and RETN (C-179G, A-296G, C30T, A537C, G540A, C980G). Gender-specific ANCOVAs including age as a covariate and a genotype x BMI interaction term was performed on each metabolic phenotype. Significant interactions were evaluated by pairwise testing of the slopes for each genotype group.

**RESULTS:** A BMI x Genotype interaction for INS was found in males for RETN C-179G (G/G (n=18) vs. C/C (n=46), p=0.03 and C/G (n=56), p=0.005) and RETN A537C (A/A (n=108) vs. A/C (n=12), p=0.005). A BMI X Genotype interaction for GLU was found in males for LEPR (A/A (n=46) vs. GG (n=6), p=0.03 and A/G (n=33), p=0.03), RETN A-296C (A/A (n=108) vs. A/C (n=12), p=0.01) , RETN G540A (G/G(n=55) vs. G/A (n=53), p=0.02), and modestly in TNFA (G/G (n=83) vs. G/A (n=36), p=0.051). Only RETN C30T (C/C (n=242) vs. C/T (n=8), p=0.03) was identified in females. BMI X Genotype interactions for HOMA-IR were found only in males for RETN C-179G (G/G (n=18) vs. C/C (n=46), p=0.02 and C/G (n=56), p=0.003) and RETN A537C (A/A (n=108) vs. A/C (n=12), p=0.0006).

**CONCLUSIONS:** The interactive effects of BMI and adiposity-related gene polymorphisms on markers for metabolic syndrome suggest that the influence of excess body weight on risk of metabolic syndrome is not uniform in individuals with different genotypes. Additional research is needed to confirm these findings and further clarify those with heightened risk.

(No relationships reported)

**PURPOSE:** The present study examined associations among vitamin D receptor (VDR) polymorphisms and the muscle size and strength response to a unilateral, upper-arm resistance training (RT) program in healthy, young adults.

**METHODS:** Caucasian men (n=236) and women (n=356) were genotyped for three VDR single nucleotide polymorphisms: TAQI (rs7975232), BSMI (rs1544410), and FOKI (rs2228570). Subjects underwent a RT program of the non-dominant arm (trained, T) with the dominant arm (untrained, UT) as a comparison. Elbow flexor strength was measured with one repetition maximum (IRM) and maximum voluntary contraction (MVC), while cross-sectional area (CSA) was measured by magnetic resonance imaging in both arms pre- and post-RT. Phenotypes were analyzed using analysis of covariance with gender and genotype as fixed factors and body mass index and age as covariates.

**RESULTS:** CSA: In the T arm, men with the TAQI TT (22.4%) and CT (20.4%) genotypes had greater % CSA increases versus men with the CC genotype (15.0%) pre- to post-RT (p<0.05). IRM: In the T arm, women with the TAQI CC (76.1%) genotype experienced greater % IRM increases than women with the TAQI CT (61.1%) and TAQI TT (63.0%) genotypes pre- to post-RT (p<0.05). Pre-RT IRM of the T arm was lower among women with the FOKI AA genotype compared to women with the FOKI GG genotype (13.1 ± 0.5 vs 14.4 ± 0.3 kg, respectively) (p<0.05). However, women with the FOKI AA genotype gained more IRM strength (74.7%) in the T arm post-RT versus women with the FOKI GG (60.5%) genotype (p<0.05). MVC: Pre-RT MVC of the T arm was lower in men with the FOKI GG genotype than men with the FOKI GA and AA genotypes (129.4 ± 5.4 vs 146.1 ± 3.9 vs 141.4 ± 7.6 kg, respectively) (p<0.05). However, men with the FOKI GG (20.8%) genotype gained more MVC strength than men with the FOKI AA (11.1%) genotype in the T arm post-RT (p<0.05).

**CONCLUSIONS:** VDR SNPs contribute to gender-specific, individual variation in baseline muscle strength and gains in muscle strength and size resulting from RT. Potential mechanisms may be linked to differences in VDR genotype influencing skeletal muscle calcium uptake, cell proliferation, and/or differentiation.

**2958 Board #105 May 30 9:30 AM - 11:00 AM**  
**Body Fatness And Fitness Modulate The Associations Between The Gnb3 Genotype And Resting Blood Pressures In Korean Women**

Hyun-Sik Kang, Soohyun Park, Jin-Kyung Cho, Tae-Kyung Kim, Su-Jin Lee. *Sungkyunkwan University, Suwon, Republic of Korea.*  
Email: hkang@skku.edu  
(No relationships reported)

Unlike in Caucasians and black Africans, the relationships between the C825T allele variant in exon 10 of the G protein b3 gene (GNB3) and blood pressures are inconsistent in Asians.

**PURPOSE:** To investigate whether or not the GNB3 genotype is differently associated with resting blood pressures and body fatness across cardio/respiratory fitness (CRF) levels. **METHODS:** A total of 727 Korean women aged 31-60 years (mean age, 47.8±5.4 yrs old) voluntarily participated in the study. Body fatness and fitness and resting blood pressure were measured by using standardized protocols. The GNB3 genotype (C825T) was determined by using polymerase chain reaction-restriction fragment length polymorphism.

**RESULTS:** For the obese group with body mass index of ≥25 kg/m<sup>2</sup>, subgroup analyses showed that TT individuals were younger (P =0.049 & P=0.002, respectively) and had significantly higher values in body weight (P=0.006 & P=0.006, respectively) and BMI (P=0.002 & P=0.011, respectively) than CC and CT individuals. Further, TT and CT individuals tended to have higher values in CRF than CC individuals. Regression analyses showed that the relationships between the GNB3 genotype and resting blood pressures remained significant even after adjustments for age and menopause, but the relationships were no longer significant when additionally controlling for body fatness.

**CONCLUSION:** The findings of this study suggest that both body fatness and CRF might differently influence the genetic susceptibility of the GNB3 genotype to elevated resting blood pressures in middle-aged Korean women.

Supported by the Korean Research Foundation funded by the Korean Government (KRF-2005-042-G00025)

**2959 Board #106 May 30 9:30 AM - 11:00 AM**  
**Actn3 Genotype Is Not Associated With Muscle Fatigue Performance**

Erik D. Hanson, Andrew T. Ludlow, Andrew K. Sheaff, Jaebum Park, Stephen M. Roth, FACSM. *University of Maryland, College Park, MD.*  
Email: edhanson@umd.edu  
(No relationships reported)

The R577X polymorphism within the alpha-actinin-3 gene (*ACTN3*) has been associated with elite athletic performance, and more recently with muscle strength, muscle power, fat free mass, and adaptations to strength training, though inconsistencies exist in the literature. The specific skeletal muscle phenotypes most influenced by the polymorphism are uncertain.

**PURPOSE:** To examine the association between *ACTN3* R577X genotype and muscle fatigue performance phenotypes in young men and women.

**METHODS:** Forty-one healthy and recreationally active (less than 60 minutes of aerobic exercise per week, no lower body strength training) individuals (n=15 men; n=26 women), aged 18-30 yr. (mean: 22 yr.) participated in this study. Muscle fatigue performance was assessed using two **METHODS:** 1) a 30 repetition knee extension (KE) and knee flexion fatigue protocol on an isokinetic dynamometer at testing speeds of 180 deg/sec and 250 deg/sec, and 2) a 30 second Wingate Anaerobic Cycling Test (WAnT). Differences in absolute and relative peak power, peak torque, total work, and fatigue index were compared among *ACTN3* genotype groups.

**RESULTS:** Sample sizes for each genotype group were as follows: RR = 18; RX = 17; XX = 6. Isokinetic torque and WAnT cycling power values significantly decreased over the duration of each test (both  $P < 0.05$ ), but no significant differences were observed among *ACTN3* genotype groups. Similarly, no significant genotype differences (RR vs. RX vs. XX, respectively) were observed for: KE peak torque (180 deg/sec  $51.2 \pm 5.3$  vs.  $48.4 \pm 4.6$  vs.  $52.4 \pm 6.7$  Nm; 250 deg/sec  $29.3 \pm 2.8$  vs.  $30.7 \pm 3.8$  vs.  $33.2 \pm 8.4$  Nm); WAnT absolute peak power ( $613.8 \pm 53.7$  vs.  $598.5 \pm 61.0$  vs.  $677.6 \pm 103.9$  W); relative peak power ( $9.1 \pm 0.4$  vs.  $8.7 \pm 0.5$  vs.  $8.8 \pm 0.9$  W/kg); total work ( $11.1 \pm 1.1$  vs.  $9.9 \pm 1.2$  vs.  $12.0 \pm 1.4$  kJ); or fatigue index (WAnT  $62.3 \pm 1.5$  vs.  $63.9 \pm 2.2$  vs.  $58.9 \pm 4.2\%$ ).

**CONCLUSIONS:** The present results indicate that in recreationally active individuals the *ACTN3* R577X polymorphism is not associated with muscle fatigue performance phenotypes.

*This study was Supported by NIH grants AG022791 and AG00268.*

**Visfatin Genotypes Influence Glucose And Obesity-related Variables And Their Aerobic Exercise Training Responses**

Jennifer A. McKenzie<sup>1</sup>, Sarah Witkowski<sup>2</sup>, Andrew T. Ludlow<sup>2</sup>, Stephen M. Roth, FACSM<sup>2</sup>, James M. Hagberg, FACSM<sup>2</sup>. <sup>1</sup>McDaniel College, Westminster, MD. <sup>2</sup>University of Maryland, School of Public Health, College Park, MD.  
(No relationships reported)

Previous research has linked the proposed adipokine visfatin and its gene (PBEF1) polymorphisms with glucose and obesity-related conditions; however, no one has examined them in connection with aerobic exercise training in generally healthy older individuals.

**PURPOSE:** To determine whether PBEF1 polymorphisms are associated with the response of glucose and obesity-related variables to aerobic exercise training.

**METHODS:** Following the completion of 6 wks of dietary stabilization, 116 healthy, sedentary, middle-aged, Caucasian men and women underwent 24 wks of aerobic exercise training. DEXA was used to assess body composition, and oral glucose tolerance testing was used to determine glucose and insulin response variables, including total area under the curve (AUC) and insulin sensitivity (IS), before and after 6 months of aerobic exercise training. TaqMan and RFLP assays were used to determine PBEF1 genotypes, and ANCOVA was used to test for differences between genotype groups.

**RESULTS:** There were several associations at baseline between glucose and obesity-related variables and the PBEF1 polymorphisms. The -4689 (rs2110385) TT genotype group had lower insulin AUC ( $p < 0.01$ ) and higher IS ( $p < 0.02$ ) values than the GG genotype group, whereas PBEF1 -1001 (rs9770242) G allele carriers had lower fasting insulin ( $p < 0.03$ ), lower body mass index (BMI;  $p < 0.02$ ), and higher IS values than the TT genotype group ( $p = 0.04$ ). Additionally, the -948 T allele carriers group had lower glucose AUC ( $p = 0.03$ ), lower insulin AUC ( $p < 0.02$ ), and higher IS values than the GG genotype group ( $p < 0.02$ ). Finally, the SER301SER (rs2302559) TT genotype group had lower fasting insulin ( $p < 0.02$ ), lower insulin AUC ( $p < 0.01$ ), and higher IS ( $p < 0.01$ ) values than the CC genotype group. The SER301SER polymorphism also influenced aerobic exercise training-induced changes in percent body fat ( $p < 0.02$ ) and BMI ( $p = 0.03$ ).

**CONCLUSIONS:** Our results suggest that variation at the PBEF1 locus is associated with baseline and aerobic exercise training-induced changes in glucose and obesity-related variables. Future studies need to address the physiological mechanisms and functional significance of visfatin polymorphic variation.

(No relationships reported)

The influence of ACE gene on athletic performance has been widely explored. Most published data concern to a polymorphism in the presence (insertion, I allele) or absence (deletion, D allele) of a 287-bp in intron 16 that determines ACE levels in serum and tissues, heart cells included. A higher I allele frequency has been reported amongst elite endurance athletes and a higher D allele frequency amongst those engaged in more power-orientated sports. However, such associations has not been well clarified in swimming, particularly in pool competitions events, ranged between 50m to 1500m, or in longer duration trials, such in triathlon.

**PURPOSE:** To examine the role of ACE I/D amongst Portuguese elite swimmers and triathletes with diverse competitive distance specialization and compared to healthy control subjects.

**METHODS:** The study groups included 39 swimmers (22 male and 17 female,  $18.84 \pm 2.97$  years) and 25 triathletes (16 male and 9 female  $18.491 \pm 3.086$  years), both groups representing over than 75% of the elite Portuguese swimmers and triathletes (Olympic candidates). The athletes were stratified into 3 homogeneous groups based on sporting discipline and actual duration of their event: short duration athletes - SDA (between 50m and 200m swim events, predominantly anaerobic, swimmers, n=25); medium duration athletes - MDA (over 400m to 1500m swim events, mixed: anaerobic/aerobic, swimmers, n=14); long duration athletes - LDA (1500m and above swim events, predominantly aerobic, triathletes, n=25). A control group (n=100) was selected from the Portuguese population. Chelex 100® was used for DNA extraction and PCR-RFLP methods determined the genotype.

**RESULTS:** Significant differences were found between elite SDA and controls among DD genotype groups ( $P = 0.029$ ) and alleles (I/D) frequencies ( $P = 0.021$ ). In addition, there was a significant decrease in the frequency of the D allele with swimming distance increase: between SDA and MDA ( $P < 0.001$ ) and between SDA and LDA ( $P < 0.001$ ).

**CONCLUSIONS:** These data are consistent with an association between the D allele and short mainly anaerobic swimming events.

**Angiotensin-I Converting Enzyme Genotype Does Not Strongly Correlate With Elite Endurance Athlete Status In Ethiopians**

Garrett I. Ash<sup>1</sup>, Robert A. Scott<sup>2</sup>, Tom A. Dawson<sup>1</sup>, Bezubih Wolde<sup>3</sup>, Zeru Bekele<sup>3</sup>, Solomon Teku<sup>3</sup>, Yannis P. Pitsiladis<sup>4</sup>. <sup>1</sup>Oxford University, Oxford, United Kingdom. <sup>2</sup>University of Glasgow, Glasgow, United Kingdom. <sup>3</sup>Addis Ababa University, Addis Ababa, Ethiopia. <sup>4</sup>Glasgow University, Glasgow, United Kingdom.

Email: garrett.ash@dpag.ox.ac.uk

(No relationships reported)

There has been considerable interest over recent years in the use of the Angiotensin-I Converting Enzyme (ACE) gene as a marker of athletic performance. A previous study found no difference in ACE polymorphism between elite Kenyan endurance runners and demographically-matched controls (Scott et al. Comp Biochem Physiol A Mol Integr Physiol 141(2):169-175, 2005), a result that was somewhat surprising in view of contrasting findings in Caucasian populations.

**PURPOSE:** To investigate the association between ACE polymorphisms and elite endurance athlete status in Ethiopians.

**METHODS:** DNA was extracted from buccal swabs collected from 114 members of the Ethiopian national athletics team (E), 315 individuals representative of the general Ethiopian population (C), and 93 individuals from the Arsi region (A), where the majority of elite Ethiopian distance runners originate.

**RESULTS:** There were no significant deviations from Hardy-Weinberg equilibrium in athletes or controls. Ethiopian athletes did not differ significantly from general controls ( $P = 0.076$ ) or Arsi ( $P = 0.87$ ) in their ACE ID genotype frequencies (E: 16% II, C: 8% II, A: 13% II). The tendency towards significance in ID genotype frequency between athletes and general controls was not replicated in ACE 22982 genotype (E: 13% AA, C: 12% AA, A: 13% AA), where no significant differences were found (E vs C:  $P = 0.95$ , E vs A:  $P = 0.73$ ).

**CONCLUSIONS:** As previously shown in elite Kenyan athletes, the ACE genotype is not directly associated with elite endurance status in Ethiopians. The tendency towards significance in ID genotype frequency between athletes and general controls may be a reflection of the region of Arsi where the majority of Ethiopian athletes originate.

**Physical Activity Ancestry Affects Body Composition Phenotypes And Gene Expression In Mice Offspring**

Andrew T. Ludlow, Pallavi Nadendla, Sarah Witkowski, Lindsay M. Wohlers, Espen E. Spangenburg, Stephen M. Roth, FACSM. *University of Maryland, College Park, MD.*

Email: aludlow@umd.edu

(No relationships reported)

**PURPOSE:** To investigate the possible role of physical activity ancestry on body composition phenotypes and gene expression in multiple tissues (e.g., skeletal muscle, brain).

**METHODS:** We initiated a breeding program in Balb/C mice in which half of the first generation (F0) was subjected to voluntary wheel running for 12 weeks prior to breeding, with the second half of animals housed in sedentary conditions. The breeding pairs and pregnant females continued to have access to the running wheel. The resulting F1 pups of both groups were sacrificed at 10 wks without having an exercise exposure. A number of tissues were removed including gastrocnemius muscle and hippocampus.

**RESULTS:** The physically active animals successfully performed the intervention, running an average of 7 km/day (males) and 10 km/day (females) during the period leading up to breeding. The 10 wk-old F1 offspring with physical activity ancestry ( $n=6$ ) exhibited lower values for body weight (males:  $18.6 \pm 0.1$  vs.  $20.1 \pm 0.5$  g; females:  $23.6 \pm 0.3$  vs.  $25.8 \pm 0.4$  g), visceral fat pad mass (males:  $0.26 \pm 0.04$  vs.  $0.37 \pm 0.03$  g; females:  $0.30 \pm 0.08$  vs.  $0.58 \pm 0.18$  g), and gastrocnemius muscle mass (males:  $0.07 \pm 0.01$  vs.  $0.14 \pm 0.03$  g; females:  $0.11 \pm 0.02$  vs.  $0.16 \pm 0.01$  g) compared to F1 offspring with sedentary ancestry ( $n=7$ ). Higher levels of gastrocnemius muscle mRNA were observed for the *Ppargc1a* (PGC-1 $\alpha$ ) gene in the F1 offspring with exercise ancestry compared to F1 sedentary ancestry offspring. Similarly, higher levels of hippocampus mRNA were observed for the *Bdnf* gene in the F1 offspring with exercise ancestry compared to F1 sedentary ancestry offspring.

**CONCLUSION:** These preliminary data support the hypothesis that physical activity ancestry can affect both body composition and gene expression in mice offspring, with elevated expression of metabolic and neurotrophic genes compared to offspring of sedentary animals.

Funding was provided by the SPH Seed Grant Program and NIH AG00268.

**Gene Expression Analysis Of Peripheral Blood Following Resistance Exercise**

Lara A. Carlson<sup>1</sup>, Nicholas W. Westcott<sup>1</sup>, Travis J. Martell<sup>1</sup>, Vanessa L. Carter<sup>1</sup>, Blair S. Marelli<sup>1</sup>, Scott W. Tighe<sup>2</sup>. <sup>1</sup>Castleton State College, Castleton, VT. <sup>2</sup>University of Vermont, Burlington, VT. (Sponsor: Samuel Headley, FACSM)

Email: lara.carlson@castleton.edu

(No relationships reported)

**PURPOSE:** Phenotypic studies suggest a strong correlation between exhaustive resistance exercise and effects on the immune system. The goal of this study was to characterize the gene expression changes using Affymetrix microarrays during these exercise regimens and determine whether these expression changes correlate to standard differential blood counts or other immunophenotyping data.

**METHODS:** Ten resistance-trained male collegiate athletes between 20-24 yr of age ( $22.30 \pm 1.25$  yr) with at least 2 yr resistance training experience ( $5.00 \pm 2.31$  yr) performed an acute bout of RE for 30.59 min ( $\pm 0.59$ ). The RE included the back parallel squat and the leg press each at 45% & 55% of 1-RM for first 2 sets, and 65% of 1-RM for the remaining 4 sets. All exercises were performed with a 2.2 cadence followed by 2 min rest periods. Following a 12 hr fast, blood samples were collected at baseline, immediately following exercise, and at 2 hr postexercise. RNA was prepared by combining 3.75 ml of TriReagent BD to 1 ml of whole blood containing EDTA immediately after sampling and frozen at  $-80^{\circ}\text{C}$ . RNA was extracted using the standard blood method outlined by the manufacturer, analyzed for quality, and prepared for hybridization to an Affymetrix U133a 2.0 GeneChip using the NuGEN Ovation WB system.

**RESULTS:** Initial results of our microarray data indicate that, with high statistical significance, gene expression features are highly correlated with blood counts. Differentially expressed genes were statistically significantly associated with immune system function.

**CONCLUSION:** These data suggest that an acute bout of RE induced substantial changes in immune system function that was reflected in differential gene expression.

Support made possible by the Vermont Genetics Network through Grant Number P20 RR16462 from the INBRE Program of the National Center for Research Resources (NCRR), a component of the National Institutes of Health (NIH). (No relationships reported)

Atrogin-1 is an important regulator of the atrophy response pathway. It directs the breakdown of muscle protein in response to various conditions (ex. disuse, cancer, starvation), and it is down-regulated during the hypertrophy response. Consequently, it has strong potential as a modifier of muscle size and strength.

**PURPOSE:** To examine the effects of single nucleotide polymorphisms (SNPs) in the human Atrogin-1 gene on muscle size and strength and the response of these variables to a strength training program in a young, college-age population.

**METHODS:** We genotyped five Atrogin-1 SNPs (rs4871385, rs6990663, rs3739287, rs22891779, rs16898553) in a Caucasian population (446 females; 312 males; age  $24 \pm 8$  y) that participated in a 12 wk supervised resistance training program. Baseline muscle size (via MRI) and strength (isometric and 1-RM) were measured for each subject at the start of the study and again after the completion of the training program. Genotyping for the Atrogin-1 SNPs was performed using the TaqMan (Applied Biosystems) allele discrimination assay. Associations between the SNP and each phenotype were tested using ANCOVA with Sidak post-hoc tests. Each model included baseline body weight and age as covariates.

**RESULTS:** We found significant associations between Atrogin-1 SNPs and several muscle phenotypes. The most significant results were found in females with the rs2891779 SNP, which is located in the putative promoter region of the Atrogin-1 gene. Specifically, when a dominant model was applied, females having 1 or 2 copies of the A allele had significantly higher baseline isometric strength, torque, and muscle quality than those who were homozygous for the G allele. These same associations were seen in both the dominant and non-dominant arms.

**CONCLUSIONS:** This data suggests that the Atrogin-1 rs2891779 SNP influences baseline muscle strength, torque, and muscle quality in females, which may indicate a sex-specific effect for this SNP. The location of this SNP in the promoter region of Atrogin-1 suggests that it may exert its influence through regulation of Atrogin-1 expression. This data contributes additional insight to the complex genetic milieu that affects muscle size and strength.

**The Physical Fitness Is Associated With Pgc-1 Gene Gly482ser Polymorphism In Japanese Elderly.**

Takuro Tobina, Yukari Mori, Fuki Nakayama, Yukiko Doi, Akira Kiyonaga, Hiroaki Tanaka. *Fukuoka University, Fukuoka, Japan.*

Email: tobitaku@ck9.so-net.ne.jp

(No relationships reported)

Mitochondria are predominant organ to provide ATP to working muscle during endurance exercise. The muscle mitochondrial content and function could be influence endurance performance. PGC-1 $\alpha$  plays as a stronger activator of mitochondrial biogenesis, thus, the activation of PGC-1 $\alpha$  expression could be key factor to improve a physical fitness. Muscle PGC-1 $\alpha$  and PGC-1 $\beta$  gene expression are affected by the Gly482Ser gene polymorphism. The PGC-1 gene Gly482Ser polymorphism could influence muscle mitochondrial content and function, the gene polymorphisms determine human physical fitness.

**PURPOSE:** To determine whether the PGC-1 gene Gly482Ser polymorphism affects physical fitness and trainability in Japanese elderly.

**METHODS:** Two hundreds forty six subjects (96 men and 150 women) were participated in cross sectional study. In 184 subjects (75 men and 109 women) carried out exercise training for 12 weeks at lactate threshold (LT) intensity. The LT intensity was evaluation as physical fitness. Values were compared by ANCOVA and Tukey-Kramer. Age, baseline of LT and training volume were adjusted.

**RESULTS:** The distributions of Gly482Ser polymorphism are in Hardy-Weinberg equilibrium (Gly/Gly: 62, Gly/Ser: 129, Ser/Ser: 55 in cross sectional study, Gly/Gly: 46, Gly/Ser: 94, Ser/Ser: 44 in training study). The age, men-women ratio, height, weight and training time were no significant difference among the genotypes. Physical fitness is significantly higher in Gly/Gly+Gly/Ser ( $4.7 \pm 0.9$  METs) than Ser/Ser ( $4.4 \pm 0.9$  METs) in cross sectional study and baseline of training study (Gly/Gly+Gly/Ser:  $4.8 \pm 0.9$  METs, Ser/Ser:  $4.4 \pm 0.9$  METs). However, the training effect of physical fitness is no significant difference among the genotypes.

**CONCLUSION:** The PGC-1 gene Gly482Ser polymorphism is weakly influence physical fitness in Japanese elderly.

**Aquaporin-1 Gene Polymorphism Association With Acute Body Fluid Loss In Long Distance Runners**

Juan L. Martinez Barreda<sup>1</sup>, Cesar Gomez Ruiz<sup>2</sup>, Angel Delgado<sup>2</sup>, Carlos Perez<sup>2</sup>, Miguel A. Rivera, FACSM<sup>3</sup>. <sup>1</sup>Instituto Sinaloense del Deporte, Culiacan, Mexico. <sup>2</sup>University of Puerto Rico, Rio Piedras, Puerto Rico. <sup>3</sup>School of Medicine University of Puerto Rico, San Juan, Puerto Rico.

(No relationships reported)

Intrinsic body fluid regulation is critical for optimizing endurance performance. Aquaporins (AQPs) are a family of transmembrane proteins that transport water and glycerol across cellular membranes. A recent report (MSSE 37(5): S164, 2005) revealed an association between a single nucleotide polymorphisms (SNP) in the Aquaporin-1 (AQP1) gene and endurance performance.

**PURPOSE:** This study explored the association between the AQP1 SNP and acute body fluid loss in long distance runners.

**METHODS:** The subjects (N = 91, Age =  $26 \pm 3$  yrs; Ht =  $170 \pm 11$  cm; Wt =  $61 \pm 5$  kg) were biologically unrelated male long distance runners. Data were collected before and after an international 10km road race. Body fluid loss was determined by the difference between "naked weights" before and after the 10km run. The AQP1 (G  $\rightarrow$  C) gene variation was detected by the tetra-primer Amplification Refractory Mutation System Polymerase Chain Reaction (ARMS-PCR) procedure. Genotypes were determined by PCR product size.

**RESULTS:** The three expected genotypes for the AQP1 were observed and consistent with a Hardy-Weinberg equilibrium. Carriers of the AQP1 SNP had a significantly greater adjusted body fluid loss ( $3.7 \pm 0.9$  kg) than non-carriers ( $1.5 \pm 1.1$  kg) ( $P < 0.05$ ). No significant associations were observed between genotypes ( $P > 0.05$ ).

**CONCLUSION:** Our study supports the notion of an association between the AQP1 SNP and acute body fluid loss in long distance runners. :

**Relationships Of Ace Gene Polymorphisms To Experience And Physiological Parameters In Cross Country Runners**

Rachel E. Harder, Kale M. Olson, Lauren E. Koth, Holly E. Felter, Allison L. Annala, Jason R. Boynton, Steven J. Albrechtsen, Kirsten Crossgrove. *University of Wisconsin, Whitewater, WI.*

Email: albrechs@uww.edu

(No relationships reported)

**PURPOSE:** To evaluate the relationships of angiotensin converting enzyme (ACE) gene polymorphisms to experience and physiological parameters in cross country runners. A diploid gene with two alleles located on chromosome 17 codes for ACE. The ACE I allele has an insertion of a 287 base pair fragment and the ACE D allele has an absence of this fragment. The enzyme coded by the ACE I allele has been shown to be slightly less efficient at converting angiotensin I into angiotensin II than the enzyme expressed by the ACE D allele.

**METHODS:** Thirty-nine males and 49 females participating in a cross country camp performed standard Wingate Anaerobic Tests to evaluate lower body anaerobic power (AnP-L), performed modified Wingate Anaerobic Tests to evaluate upper body anaerobic power (AnP-U), and performed graded exercise tests on a motor driven treadmill to determine maximal oxygen consumption (VO<sub>2</sub>MAX). The DNA sample was obtained from using a buccal swab, and the polymerase chain reaction was based on the technique

of Lindpaintner, Pfeffer, Kreutz and Stampfer.

**RESULTS:** The subjects ranged in age from 12 to 19 years (15.33±1.39 years). Thirteen subjects were I/I, 40 subjects were I/D and 33 subjects were D/D. Years of experience was highest for the I/I runners (3.50±2.78 yrs) followed by the I/D runners (2.71±1.68 yrs) and lowest for the D/D runner (1.94±1.61 yrs). No significant differences by ACE genotype were found for peak or average AnP-L or peak or average AnP-U (6.78±1.46 W/kg, 5.39±1.19 W/kg, 1.93±0.59 W/kg, 1.50±0.48). No significant differences by ACE genotype were found for VO<sub>2</sub>MAX (3.42±0.85 L/min, 60.12±9.99 ml/kg/min), duration of the graded exercise test (10.70±1.40 min), or maximal heart rate achieved during the graded exercise test (193.02±8.28 bpm) which was slightly lower than the maximal heart rate predicted by 200 - age (204.62±1.26).

**CONCLUSIONS:** The results for VO<sub>2</sub>MAX contrast with the results of other studies of endurance athletes, including a study of elite bicycle racers in this laboratory. High school cross country runners may not be properly challenged in training and/or competition to obtain the benefits of the I/I and I/D genotypes in contrast to collegiate and elite endurance athletes.

Germán Rodríguez-González<sup>2</sup>, Amelia Guadalupe-Grau<sup>1</sup>, Teresa Fuentes<sup>1</sup>, Jorge Pérez-Gómez<sup>1</sup>, Hugo Olmedillas<sup>1</sup>, Safira Delgado-Guerra<sup>1</sup>, Lorena Rodríguez-García<sup>1</sup>, Cecilia Dorado<sup>1</sup>, José A. L. Calbet<sup>1</sup>, Nicolás Díaz-Chico<sup>1</sup>. <sup>1</sup>UNIVERSITY OF LAS PALMAS DE GRAN CANARIA, Las Palmas de Gran Canaria, Spain. <sup>2</sup>Canary Islands Cancer Research Institute (ICIC), Las Palmas de Gran Canaria, Spain.

Email: [jesus.ponce.gonzalez@gmail.com](mailto:jesus.ponce.gonzalez@gmail.com)

(No relationships reported)

The exon-1 of the androgen receptor (AR) gene contains two length polymorphisms which modify either the amount of AR protein inside the cell (GGN<sub>n</sub>, polyglycine) or its transcriptional activity (CAG<sub>n</sub>, polyglutamine). Shorter CAG and/or GGN repeats provide stronger androgen signaling, and vice versa. On the other hand, androgen levels are inversely associated with fat mass.

**PURPOSE:** To test the hypothesis that CAG and GGN repeat AR polymorphism influences body fat and serum leptin concentrations.

**METHODS:** The length of CAG and GGN repeats was determined by PCR and fragment length analysis, serum leptin concentration by ELISA, and fat mass with DEXA in 282 men (28.6 ± 7.6 years) and 61 women (25.5 ± 6.7 years). All subjects were healthy and physically active. Individuals were grouped as CAG short (CAG<sub>s</sub>) if harboring repeat lengths of ≤21 in men and ≤22 in women, and CAG long (CAG<sub>L</sub>) if CAG >21 in men and >22 in women. GGN was considered short (GGN<sub>s</sub>) or long (GGN<sub>L</sub>) if GGN ≤23 or >23 in men and women.

**RESULTS:** There was no relationship between GGN and CAG repeat length and serum leptin concentration neither in women nor men. CAG<sub>s</sub> and CAG<sub>L</sub> groups had similar leptin concentrations, and GGN<sub>s</sub> and GGN<sub>L</sub> groups as well. There was no relationship between CAG repeat length and whole body fat mass, percentage of fat mass accumulated in the trunk region and percentage of body fat neither in men nor women. The GGN repeat length was not associated to fat mass or to the percentage of body fat in men. However, in women, there was a linear relationship between the length of GGN repeat microsatellite and the percentage of body fat (% fat=2.16xGGN -21.73, r=0.31, P<0.05) and a trend for a similar relationship between whole body fat mass and GGN repeat length (fat mass (kg) = 1.41xGGN - 14.97, r=0.22, P=0.09). No association between CAG or GGN repeat length and trunk fat accumulation was observed.

**CONCLUSIONS:** A long repeat GGN polymorphism is positively associated with increased percentage of body fat in physically active young women.

**The Heritability Of Consistent Leisure Time Physical Activity And Inactivity In The Finnish Twin Cohort**

Sari Aaltonen<sup>1</sup>, Alfredo Ortega-Alonso<sup>1</sup>, Jaakko Kaprio<sup>2</sup>, Urho M. Kujala<sup>1</sup>. <sup>1</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>2</sup>University of Helsinki, Helsinki, Finland.

Email: [sari.aaltonen@sport.jyu.fi](mailto:sari.aaltonen@sport.jyu.fi)

(No relationships reported)

Understanding the genetic regulation of physical activity/inactivity is important in tailoring effective ways to promote physical activity. Previous twin studies have shown that genes play an important role in explaining individual differences in exercise participation at a given moment in life. To the present there is little knowledge on possible genetic influences on sustained behaviors over time.

**PURPOSE:** To examine the role of genetic and environmental factors explaining individual differences in consistent leisure time physical activity and inactivity in both males and females.

**METHODS:** This investigation is part of the Finnish Twin Cohort study. Data was available from two occasions: years 1975 and 1981. We analyze the total leisure time physical activity in metabolic equivalent units (MET index) utilizing a 2 MET-hours/day threshold. Persons with a MET index ≥2M-hours/day in 1975 and 1981 were categorized as "consistently active" while those persons with a MET index <2M-hours/day were "consistently inactive". The total numbers of twins analyzed were 1840 MZ and 4366 DZ males, 2200 MZ and 4403 DZ females. We analyzed genetic and environmental influences on both consistent activity and inactivity by fitting structural equation models to raw dichotomous data utilizing biometric methods.

**RESULTS:** 36% of the males and 31% of the females were consistently active, while 30% of the males and 31% of the females were consistently inactive. The results from the model fitting analyses indicated that the heritability for consistent physical activity was 45% (95% CI 39 to 51%) for males and females, while the heritability for consistent inactivity was 53% (44 to 60%) for males and 38% (28 to 40%) for females.

**CONCLUSION:** The heritability estimates for consistent physical activity were moderate and in the range of those reported earlier for physical activity at a given occasion. Interestingly, estimates of genetic influences for consistent inactivity for males and females differed being higher for males than for females. Environmental influences, such as social factors, seemed to be more important for women to remain sedentary. These findings can be used by public health promoters to understand the gender differences to promote physical activity habits within sedentary populations.

**Exercise Associated Hyponatremia And Weight Change: When Should The Athletes Be Weighed?**

Michael Chapman, Joseph Chorley, FACSM. *Baylor College of Medicine, Houston, TX.*  
Email: mcchapma@bcm.edu  
(No relationships reported)

Exercise associated hyponatremia (EAH) is a potentially fatal complication of endurance event participation and is difficult to diagnose. Most participants with EAH present with a weight gain after the event. Weighing athletes before and after a race would provide objective data as part of a screening program. Logistically, weighing athletes immediately before a morning race is difficult.

**PURPOSE:** To determine if the timing of weight measurement before a marathon affects the performance of using weight change as a screening test.

**METHODS:** As part of the 2008 Houston Marathon Hydration Initiative, all registered marathon runners were encouraged to be weighed at packet pick up, which was held 1-2 days before the race (EXPO). Weights were measured on 92% of the runners (5358/5824 starters) in regular clothes with empty pockets. One pound was subtracted from the registered weight to account for differences from standard running attire. Digital scales were used for all weight measurements and were calibrated on the morning prior to use. 90 participants were weighed on the morning of the race (PRE) and 1757 athletes (30% of finishers) were weighed after the race (POST). 37 contestants had all three measurements. Athletes were considered at risk for EAH if they did not lose weight during the marathon. The weight change from the PRE to POST was considered the gold standard with the EXPO to POST as the experimental test. Bland Altman analysis was used to evaluate the correlation between weight difference measurement techniques. Tolerable limits of agreement were set at 4.4 pounds based on previous EAH studies.

**RESULTS:** The sensitivity was 100% and specificity was 94% when determining weight gain or weight loss of the participants. The Positive Predictive Value was 50% and Negative Predictive Value was 100%. The average difference of weight loss from the EXPO and PRE subtracted from the POST was -0.16 pounds + 2.67. Analysis of plot demonstrated that approximately 95% were within tolerable limits.

**CONCLUSION:** Determining weight change from the difference between a post-race weight and a weight taken 1-2 days prior to the marathon is adequate as a screening test for weight gain during a marathon. This may be useful as part of a screening process for EAH.

**Relation Between Lower Limb Alignment And Injury In Runners With Achilles Tendinopathy**

Liane B. Azevedo<sup>1</sup>, Mike I. Lambert<sup>2</sup>, Christopher L. Vaughan<sup>2</sup>, Martin P. Schwellnus, FACSM<sup>2</sup>. <sup>1</sup>*University Worcester, Worcester, United Kingdom.*  
<sup>2</sup>*University of Cape Town, Cape Town, South Africa.*  
Email: lazevedo@worc.ac.uk  
(No relationships reported)

Although there is limited support from the literature, static lower limb alignment has been proposed as an intrinsic risk factor to running injuries. However, most of the studies have investigated a group of injuries and there is limited evidence on specific injuries.

**PURPOSE:** The aim of this study was to examine the relation between lower limb static measurements and Achilles Tendinopathy injury.

**METHODS:** Thirty four injury free runners (CON) (19 males:15 females; weight: 67.8±10.5 kg; height: 1.71±0.09 m; age: 37.0±9.2 years) and twenty one runners with Achilles tendinopathy (AT) (18 males:7 females; weight: 77.6±12.6 kg; height: 1.78±0.07 m; age: 41.8± 9.7 years) were selected for this study. The following lower limb static measurements were performed on both legs: rearfoot alignment, pronation angle at 45 degrees, Q angle, standing foot angle, navicular drop, forefoot alignment, subtalar joint passive range of motion for eversion and inversion, knee range of motion, functional foot type, knee alignment and leg length. The data of the left and right side were compared between groups and the afflicted side was compared to a random side of the uninjured group, matched with the percentage of left and right foot equal to the injured group. The relationship between lower limb alignment and the incidence of injury was evaluated by calculating 95% confidence interval (95% CI) for the difference between the mean measures in the injured and non-injured runners.

**RESULTS:** None of the anthropometrical variables of the right leg and injured limb versus the matched limb from uninjured group were considered significant discriminator between injured and uninjured runners. However, on the left side subtalar joint passive range of motion for eversion (STJE) and knee range of motion (KROM) were considered significant discriminators between the two groups (CON: 8.73±5.51; AT: 6.00±3.65, 95% CI -0.49 to 0.00; CON: 140.1±8.1; AT: 135.6±5.8, 95% CI -0.51 to -0.04).

**CONCLUSIONS:** Although subtalar joint passive range of motion for eversion and knee range of motion were significantly lower in runners with Achilles injury, this result was not replicated for the right leg and on the injured versus matched leg. We can therefore conclude that static lower limb alignment is not associated with Achilles Tendinopathy.

**2973 Board #120 May 30 8:00 AM - 9:30 AM**  
**The Landing Error Scoring System Predicts Non-contact Injury In Youth Soccer Players**

Lindsay J. DiStefano, Darin A. Padua, Michael J. DiStefano, Stephen W. Marshall. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*  
(Sponsor: Kevin Guskiewicz, FACSM)  
Email: distefano@unc.edu  
(No relationships reported)

Non-contact lower extremity injuries, such as anterior cruciate ligament (ACL) sprains, are common and costly. Understanding the risk factors associated with these injuries is critical for developing prevention strategies.

**PURPOSE:** To prospectively compare movement measured by a clinical movement analysis tool between youth subjects who sustain an ACL or other non-contact movement injury and those who do not become injured.

**METHODS:** Subjects (males: n=138, age=14±2 years, height=163±14 cm, mass=51±15 kg; females: n=160, age=14±2 years, height=162±9 cm, mass=51±10 kg) were recorded with videography while they performed three trials of a jump landing task prior to three consecutive soccer seasons. The videography was assessed using the Landing Error Scoring System, which uses a binary system based on landing characteristics including knee flexion and valgus, trunk flexion, and stance width. A higher LESS score indicates a greater number of errors committed. The average LESS score across the three trials was used for the analyses. Subjects were monitored for injury during each season. A non-contact lower extremity injury was defined as an injury if it occurred during physical activity, resulted in time lost from soccer, and did not involve direct contact between the injured body part and another player or object. Separate linear regression models evaluated the relationships between LESS score and ACL or other injury status (injured or uninjured) after controlling for age group (high school or pre-high school) and sex.

**RESULTS:** Six subjects sustained an ACL injury and 45 subjects sustained other non-contact injuries. There was a significant association between LESS score and ACL injury status ( $F_{(3, 252)}=5.19$ ,  $p=0.002$ ,  $R^2=0.06$ ) and between LESS score and other injury status ( $F_{(3, 297)}=3.87$ ,  $p=0.01$ ,  $R^2=0.04$ ). Individuals with an ACL injury (LESS: 5.4±2.1) and other injuries (LESS: 4.5±2.0) scored higher on the LESS, indicating worse landing technique, compared to those who did not sustain an injury (LESS: 4.0±1.7).

**CONCLUSION:** The LESS is a clinical movement analysis tool that appears to identify individuals with a higher risk of injury, which may enhance the ability to screen large numbers of subjects and target them for injury prevention movement training.

**Injury Rates On Fieldturf And Natural Grass For High School Football And Soccer.**

Patrick G. Garlock, PT, MHS<sup>1</sup>, Mitchell J. Rauh, PT, PhD, FACSM<sup>2</sup>, Kathie Hummel-Berry, PT, PhD<sup>3</sup>, Michael J. Bateman, MD<sup>3</sup>. <sup>1</sup>*MVP Physical Therapy,*

*Fircrest, WA.* <sup>2</sup>*Rocky Mountain University of Health Professions, Provo, UT.* <sup>3</sup>*University of Puget Sound, Tacoma, WA.*  
Email: pgarlock@mvppt.com  
(No relationships reported)

**PURPOSE:** Few studies have compared injury rates on natural grass and FieldTurf surfaces, especially in interscholastic sport populations. Prior studies have not reported differences in injury rates between FieldTurf and natural grass during practice and games in football and soccer. The purpose of our study was to compare the incidence of injury in high school football and soccer on natural grass and FieldTurf surfaces.

**METHODS:** A total of 539 athletes who participated on eight boys' football (283 boys) and sixteen soccer (131 boys, 125 girls) teams in Western Washington were followed between the 1998 to 2001 interscholastic seasons for injury occurrence on FieldTurf and natural grass surfaces. All injuries were reported and verified by an athletic trainer/physical therapist. Injury rates were calculated per 1,000 athletic exposures.

**RESULTS:** Injury rates on natural grass were significantly higher on FieldTurf for football ( $p<0.0001$ ) and girls' soccer ( $p=0.0005$ ). Injury rates were significantly higher on natural grass than FieldTurf for practices and games for football ( $p<0.0001$ ) and girls' soccer ( $p=0.008$ ). No significant differences were found between natural grass and FieldTurf in head-related trauma for football players ( $p=0.55$ ). For other body locations, higher rates of knee injury for football ( $p=0.002$ ) and ankle injury for girls' soccer ( $p=0.01$ ) occurred on natural grass compared to FieldTurf. By injury type, higher rates of sprains for girls' soccer ( $p=0.03$ ) and strains for football ( $p=0.003$ ) occurred on natural grass compared to FieldTurf. By position, for football, higher rates of injury occurred on natural grass than FieldTurf for lineman ( $p<0.0001$ ) and defensive backs ( $p=0.03$ ). For girls' soccer, defenders had higher rates of injury on natural grass than FieldTurf ( $p=0.006$ ).

**CONCLUSION:** The results of this study suggest that a new generation of synthetic turf, FieldTurf, may lower the risk of injury in football and girls' soccer at the high school level. Further studies are needed to compare the risk of injury between the two surfaces in other high school sports like field hockey or lacrosse that also play on these field surfaces.

Keywords: FieldTurf, injuries, prospective, high school

**2975    Board #122    May 30    8:00 AM - 9:30 AM**  
**Sex-by-weapon Variations In Type And Location Of Time-loss Injuries In Competitive Fencing**

Peter A. Harmer, FACSM. *Willamette University, Salem, OR.*  
Email: pharmer@willamette.edu  
(No relationships reported)

Recent research has indicated that the risk of time-loss injury in competitive fencers is low. However, little is known about sub-group differences in injury characteristics in this population.

**PURPOSE:** To examine the sex-by-weapon variation in type and location of time-loss injuries in national fencing competitions.

**METHODS:** Data from a prospective, 5-year study of the United States Fencing Association were analyzed. Information on the number, sex, and event distribution of participants was compiled from official entry lists for the 2001-2006 seasons. Injury details were obtained from the competition medical records. Exposure data were derived from official score sheets and calculated as the combined number of bouts in pool play and direct elimination for each event. Each bout represented two (2) athlete exposures (AE). Injury type and location data were standardized to #/1,000 AE across six sex-by-weapon sub-groups.

**RESULTS:** A total of 78,223 competitors were involved. One hundred eighty four (184) time-loss injuries were recorded (Men: foil=35, epee=29, sabre=34; Women: foil=33, epee=23, sabre=30). The patterns of injury type and location in each sex-by-weapon group reflected the overall characteristics of time-loss injuries (predominantly sprains and strains in the lower extremities) but sub-groups differences were evident: a) Type: Male sabre fencers had 2.0-2.5 times greater risk of sprain than foil or epee fencers; Female foil and sabre fencers had 2.0 greater risk for sprains than epee fencers; Female sabre fencers had 5.0 times greater risk for puncture wounds than foil or epee fencers, b) Location: Male sabre fencers had 1.8-3.2 greater risk for knee injury and 4.2-4.8 greater risk for foot injury than epee or foil fencers; Female sabre fencers had 8.1-10.0 greater risk for hand injury than those in epee or foil. Female foil fencers had 4.0-6.0 greater risk of knee injury compared to epee or sabre fencers.

**CONCLUSIONS:** The overall rate of time-loss injury in competitive fencing is low but there are important sex-by-weapon differences in the rates of specific injury types and locations. Identifying these variations is fundamental to understanding the mechanisms by which they occur and developing effective interventions to further reduce the risk of time-loss injuries in fencing.

**2976    Board #123    May 30    8:00 AM - 9:30 AM**  
**Mechanisms And External Causes Of Injuries Among Patients At A Ski And Snowboard Resort Clinic**

Stuart E. Willick, Christina A. Porucznik, Dutch M. Plante, Matthew S. Thiese, Elizabeth A. Joy, FACSM. *University of Utah, Salt Lake City, UT.*  
(No relationships reported)

**BACKGROUND:** We are developing a multi-center, long-term injury surveillance system for ski and snowboard injuries and have collected two years of pilot-scale data at a single resort. We retrospectively reviewed all injuries seen at a single medical clinic located at the base of a mountain resort. An analysis of two aspects of these injuries \_ spine injuries and listening to music as an external cause \_ is presented here. Our longer term goal is to use surveillance data to identify mechanisms of injury and devise and test injury prevention interventions.

**PURPOSE:** To quantify and describe the injuries seen at one clinic during the 2007-2008 winter season, accounting for patron load with emphasis on spinal injuries and listening to music.

**METHODS:** Medical records and ski patrol report forms were analyzed for N=1,639 patients seen at a mountainside clinic between November 2007 and April 2008.

**RESULTS:** Median age of all patients was 22 years with males younger than females ( $p<0.05$ ) and helmet use more common among younger patients ( $p<0.001$ ). Injured snowboarders (mean=21 years) were younger than injured skiers (34 years) ( $p<0.001$ ) and had increased odds (OR=1.5) of spinal injury, but were more likely to be wearing a helmet (OR=1.4) ( $p<0.05$ ). Several mechanisms were associated with increased odds of spinal injury compared to the most common mechanism of 'catching an edge' including: out of control (OR=2.4), landing short (OR=2.8) or long (OR=6.9) off of a jump, and hit by a snowboarder (OR=6.3). Patients injured in a terrain park were younger (20 vs. 29 years), more likely to be male (OR=5.3), and listening to music (OR=4.8) than those injured elsewhere. ( $p<0.001$ ). Snowboarders comprised 70% of patients injured in a terrain park. Patients listening to music when injured were younger (23 vs. 28 years) and more likely to be snowboarding (OR=2.9) than those patients not listening to music ( $p<0.001$ ).

**CONCLUSIONS:** Reported results are limited to patients seen in clinic. Without denominator data, rates cannot be calculated. Demographics and behaviors can predict risk of some injuries. Modifiable factors such as skill level and concomitant distractions affect risk of injury. Surveillance is ongoing. We will begin data collection using an electronic medical record for the 2008/9 season.

**ACKNOWLEDGMENTS:** Utah Sports Research Network.

**A Detailed Survey of Injuries Sustained in Short Track Speed Skating Competition.**

Brian N. Victoroff, Catherine Curley, Brian Hardy. *Case Western Reserve School of Medicine, Cleveland, OH.*  
Email: bnvic@sbcglobal.net

(No relationships reported)

**PURPOSE:** The purpose of this study was to document injuries sustained by participants in Short Track speed skating competition. These data provide insight into the demographics of injured participants, the circumstances, conditions and mechanisms of injury associated with the sport, and the relative risk to competitors.

**METHODS:** Using a standardized report form, detailed injury data were obtained by medical personnel at nine State, National or International Short Track competitions. Data included competitor demographics, injury type, region and severity, relevant previous history, treatment and outcomes, as well as injury mechanisms, circumstances, ice conditions and track position.

**RESULTS:** Over the course of nine competitions, 53 participants sustained 59 injuries requiring medical evaluation or treatment, representing an injury risk of 3.2% per athlete per competition. Most injuries were classified as minor or moderate (each 39%) and 22 % were severe. By region, most injuries were to extremities (59%) followed by thoracic or lumbar spine (14%) and head/neck (27%). By type, the highest percentage injuries were lacerations (25%) followed by contusions (22%) cervical, thoracic or lumbar strain or sprain (17%) and extremity strain or sprain (17 %). Injuries were most likely to occur during passing maneuvers on a narrow track position.

**CONCLUSIONS:** Based on our findings, Short Track speed skating is a relatively safe sport at all levels. While severe injury is possible, most injuries are minor, with little time lost from participation. Appropriate rink padding and cut-resistant suits are critical in prevention of serious injury. To our knowledge, this study represents the first analysis of injuries sustained in Short Track speed skating competition.

### 2978 Board #125 May 30 8:00 AM - 9:30 AM

#### **Carotid Intima-media Thickness, Dietary Intake And Cardiovascular Phenotypes In Adolescents: Relation To Metabolic Syndrome**

Daniel M. Croymans, B.S.<sup>1</sup>, Jacques D. Barth, M.D. Ph.D.<sup>2</sup>, Albert Sanchez, M.D.<sup>3</sup>, Christian K. Roberts, Ph.D., FACSM<sup>1</sup>. <sup>1</sup>UCLA, Los Angeles, CA. <sup>2</sup>Vasstech Foundation, Santa Monica, CA. <sup>3</sup>Pacific Health Education Center, Bakersfield, CA.

(No relationships reported)

**PURPOSE:** We assessed the association of carotid intima-media thickness (cIMT) with metabolic syndrome (MS), dietary intake and other cardiovascular phenotypes in adolescents using nonparametric exploratory analysis.

**METHODS:** 249 adolescents from three high-schools in Central California, a predominately Hispanic (N=119, 16.1±0.9 yrs), a predominately Caucasian (N=94, 15.7±1.2 yrs), and a 7<sup>th</sup> Day Adventist (7DA) (N=33, 17.0±1.3 yrs) high-school were assessed for cIMT, total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL), triglycerides, uric acid, blood glucose, systolic and diastolic blood pressure (SBP and DBP), body mass index (BMI), and food frequency questionnaire based dietary intake. Significance was set to  $\alpha < 0.01$ .

**RESULTS:** Compared to 7DA, the predominately Hispanic and Caucasian high-schools exhibited higher LDL and BMI percentile, while 7DA and the Caucasian high-school exhibited lower uric acid and fasting glucose levels than the Hispanic high-school. Both Hispanic and Caucasian high-schools consumed more protein, meat and dietary cholesterol and less dairy products; the Hispanic high-school consumed fewer fruit/vegetables than 7DA. In all subjects, BMI percentile was positively correlated with total cholesterol ( $\rho = 0.28$ ), LDL ( $\rho = 0.34$ ), uric acid ( $\rho = 0.31$ ), triglycerides ( $\rho = 0.37$ ), SBP percentile ( $\rho = 0.33$ ), DBP percentile ( $\rho = 0.30$ ) (all  $p < 0.0001$ ), and glucose ( $\rho = 0.18$ ,  $p < 0.004$ ), and negatively correlated with HDL percentile ( $\rho = -0.31$ ,  $p < 0.0001$ ). Uric acid correlated with total fat intake ( $\rho = 0.25$ ), dietary cholesterol ( $\rho = 0.35$ ) and meat consumption ( $\rho = 0.33$ ) (all  $p < 0.001$ ). cIMT was only weakly correlated with SBP percentile ( $\rho = 0.20$ ,  $p < 0.01$ ) and uric acid ( $\rho = 0.20$ ,  $p < 0.003$ ). Despite no significant differences in the high-school frequency of MS risk factors, 58.6% of adolescents had 1 or more MS risk factor. Adolescents with MS exhibited higher uric acid levels compared to those without MS ( $p < 0.007$ ).

**CONCLUSION:** A majority of adolescents presented MS risk factors independent of ethnicity or a purportedly healthier lifestyle (7DA). Uric acid positively correlated with cIMT, BMI percentile, MS and dietary factors suggesting its potentially heightened importance for the assessment of adolescent cardiovascular health.

#### **Does Metabolic Syndrome Cause Arteriosclerosis In Japanese Children?**

Oguri Kazuo<sup>1</sup>, Kasuga Kosho<sup>2</sup>, Nakano Takahiko<sup>3</sup>, Murase Tomohiko<sup>4</sup>, Tachi Toshiki<sup>1</sup>, Kumagai Kayo<sup>5</sup>. <sup>1</sup>Shizuoka Sangyo University, Iwata, Shizuoka, Japan. <sup>2</sup>Gifu University, Gifu, Japan. <sup>3</sup>Nagoya Gakuin University, Seto, Aichi, Japan. <sup>4</sup>Aichi University, Nishikamo, Aichi, Japan. <sup>5</sup>Gifu University, Gifu, Japan.

Email: oguri@iwata.ssu.ac.jp

(No relationships reported)

Information on whether metabolic syndrome (MS) is involved in development of arteriosclerosis in children is sparse. Small, dense low-density lipoprotein (LDL) particle size and level of high sensitive C-reactive protein (hsCRP) are known to be novel markers characterizing the atherosclerotic process at an early stage.

**PURPOSE:** To examine the relationship between MS and early arteriosclerosis in childhood, we compared LDL size and hsCRP level among obese children with MS, normal and non-obese children without MS.

**METHODS:** The subjects were 67 Japanese children (32 non-obese, 35 obese) aged 7.0-12.6 yrs. Obesity was determined upon an obesity index score ((real weight - standard weight) / standard weight × 100) of more than +20%. Fasting levels of LDL size, hsCRP, glucose, insulin, lipid profile, and blood pressure were determined. Insulin resistance was quantified by the homeostatic model assessment (HOMA) index. Visceral fat area (cm<sup>2</sup>) was determined by magnetic resonance imaging. Obese children were grouped into with (n=5) and without (n=30) MS. MS was determined upon abdominal obesity (waist circumference: ≥75 cm) plus at least two other factors from elevated triglyceride (TG, ≥120 mg/dl), low high-density lipoprotein-cholesterol (HDL-C, <40 mg/dl), high systolic or diastolic blood pressure (≥125 or ≥70 mmHg), and fasting glucose (≥100 mg/dl) as per criteria newly established by a task force financed by the Ministry of Health, Labor and Welfare, Japan. Statistical treatment comprised ANOVA followed by Tukey's honestly significant difference adjustment for multiple comparisons.

**RESULTS:** Obese children with MS had significantly smaller LDL size and higher hsCRP level than normal and obese children without MS ( $p < 0.05$ ). No differences between normal and obese children without MS were observed for LDL size or hsCRP level. Obese children with MS showed higher TG, insulin, HOMA index, blood pressure, visceral fat area, and lower HDL-C than normal and obese children without MS ( $p < 0.05$ ).

**CONCLUSIONS:** Our findings suggest that metabolic syndrome more than obesity per se may be involved in early arteriosclerosis in children.

### 2980 Board #127 May 30 8:00 AM - 9:30 AM

## Exercise And The Metabolic Syndrome With Weight Regain

Tom R. Thomas, Shana O. Warner, Ying Liu, Melissa A. Linden, Pam S. Hinton, R Scott Rector, Kevin C. Dellsperger, Anand Chockalingam, Adam T. Whaley-Connell, John P. Thyfault, David R. Huyette. *University of Missouri, Columbia, MO.*

(No relationships reported)

**PURPOSE:** Metabolic syndrome (MetS) risk factors are improved with weight loss, but most individuals regain the weight. The primary aim was to determine if exercise training is effective in maintaining improvements in MetS risk factors during weight regain.

**METHODS:** Sixty-three overweight or obese (25.0-39.9 kg/m<sup>2</sup>) men and women (39±1y), with characteristics of the MetS, targeted 10% weight loss with individually prescribed and supervised walking/jogging exercise at 60% VO<sub>2</sub> max (-400 kcal/session), 5d/wk, and caloric restriction (-600 kcal/d) over a 4-6 mo period. Each subject met weekly with a study nutritionist and exercised daily under the supervision of a personal trainer in a dedicated fitness center. After weight loss, the 52 remaining subjects (dropout rate = 17%) were randomly assigned to two groups that underwent controlled partial weight regain (+50% of lost weight) over the subsequent 4-6 mo: Group 1- Continued supervised exercise, Group 2- No exercise. MetS parameters were assessed at Baseline, Post Weight Loss, and Post Weight Regain and groups compared by two-way repeated measures ANOVA. Forty-six subjects completed the entire study (total dropout rate = 27%). Exercise compliance for the entire study was 96%.

**RESULTS:** After weight loss (9.5±0.2%), significant (p<.05) improvements were observed in all metabolic parameters: VO<sub>2</sub>max, waist circumference, systolic and diastolic blood pressure (BP), total and subcutaneous and visceral abdominal fat and intermuscular fat (by computed tomography), insulin, glucose, insulin resistance (by homeostasis model assessment - HOMA), cholesterol, HDL-C, LDL-C, and oxidized LDL. With weight regain (54.4±1.6%), many of the outcome parameters were reversed in both groups. However, the exercise group did maintain the improvements in BP, insulin, HOMA, and oxidized LDL, but the non-exercise group did not maintain any parameters after partial weight regain.

**CONCLUSION:** Although aerobic exercise maintained improvements in some important MetS risk factors despite weight regain, the deleterious effects caused by weight regain on other parameters suggest that weight maintenance is important for metabolic health status.

#### Maximal Rate Of Fat Oxidation Not Related To Lactate Threshold In Women With Metabolic Syndrome

Corey A. Rynders, Siddhartha S. Angadi, Nathan Y. Weltman, Glenn A. Gaesser, FACSM, Arthur Weltman, FACSM. *University of Virginia, Charlottesville, VA.*

(No relationships reported)

**PURPOSE:** To examine the relationship between VO<sub>2</sub> at lactate threshold (LT) and at the maximal rate of fat oxidation (FAT<sub>max</sub>) in abdominally obese women with and without the metabolic syndrome (MS).

**METHODS:** Three groups of females 1) MS (n=26; age, 47.8 ± 2.2 yrs; BMI, 34.5 ± 1.2 kg/m<sup>2</sup>; % body fat, 44.7 ± 0.9%; VO<sub>2</sub>peak, 21.1 ± 0.7 ml/kg/min); 2) obese % body fat matched controls without MS (O) (n=52; age, 37.2 ± 2.4 yrs; BMI, 34.1 ± 1.1 kg/m<sup>2</sup>; % body fat, 44.7 ± 0.8%; VO<sub>2</sub>peak, 17.6 ± 0.6 ml/kg/min); and 3) lean (L) (n=41; age, 28.9 ± 2.1 yrs; BMI, 21.8 ± 0.2 kg/m<sup>2</sup>; % body fat, 24.9 ± 1.0%, VO<sub>2</sub>peak, 33.1 ± 1.3 ml/kg/min) completed a continuous incremental (3 min stages) VO<sub>2</sub>peak/LT protocol. Fat oxidation rates were determined using indirect calorimetry and averaged over the last minute of each stage. The exercise intensity corresponding to the highest recorded fat oxidation rate was chosen as FAT<sub>max</sub> and LT was chosen as the breakpoint in the VO<sub>2</sub> blood lactate relationship.

**RESULTS:** LT occurred at a higher %VO<sub>2</sub> than FAT<sub>max</sub> in all groups (63% v. 52%, 57% v. 48%, and 53% v. 46% in MS, O, and L respectively, p<.05). Strong correlations between VO<sub>2</sub> at LT and FAT<sub>max</sub> were observed in O and L (r=.68, r=.69; p<.001) but not in the MS group (r=.39, p=.053) after controlling for age and when VO<sub>2</sub> was expressed as ml/kg/min. This relationship persisted when VO<sub>2</sub> was normalized to fat-free mass (ml/kgFFM/min; MS, r=.38, p=.058; O, r=.64, p<.001; L, r=.64, p<.001).

**CONCLUSION:** In abdominally obese females with MS, the VO<sub>2</sub> at FAT<sub>max</sub> and LT are not related even after accounting for differences in fat free mass.

### 2982 Board #129 May 30 8:00 AM - 9:30 AM

#### Abdominally Obese Women With Metabolic Syndrome Have Higher Maximal Fat Oxidation Rates During Submaximal Treadmill Exercise.

Brian A. Irving, Corey A. Rynders, Siddhartha S. Angadi, Nathan Y. Weltman, Glenn A. Gaesser, FACSM, Arthur Weltman, FACSM. *University of Virginia, Charlottesville, VA.*

(No relationships reported)

**PURPOSE:** To compare absolute and relative fat oxidation rates between abdominally obese women who meet the International Diabetes Federation criteria for metabolic syndrome (MS) and lean without MS.

**METHODS:** Two groups of females 1) MS (n=26; age, 47.8 ± 2.2 yrs; BMI, 34.5 ± 1.2 kg/m<sup>2</sup>; % body fat, 44.7 ± 0.9%; VO<sub>2</sub>peak, 21.1 ± 0.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>); 2) lean (L) without MS (n=21; age, 51.1 ± 3.9 yrs; BMI, 22.9 ± 0.5 kg/m<sup>2</sup>; % body fat, 32.7 ± 2.3%; VO<sub>2</sub>peak, 29.8 ± 2.0 ml·kg<sup>-1</sup>·min<sup>-1</sup>); completed a continuous incremental treadmill VO<sub>2</sub>peak/LT protocol. Fat oxidation rates were determined using indirect calorimetry and averaged over the last minute of each 3 min stage. LT was chosen as the breakpoint in the blood lactate - VO<sub>2</sub> relationship.

**RESULTS:** Although VO<sub>2</sub> at LT occurred at similar relative percentages of VO<sub>2</sub> peak (63 vs 58 % for MS and L respectively, p = 0.27) there was a dissociation between groups for maximal rate of fat oxidation (FAT<sub>max</sub>) (53 vs 43 % of VO<sub>2</sub> peak for MS and L respectively, p = 0.008). Absolute and relative FAT<sub>max</sub> were higher in MS compared to L (0.35 ± 0.03 g/min v. 0.21 ± 0.02 g/min, p<.001; 6.7 ± 0.4 mg/kgFFM/min v. 5.0 ± 0.4 mg/kgFFM/min, p=.005; respectively).

**CONCLUSIONS:** The present findings support previous research that indicates that obese subjects have higher rates of fat oxidation than lean subjects (in part due to higher rates non plasma fatty acid utilization) and extends these findings to abdominally obese subjects with MS.

### 2983 Board #130 May 30 8:00 AM - 9:30 AM

#### Aerobic Exercise And Niacin Therapy Alter Lipoprotein Characteristics In Metabolic Syndrome

Peter W. Grandjean, FACSM<sup>1</sup>, Eric P. Plaisance<sup>1</sup>, A. Jack Mahurin<sup>2</sup>, Michael L. Mestek<sup>1</sup>, J. Kyle Taylor<sup>3</sup>, Jose Moncada-Jiminez<sup>1</sup>, Felipe Araya-Ramirez<sup>1</sup>, David M. Dean<sup>1</sup>. <sup>1</sup>Auburn University, Auburn, AL. <sup>2</sup>Baptist Family Medicine, Montgomery, AL. <sup>3</sup>Auburn University-Montgomery, Montgomery, AL.

Email: grandpw@auburn.edu

( P.W. Grandjean, Abbott Laboratories, Contracted Research.)

Changes in lipoprotein characteristics, such as particle size and number, may contribute to our understanding of the biochemical pathways that are influenced by exercise and niacin therapy to ameliorate secondary dyslipidemias.

**PURPOSE:** Our purpose was to characterize changes in lipoprotein characteristics after single episodes of aerobic exercise conducted before and after 6 wks of niacin therapy in men with metabolic syndrome.

**METHODS:** Thirteen men (44 ± 7 yrs; BMI = 34.5 ± 3.4 kg·m<sup>-2</sup>; % fat = 35 ± 5; VO<sub>2</sub>max = 27.7 ± 5.1 mL·min<sup>-1</sup>·kg<sup>-1</sup>; waist circumference = 108.8 ± 8.2 cm; HDL-C = 39 ± 8 and triglycerides = 287 ± 96 mg/dL; HOMA score = 4.4 ± 2.0) expended 500 kcals by treadmill walking at 65% of VO<sub>2</sub>max before and after a 6-wk regimen of prescription

niacin. Niacin doses were titrated by 500 mg/wk from 500 to 1500 mg/dy and maintained at 1500 mg/dy for the last 4 wks. Fasting blood samples were collected before and 24 hr after each exercise session for blood lipid and NMR analyses of lipoprotein characteristics (*Lipoprotein®*, *Liposcience Inc., Raleigh, NC*). Changes in lipid concentrations and lipoprotein particle size and number were determined by paired t-tests and multiple 1 (group) by 4 (condition) repeated-measures ANOVAs.

**RESULTS:** A 12% reduction in cholesterol, a 34% reduction in triglyceride and an 18% increase in HDL-cholesterol were observed after six weeks of niacin therapy ( $p < 0.018$  for all). Niacin, but not exercise, reduced total LDL particle number by 11% ( $p = 0.009$ ). The reduction in LDL particle number with niacin was observed across small LDL subclasses (16 to 23%,  $p < 0.0032$  for all) but not in the number of large LDL particles. The combination of exercise and niacin therapy reduced mean VLDL particle size 7% ( $p = 0.035$ ) and the increase in mean LDL particle size approached statistical significance ( $p = 0.081$ ). Participants' body weight and characteristics of VLDL, IDL, and HDL particles remained unchanged from baseline ( $p > 0.05$  for all).

**CONCLUSIONS:** The therapeutic effects of niacin include reducing LDL particle number - particularly in smaller, more atherogenic LDL subclasses. Moderate-intensity aerobic exercise in combination with niacin reduces mean VLDL particle size, an effect that may contribute to reductions in smaller LDL particles and triglyceride concentrations and to elevations in HDL-cholesterol.

**2984 Board #131 May 30 8:00 AM - 9:30 AM**  
**Fetuin - A Responses To Exercise In Men With Metabolic Syndrome**

Robert L. Bowers<sup>1</sup>, Felipe Araya-Ramirez<sup>1</sup>, Teayoun Kim<sup>1</sup>, Rebecca A. Ludvigsen<sup>1</sup>, A. Jack Mahurin<sup>2</sup>, Jennifer D. Dennis<sup>1</sup>, David M. Dean<sup>1</sup>, Suresh T. Mathews<sup>1</sup>, Peter W. Grandjean, FACSM<sup>1</sup>. <sup>1</sup>Auburn University, Auburn, AL. <sup>2</sup>Baptist Family Medicine, Montgomery, AL

Email: grandpw@auburn.edu

(No relationships reported)

Fetuin-A, particularly the phosphorylated isoform, appears to attenuate insulin action by suppressing insulin receptor tyrosine kinase activity. In fact, fetuin-A is elevated in obesity, insulin resistance and Type 2 diabetes. Aerobic exercise is known to improve insulin action; however, the fetuin-A response to exercise in men with metabolic syndrome is unknown.

**PURPOSE:** Our purpose was to characterize the influence of a single episode of aerobic exercise on fetuin-A and markers of insulin action in obese men with metabolic syndrome.

**METHODS:** Ten men (39 + 8 yrs of age; BMI = 35.6 + 6.7 kg·m<sup>-2</sup>; % fat = 38 + 5; VO<sub>2</sub>max = 28.8 + 6.2 mL·min<sup>-1</sup>·kg<sup>-1</sup>; waist circumference = 45.9 + 6.3 in; HDL-C = 36 + 6 and triglycerides = 163 + 99 mg/dL; HOMA score = 5.3 + 4.4) expended 500 kcal by treadmill walking at 60-70% of VO<sub>2</sub>max. Fasting blood samples were collected prior to, immediately, and 24 hr post-exercise. Samples collected during a 2 hr oral glucose tolerance test (OGTT, 75g glucose load) were obtained prior to and 24 hr after exercise. Changes in serum glucose, insulin, non-esterified fatty acids, fetuin-A, phosphofetuin-A concentrations, HOMA, the glucose/insulin ratio, and OGTT areas under the curve (AUC) for glucose, insulin, fetuin-A and phosphofetuin-A were determined by multiple repeated-measures ANOVAs.

**RESULTS:** The glucose/insulin ratio increased 92% 24 hr after exercise ( $p = 0.0067$ ) and the insulin AUC was reduced 16% post-exercise ( $p = 0.049$ ). Serum phosphofetuin-A AUC was significantly lower ( $p < 0.006$ ) 24 hours after a single bout of exercise. HOMA ( $p = 0.062$ ) and fetuin-A concentrations remained unchanged with exercise.

**CONCLUSIONS:** The reduced phosphofetuin-A AUC observed after a single exercise session is consistent with improvements in surrogate markers of insulin sensitivity and may be a mechanism by which exercise improves insulin action.

---

**2985 Board #132 May 30 8:00 AM - 9:30 AM**  
**Prevalence Of The Female Athlete Triad/Tetrad In Professional Ballet Dancers**

Anne Z. Hoch, FACSM<sup>1</sup>, Paula Papanek, FACSM<sup>2</sup>, Heather S. Havlik<sup>1</sup>, William G. Raasch<sup>1</sup>, Michael E. Widlansky<sup>1</sup>, Jane E. Schimke<sup>1</sup>, David D. Guterman<sup>1</sup>. <sup>1</sup>Medical College of Wisconsin, Milwaukee, WI. <sup>2</sup>Marquette University, Milwaukee, WI.

Email: azeni@mcw.edu

(No relationships reported)

The prevalence of the female athlete triad in professional dancers is unknown. Furthermore, amenorrhea may increase the risk of endothelial dysfunction, a predictor of cardiovascular risk in this population.

**PURPOSE:** To determine the prevalence of disordered eating, menstrual dysfunction, reduced bone mineral density and endothelial dysfunction in professional ballet dancers.

**METHODS:** Twenty two professional ballet dancers volunteered for this study. Subjects completed a questionnaire in regards to disordered eating (EDE-Q). Whole serum blood was drawn to determine hormonal, TSH and prolactin levels. Subjects also completed a questionnaire about their menstrual history. Bone mineral density (BMD) and body composition were measured with a GE Lunar Prodigy DXA. Endothelial function was measured in the brachial artery by high resolution ultrasound employing standard methods for measuring brachial reactivity testing. An increase in brachial diameter < 5% to hyperemic flow stimulus was *a priori* defined as endothelial dysfunction.

**RESULTS:** Disordered eating. Thirty two percent had abnormal EDE-Q scores. Menstrual dysfunction. Eighteen percent reported a history primary amenorrhea, 27% currently had menstrual dysfunction and 9% were currently taking birth control. Bone mineral density. Thirty two percent had evidence of low bone density (Z score < 1.0). Cardiovascular. Sixty four percent of dancers had abnormal brachial artery flow mediated dilation (<5%).

**CONCLUSIONS:** Triad characteristics including endothelial dysfunction were common in this group. Eighteen percent had one component, 45% had two components, 18% had 3 components and 5% had all four components of the Triad (Tetrad).

**FUNDING:** This study was funded by a grant from the General Clinical Research Center, Grant #M01 RR00058, by the Clinical & Translational Science Institute Adult Translational Research Unit, Medical College of Wisconsin, and Recipient of Steve Cullen Healthy Heart Club Funding 2008.

**Association Between Regular And Sugar-free Soda Consumption With Risk Of Metabolic Syndrome**

Jason R. Jagers, Duck-chul Lee, Xuemei Sui, Gregory A. Hand, FACSM, Steven N. Blair, FACSM. University of South Carolina, Columbia, SC.

(Sponsor: Steven Blair, FACSM)

Email: jagersj@mailbox.sc.edu

(No relationships reported)

**PURPOSE:** The association between daily intake of sugar-free soda (SFS) and health consequences are not well understood. Recent findings suggest that SFS consumption is associated with an increased risk of metabolic syndrome (MetS). The purpose of this study was to examine the cross-sectional association between soda consumption and MetS.

**METHODS:** A sample of 3,320 participants (12.7% women, mean age 45.0 years) from the Aerobics Center Longitudinal Study who completed a series of health history questionnaires that included a dietary record and a treadmill fitness test were used for this cross-sectional analysis. MetS was defined according to NCEP-ATP III criteria. The sample was classified into seven groups of soda consumption (<1/wk SFS or regular; 1-6/wk SFS; ≥1/d SFS; 1-6/wk regular; ≥1/d regular; 1-6/wk SFS or regular; ≥1/d SFS or regular). Logistic regression analysis was used to compute odds ratios (ORs) and 95% confidence intervals (CIs).

**RESULTS:** Compared with <1/wk SFS or regular soda, age and sex adjusted ORs (95% CIs) were 1.63 (1.11-2.39) in 1-6/wk SFS, 2.85 (1.96-4.15) in ≥1/d SFS, 1.29 (0.96-1.74) in 1-6/wk regular, 1.54 (1.15-2.08) in ≥1/d regular, 1.22 (0.89-1.68) in 1-6/wk SFS or regular, and 1.85 (1.40-2.44) in ≥1/d SFS or regular. After adjustment for physical activity, smoking status, alcohol intake, dietary pattern, and total calorie intake, only ≥1/d SFS was significantly associated with higher risk of MetS. This OR remained significant after adjustment for

cardiorespiratory fitness (CRF). In analyses for individual the MetS components,  $\geq 1/d$  regular soda was positively associated with abdominal obesity ( $P=0.02$ ) whereas  $\geq 1/d$  SFS showed increased association with high triglycerides ( $P=0.04$ ) and impaired fasting glucose ( $P=0.03$ ) compared with  $<1/wk$  SFS or regular.

**CONCLUSIONS:** This cross-sectional analysis showed that drinking more than one SFS a day may be associated with increased prevalence of MetS. Additional studies are needed to further investigate the association between soda consumption and MetS.

#### Effects Of Exercise On The Regeneration Of Injured Nerve And Soleus Muscle After Spinal Cord Contusion In Rats

Ilguy Jeong<sup>1</sup>, Myungjin Oho<sup>1</sup>, Moonnyeo Jang<sup>1</sup>, Donghee Kim<sup>2</sup>, Hayan Lee<sup>2</sup>, Jinhwan Yoon<sup>1</sup>. <sup>1</sup>Hannam University, Daejeon, Republic of Korea. <sup>2</sup>Chonnam National University, Gwangju, Republic of Korea.

Email: Jig1229@hanmail.net

(No relationships reported)

It has been suggested that the functional recovery promoted by exercise training after spinal cord injury (SCI) might be associated with neurotrophic factors such as BDNF and GAP-43 in nerve tissue and insulin-like growth factor (IGF-1) in the inflicted muscle. However, it is needed to be elucidated more clearly how SCI and training followed by SCI affect the morphological changes as well as the neurotrophic and muscle growth factors.

**PURPOSE:** This study was designed to investigate the effects of treadmill training on the morphological change of injured spinal cord and the expression of BDNF, GAP-43 in injured nerve tissue and IGF-1 of soleus muscle in rats with SCI.

**METHODS:** Forty five male rats (7wk in age) were used and assigned into three groups: None-Contusion Group (NC, n=15), Contusion Control Group (CC, n=15) and Exercise after Contusion Group (EC, n=15). Every rat in CC and EC groups underwent laminectomy at T9 level and then contusion on the exposed spinal cord site in the anesthetized condition. After one week-recovery from contusion, every rat in EC group exercised on a motorized treadmill for 30 min/d, 5 d/wk for 7 wks. Immunofluorescence staining and microscopic observation was used in order to confirm the axon regeneration at the injured site and Western blot was used to analyze the nerve and muscle regeneration associated proteins. Functional recovery was also evaluated by BBB test (Basso, Brestti, Brenahan). The variables were analyzed using T test and repeated two-way ANOVA and Turkey post-hoc test.

**RESULTS:** The size of cavity formed in spinal cord remarkably decreased along with the significant axonal regrowth in EC compared to CC after 7 wks. BDNF and GAP-43 increased significantly 7 wks after SCI and treadmill exercise after SCI further up-regulated the proteins ( $p \leq .001$ ). The cross-sectional size of soleus muscle was decreased along with the reduction of IGF-1 protein after SCI and recovered with the increase of IGF-1 due to exercise training in EC ( $p \leq .001$ ). The higher score of functional test (BBB test) also appeared from 4 wks of training in EC group ( $p \leq .01 \sim .001$ ).

**CONCLUSIONS:** These results suggest that treadmill exercise after SCI might promote the functional recovery along with the axon regeneration and muscle regrowth through the up-regulation of BDNF, GAP-43 in nerve tissue and IGF-1 in muscle tissue.

#### Establishment Of Accurate Estimation Of Muscle Atrophy Based On Muscle Thickness In Knee Surgery Patients

Maya Hioki<sup>1</sup>, Takemitsu Furukawa<sup>2</sup>, Hiroshi Akima<sup>1</sup>. <sup>1</sup>Nagoya University, Nagoya, Japan. <sup>2</sup>Ogaki Orthopedic Surgery, Ogaki, Japan. (Sponsor:

Katsumi Asano, FACSM)

Email: maya@mri.biglobe.ne.jp

(No relationships reported)

Girth measurement has been widely used for estimation of change in muscle size following surgery-related disuse in clinical medicine. This method is simple and easy to use; however, the accuracy of estimation remains a matter of debate in the previous studies.

**PURPOSE:** The purpose of this study was to establish the accurate estimation of atrophy in quadriceps femoris (QF) muscles in patients who underwent knee surgery.

**METHODS:** A total of 32 individuals (men: 16, women: 16) (age,  $45.3 \pm 3.7$  yr; height,  $162.2 \pm 7.5$  cm; weight,  $62.5 \pm 11.5$  kg) who underwent arthroscopic knee surgery participated in the study. Their operated and non-operated thighs were scanned by magnetic resonance imaging to determine the volume and thickness of the QF muscles. Muscle volume was calculated using eleven axial images and muscle thickness was measured at the anterior, lateral and medial regions at the proximal (70% of length of the thigh; 70%Lt), middle (50%Lt) and distal (30%Lt) levels. To obtain the relationship between difference in muscle volume and difference in muscle thickness between operated and non-operated thighs, stepwise regression analysis was performed. The muscle volume difference between operated and non-operated limb was analyzed with a paired t-test.

**RESULTS:** The muscle volume of the QF muscles of the operated limb ( $789.9 \pm 226.0$  cm<sup>3</sup>) was significantly smaller than the non-operated limb ( $907.8 \pm 243.4$  cm<sup>3</sup>). As a result of stepwise regression analysis, the difference in muscle volume was significantly correlated with difference in muscle thickness in the anterior and lateral regions at the middle level and medial region at the distal level ( $R = 0.84$ ,  $R^2 = 0.71$ ) ( $p < 0.001$ ).

**CONCLUSIONS:** It is concluded that the difference in muscle volume of the QF muscles between operated and non-operated could be estimated by muscle thickness at three different regions, i.e. anterior and lateral regions at 50%Lt and medial region at 30%Lt, which can be measured using costless imaging technique such as ultrasonography. It would be useful for accurate estimation of muscle atrophy induced by disuse due to injury and/or bed rest in clinical medicine.

### 2989 Board #136 May 30 9:30 AM - 11:00 AM

#### Attenuation Of Muscle Impairments Relates To Functional Improvements During Rehabilitation Following Immobilization.

Chris Gregory, Sunita Mathur, Robyn Hinds, Jessica Ball, Trevor Lentz, Glenn Walter, Krista Vandenberg. University of Florida, Gainesville, FL

(No relationships reported)

**PURPOSE:** The purpose of this study was to 1) quantify the effects of immobilization and subsequent rehabilitation training on muscle size and strength about the ankle and 2) determine the extent to which improvements in physical function relate to gains in strength in ankle plantar- and dorsi-flexor muscles. We hypothesized that greater relative changes in both muscle strength and size would be seen in the plantar- versus the dorsi-flexor muscle group, reflective of the anti-gravity responsibilities of the plantar flexor muscles.

**METHODS:** Following immobilization, fourteen subjects enrolled in a standardized rehabilitation program involving progressive resistance exercises and treadmill walking. Plantar- and dorsi-flexor strength were determined via dynamometry and functional ability was assessed during stair climbing and over ground walking immediately prior to, during and following rehabilitation. In addition, maximum cross-sectional area (CSA) of the muscles that elicit ankle plantar- and dorsi flexion were determined via magnetic resonance imaging (MRI).

**RESULTS:** A greater degree of atrophy was noted in the plantar- compared to the dorsi-flexors following immobilization ( $25.5 \pm 6.4\%$  versus  $20.5 \pm 3.8\%$ , respectively). Similarly, plantar flexor strength was reduced  $73.3 \pm 12.4\%$  relative to the contralateral limb, while dorsi-flexor strength was reduced  $52.1 \pm 9.9\%$ . Following rehabilitation, increases in both plantar ( $55.1 \pm 14.9\%$ ) and dorsi-flexor ( $29.9 \pm 8.5\%$ ) strength were noted. Increased functional ability was also realized, with improvements in both stair climbing and over ground walking velocity following rehabilitation. Of note, recovery of function significantly correlated to the recovery of dorsi flexor ( $R^2 = 0.79$  and  $0.85$ ) and plantar flexor ( $R^2 = 0.86$  and  $0.88$ ) strength, respectively.

**CONCLUSIONS:** A discrepancy in the hierarchy of response was found between changes in muscle size and strength in the ankle plantar- versus dorsi-flexor muscles following immobilization. Rehabilitation induced improvements in muscle strength were realized in both the plantar and dorsi-flexion, with improvements significantly related to improved functional performance.

**A Simple Prediction Model For Stress Fracture In New Recruits**

Daniel S. Moran, FACSM<sup>1</sup>, Rachel K. Evans<sup>2</sup>, Ran Yanovich<sup>1</sup>, Tomer Erlich<sup>1</sup>, Yael Arbel<sup>1</sup>. <sup>1</sup>Heller Institute of Medical Research, Tel Hashomer, Israel.  
<sup>2</sup>US Army Research Institute of Environmental Medicine, Natick, MA.  
Email: dmoran@sheba.health.gov.il  
(No relationships reported)

**PURPOSE:** To develop a simple prediction model for stress fracture (SF) in new military recruits using an activity assessment questionnaire and anthropometry measurements.

**METHODS:** Data were collected from 63 young ( $18.5 \pm 0.5$  yrs) males prior to Special Forces Army basic training (ABT). A detailed history of physical activity included questions on the type and frequency of the activity, the age span during which the subject was involved in the activity, and the average number of minutes each activity was performed per week. The type of sport activities performed were further divided into four categories: high impact (i.e., running), multi-directional impact (i.e., court sports), and high and low magnitude. Anthropometric variables included weight, height, percent body fat, waist circumference, and BMI. Stress fractures were diagnosed during ABT by bone scintigraphy and/or MR imaging. All variables from the various categories were analyzed to evaluate the correlation with SF and to construct a new SF prediction model using logistic regression analysis.

**RESULTS:** Three variables were found to be significantly related to SF occurrence during ABT ( $p < 0.05$ ): aerobic training frequency (e.g., running), aerobic training duration, and waist circumference. The following model successfully predicted 78% of the soldiers with ( $n=23$ ) and without ( $n=28$ ) SF:

$PSF = 12.166 - 1.169ATn + 0.436ATt - 0.145Waist$

where: PSF= Stress fracture prediction according to the Log Odds(SF); Odds(SF)= Ratio between probability of SF existence and nonexistence; ATn= Aerobic training (times/week); ATt= Aerobic training (min/week); Waist = circumference (cm).

**CONCLUSIONS:** A simple, applicable prediction model for SF was developed. A young male soldier is at greater risk of developing SF if, before entering ABT, he trained aerobically <2 times a week, each training was >40 min, and his waist circumference was less than 75cm. This modeling effort identified candidate variables that may play a major role in SF occurrence. If validated through testing using a larger sample size, these findings may enable prevention of orthopedic injuries through the adjustment of the training program for at-risk individuals.

**Effects Of Near-infrared Photobiomodulation On Body Weight Of Type 1 Diabetic Animals**

Robert W. Wilson, II, Sandeep Gotpalakrishnan, Janis T. Eells, Ann C. Snyder, FACSM. University of Wisconsin - Milwaukee, Milwaukee, WI.  
Email: RWWilson@uwm.edu  
(No relationships reported)

**INTRODUCTION:** Diabetes mellitus can lead to the loss of muscle mass and an accumulation of fat mass. If these factors lead to a decrease in physical activity, the systemic health of the individual may deteriorate. Near-infrared light has already been shown to accelerate wound healing in diabetic animals. Near-infrared therapy has also been shown to increase energy production, attenuate oxidative stress, reduce toxic effects of mitochondrial poisoning and reduce pain.

**PURPOSE:** The purpose of this study was to determine the effect of a 670 LED non-thermal light on the body weight of a group of diabetic rats.

**METHODS:** Twenty-four male rats were randomly placed into 3 groups. All groups were given intraperitoneal injections; eight were given injections of a saline solution (CTR) and sixteen were given an injection of streptozotocin. The sixteen animals injected with streptozotocin were randomly assigned to two equal groups: one group received no treatment (STZ) and the other group received the near-infrared light treatment (NIP). Animal treatment and data collection began one week post-injections. Five days per week, all of the animals were placed in Plexiglas restrainers for five minutes. During this time, the NIP group received their light treatment. Animals were weighed midweek and harvested on day ninety-six.

**RESULTS:** Body weights were significantly different between CTR and STZ and between CTR and NIP at all time points. A trend of greater body weight by the NIP group as compared to the STZ group did exist, which may have physiological significance though it was not statistically significant. Cumulative muscle weight measures support this finding.

**DISCUSSION AND CONCLUSIONS:** A tendency to maintain or increase body weight, especially through muscle mass, may indicate an enhanced state of systemic health. Muscle mass is important to an individual with diabetes, as it may allow them the ability to be physically active. These results indicate that the dose of light treatment administered may lead to a persistent difference in bodyweight and greater muscle weights. Therefore, we hypothesize that the NIP group had the potential to deal with the hyperglycemic stress better and to function at a greater capacity.

This research was funded by a Research Growth Initiative grant from the University of Wisconsin - Milwaukee.

**2992 Board #139 May 30 9:30 AM - 11:00 AM**  
**Voluntary Wheel Running Attenuates Muscle Mass And Myosin Isoform Changes In Cancer Cachexia**

Gary M. Diffie, Hayley Piepmeyer. University of Wisconsin, Madison, WI. (Sponsor: Li Li Ji, FACSM)  
(No relationships reported)

**PURPOSE:** Cancer cachexia is characterized by significant decreases in skeletal muscle mass as well as alterations in skeletal muscle myosin heavy chain (MHC) isoform expression characterized by an increase in fast (type IIb) MHC expression. Increased muscle activity generally causes increases in both muscle mass and slow MHC isoform expression. As such, increased physical activity may be an attractive paradigm to attenuate the effects of cancer cachexia. Resistance activity has been shown to reduce tumor-induced muscle atrophy, but the effects of running activity on cancer cachexia are unknown.

**METHODS:** To determine the effect of running activity on muscle mass and MHC isoform expression during cancer, mice were injected with Lewis Lung carcinoma cells and were divided randomly into groups with access to running wheels (Exercise = EX) and groups without wheel access (No exercise = NE). The mice in the EX groups ran an

average of 4.5 km/day for 21 days. Upon sacrifice, hindlimb muscle mass was measured and MHC isoform content was determined by 1-D SDS-PAGE.

**RESULTS:** Mice injected with tumor cells developed tumors with an average mass of 1.75 g at 3 weeks post-injection. Exercise had no effect on tumor mass. The presence of the tumor had a significant effect on muscle mass in some muscles. In NE mice, cancer was shown to cause a 21% decrease in soleus mass and a 14% decrease in gastrocnemius mass. In addition, the tumor was associated with a significant slow-to-fast MHC isoform shift (-9.5% type I MHC, -8.5% type IIa MHC, +19% type IIb MHC) in the soleus muscle. The addition of voluntary wheel running had no effect on muscle mass or MHC isoform content in non-tumor-bearing mice. However, wheel running attenuated changes in muscle mass and MHC isoform expression in tumor bearing animals, such that there were no significant differences in either muscle mass or MHC content between the tumor bearing and the non-tumor-bearing groups.

**CONCLUSIONS:** Voluntary wheel running is not typically known to have significant effects on muscle mass in healthy animals, but these results suggest that both mass and MHC isoform content are sensitive to increases in muscle activity levels in tumor-bearing animals. These results further suggest that running activity may be an effective therapeutic strategy for cancer cachexia.

**Determinants Of Bone Mineral Density In Persons With Multiple Sclerosis**

Alexander V. Ng, FACSM<sup>1</sup>, Douglas Woo<sup>2</sup>, April Harkins<sup>1</sup>, Mary Ellen Csuka<sup>2</sup>, Ellen Heyer<sup>1</sup>, Benjamin A. Ingraham<sup>1</sup>, Jennifer Dixon<sup>1</sup>, Paula E. Papanek, FACSM<sup>1</sup>. <sup>1</sup>Marquette University, Milwaukee, WI. <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.  
Email: alexander.ng@marquette.edu  
(No relationships reported)

Persons with multiple sclerosis (MS), including men and premenopausal women, have significantly increased risk of reduced bone mineral density (BMD). Therapeutic glucocorticoid use in MS does not appear to consistently result in this reduced BMD. There is evidence that low vitamin D (25(OH)D) and the suggestion that reduced physical activity negatively affects BMD in MS. In addition, depression and elevated cortisol are known to be associated with decreased BMD and are also common in MS.

**PURPOSE:** The overall aim of this study was to determine associations of 25(OH)D, physical activity, endogenous cortisol, and depression, to BMD in persons with MS.

**METHODS:** We tested 7 persons with MS (5 Female, 2 Male; Md EDSS = 2) and 11 control (C) subjects (10 Female, 1 Male). Depression (Beck Depression Inventory) and the Multiple Sclerosis Functional Composite score (MSFC) was obtained from all subjects as were the following measures: Bone mineral density (BMD) of the lumbar spine (L2-L4) and femoral neck (mean left and right) was measured with dual X-ray absorptiometry. Vitamin D (25(OH)D) was measured from serum and cortisol from a nighttime salivary sample (11:00PM, EIA). Physical activity was indicated by accelerometers worn for 7 days around the waist and recorded as raw acceleration units. Analysis was by unpaired t-tests and Pearson correlations. Data are Mean (SE). Significance was  $p \leq 0.05$ .

**RESULTS:** MS subjects compared to C reported greater depression (MS = 7(3), C = 3(0.5),  $p = 0.001$ ), and had lower MSFC (MS = 2.2, C = 2.8). There were no differences between groups in BMD, 25(OH)D, cortisol, or physical activity. Despite the lack of difference between groups, physical activity was strongly correlated to femoral neck BMD in the MS group ( $r = 0.77$ ,  $p = 0.04$ ) but not control ( $r = -0.07$ ,  $p = 0.87$ ). Neither 25(OH)D, cortisol, or depression was correlated to BMD in MS or C.

**CONCLUSIONS:** In MS subjects with normal BMD and replete 25(OH)D, physical activity but not cortisol or depression, contributes to BMD.

*This study was Supported by NMSS grant PP1509*

**2994 Board #141 May 30 9:30 AM - 11:00 AM**  
**The Relationship Between Knowledge And Beliefs Of Osteoporosis And Bone Mineral Density**

Michelle Gray, Teri Lake. University of Central Oklahoma, Edmond, OK.  
Email: rgray11@uco.edu  
(No relationships reported)

There are over 20 million individuals that currently have osteoporosis contributing to the 1.5 million fractures in the U.S. each year. It has been previously determined that one's knowledge of a disease or health condition is related to the health behaviors toward preventing that particular illness. However, this concept has not been studied sufficiently with osteoporosis.

**PURPOSE:** Therefore the aim of this proposed project is to determine if specific knowledge of osteoporosis and its prevention are related to bone density.

**METHODS:** Women from the surrounding community volunteered to participate in the present investigation. Each participant completed the previously approved informed consent, health history questionnaire, Osteoporosis Knowledge Test (OKT), and Osteoporosis Health Belief Scale (OHBS). Upon completion of all surveys, the participants had their bone density analyzed via dual-energy x-ray absorptiometry (iDXA, GE Lunar, Madison, WI). A total of three scans were completed; total-body, left hip, and lumbar spine. Multiple regression analyses were used to determine if the results of the surveys predicted bone density (total-body, left femur, and spine). Independent variables used were the OKT and OHBS surveys. Dependent variables were the participant's bone density values for total-body, left femur, and lumbar spine.

**RESULTS:** The sample consisted of 16 women ranging in age from 18 to 65 years (41.44 + 13.69). Analyses revealed that the OHBS and OKT are significant predictors of total-body BMD ( $F[2,13] = 4.23$ ,  $p = .04$ ) and left femoral neck BMD ( $F[2,13] = 6.35$ ,  $p = .01$ ). However, the two surveys did not significantly predict BMD of the lumbar ( $F[2,13] = 0.25$ ,  $p = .78$ ).

**CONCLUSIONS:** It has been previously stated that knowledge and/or health beliefs affect the personal habits of individuals. In the present investigation, this was affirmed with the femoral neck and total-body bone density; however, this was not the case with the lumbar spine. Further research should be implemented to determine if, in fact, beliefs and knowledge are actually related to this specific health outcome. With over 20 million Americans afflicted with this incurable disease, education is the key to prevention.

**2995 Board #142 May 30 9:30 AM - 11:00 AM**  
**Influence Of Hormone Replacement Therapy With Maximal Eccentric Exercise On Estrogen Receptor Coregulators And Skeletal Muscle Damage In Postmenopausal Women**

Christina Dieli-Conwright, Tanya M. Spektor, Judd C. Rice, E. Todd Schroeder. University of Southern California, Los Angeles, CA. (Sponsor: Steven Hawkins, FACSM)  
Email: cdieli@usc.edu  
(No relationships reported)

The use of hormone replacement therapy (HRT) is a potential treatment to relieve symptoms of menopause and prevent the onset of disease such as osteoporosis in postmenopausal women. Although estrogen has a possible protective effect against exercise-induced skeletal muscle damage, it is unclear if HRT therapy enhances estrogen receptor (ER) activity in skeletal muscle at rest and following resistance exercise.

**PURPOSE:** To evaluate changes in the mRNA gene expression of ER coregulators (SRC and SMRT) and markers of skeletal muscle damage (CK, LDH, and TNF- $\alpha$ ) in postmenopausal women following a high-intensity resistance exercise bout.

**METHODS:** Fourteen postmenopausal women were divided into two groups: Control, women not using HRT ( $n=6$ ,  $59 \pm 2$  yr,  $63 \pm 7$  kg), or HRT, women using traditional HRT ( $n=8$ ,  $59 \pm 1$  yr,  $89.5 \pm 8.4$  kg). Both groups performed 10 sets of 10 maximal eccentric repetitions of single-leg extension on the Cybex dynamometer at  $60^\circ/\text{s}$  with 20 second rest periods between sets. Two muscle biopsies of the vastus lateralis were obtained from the exercised leg at baseline and 4 hours after the exercise bout. mRNA gene expression was determined using RT-PCR for SRC, SMRT, and TNF- $\alpha$ . Blood draws were performed at baseline and 3 days post-exercise to measure CK and LDH. Independent t-tests were performed to test

group differences (Control vs HRT). A probability level of  $p \leq 0.05$  was used to determine statistical significance with Bonferroni adjustments.

**RESULTS:** We observed significantly greater changes in mRNA expression of SRC and SMRT ( $p \leq 0.01$ ) and significantly lower changes in mRNA expression of TNF- $\alpha$  ( $p \leq 0.01$ ) in the HRT group compared to controls following the exercise bout. mRNA expression of SRC significantly increased ( $p \leq 0.01$ ) and mRNA expression of SMRT significantly decreased ( $p \leq 0.01$ ) following the exercise bout in both groups. CK and LDH levels were significantly greater post-exercise ( $p \leq 0.01$ ) in the Control group.

**CONCLUSIONS:** These data suggest a single bout of maximal eccentric exercise significantly enhances ER activity with greater response present in postmenopausal women using HRT. Postmenopausal women not using HRT experienced greater muscle damage after exercise indicating a possible protective effect of HRT against exercise-induced skeletal muscle damage.

**Intrinsic Muscle Properties Of The M. Quadriceps Femoris After Subacute Stroke**

Astrid M. Horstman<sup>1</sup>, Karin H. Gerrits<sup>1</sup>, Thomas W. Janssen, FACS<sup>2</sup>, Arnold de Haan<sup>1</sup>. <sup>1</sup>VU University Amsterdam, Amsterdam, Netherlands.

<sup>2</sup>Rehabilitation Centre Amsterdam, Amsterdam, Netherlands.

Email: a.horstman@fbw.vu.nl

(No relationships reported)

For optimizing rehabilitation programs, a better understanding is needed of the nature of weakness and fatigability of muscles of patients with stroke.

**PURPOSE:** To characterize muscle properties of paretic (PL) and non paretic (NL) knee extensors in subacute stroke patients compared to able-bodied controls.

**METHODS:** Maximal rate of torque development (MRTD) was assessed as an indicator of speed using both voluntary and electrically evoked contractions of knee extensors in 14 patients with a hemi paresis of the lower extremity (56 $\pm$ 10 years, 3.5 $\pm$ 2 months after stroke) and in 12 age-matched able-bodied controls. In addition, changes in torque and half relaxation time (HRT) were measured during a fatigue protocol (35 electrically evoked intermittent contractions (1.5s on, 2 off)) and during electrically evoked 20Hz contractions. Force frequency relations (FFR) were established.

**RESULTS:** No differences among groups were found for normalized MRTD during electrically evoked contractions ( $p=0.117$ ). However, during voluntary contractions both PL (0.55  $\pm$  0.21%.ms<sup>-1</sup>) and NL (0.76  $\pm$  0.14%.ms<sup>-1</sup>) had significantly lower MRTD compared to control (1.04  $\pm$  0.31 %.ms<sup>-1</sup>) ( $p=0.022$  and  $p<0.001$  resp.). The course of torque decline showed that PL fatigued more and faster than control ( $p=0.011$ ). Furthermore, PL and NL relaxed more slowly than control as indicated by longer HRT in PL and NL during fatigue ( $p<0.001$ ) and during the 20Hz contractions (PL: 91.9  $\pm$  15.6ms, NL: 89.2  $\pm$  11.8ms, control: 80.5  $\pm$  8.2ms) ( $p=0.067$ ). Moreover, at the same stimulation frequencies, PL had a higher torque response than NL and control, but no differences in twitch torque were found among groups ( $p=0.125$ ).

**CONCLUSION:** Longer HRT in both PL and NL indicate muscle 'slowing' after stroke, although no differences were found in 'electrically evoked' MRTD. In addition, in PL this was accompanied by a left-shift of FFR and more rapid fatigue. These changes suggest adaptations in muscle properties towards slower, less fatigue resistant muscle which develop shortly after stroke. Moreover, the capacity to develop adequate torque rapidly (lower voluntary MRTD) is decreased after stroke. Thus, besides strengthening, also muscle endurance and speed should be addressed during rehabilitation to reverse adaptations in intrinsic muscle properties after stroke.

Malignant hyperthermia (MH) is a potentially lethal skeletal muscle disorder in which uncontrolled SR Ca<sup>++</sup> release is induced by halogenated anesthetics, heat, and potentially endurance exercise.

**PURPOSE:** To determine if MH susceptible mice (Y522S; heterozygous expression of ryanodine receptor 1 Y522S mutation) can perform 6 weeks of voluntary wheel running without inducing a fatal MH episode or excessive muscle damage and to assess the adaptive potential of Y522S anterior crural muscles [tibialis anterior (TA) and extensor digitorum longus (EDL) muscles].

**METHODS:** Wild type (WT) and Y522S mice were housed (~22°C) individually with a running wheel, while age-matched sedentary mice served as controls (n = 8/group). Trained and sedentary mice performed an *in vivo* anterior crural muscle fatigue test (360 concentric contractions in 30 minutes; 300 Hz, 38° angular movement at 400°/s). Citrate synthase activity and cytochrome C oxidase (COXIV subunit) protein content were determined in TA and EDL muscles respectively.

**RESULTS:** Y522S mice voluntarily ran without inducing a fatal MH episode, but ran 42% less distance per day than WT mice (4.0 $\pm$ 1.1 vs 6.9 $\pm$ 1.0 km/d). Neither Y522S nor WT trained mice exhibited exacerbated histological signs (H&E stain; right TA) of muscle damage. Sedentary Y522S mice exhibited a greater intrinsic fatigue resistance than WT mice (fatigue index: -13.4 $\pm$ 2.7 vs -28.9 $\pm$ 3.1%), as well as a ~67% greater EDL muscle COXIV protein content. Additionally, citrate synthase activity was greater in Y522S than WT TA muscle (28.1 $\pm$ 0.9 vs 26.0 $\pm$ 0.6  $\mu$ mol/min/g wet weight), regardless of training status. Wheel running improved fatigability (WT & Y522S fatigue index: -19.2 $\pm$ 1.6 & -12.0 $\pm$ 1.3%) and increased COXIV protein content (WT & Y522S: ~57 & ~17%) in WT but not Y522S mice. Trained Y522S mice remained more fatigue resistant than WT mice, although COXIV protein content was similar between groups after training.

**CONCLUSION:** Y522S mice can run voluntarily in an environment that is not thermally stressful (i.e., ~22°C) without inducing a MH episode and have an enhanced intrinsic resistance to fatigue, which may partially stem from a greater aerobic capacity.

**Determinants Of Peak Leg Extensor Muscle Power In Overweight And Obese Older Adults**

Joshua J. Avila, Megan E. Sheehy, Julie A. Gutierrez, Thomas G. Manfredi, FACS<sup>M</sup>, Ingrid E. Lofgren, Matthew J. Delmonico. University of Rhode Island, Kingston, RI.

Email: joshavila@mail.uri.edu

(No relationships reported)

Peak muscle power (MP) has been shown to be a strong predictor of physical functioning in older adults. Additionally, although it has been reported that both fat and skeletal muscle need to be included in a sarcopenia definition, it has been recently suggested that a predictor of physical function should also be included. However, there is no consensus as to what measure of function should be included when assessing sarcopenic obesity.

**PURPOSE:** To assess the determinants of peak leg extensor MP in overweight and obese older adults.

**METHODS:** Thirty-one relatively healthy overweight and obese (BMI=31.8 $\pm$ 0.6) community-dwelling older (age = 66 $\pm$ 1 yrs) men (n=12) and women (n=19) were recruited for an ongoing dietary weight loss and exercise intervention trial. MP of the leg extensors was measured using a pneumatic leg extension power machine at 40%-80% of measured strength. Potential determinants of MP included age, sex, height, % body fat and fat-free mass (from air-displacement plethysmography), bi-lateral mid-thigh muscle and intermuscular fat cross-sectional areas (CSA) from computed tomography, and thigh muscle CSA/total body fat mass. Backward elimination regression was used to assess the contributions of these potential

determinants on MP ( $p < 0.10$  to remain in the final model).

**RESULTS:** In men, when adjusted for age, thigh muscle CSA was the only determinant of MP ( $p=0.065$ ). In women, the only significant determinant of MP was thigh muscle CSA/total body fat mass ( $p=0.010$ ).

**CONCLUSIONS:** These results indicate that thigh muscle CSA as a percentage of total body fat mass is a determinant of leg MP in older, overweight and obese women, suggesting that fat mass may play an important role in physical performance in women. However, thigh muscle CSA alone appears to be a better determinant of MP in men. Although results need to be validated with a larger sample size, these data provide support for the importance of both thigh muscle CSA and body mass fat when assessing function in a population at risk for obesity-related disability. These results also have implications for the development of a sarcopenia definition that includes peak MP.

**Skeletal Muscle Alterations In Chronic Heart Failure (CHF): Differential Effects Of Left Ventricular Dysfunction On Catabolic Activation In The Quadriceps Muscle And The Diaphragm**

Norman Mangner<sup>1</sup>, Stephan Gielen<sup>1</sup>, Marcus Sandri<sup>1</sup>, Robert Hoellriegel<sup>1</sup>, Volker Adams<sup>1</sup>, Rainer Hambrecht<sup>2</sup>, Gerhard Schuler<sup>1</sup>. <sup>1</sup>University of Leipzig - Heart Center, Leipzig, Germany. <sup>2</sup>Klinik Links der Weser, Bremen, Germany.  
Email: norman.mangner@med.uni-leipzig.de

(No relationships reported)

**PURPOSE:** Muscle wasting is increasingly recognized as a cause of exercise intolerance in CHF. The catabolic process is in part mediated by the E3-Ligase Murf-1 via activation of the ubiquitin proteasome system. It is, however, unclear if respiratory muscles are equally affected by muscle catabolism as compared to peripheral skeletal muscles: Aim of this study was to examine the effects of CHF on expression of Murf-1 and the activity of manganese superoxide dismutase (Mn-SOD) in quadriceps muscle (Qua) and diaphragm (Dia) in LAD-ligated rats (MI).

**METHODS:** Left ventricular function was assessed in MI ( $n=12$ ) and sham operated (C,  $n=9$ ) rats using echocardiography and Millar-catheter 12 weeks after operation. Murf-1 protein expression and multi-ubiquitin content were quantified using Western Blot and Mn-SOD activity was measured in Qua and Dia.

**RESULTS:** Compared to C, MI resulted in CHF (EF:  $33.4 \pm 3.3$  vs.  $64.8 \pm 2.6$  %,  $p < 0.01$ ; LVEDD:  $9.6 \pm 0.3$  vs.  $6.8 \pm 0.2$  mm,  $p < 0.01$ , dp/dt max:  $4.4 \pm 0.3$  vs.  $5.8 \pm 0.5$ ,  $p = 0.02$ ). MI resulted in a 4.5-fold increase in Murf-1 expression in Qua ( $3.7 \pm 0.7$  vs.  $0.8 \pm 0.1$  arb. units,  $p < 0.001$ ). A negative correlation was observed with EF ( $r = -0.66$ ,  $p = 0.01$ ), a positive one with LVEDD ( $r = 0.59$ ,  $p = 0.03$ ). MI also resulted in an increase in the ubiquitin content in Qua ( $51.4 \pm 7.1$  vs.  $29.5 \pm 4.7$  arb. units,  $p = 0.05$ ). Mn-SOD activity decreased in MI ( $0.15 \pm 0.1$  vs.  $1.4 \pm 0.4$ ,  $p < 0.01$ ). This was negatively correlated with Murf-1 expression ( $r = -0.53$ ,  $p = 0.04$ ). MI also resulted in an increase of Murf-1 expression in Dia ( $2.2$  fold,  $2.8 \pm 0.4$  vs.  $1.3 \pm 0.3$  arb. units,  $p < 0.05$ ) but no difference in ubiquitin content was detectable ( $46.3 \pm 3.7$  vs.  $46.3 \pm 5.9$  arb. units,  $p = 0.99$ ). In contrast to Qua Mn-SOD activity increased with CHF in Dia ( $2.4 \pm 0.5$  vs.  $0.7 \pm 0.3$ ,  $p = 0.01$ ). All observed correlations in Qua could not be detected in Dia.

**CONCLUSIONS:** MI resulted in CHF accompanied by an increase of E3-Ligase Murf-1 and ubiquitinated proteins in peripheral muscle. This increase was significantly correlated with left ventricular dysfunction and decreased antioxidative capacity in quadriceps muscle. One reason for the attenuation of catabolic activation and the increase of Mn-SOD activity in Dia may be a dyspnea related training effect. These findings indicate differential effects of CHF on peripheral skeletal muscle and diaphragm.

**Lack Of Myosin Light Chain Isoform Expression In The Mechanical Overloaded Obese Zucker Rat Plantaris**

C. Eric Arnold<sup>1</sup>, Gina Sobrero Evans<sup>1</sup>, Eric R. Blough<sup>1</sup>, Sunil Kakarla<sup>1</sup>, Aunil Gutta<sup>1</sup>, William P. Marley, FACSM<sup>1</sup>, Peter J. Reiser<sup>2</sup>. <sup>1</sup>Marshall University, Huntington, WV. <sup>2</sup>The Ohio State University, Columbus, OH.  
Email: arnolde@marshall.edu

(No relationships reported)

Myosin light chain (MLC) isoforms play an integral role in modulating maximal shortening velocity and power output in skeletal, cardiac, and smooth muscles. It is thought that the expression of MLCs is regulated, at least in part, by muscle contractile activity. Recent data has suggested that insulin resistance may affect the ability of skeletal muscle to adapt to an overload stimulus. How insulin resistance may affect the regulation of MLC expression following an overload stimulus is not well understood.

**PURPOSE:** The purpose of the study was to investigate the effect of mechanical overload (MOV) on MLC1S (Slow), MLC1F (Fast), and MLC3 expression in the insulin resistant Obese Zucker (OZ) (Lep<sup>fa</sup>) rat plantaris.

**METHODS:** Young (2 mo,  $n = 5$ ) male Lean Zucker (LZ) and young (2 mo,  $n = 5$ ) male OZ rats underwent unilateral surgical ablation of the gastrocnemius muscle to MOV the fast-twitch plantaris muscle for 8 weeks. A 20 mg proximal section from both the OZ and LZ MOV and Contralateral Control Plantaris (CCP) muscle was analyzed for changes in MLC expression using SDS-PAGE.

**RESULTS:** MOV increased MLC1S expression by 50.65% ( $p = 0.02$ ) in the LZ plantaris compared to the LZ CCP. There were no significant differences in MLC1F and MLC3 between the LZ MOV and LZ CCP. Obese Zucker MOV and OZ CCP muscle MLC1S, MLC1F, and MLC3 did not differ significantly. Furthermore, there were no significant differences observed between the OZ MOV, LZ MOV, OZ CCP, and LZ CCP muscle MLC1S, MLC1F, and MLC3 isoforms, respectively.

**CONCLUSION:** These results suggest that insulin resistance may affect the ability of skeletal muscle to alter MLC isoform expression in response to MOV.

**Feet Alterations Prevalence In Elder Mexican Women.**

Fernando Sotelo<sup>1</sup>, Cipriana Caudillo-Cisneros<sup>2</sup>, Sergio Márquez-Gamiño<sup>2</sup>, Nieves Serratos-Pérez<sup>2</sup>. <sup>1</sup>Universidad de Guanajuato/Instituto Mexicano del Seguro Social, León, Mexico. <sup>2</sup>Universidad de Guanajuato, León, Mexico. (Sponsor: Francisco José Díaz-Cisneros, FACSM)  
Email: sotelo@fisica.ugto.mx

(No relationships reported)

**PURPOSE:** to determine feet musculoskeletal alterations in elder Mexican women.

**METHODS:** We evaluated 182 women mean age  $71 \pm 11.26$  years old (range 51-106). The study consisted of two phases. First, a musculoskeletal evaluation, with emphasis in the morphological and pathological characteristics of the feet, was done. The plantar support was also evaluated. In a second session, feet were measured by means of a 3D digitizer. In addition, the participants' inner antero-posterior footwear length was measured. Data was processed using descriptive statistics. The difference between right and left feet's length, as well as that between feet and footwear's length was assessed by a Student's  $t$  test.

**RESULTS:** At least one musculoskeletal alteration was found in 73.3% of the participants. The most prevalent was *Hallux Valgus* (48.0%), followed by flat foot (37.9%) and cavus foot (28.5%). Statistically significant difference ( $p=0.028$ ) between length of the right and left feet was observed,  $233.25 \pm 11.05$  and  $232.01 \pm 10.13$  cm, respectively. The mean foot length, both sides included, was  $241.5663 \pm 9.17073$  cm. Also, a statistical difference between the footwear and the feet length, right side ( $p=0.001$ ), and left side ( $p=0.001$ ) was found.

**CONCLUSIONS:** The study displays a high prevalence of musculoskeletal alterations in the elder Mexican women feet. Differences between feet and footwear length suggest that inadequate footwear could be a cause for appearance and/or aggravation of these organ musculoskeletal alterations.

**The Relationship Of Intramuscular Fat And Glucose Tolerance In Hispanic Women**

Angela Baldwin Lanier<sup>1</sup>, Chris Elder<sup>2</sup>, Jill Slade<sup>3</sup>. <sup>1</sup>Berry College, Mount Berry, GA. <sup>2</sup>Vanderbilt University, Nashville, TN. <sup>3</sup>Michigan State University, East Lansing, MI.  
Email: alanier@berry.edu  
(No relationships reported)

Hispanic Americans are 1.5 times more likely to develop diabetes than non-Hispanic whites of similar age, and in almost every age group, the prevalence is higher in women than in men. Intramuscular fat (IMF) in the thigh has been related to impaired glucose tolerance (IGT) and physical inactivity which are risk factors for type 2 diabetes.

**PURPOSE:** The objective of this pilot study was to determine whether thigh IMF and aerobic fitness are related to glucose tolerance in Hispanic females.

**METHODS:** Participants were 18 Hispanic women (29.4 ± 8.3 years). T1-weighted magnetic resonance images of the right thigh were analyzed for IMF and muscle cross-sectional area (CSA). Peak oxygen uptake (VO<sub>2</sub>) during cycle ergometry was assessed, and fasting, 30, 60, and 120-minute glucose levels were measured. Differences between participants with (n=6) or without (n=12) IGT were assessed. Independent t-tests and simple linear regression were performed to assess relationships between IMF and the dependent variables.

**RESULTS:** Participants with IGT had 96 % more intramuscular fat CSA (5.7 ± 3.3 vs 2.9 ± 1.5 cm<sup>2</sup>, P = 0.028) and a higher percentage of IMF (6.8 ± 3.3 vs 3.2 ± 1.5 %, P = 0.005) than non-IGT participants. Peak VO<sub>2</sub> was 33% lower for participants with IGT (P = 0.003). Percent IMF was strongly associated with blood glucose levels for fasting (r<sup>2</sup> = .34), 30 (r<sup>2</sup> = .49), 60 (r<sup>2</sup> = .48), and 120- minutes (r<sup>2</sup> = .54) following glucose ingestion. Peak VO<sub>2</sub> was associated with percent IMF (P = 0.002) and blood glucose at 30, 60, and 120- minutes after glucose ingestion (P < 0.03).

**CONCLUSIONS:** It appears from these preliminary data that fat within the thigh muscle may be associated with impaired glucose tolerance and cardiorespiratory endurance in Hispanic women. Further work is needed to determine the underlying mechanisms behind these relationships.

**3003 Board #150 May 30 9:30 AM - 11:00 AM**  
**Assessment Of Bone Density In Hispanic Women Living In Rural East Texas**

Luke O. Pearson<sup>1</sup>, Cheryl M. Cooper<sup>1</sup>, Mary A. Bone<sup>2</sup>, Guillermo A. Saade<sup>3</sup>, Joyce E. Ballard, FACSM<sup>1</sup>. <sup>1</sup>University of Texas at Tyler, Tyler, TX. <sup>2</sup>Cherokee County Health Department, Jacksonville, TX. <sup>3</sup>East Texas Medical Center, Jacksonville, TX.  
(No relationships reported)

Most previous studies evaluating low bone density (BD), osteopenia, osteoporosis and non-traumatic fractures have involved Anglo women. Currently, bone research is being geared to other racial and ethnic groups. However research for bone density in Hispanic women lags behind that of African American and Asian women (Pothiwala, et al., 2006).

**PURPOSE:** To assess Bone Mineral Density (BMD) of the AP spine (APS), femoral Neck (FN), Total Hip (TH), Ultra Distal Forearm (UDF) and the Total Distal Forearm (TDF) in a group of Hispanic women who resided in rural East Texas.

**METHODS:** Subjects (Ss) consisted of 66 volunteer Hispanic women, referred by a private physician or by the Medical Director of the County Health Department. The criteria for Hispanic ethnicity were having a Hispanic surname and having a mother with a Hispanic surname. Anthropometric measures were: standing height, body weight, skinfolds, body circumferences, and skeletal widths. Body density was determined by the skinfold equation of Jackson et al., (1980) and converted to % body fat by the Siri equation (1961). Also, a survey of demographic, lifestyle and nutritional factors was obtained but only the demographic data will be reported here. Bone density was assessed on a Hologic Discovery (Model C) DEXA Bone Densitometer and all scans were obtained by the same technician. World Health Organization (WHO) Standards were used to determine Normal (Nm) Osteopenic (Pa) and Osteoporotic (Po) BMD status.

**RESULTS:** Ss birth places were: Mexico (n=55, 89%), other Central American countries (n=4, 6%), and US (n=3, 5%). Ss from Mexico had lived in the US for 14.1 ± 8.9 yrs, and from Central America for 12.5 ± 8.5 yrs. Means and SDs across all Ss for anthropometric data were: Age= 46.8 ± 5.3 yrs, Standing Ht=152.6 ± 7.1 cm, Body Wt=75.2 ± 14.3 kg, % Body Fat=35.4 ± 4.0 %, BMI=32.3 ± 6.1, and Waist Girth 96.6 ± 12.5 cm. Mean BMD (g/cm<sup>2</sup>) values evaluated by the number of Ss in WHO categories were: AP Spine=0.963 ± 0.098 (Nm=27 Pa=37 Po=2); FN=0.856 ± 0.111 (Nm=52, Pa=14); TH=1.015 ± 0.127, (Nm=61 Pa=5); UDF= 0.415 ± 0.043 (Nm=56 Pa=10); and TDF=0.548 ± 0.038 (Nm=50 Pa=16).

**CONCLUSIONS:** Although these Hispanic women in their mid 40s were overweight, their BMD values showed considerable osteopenia, especially in the spine. Thus, measures should be taken to prevent osteoporosis in this population.

**Physical Performance In Geriatrics: Affected By Rollator Use?**

Katrin Lucki<sup>1</sup>, Lutz Vogt<sup>1</sup>, Matthias Bach<sup>2</sup>, Bettina Schulze<sup>2</sup>, Winfried Banzer<sup>1</sup>. <sup>1</sup>Goethe-University Frankfurt, Frankfurt/Main, Germany. <sup>2</sup>St. Elisabethen-Krankenhaus Frankfurt, Frankfurt/Main, Germany.  
(No relationships reported)

Ambulation assistive devices are frequently prescribed to reduce fear of falling, increase stability and enhance mobility and independence. Nevertheless, authors have assumed that the regular use of walking aids will predict decline in ADL function and may be associated with hospitalization.

**PURPOSE:** The present study examined the effect of rollator use on gait and stair climbing rehabilitation outcome in geriatric patients.

**METHODS:** In a prospective randomized controlled trial, the admission ambulatory status of geriatric rehabilitation patients, was determined by the Performance-Oriented Mobility Assessment (POMA) and standardized judgements about stair climbing. After initial testing, 55 patients (47 women and 8 men; age range 67-97 years) with a high risk of falling (POMA-T<19) were randomly assigned to the experimental (wheeled walker, n=29) or the control group (no device, n=26). None of the subjects were using assistive devices in their every day lives. Measurements (balance, gait, stair ambulation) were repeated after the inpatient rehabilitation regimen (mean length of stay 28.7 (standard deviation 13.9) days) by a single experienced observer who was blinded to group randomization.

**RESULTS:** Mann-Whitney-U-test did not reveal significant group differences between the POMA-T admission and discharge scores. More than 70% of the patients in both groups (19 control; 21 verum) demonstrated individual functional ability improvements of at least 5 points during rehabilitation (POMA-T). However, at rehabilitation discharge 19 subjects of the control and 24 of the experimental group still demonstrated a increased fall risk. No significant staircase examination differences were observed for device users compared to the control subjects. At discharge less than 5% of both cohorts were able to negotiate stairs with slight or no limitations.

**CONCLUSION:** The present study evidenced that rollator assistance does not interfere with functional gains and rehabilitation outcome. Thus, patients with greater risk of

**Reference Values And Prediction Models Of Sarcopenia In Japanese Men And Women**

Kiyoshi Sanada<sup>1</sup>, Motohiko Miyachi<sup>2</sup>, Kenta Yamamoto<sup>1</sup>, Mitsuru Higuchi, FACSM<sup>1</sup>, Izumi Tabata, FACSM<sup>2</sup>. <sup>1</sup>Waseda University, Tokyo, Japan. <sup>2</sup>National Institute of Health and Nutrition, Tokyo, Japan.

Email: sanada@wasda.jp

(No relationships reported)

Sarcopenia is the loss of skeletal muscle mass resulting in a reduction of physical strength and ability to perform activities of daily living. However the reference values and prediction models of sarcopenia for Japanese adults still are not investigated.

**PURPOSE:** The purposes of this study were to investigate the reference values and prediction models of sarcopenia using dual-energy X-ray absorptiometry (DXA) and anthropometric measurements in Japanese men and women.

**METHODS:** Subjects were healthy Japanese men (n=529) and women (n=1239) aged 18-85 yrs. All subjects were randomly separated into 2 groups, a model development group (n=1374) and a validation group (n=394). Appendicular muscle mass was measured by DXA. Reference values for sarcopenia (skeletal muscle index, SMI; appendicular muscle mass/height<sup>2</sup>, kg/m<sup>2</sup>) in each sex were defined as values two standard deviations below the sex-specific means of this study reference data for young adults aged 18-40 years.

**RESULTS:** The subjects with sarcopenia were 2.1 % in men and 1.9% in women. The whole body bone mineral density in sarcopenia men and women ( $1.091 \pm 0.094$  and  $0.918 \pm 0.077$  g/cm<sup>2</sup>) were significantly lower than in normal subjects ( $1.161 \pm 0.103$  and  $1.041 \pm 0.121$  g/cm<sup>2</sup>,  $P < 0.05$ ), respectively. The handgrip strength in sarcopenia men and women ( $42.2 \pm 7.7$  and  $20.9 \pm 4.0$  kg) were significantly lower than in normal subjects ( $44.4 \pm 6.7$  and  $27.0 \pm 5.3$  kg,  $P < 0.05$ ). Stepwise regression analysis indicated that the handgrip strength, body mass, body height and age were independently associated with DXA-measured SMI both in men and women. The SMI prediction equations were applied to the validation group, and significant correlations were also observed between the DXA-measured and predicted SMI (n=386,  $r = 0.918$ ,  $P < 0.001$ ,  $SEE = 0.172$  kg/m<sup>2</sup>). The predicted SMI for the validation group was  $7.299 \pm 0.990$  kg/m<sup>2</sup>, which was very similar to the DXA-measured SMI of  $7.342 \pm 1.153$  kg/m<sup>2</sup>.

**CONCLUSION:** This study provides reference values of sarcopenia, and the prediction models of SMI using anthropometric measurement are valid for alternative DXA-measured SMI in Japanese men and women.

**Effects Of Pilates Mat Work On Pelvic Floor Muscles And Postpartum Depression In Puerperium Women**

Young-Nam Jeon, Sang-Keun Shin, Jin-Kyoung Kim, Joo-Seong Kang, Ki-Bong Kim, Jung-Jun Park, Jum-Hong Yang. Pusan National University, Busan, Republic of Korea.

Email: dorothea77@naver.com

(No relationships reported)

**PURPOSE:** To investigate the effects of Pilates mat work on the pelvic floor muscles and postpartum depression of women in puerperium.

**METHODS:** Puerperium women at postpartum care center of a lying-in hospital located in B Metropolitan City participated in this study and divided into exercise and control group, consisting of 9 and 8 members respectively. Pilates mat work was applied to the exercise group for 7 weeks with 3 days a week, RPE 11-15 and 40-60 minutes per day. Independent t-test (between groups) and paired t-test (within group) were used for data analysis (SPSS ver. 12.0). The statistical significant level was  $p < .05$ . Based on results of the application compared pelvic floor muscles (maximal vaginal contraction pressure and maximal vaginal contraction duration) and postpartum depression (postpartum depression scale) were compared between two groups.

**RESULTS:** Both between-group and within-group comparisons showed that after the exercise, maximal vaginal contraction pressure ( $p < .001$ ) improved in the exercise group. The within-group comparison, it was found that after Pilates mat work, the exercise group showed improvements in maximal vaginal contraction duration ( $p < .05$ ) and postpartum depression scale ( $p < .05$ ). But control group was not statistically difference.

**CONCLUSIONS:** Pilates mat work is an exercise that is effective in improving the pelvic floor muscles and postpartum depression of puerperium women. This suggest that Pilates mat work can be positively used as a postpartum exercise program.

**Response To Prolonged Endurance Training and Detraining In Mitochondrial Myopathy**

Phillip S. Wyrick<sup>1</sup>, Katja Heinicke<sup>2</sup>, Ronald G. Haller<sup>2</sup>. <sup>1</sup>IEEM, Presbyterian Hospital-Dallas, Dallas, TX. <sup>2</sup>IEEM, Presbyterian Hospital-Dallas & University of Texas Southwestern Medical Center, Dallas, TX.

Email: PhilWyrick@TexasHealth.org

(No relationships reported)

Patients with mitochondrial myopathies (MM) due to mtDNA mutations in skeletal muscle often suffer disabling exercise intolerance. Our previous studies suggest that short duration (14 weeks) endurance training improves exercise capacity and increases the activity of rate-limiting enzymes. The effect of a longer duration exercise training has not been studied.

**PURPOSE:** To assess the effect of 6 months of regular endurance training on exercise capacity and to determine if training adaptations are maintained after a prolonged period of self-selected activity in a patient with severe muscle oxidative impairment due to a mitochondrial myopathy.

**METHODS:** A 26-year male with a heteroplasmic single large-scale deletion of mtDNA underwent 26 weeks of cycle exercise training followed by a 52 week period of self-selected activity level. Peak work, oxygen uptake (VO<sub>2</sub>), and submaximal heart rate and blood lactate were determined at baseline, after training and following 52 weeks of self-determined activity.

**RESULTS:** Compared to baseline, training increased peak work from 110 to 130 watts and VO<sub>2</sub> from 1.527 to 1.837 L/min. During submaximal (50 watt) exercise, peak heart rate decreased from 153 to 120 bpm and venous lactate from 6.41 to 3.25 mM. After 52 weeks of self-selected activity following 6 months of endurance training, peak work and VO<sub>2</sub> fell to 110 watts and 1.684 L/min respectively. During submaximal exercise, after the self-selected activity period compared to post training, heart rate (133 vs. 120 bpm) and lactate levels (4.36 vs. 3.25 mM) were higher.

**CONCLUSION:** Endurance training in MM improved work and oxidative capacity supporting the efficacy of this therapy in patients with mitochondrial myopathy due to single large-scale mtDNA deletions. Despite the substantial benefits of exercise training, the patient did not choose to maintain regular exercise training and after the 52 week period of self-selected activity, exercise capacity declined to near pre-training levels indicating that deconditioning contributes to exercise limitations in these patients and that the applicability of exercise training as therapy is limited by patient motivation.

**Therapeutic Role Of Resistance Training With Vascular Occlusion In Inclusion Body Myositis: A Case Report**

Bruno Gualano<sup>1</sup>, Manoel Neves<sup>1</sup>, Felipe Freitas<sup>1</sup>, Ana LS Pinto<sup>1</sup>, Gilberto Laurentino<sup>1</sup>, Claudia TL Borges<sup>1</sup>, Luciana Baptista<sup>2</sup>, Guilherme G. Artioli<sup>1</sup>,

Valmor AA Tricoli<sup>1</sup>, Antonio H. Lancha Jr<sup>1</sup>, Fernanda R. Lima<sup>1</sup>, Carlos Ugrinowitsch<sup>1</sup>. <sup>1</sup>University of São Paulo, São Paulo, Brazil. <sup>2</sup>Hospital Nove de Julho, São Paulo, Brazil. (Sponsor: Fernanda Rodrigues Lima, FACSM)  
Email: gualano@usp.br  
(No relationships reported)

Inclusion body myositis (IBM) is a rare inflammatory idiopathic myopathy (4-9:1 million) that mainly affects middle-aged to older people. Little or no response to pharmacological treatment is the rule in this chronic, progressive and severe disease. Rehabilitation is indicated in those with stable disease activity but generally limited to mild exercises as intense physical training could possibly worsen muscle inflammation. As low-intensity resistance training with vascular occlusion can yield muscular adaptations comparable to those found in intensive training, we hypothesized that it could improve functional capacity in these patients.

**PURPOSE:** To assess the effects of low-intensity resistance training with vascular occlusion on muscle functional capacity, quality of life and disease activity in patients with IBM.

**METHODS:** A 65-year-old male with IBM (wt: 85 kg; ht: 180 cm;  $\text{VO}_{2\text{peak}}$ :  $10 \text{ ml}^{-1} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) engaged a moderate resistance training program with vascular occlusion for 12 weeks. We assessed 1RM leg press strength, quadriceps cross-sectional area (by computerized tomography), balance and mobility function (timed up-and-go test), quality of life (SF-36 and HAQ), blood markers of inflammation (VHS, PCR) and muscle damage (CK, LDH, aldolase) at baseline (PRE) and after (POST) the 12-week program. Resistance training was performed twice a week and consisted of 3x15 RM (30 sec between sets) leg-press, knee extension and squat exercises performed with vascular occlusion at 50% of occlusion pressure (determined by doppler at each session).

**RESULTS:** The patient showed improvements in lower limbs strength (11.6%), quadriceps cross-sectional area (4.7%) and balance and mobility function (60%). The SF-36 subscale activities of daily life exhibited great improvements but HAQ scores were not different between PRE and POST. Exercise training did not increase levels of CK, LDH, aldolase VHS or PCR above normal range.

**CONCLUSION:** Low-intensity resistance training with vascular occlusion may improve strength, quadriceps cross-sectional area functional capacity and daily activities without worsening muscle inflammation or disease activity in an IBM patient. Prospective randomized studies should confirm these findings.

**Active Warm Up On Isokinetic Peak Torque And Hamstring To Quadriceps Ratio**

CK LI, N Luchini, S Racinais, B Sas. *Aspetar, Doha, Qatar.*  
Email: lichikei@yahoo.com.hk  
(No relationships reported)

Warm up exercise has been practiced widely on the field by coaches and athletes because it is believed that the change in muscular performance play role in injury prevention. However, its effectiveness is still not well defined. Hamstring to quadriceps (HQ) ratio, which use to address the strength imbalance of lower limb, have been used as an index to predict knee injury. A low HQ ratio is proposed to have a higher risk of injury. Therefore, it is interested to see whether active warm up can influence the HQ ratio in order to lower the risk of injury.

**PURPOSE:** The objective of this study is to investigate the effect of active warm up exercises in isokinetic peak torque (PT) and HQ ratio for the sake of injury prevention.

**METHODS:** During four laboratory visits, 21 male subjects (mean age  $34.6 \pm 9.3$  yrs) randomly performed three 15 minutes active warm up protocol (general, task specific and functional) and a control (no warm up). General - constant pace exercise on static bicycle at 60% age predicted maximum heart rate; Task Specific - leg curl exercise with 6 kg load at pace of 70 beats per min; Functional - exercise on bicycle, stepper and trampoline with variable speed and resistance. After each routine, PT and HQ ratio were determined with 5 maximum concentric contractions on right lower limb with isokinetic testing at 60, 180 and 300 °/sec. The HQ ratio was calculated as the ratio between concentric PT of hamstring and quadriceps.

**RESULTS:** There was no significant difference ( $p > 0.05$ ) between each warm up exercise and with control in PT on either quadriceps or hamstring in all test speeds. Also, none of the warm up exercises caused a significant ( $p > 0.05$ ) modification in the HQ ratio.

**CONCLUSIONS:** Active warm up (general, task specific and functional) in comparison to control did not alter PT and HQ ratio with isokinetic testing in concentric mode. Our finding suggested that 15 minutes of warm up failed to improve muscular torque, despite general believe of warm up from athletes and coaches. Also the risk of lower limb injury after may not alter if use HQ ratio as an index.

**The Effects Of Proprioception Training On Neuromuscular And Sensorimotor Control Abilities In Subjects With Functional Ankle Instability**

Wei-Hsiu Lin<sup>1</sup>, Alex J. Y. Lee<sup>2</sup>, Chi-Huang Huang<sup>3</sup>. <sup>1</sup>National Chiayi University, Chiayi, Taiwan. <sup>2</sup>National Hsinchu University of Education, Hsinchu, Taiwan. <sup>3</sup>National Taiwan Sport University, Taoyuan, Taiwan.  
Email: whlin0825@gmail.com  
(No relationships reported)

**PURPOSE:** To examine the effects of 6-week proprioception training on neuromuscular and sensorimotor control abilities in subjects with functional ankle instability.

**METHODS:** Ten untrained subjects ( $21.10 \pm 2.42$  yrs,  $166.65 \pm 9.63$  cm and  $58.84 \pm 13.55$  kg) with 11 functional unstable ankles participated in this study. The proprioception training was performed for 30 minutes per day and 3 days per week for 6 weeks. Ankle active and passive joint position sense (JPS), balance steadiness and alpha-motoneuron excitability were measured in the measurement weeks which occurred one week prior to the inception of the proprioception training and one week following the conclusion of proprioception training. The JPS was measured using Biodex system III isokinetic dynamometer (Biodex Medical, Inc., Shirley, NY). Joint reposition absolute errors were recorded in degrees of error from three target angles in active mode and passive mode. The force platform (AMTI Inc., Watertown, MA) was used to measure balance steadiness as the center of pressure (COP) displacement radius in open eye (OE) and closed eye (CE) condition. The maximal M-wave and the H-reflex amplitude were measured in the soleus muscle. Multivariate repeated measurement ANOVA was used to evaluate the effects of training on JPS (mode x target angle x time) and balance steadiness (condition x time) respectively. Repeated measures t-test was used to determine if any difference in Hmax/Mmax ratios before and after training.

**RESULTS:** The results showed there were main effects in the COP displacement radius between OE and CE conditions ( $P < .05$ ,  $F = 25.65$ ) and joint reposition absolute errors between active mode and passive mode. ( $P < .05$ ,  $F = 5.92$ ) There were no significant differences in the COP displacement radius in either OE or CE conditions between pre and post-training and also joint reposition absolute errors in either active mode or passive mode between pre and post-training. However, there was a significant ( $P < 0.05$ ) decrease (10%) in Hmax/Mmax ratios (from  $55.74 \pm 5.65\%$  to  $50.11 \pm 6.28\%$ ) after training.

**CONCLUSIONS:** Motoneuron excitation decreased following the 6-week training. However, 6-week training could not significantly influence the balance steadiness and proprioception in subjects with functional ankle instability.

**Effects Of Pre-operative Exercise Training On Knee Strength And Proprioceptive Functions After Anterior Cruciate Ligament Reconstruction**

Do-Kyung Kim, Won-Hah Park. *Samsung Medical Center, SungKyunKwan University, seoul, Republic of Korea.*  
Email: hrmax1@naver.com

(No relationships reported)

Anterior cruciate ligament (ACL) has mechanical and proprioceptive functions.

**PURPOSE:** To examine the effect of a short period pre-operative exercise intervention (4weeks) on the muscle strength and proprioceptive functions of patients after ACL reconstruction.

**METHODS:** Sixty male patients(31.5±6.2) who had undergone ACL reconstruction by auto graft-hamstring tendon. Subjects were randomly assigned into two groups: Pre-op exercise group (PEG, n=30) and Pre-op non-exercise group (PNEG, n=30). PEG participated in 4 weeks of pre-operative and 12 weeks of post-operative rehabilitation program with 3 days per week for each program, PNEG only participated in the 12 weeks of post-operative rehabilitation program. The pre-operative rehabilitation program includes gait training and proprioception, quadriceps strengths exercise. The program can be used safely without compromising the initial goals of surgery. We measured concentric peak torque measurements of the knee extensors and flexors at 60°/sec and 180°/sec on an Isokinetic dynamometry. Proprioceptive functions has been assessed using Joint position sense(JPS) and dynamic postural stability. Dynamic postural stability was measured as a stability index in the anterior-posterior and medial-lateral planes with the Biodex Stability System. All tests were measured 4 weeks preoperatively and 3 months postoperatively.

**RESULTS:** At the 60°/sec and 180°/sec of involved knee extensor strength result of PEG was significant higher than PNEG ( $p<.01$ ). In PEG, it increased by  $28.7\pm5.2\%$  at 60°/sec and  $21.7\pm4.4\%$  at 180°/sec for the extensor strength (In PNEG:  $19.6\pm5.7\%$  and  $15.4\pm4.9\%$ , respectively). For the dynamic postural stability index, the improvement of PEG was significantly higher than the result of PNEG( $11.7\pm7.9\%$  vs  $26.2\pm9.2\%$ ,  $p<.05$ ). But, we found no significant difference between the PEG and PNEG for Joint position sense( $1.25\pm0.65^\circ$  vs  $1.40\pm1.03^\circ$ ,  $p=1.00$ ).

**CONCLUSIONS:** The 4 weeks of pre-op exercise may elicit many positive changes for the ACL reconstruction patients. Therefore, the pre-op exercise in ACL reconstruction helps the patient to provide dynamic knee stability and return to work and sport as soon as possible.

---

**3012 Board #159 May 30 8:00 AM - 9:30 AM**  
**Effect Of Forced Adduction On Emg Activity Of The Vastus Medialis Oblique And Vastus Lateralis**

Tim R. Burnham, Teresa Schlafer, Charilaos Papadopoulos. *Central Washington University, Ellensburg, WA.* (Sponsor: Scott O. Roberts, FACSM)

Email: tim.burnham@cwu.edu

(No relationships reported)

Atrophy of the vastus medialis oblique (VMO) muscle often occurs after knee injury. Since traditional quadriceps exercises do not selectively increase VMO activity, adduction is often added. The literature is divided as to the effectiveness of this practice. Few studies have explored this effect during isotonic closed chain exercises. Additionally, no information is available on the amount of force that must be applied during adduction to elicit a greater response from the VMO than the vastus lateralis (VL) muscle.

**PURPOSE:** To examine the effects of several levels of forced adduction on the electrical activation of the VMO and VL during open and closed kinetic chain exercises and to investigate these effects by gender.

**METHODS:** Twenty subjects, 10 males and 10 females had their VMO and VL electromyographical activity measured during an isometric maximal voluntary contraction (IMC), straight leg raises (SLR), knee extensions (KE), and single leg quarter squats (QS) while using three different levels of forced adduction (0, 10, and 15 lbs).

**RESULTS:** The level of adduction had no significant effect on the activation of the peak or mean VMO, VL, or VMO/VL ratio. The different exercises did have a significant effect on VMO and VL activity. QS and KE elicited a significantly higher peak VMO, VL, and VMO/VL ratio than SLR. When analyzed by gender, males showed a greater peak VMO for KE and QS compared to SLR while females showed a greater peak VMO for KE compared to SLR and QS. Peak VMO/VL ratio revealed a significant gender difference with males showing a greater KE and QS response than females. Comparing the exercises to the IMC showed a significantly higher peak VMO/VL ratio during the QS exercise at 10 and 15 lbs adduction for males and 0 lbs adduction for females.

**CONCLUSIONS:** Although adduction did not significantly increase VMO activity, the findings do suggest that different exercises may elicit a stronger peak response from the VMO than the VL when compared to a maximal contraction. Single-leg QS may be a preferred exercise during VMO rehabilitation. This study also showed males and females respond differently to exercises with the different levels of adduction. Because of this, care should be taken when prescribing rehabilitation for the VMO between males and females; a generic technique may not be successful for both genders.

**Associations Between Core Strength, Walking Speed, And Age In Women**

Jean R. Omodt<sup>1</sup>, Andrea L. Hokanson<sup>1</sup>, Cara M. Wall-Scheffler<sup>2</sup>, Marcella J. Myers<sup>1</sup>. <sup>1</sup>College of St. Catherine, St. Paul, MN. <sup>2</sup>Seattle Pacific University, Seattle, WA. (Sponsor: Mark Blegen, FACSM)

Email: jromodt@stkate.edu

(No relationships reported)

Age-related changes in muscle strength and walking speed are well described in the literature. Knowing what muscles to strengthen to improve walking speed in the geriatric population would improve patient treatment and outcomes.

**PURPOSE:** To investigate the relationship between core strength and self-selected walking speed as a function of age.

**METHODS:** We measured muscle strength in 8 young females (mean=20.6yr) and 10 older females (mean=51.4yr) who participated in a previous study of metabolic cost of walking with belly loads as a function of speed. At the onset of the previous experiment, women were given belly loads equal to 8% of body mass and asked to choose 3 walking speeds on a treadmill: slowest speed with normal gait (SSP), preferred mid-range speed (MSP), and fastest speed with normal gait (FSP). In the current study, manual muscle test scores of four pelvic stabilizing (core) muscle groups were assessed according to Kendall's protocol. Strength scores for back extensors, hip abductors (bi-laterally), upper abdominals, and lower abdominals were collected from each participant.

**RESULTS:** Relationships between abdominal strength and walking speed showed no difference between age groups (age group not significant in regression model): upper ( $p=0.034$ ) and lower ( $p=0.042$ ) abdominal strength were directly correlated with walking speed at MSP and lower abdominal strength was also directly correlated with walking speed at FSP ( $p=0.040$ ). Upper ( $p=0.053$ ) and lower ( $p=0.100$ ) abdominal strength was less in the older cohort while back extensor and hip abductor strength did not differ between age groups.

**CONCLUSIONS:** Because the relationship between abdominal strength and self-selected walking speed was consistent across age groups, it is advisable to assess and treat core muscle weakness in all patients who exhibit decreased walking speed. In the larger population, older individuals are more likely to present with weakened core muscles. Supported by NIH EARDA Grant G11HD03978 6 and the Center of Excellence for Women, Science, and Technology at the College of St. Catherine.

**Relationship Between Changes In Serum Hormonal Concentration And Performance Following Concurrent Resistance And Endurance Training**

David J. Bentley, PhD<sup>1</sup>, Ehsan Ghahramanloo<sup>1</sup>, Lars McNaughton, FACSM<sup>2</sup>. <sup>1</sup>University of NSW, Sydney, Australia. <sup>2</sup>University of Hull, Hull, United Kingdom.

(No relationships reported)

It is well known that skeletal muscle mass is regulated largely by circulating levels of anabolic and catabolic hormones and that androgens play an important role in muscle

hypertrophy and subsequent strength development. Circulating testosterone and Cortisol have been proposed as physiological markers in both men and women to evaluate the anabolic-catabolic status of the body and have been used to explain the variation in skeletal muscle mass.

**PURPOSE:** To examine the relationship between changes in basal hormone (Cortisol and testosterone) concentration and muscular strength in response to three different training regimes (endurance, resistance and concurrent).

**METHODS:** The subjects recruited for study were 27 untrained young male students that were randomly assigned to an endurance (E), strength (S) or concurrent (C) training group. The E group performed running on treadmill at an intensity of 65% of HR<sub>max</sub> for 16 min at the beginning of training but increased to 80% HR<sub>max</sub> for 30 min toward the end of training period. The S group performed 3 sets with 10 repetitions of bench press, leg curl, lat pull down and squat at 50% of 1RM and increased to 4 sets with 12 repetitions 80% of 1RM. The C group performed the summation of E and S training requirements.

**RESULTS:** Groups S and C showed a significant increase in fat free mass but group E did not show any significant changes. No significant changes in basal Testosterone concentration (ng/dl) were found after training for either group. In group E there was a significant correlation ( $r=0.78$ ;  $p<0.05$ ) between the change (D) in Cortisol and D fat free mass.

**CONCLUSION:** In response to concurrent training it is possible that increases in hypertrophy and muscular strength occur without any modification of basal hormone concentration. However it is also possible that transient changes in anabolic hormone production or other growth factors following exercise reflect changes in strength and muscle morphology with concurrent training.

### 3015 Board #162 May 30 8:00 AM - 9:30 AM Evaluation Of Vibration Training Platforms

Heather Corrie<sup>1</sup>, Katherine Brooke-Wavell<sup>1</sup>, Tahir Masud<sup>2</sup>, Neil Mansfield<sup>1</sup>. <sup>1</sup>Loughborough University, Leicestershire, United Kingdom. <sup>2</sup>Nottingham University Hospitals NHS Trust and University of Derby, Nottingham, United Kingdom.

Email: h.corrie@lboro.ac.uk

(No relationships reported)

Whole-body vibration (WBV) training is an emerging treatment with potential benefits for muscle and bone health. There are several WBV devices and the differences are not easily quantifiable. The development of legislation designed to minimise occupational exposure to WBV has led to the formation of standards to quantify vibration 'dose' incorporating the human response at different frequencies.

**PURPOSE:** This experiment numerically describes the vibration delivered by six devices according to the methods outlined in the Physical Agents (Vibration) Directive [PA(V)D; 2002].

**METHODS:** Acceleration was measured and analysed according to ISO 2631-1 (1997). Comparisons were made between devices, at a range of user modifiable settings where available.

**RESULTS:** All of the devices produced sinusoidal vibration in the vertical axis. The Galileo with a tilting action was the only device which delivered noteworthy vibration in more than one axis. Combinations of displacement and frequency resulted in an extensive range in magnitude of vibration in the vertical axis [1.05-112.53 r.m.s. m/s<sup>2</sup>; 0.23-22.64 r.m.s. (weighted) m/s<sup>2</sup> (see Figure 1)]. The devices with user modifiable settings provided a range of frequencies at fixed displacements. This characteristic was such that vibration 'dose' was similar for different frequencies at each displacement setting for the devices delivering higher frequency vibration [see Figure 1(b)].

**CONCLUSIONS:** The marked differences in vibration magnitude between platforms emphasise the need to describe WBV training protocols in precise terms. PA(V)D provides a standardised way to quantify vibration 'dose' however more research is required to compare the human response to tilting and vertical vibration.

### 3016 Board #163 May 30 8:00 AM - 9:30 AM Relationships Among Measures Of Muscle Strength, Power And Functional Outcomes In Older Men

Joanne B. Krasnoff, Renee Miciek, Nathan Lebrasseur, Shalender Bhasin, Thomas Storer. Boston University Medical Center, Boston, MA. (Sponsor: Patricia L. Painter, Ph.D., FACSM)

Email: jokras@bu.edu

(No relationships reported)

Many tests have been designed to evaluate skeletal muscle strength in older adults. Due to its low cost and ease of administration, handgrip dynamometry (HD) often serves as a surrogate measure for total body strength and is used as such to examine relationships between strength and physical function. Whether HD is a reasonable alternative for these purposes has not been well established.

**PURPOSE:** To examine the relationships among HD, leg and chest press (LP, CP) strength and power and functional outcomes in older men.

**METHODS:** One-Hundred and fifty-five men (72 ± 6 yr) performed dominant HD, LP and CP 1-repetition maximum (1RM) and LP and CP power tests. Unloaded and loaded timed 50-m walks (UW, LW) and a 12-step stair climb (USC, LSC) were used as functional measures. Loads consisted of carrying 20-25% body weight. Pearson product-moment correlations were calculated to determine associations. Statistical significance was set at  $P<0.05$ .

Variable	Unloaded Walk		Loaded Walk		Unloaded SC		Loaded SC	
	r	p	r	p	r	p	r	p
HD	-0.21	0.002	-0.35	<0.0001	-0.19	0.022	-0.26	0.002
LP 1RM	-0.46	<0.0001	-0.53	<0.0001	-0.44	<0.0001	-0.48	<0.0001
CP 1RM	-0.34	<0.0001	-0.44	<0.0001	-0.32	<0.0001	-0.39	<0.0001
LP Power	-0.53	<0.0001	-0.59	<0.0001	-0.48	<0.0001	-0.50	<0.0001
CP Power	-0.39	<0.0001	-0.48	<0.0001	-0.53	<0.0001	-0.39	<0.0001

**RESULTS:** HD was weakly, but significantly, correlated with LSC, LP and CP 1RM and power ( $r \leq 0.490$ ,  $P<0.05$  for all associations). LP 1RM was significantly correlated with CP 1RM ( $r=0.66$ ), LP power ( $r=0.77$ ), and CP power ( $r=0.65$ ). For all functional measures, HD exhibited statistically significant, but weaker correlations than those seen with the dynamic strength and power measures:

**CONCLUSION:** These data suggest only weak relationships between HD and dynamic strength and power measures and with two common measures of physical function. Leg press power demonstrated the strongest relationship with physical function measures. The use of HD as a strength measure for examining relationships between strength and physical function should be avoided.

### 3017 Board #164 May 30 8:00 AM - 9:30 AM Acute Effects Of Aquatic Exercise On Gait Patterns In Patients With Lower Extremity Arthritis

Chiho Fukusaki<sup>1</sup>, Kimitaka Nakazawa<sup>2</sup>. <sup>1</sup>University of Tokyo, Kashiwa, Japan. <sup>2</sup>National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Japan. (Sponsor: Mitsumasa Miyashita, FACSM)

Email: fukusaki@k.u-tokyo.ac.jp

(No relationships reported)

**PURPOSE:** It is well-established that individuals with lower extremity arthritis experience difficulty in walking; it is difficult for them to walk fast and for a long distance. However, they are capable of walking and moving their lower extremities in water with ease. Our previous studies have shown the acute effects of aquatic exercise on their postural control. The purpose of this study was to investigate its effects on their gait patterns.

**METHODS:** Subjects included 7 females with lower extremity arthritis (60.6 ± 6.1 years). They gave written informed consent to participate. They were asked to walk at their usual speed and at a fast speed (as fast as possible) before and after an aquatic exercise session. The gait patterns were recorded with digital video camera from the side (60 fps).

The image data was analyzed using 2-D panning direct liner transformation (DLT) method; further, the average values of walking speed, step length and step frequency were calculated. The exercise session in water lasted 70 min; it consisted of 20-min warm up and walking, 15-min resistance exercise and stretching in water, 10-min break, 20-min walking or swimming, and 5-min cooling down. The pre- and post-exercise data were statistically compared using paired *t*-test.

**RESULTS:** Significant increases were observed ( $p < 0.05$ ) in walking speed (1.53 vs 1.65 m/sec; pre vs post), step length (59.5 vs 60.8 cm), and step frequency (2.54 vs 2.68 Hz) in walking at a fast speed following an aquatic exercise session, while there were no significant differences in these variables in walking at a usual speed. However, the difference between step lengths with right and left leg support in walking at a usual speed decreased significantly (6.66 vs 3.99 cm) ( $p < 0.05$ ) following an aquatic exercise session.

**CONCLUSIONS:** This study revealed the acute effects of aquatic exercise on gait patterns of patients with lower extremity arthritis; walking speed and step length, and step frequency in walking at a fast speed increased, and difference between right and left step lengths in walking at a usual speed decreased following an aquatic exercise session.

**3018 Board #165 May 30 8:00 AM - 9:30 AM**

### The Influence Of Exercise Volume In Chronic Non-specific Low Back Pain Rehabilitation

Robert Kell<sup>1</sup>, John M. Barden<sup>2</sup>, Nicole Finseth<sup>3</sup>, Alaina Risi<sup>1</sup>. <sup>1</sup>University of Alberta, Camrose, AB, Canada. <sup>2</sup>University of Regina, Regina, SK, Canada.

<sup>3</sup>University of Alberta, Edmonton, AB, Canada. (Sponsor: Dr. Robert (Bob) Haennel, FACSM)

Email: rob.kell@ualberta.ca

(No relationships reported)

Approximately 80% of North Americans suffer from low back pain, and 85% of these are diagnosed as chronic non-specific low back pain (CLBP). In 2005, the economic cost associated with back pain was ~\$38 million as reported by Workers' Compensation Board-Alberta.

**PURPOSE:** To determine the impact of 3 different volumes of CLBP rehabilitation (exercise therapy) on the outcome measures of strength, pain, and quality of life (QOL).

**METHODS:** One hundred and twenty (N=30/group) CLBP males were randomly assigned to one of the following groups: 2 days/wk (2D), 3 days/wk (3D), 4 days/wk (4D) rehabilitation, or Control (C; no rehabilitation). Rehabilitation group participants completed a 2-wk exercise familiarization period. Musculoskeletal (repetition maximum) testing occurred following familiarization at baseline, wks 8 and 12. The participant's pain (11-point visual analogue scale; VAS) and QOL (Short Form-36: Physical and Mental Composite Summaries) were measured at baseline, wks 8 and 12.

**RESULTS:** The *p*-level was set at  $\leq 0.05$ . There were no significant differences between groups at baseline, but significant differences were present within groups across time and between groups on strength, pain, and QOL (Table). All rehabilitation groups were significantly different than the control group at wk 12.

**CONCLUSION:** A volume of 4 days/wk demonstrated greater improvement in outcome measures, especially pain and QOL, than either 2 or 3 day/wk programs. Sponsored by the Augustana Research grant.

#### **The Effects Of A Healthy Lifestyle Intervention On Physical Activity And Aerobic Capacity In Minority Girls**

Jessica McLeod<sup>1</sup>, Stephanie Kellam<sup>1</sup>, Marilynn Graham<sup>1</sup>, Kendall McCarley<sup>2</sup>, Kayce Hall<sup>1</sup>, Rhonda Scherer<sup>1</sup>, Eugene Chaung<sup>1</sup>, Jill A. Bush, FACSM<sup>3</sup>, Norma Olvera<sup>1</sup>. <sup>1</sup>University of Houston, Houston, TX. <sup>2</sup>University of Denver, Denver, CO. <sup>3</sup>Towson University, Towson, MD.

(No relationships reported)

Despite the low activity levels in minority girls, few interventions have been conducted to promote physical activity levels with this population.

**PURPOSE:** To assess the impact of a 4-week healthy lifestyle summer program on: a) increasing minutes of daily moderate-vigorous physical activity (MVPA), b) increasing aerobic capacity, and c) increasing preference for physical activity in overweight Hispanic and African American girls. A secondary purpose was to assess the impact of the program on reducing weight, waist girth, and percentage of body fat.

**METHODS:** Thirty-eight Hispanic and African American girls aged 8-14y (11.5±1.4y) and their parents participated. Fifteen percent of the girls were at risk for overweight (BMI 85%-94%) and 85% were categorized as being overweight (BMI >95%). Girls participated in 3-4 different physical activities (e.g., Hip-Hop, Latin dance, Pilates, martial arts, yoga, spinning, sports, cheerleading, and circuit training) per day and received daily nutrition classes for 4-weeks. Girls also engaged in self-esteem enhancing activities. Participant's parents participated in 2 hour weekly workshops. Accelerometry and a timed one-mile run assessment were used to determine changes in physical activity and aerobic capacity respectively. Child's height and weight, waist girth, and body fat % were assessed pre-and post intervention.

**RESULTS:** The BOUNCE healthy lifestyle summer camp program had a significant impact on girls' average minutes of daily MPVA increasing from the 69.1 to 89.5 minutes ( $p<0.001$ ) and on aerobic capacity, with the average number of minutes taken to complete a one-mile run decreasing from 19.5 to 16.6 minutes ( $p<0.0005$ ) from beginning to the end of the program. The BOUNCE program also had an impact on physical activity preferences such that preferences for specific physical activities (listed above) taught during the intervention significantly increased ( $p<0.0005$ ). Additionally, participant's body weight ( $p=0.002$ ) and waist circumference ( $p<0.0005$ ) significantly decreased, but not their percentage of body fat ( $p=0.283$ ).

**CONCLUSIONS:** Results from this study indicated that a healthy lifestyle intervention can positively impact physical activity levels and aerobic capacity in overweight minority girls.

#### **Changes In Fatness In Norwegian Children, 2000-2005**

Elin Kolle, Jostein Steene-Johannessen, Lars B. Andersen, Sigmund A. Anderssen. *Norwegian School of Sport Sciences, Oslo, Norway.*

Email: elin.kolle@nih.no

(No relationships reported)

The prevalence of overweight and obesity among children is increasing worldwide. There is, however, a lack of studies investigating change in the distribution of body fat. This knowledge is essential as central adiposity has been shown to be more strongly associated with type 2 diabetes and dyslipidaemia, than overall fatness in adults. Moreover, visceral adipose tissue is directly associated with low density lipoprotein cholesterol and triglycerides, and inversely related to high density lipoprotein cholesterol among children.

**PURPOSE:** To investigate 5-year changes in waist circumference, skinfold measures, and body mass index (BMI) among 9- year-old children living in Oslo, Norway.

**METHODS:** A total of 854 9-year-olds measured in the European Youth Heart Study (2000) and in the Physical Activity in Norwegian Children Study (2005) were included in the analyses. Indicators of body fatness were skinfold thickness (triceps, biceps, subscapular and suprailiac), waist circumference and body mass index (BMI; in kg/m<sup>2</sup>). The International Obesity Task Force (IOTF) cut-offs were used to define overweight and obese subjects. Changes in fatness were tested by using general linear models, adjusted for age and sexual maturity.

**RESULTS:** In 2005, 9-year-old girls had significantly higher BMI ( $p = 0.04$ ), waist circumference ( $p < 0.001$ ), and all 4 skinfold measures ( $p<0.001$ ) than girls in 2000. Nine-year-old boys increased their waist circumference by 2.2 cm ( $p = 0.002$ ), and their triceps ( $p=0.02$ ) and suprailiac ( $p=0.02$ ) skinfold measures between the study periods. The overall prevalence of overweight and obesity was slightly higher in 2005, however, chi-square analysis revealed that the increase was significant in girls only ( $p = 0.04$ ).

**CONCLUSIONS:** In 9-year-old children living in Oslo, there have been increases in measures of fatness and central adiposity over the last 5 years. The increase was more pronounced in girls than boys. The results indicate that the reported increases in BMI under-estimates the increase in body fatness among children.

#### **The Gap In Physical Fitness Levels Among Young Children**

kosho kasuga<sup>1</sup>, takahiro nakano<sup>2</sup>, tomohtoko murase<sup>3</sup>, kayo kumagai<sup>1</sup>, kazuo oguri<sup>4</sup>, toshiki tachi<sup>4</sup>, kiyoji tanaka, FACSM<sup>5</sup>. <sup>1</sup>Gifu University, gifu, Japan. <sup>2</sup>Nagoya Gakuin University, nagoya, Japan. <sup>3</sup>Aichi University, nagoya, Japan. <sup>4</sup>Shizuoka Sangyo University, iwata, Japan. <sup>5</sup>University of Tsukuba, tsukuba, Japan. (Sponsor: Kiyoji Tanaka, FACSM)

(No relationships reported)

The physical fitness levels of Japanese pupils have been on a decline year by year after peaking in 1985. The decline is already apparent in young children, according to an in-depth analysis of the data collected on this group. Moreover, the difference between individuals is expanding, and this gap has come to be seen not only in the economy and scholastic abilities but also their physical fitness levels. However, the age at which the gap in fitness levels arises is unclear.

**PURPOSE:** The purpose of this study to examine the gap in physical fitness levels among young children from age of three until the age of five. The study analyzed data obtained through a pursuit measurement of the same subjects conducted for a period of three years.

**METHODS:** The subjects were 206 young children (104 boys and 102 girls) with standard physiques. We administered physical tests comprising seven types of exercises (grip strength, standing long jump, softball throw, 25-m run, side-step, upright hand standing time, and sitting trunk flexion) to understand their physical fitness characteristics; the tests were conducted every year in November for three years. Finally, the subjects were divided into the upper-ranking group (25%) and the lower-ranking group (25%) on the basis of the results of the physical tests at three-years old that corrected the age; further, the extent to which the gap between the two groups changed after two years was examined for each type of exercise. To conduct a statistical analysis of the data, a two-way ANOVA and the multiple comparisons were employed.

**RESULTS:** The analysis revealed a significant difference between the two groups for all types of exercises (in the case of both boys and girls). The gap reduced with each passing year for the side-step, 25-m run, and sitting trunk flexion. The exercise types for which the gap reduced until the age of four were grip strength and standing long jump. In the case of softball throw and upright hand standing time, the gap reduced until the age of four and then increased at the age of five. However, the gap did not reverse at the age of five for any exercise type.

**CONCLUSIONS:** The level of physical fitness at the age of five remains strongly influenced by that at the age of three. The results suggested that the gap in the physical fitness among Japanese pupils has already begun to be observed in young children.

**Contribution Of Organized Sport Participation To Estimated Daily Energy Expenditure: Preliminary Results Of Portuguese Boys**

Aristides MC Machado Rodrigues<sup>1</sup>, José Proença<sup>1</sup>, Manuel J. Coelho e Silva<sup>1</sup>, Jorge Mota<sup>2</sup>. <sup>1</sup>University of Coimbra, Coimbra, Portugal. <sup>2</sup>University of Porto, Porto, Portugal.

Email: rodriguesari@hotmail.com

(No relationships reported)

**PURPOSE:** National Statistics from sport participation showed a substantial increase of 42% in the amount of regular participants in the period 1996-2003 (Adelino et al., 2005). In addition, organized sport is among the major sources of physical activity in children and youth. The present study examines the contribution of organized sport in daily energy expenditure.

**METHODS:** The sample is composed of 129 boys aged from 13 to 14 years. Somatic characteristics included weight, stature, sum of six skinfolds and waist circumference. Energy expenditure [EE] and EE in moderate-to-vigorous physical activity [MVPA] were assessed using the 3-day diary (Bouchard et al., 1983). The diary also provided information on TV viewing and screen activities [TV&SC]. Organized sport effect was tested on total EE, EEMVPA and time spent in TV&SC.

**RESULTS:** Organized sport contributed to 13.2% of daily energy expenditure and to 40% of its moderate to vigorous physical activity portion. Compared with peers who did not engage in sport activities, boys who participated in organized sports spent higher values of daily EE [46 Kcal/Kg/day versus 43 Kcal/Kg/day,  $p < 0.05$ ], specially during week days [47 Kcal/Kg/day versus 44 Kcal/Kg/day,  $p < 0.05$ ]. Sport participants were also more active in moderate to vigorous physical activity [16 Kcal/Kg/day versus 11 Kcal/Kg/day,  $p < 0.05$ ] and tend to spend less time in screen activities during week days [162 minutes/day versus 146 minutes/day, respectively for participants and non-participants].

**CONCLUSIONS:** In summary, organized sport is a major contributor of moderate-to-vigorous portion of daily EE although it only accounted for 13% of total daily EE. It is also of interest to note the trend for less time devoted to screen activities among sport participants, suggesting that participation in supervised sport may also contributes to avoid sedentary activities, more evident during week days.

**3023 Board #170 May 30 9:30 AM - 11:00 AM**  
**Levels And Determinants Of Physical Activity In Puerto Rican Adolescent Girls**

Amaury J. Alvarez, Carla L. de la Torre, Farah A. Ramirez-Marrero, FACSM. University of Puerto Rico, San Juan, Puerto Rico.

Email: alvareztrainer@hotmail.com

(No relationships reported)

Physical activity (PA) is known to decline from childhood to adulthood, particularly in girls during adolescence. Childhood obesity is a known health problem in Puerto Rico; however, physical activity has not been described in this population.

**PURPOSE:** The purpose of this study was to describe PA levels and determinants in a group of Puerto Rican adolescent females aged from 11-16 years.

**METHODS:** Forty adolescent females wore an ActiGraph accelerometer during 6 consecutive days, and completed a PA questionnaire. They were grouped according to their age (11-13, and 14-16 yr). Parents completed a socio-demographic and physical activity questionnaire. ANOVA and independent t-tests were used to identify differences in moderate to vigorous PA (MVPA) by age group and between adolescents and their parents. Multiple regression analysis was performed to evaluate PA determinants (socioeconomic status, parent's education and PA, shared PA between parents and daughters).

**RESULTS:** MVPA averaged  $87 \pm 54$  min/week in all adolescent females. No significant difference in MVPA was observed by age (11-13 =  $87 \pm 58$ , 14-16 =  $86 \pm 50$  min/week,  $P = 0.95$ ). A significant association was observed between parents and adolescents MVPA ( $r = 0.67$ ,  $P < 0.01$ ). The more influential factors in adolescents MVPA were the parents MVPA and the days the parents shared PA with their daughters.

**CONCLUSION:** Puerto Rican adolescent females failed to comply with the recommended 60 min of MVPA every day. Parents involvement must be considered in any intervention designed to help increase PA levels in this population.

**3024 Board #171 May 30 9:30 AM - 11:00 AM**  
**Physical Activity Measurement Of 10-14 Year Old Northern Plains American Indian Youth**

Christiana L. Ricci<sup>1</sup>, Steven E. Gaskill, FACSM<sup>1</sup>, Todd Wilson<sup>2</sup>, Martin Parker<sup>3</sup>, Jeri Lyn Harris<sup>1</sup>, Curtis Noonan<sup>1</sup>, Kari J. Harris<sup>1</sup>, Blakely D. Brown<sup>1</sup>. <sup>1</sup>The University of Montana, Missoula, MT. <sup>2</sup>Crow Tribal Health, Crow Agency, MT. <sup>3</sup>Rocky Boy Tribal Health, Rocky Boy, MT.

Email: christiana.ricci@umontana.edu

(No relationships reported)

The health benefits of physical activity (PA) include improved cardiovascular, bone and muscle health, and decreased risk of obesity and related diseases like type 2 diabetes and heart disease. The ACSM and AMA guidelines state that for health, youth should engage in at least 60 min of moderate to vigorous physical activity (MVPA) at least 5 days per week or for aerobic fitness, 20 min of vigorous physical activity (VPA) three or more days per week.

**PURPOSE:** This pilot study assessed the feasibility of using 7-day accelerometry to measure PA in Northern Plains American Indian (AI) youth and to describe that PA as part of the outcomes of a primary prevention health curriculum.

**METHODS:** Youth, ages 10-14 years ( $n = 27$ ), were recruited from two Northern Plains AI reservation communities to participate in a pilot study of an age-adapted and culturally specific health curriculum. In addition to anthropometric, biological, and survey measures, students wore a wrist accelerometer to record PA for 7 days. Activity was recorded in 1 min epochs which were later converted to minutes of sedentary, light, moderate, and vigorous activity.

**RESULTS:** Usable PA data were obtained from 19 of the AI youth in the pilot. All met the youth PA health guidelines (mean MVPA =  $131 \pm 42$  min/day). When BMI were evaluated by age and gender percentile, students below the 85<sup>th</sup> percentile engaged in more daily MVPA (MVPA for  $< 85^{\text{th}}$  =  $146.2 \pm 45.1$  min/day) than youth at or above the 85<sup>th</sup> BMI percentile (MVPA for  $> 85^{\text{th}}$  =  $96.9 \pm 48.3$  min/day,  $p = 0.03$ ). None of the 19 AI youth met the fitness guidelines (VPA =  $4.0 \pm 7.1$  min/day).

**CONCLUSION:** These data show that the Northern Plains American Indian youth participating in this pilot study were meeting the national PA guidelines for health, but not fitness. The 7-day accelerometer compliance was lower than expected, however subsequent trials of the curriculum have provided opportunities to strengthen accelerometer methods in this population and increase AI youth compliance to the PA measurement. These preliminary data suggest that education focusing on ways to meet national guidelines for daily fitness is just as important as teaching ways to meet daily physical activity recommendations for health.

( H. Oh, N/A, Salary; N/A, Salary; NA, Salary; N/A, Royalty; N/A, Intellectual Property; N/A, Consulting Fee; N/A, Honoraria; N/A, Contracted Research; N/A, Ownership Interest.)

**PURPOSE:** One of the goals of *Healthy People 2010* (USDHHS, 2000) is to reduce health disparities among different racial and ethnic segments of the U.S. population. Few studies have been conducted to examine physical activity (PA) differences by birthplace and sex in youth of Mexican heritage. The purpose of this study was to determine whether PA differs by birthplace and by sex in youth of Mexican heritage.

**METHODS:** Participants were 101 youth (43 boys, 58 girls, M  $\pm$  SD age of 14.8  $\pm$  1.4 yrs). Approximately 59% were US-born and 41% were Mexico-born. Physical activity was assessed using a piezo-electric pedometer with a moderate to vigorous physical activity (MVPA) timer. Participants wore the pedometers for 7-days and recorded daily time worn on a PA log. Independent *t*-tests were used to determine whether the average number of steps taken per day (steps/d) and the average accumulation of MVPA time in minutes per day (min/d) differed by birthplace and sex. We intended to use chi-square tests to determine whether the percentage of youth who met the recommended values of 15,000 steps/d for boys and 12,000 steps/d for girls (Tudor-Locke et al., 2004) and the percentage of youth who met the recommended 60 min/d of MVPA (Strong et al., 2005) differed by birthplace and sex. However, insufficient numbers of youth met the PA recommendations.

**RESULTS:** Mexico-born youth took more steps, on average, than their US-born counterparts (8527.2  $\pm$  3059.1 vs. 7273.5  $\pm$  2859.4 steps/d, *p* = 0.038). However, MVPA time did not differ between Mexico- and U.S.-born youth (22.9  $\pm$  13.6 vs. 19.1  $\pm$  12.3 min/d, *p* = 0.146). By contrast to birthplace, sex-related differences were more consistent, as boys took more steps (8815.4 vs. 7016.7  $\pm$  2170.2 steps/d, *p* = 0.005) and accumulated more MVPA time (23.9  $\pm$  16.0 vs. 18.2  $\pm$  9.5 min/d, *p* = 0.043) than girls. Only 2 Mexico-born boys, 1 Mexico-born girl, 1 U.S.-born boy, and no U.S.-born girls met either one or both of the recommended amounts of PA.

**CONCLUSIONS:** We conclude that PA may differ by birthplace and by sex in youth of Mexican heritage, as U.S.-born girls were the least active segment of our sample. Culturally sensitive interventions to increase daily PA through school PE and community programs must become a higher public health priority for all youth of Mexican heritage and, in particular, for U.S.-born girls of Mexican heritage.

3026 Board #173 May 30 9:30 AM - 11:00 AM

**Pedometer-determined Physical Activity Levels In A Diverse Sample Of College Students**

Petrolina O. Sims, Kelli F. Koltyn, FACSM. University of WI- Madison, Madison, WI.

Email: posims@wisc.edu

(No relationships reported)

**PURPOSE:** Current research indicates that 30-50% of college students do not meet physical activity guidelines recommended by the American College of Sports Medicine. Limited research has been done regarding physical activity levels in a diverse sample of college students. The purpose of this study was to quantify physical activity levels using pedometers in a racially and ethnically diverse sample of college students.

**METHODS:** One hundred forty-six college men and women (72 caucasian students and 74 students of color) between the ages of 18-40 yrs participated in the study. The racial and ethnic composition included 37 African-American students, 24 Asian students, 10 Latino students, and 3 from "other" ethnic backgrounds. All of the participants signed an informed consent document, and completed a Demographic and Health History Questionnaire and a Physical Activity Preferences and Barriers Questionnaire. Participants wore a pedometer (Yamax SM200) for five days (i.e., Saturday through Wednesday), and logged pedometer steps and activities performed onto a five-day activity diary.

**RESULTS:** Descriptive statistics were computed and the data were analyzed with independent *t*-tests. Mean pedometer steps per day for the entire sample was 9803 (sd= 3652). Results indicated that there was a significant difference (*p*=.007) in pedometer steps between students of color and caucasian students. Pedometer steps for students of color averaged 8998 (sd= 3275) in comparison to an average of 10631 steps (sd= 3395) for caucasian students.

**CONCLUSIONS:** It is concluded that caucasian students had higher pedometer counts than students of color, and additional research is warranted examining factors related to physical activity behavior in multi-racial and ethnically diverse samples of college students.

Research was Supported by the University of Wisconsin Virginia Horne Henry Fund.

3027 Board #174 May 30 9:30 AM - 11:00 AM

**Obesity And Motor Abilities Of Primary School Children With Migration Background**

Gisa Falkowski, Dr., Dmytro Prokopchuk, Susanne Branstetter, Olivia Wartha, Jochen Klenk, Christoph Galm, Swantja Berg, Jürgen Michael Steinacker, FACSM, Prof Dr, FACSM. University of Ulm, Ulm, Germany.

Email: gisa.falkowski@uniklinik-ulm.de

(No relationships reported)

**PURPOSE:** Overweight and obesity in childhood is increasing worldwide while physical inactivity is decreasing steadily. The socio-economic status and migration background play important roles in this development. There is a need for drawing up effective strategies to prevent children from developing overweight. Within this paper the baseline data of the URMEL-ICE-study were presented.

**METHODS:** The URMEL-ICE-study is a randomized controlled intervention study for 1120 primary school children out of the region of Ulm, Germany, for primary prevention. Endpoints of the study are: anthropometric data (body height, body mass) and motor tests. For evaluating childrens' motor abilities eight standardized test items for assessing endurance performance, coordinative skills, physical strength, velocity and flexibility were combined. 1055 children (569 boys; 486 girls) took part in the baseline examination. The children were 7.5  $\pm$  0.4 years old; 54% were boys, 46% girls. 27.6% of the children had a migration background.

**RESULTS:** 13.7 % of the boys and 10.5% of the girls were overweight. Within the group of children with migration background 21.1% (boys) and 12.2% (girls) were overweight. 5.1% of the boys, 3.7% of the girls were obese; with migration background: 10.2% boys and 3.7% girls were obese. The children had disorders in all coordinative test items. Regarding the endurance performance and coordination skills children with a higher BMI-SDS produced the lowest results (*p*≤0.001). Children with migration background (*n*=283) achieved significantly lower scores in 7 out of 8 items of the motor tests than children without migration background (*n*=771).

**CONCLUSIONS:** Boys with migration background have the highest risk for developing overweight and obesity. In Addition, children with migration background have lower motor skills and a higher risk to develop motor disorders than children without migration background. Children with a higher BMI are at a disadvantage regarding the endurance performance and coordinative abilities; there are no differences between weight classes regarding the physical strength.

---

3028 Board #175 May 30 9:30 AM - 11:00 AM

**Association Between Sedentary Activity and CVD Risk Factors in Korean Children and Adolescents**

Wonwoo Byun, Marsha Dowda, FACSM, Russell R. Pate, FACSM. University of South Carolina, Columbia, SC.

Email: wwbyun@gmail.com

(No relationships reported)

**PURPOSE:** This study investigated whether sedentary activity (SA) was associated with CVD risk factors in 577 healthy Korean children and adolescents, aged 12 to 18 years, in the 2005 the Korean National Health and Nutrition Examination Survey (KNHANES).

**METHODS:** SA was measured using self-report questionnaires including items for time spent on TV watching and computers or video games during weekday and weekend. Height, weight, waist circumference (WC), and CVD risk factors such as LDL cholesterol (LDL-C), HDL cholesterol (HDL-C), total cholesterol (TOT-C), triglyceride (TG), glucose, systolic blood pressure (SBP), and diastolic blood pressure (DBP) were measured by trained health examination staff at the mobile examination center. Overweight among children was defined based on the age and gender specific body mass index cutoff points established by the US Centers for Disease Control and Prevention. PA was measured using self-report questionnaires including questions for frequency and duration of moderate and vigorous PA during past seven days.

**RESULTS:** The odds ratios for low HDL-C (OR=1.12, 95%CI:1.05-1.18), high TG (OR=1.25, 1.17-1.33), high SBP (OR=1.27, 1.11-1.45), and high DBP (OR=1.07, 1.01-1.12) were significantly increased as BMI increased after adjusting for age, sex, and PA. PA and SA were not significantly correlated, but individual SA were positively correlated with each other ( $r=0.16-0.45$ ,  $p<0.001$ ) among boys and girls. Age, gender, and PA adjusted logistic regression revealed that the risk of high adiposity such as BMI (OR=1.16, 1.02-1.33) and WC (OR=1.30, 1.10-1.54), and low HDL-C (OR=1.28, 1.10-1.48) increased as daily TV time increased. The odds ratios for high central adiposity (OR=1.25, 1.06-1.48), high TG (OR=1.17, 1.00-1.37), and high SBP (OR=1.36, 1.00-1.44) increased as time spent on PC use increased.

**CONCLUSION:** SA in Korean children and adolescents was associated with adiposity indices such as BMI and WC and CVD risk factors such as Low HDL-C, high TG, and systolic hypertension. More efforts are needed to reduce SA in Korean children and adolescents.

**Physical Activity, Cardiorespiratory Fitness And The Metabolic Syndrome In Adolescents**

Wagner D. Campos<sup>1</sup>, Antonio Stabelini Neto<sup>2</sup>, Anderson Ulbrich<sup>1</sup>, Luis Paulo Mascarenhas<sup>1</sup>, Jeffer Eidi Sasaki<sup>1</sup>, Sergio Gregorio Silva<sup>1</sup>. <sup>1</sup>Federal University Of Paraná, Curitiba, Pr, Brazil. <sup>2</sup>State University Of North Paraná, Jacarezinho, Pr, Brazil. (Sponsor: Alan Utter, FACSM)

(No relationships reported)

**PURPOSE:** To verify the relationship between physical activity and cardiorespiratory fitness levels with the metabolic syndrome in Brazilian adolescents.

**METHODS:** A random sample of 236 girls (mean age, 14.52±1.76 years) and 203 boys (mean age, 14.7±1.83 years) was selected for the study. Physical activity level was determined using the Bouchard questionnaire. Cardiorespiratory fitness was estimated by the Leger 20-meter shuttle run test. Terciles were used to classify the subjects as low, moderate and high physical activity and fitness levels. The metabolic syndrome components assessed included waist circumference, blood pressure, HDL-cholesterol, triglycerides, and fasting plasma glucose.

**RESULTS:** Higher prevalence of the metabolic syndrome was observed in adolescents with low physical activity (males, 13.6%; females, 7.7%) and low cardiorespiratory fitness (males, 20%; females, 10.3%) levels. Significant relationships were found for males between metabolic syndrome with low physical activity (OR: 5.13; 95% CI: 1.06-24.73) and low cardiorespiratory fitness levels (OR: 8.75; 95% CI: 1.89-40.46).

**CONCLUSIONS:** The prevalence of the metabolic syndrome is high among adolescents with low physical activity and fitness levels; a significant relationship between the metabolic syndrome, physical activity, and cardiorespiratory fitness levels was found only for male subjects. Prevention strategies for the metabolic syndrome should concentrate on enhancing fitness and physical activity levels early in life.

**Dyslipidemic States And Physical Activity In Children With Cerebral Palsy.**

Maciste H. Macias<sup>1</sup>, Martha S. Arriola<sup>2</sup>, Francisco J. Diaz<sup>1</sup>, Antonio E. Rivera<sup>1</sup>, Magdalena Najera<sup>1</sup>, María R. García<sup>1</sup>, Luis Garcidueñas<sup>1</sup>, Marco Sanchez<sup>2</sup>, Humberto Guerrero<sup>1</sup>, Promise C. Ortega<sup>1</sup>, Teresa Melchor<sup>1</sup>, José Montaña<sup>1</sup>. <sup>1</sup>University of Guanajuato, Leon, Mexico. <sup>2</sup>University of Atemajac Valley, Leon, Mexico.

Email: fisiol@prodigy.net.mx

( M.H. Macias, University of Guanajuato, Salary.)

**BACKGROUND:** People with cerebral palsy (PC) have alterations with body movements and have a high risk to develop disorders associated with the sedentarism like a serum lipids disorders (dyslipidemia and cardiovascular diseases). There is scanty information about lipid profile and related dyslipidemic disorders in people with cerebral palsy. There for the purpose of the present study was to evaluate the prevalence of dyslipidemia in children with cerebral palsy.

**METHODS:** Twenty-nine children (44%=male; 66%=female) with diagnostic of cerebral palsy from two Centers of Multiple Attention in the state of Guanajuato were evaluated. Physical activity was calculated by a physical activity scale. A venous blood sample was obtained to determine the total cholesterol (Ct), High Density Lipoprotein Cholesterol (HDL-C), Low Density Lipoprotein Cholesterol (LDL-C), Triglycerides (Tg) and calculated the relationship CT/HDL, like atherogenic index.

**RESULTS:** Forty eight % of the participants presented a dyslipidemic state. Hipertriglyceridemia (32%) and low HDL-C (35%), were the conditions more frequently founded. Twenty-two percent presented a high atherogenic index. The physical activity of PC children was smaller than the recommended for their age (135.3 ± 79.6 min/week). Sixty-two percent attended rehabilitation sessions, 10% sport classes, and 14% both activities.

**CONCLUSIONS:** The results of this research showed a high prevalence of dyslipidemia and little time dedicated to physical activity practice. It should be convened to promote a more participation of physical activity and better diet in children to improve their metabolic state and thus have a better quality of life in people's.

**The Nycomed Pharma Norwegian Sports Medicine Award - Muscular Fitness is Associated with Metabolic Risk in Youth**

Jostein Steene-Johannessen, Elin Kolle, Sigmund Alfred Anderssen, Lars Bo Andersen. *Norwegian School of Sports Sciences, Oslo, Norway.* (Sponsor: Roald Bahr, FACSM)

Email: jostein.steene-johannessen@nih.no

(No relationships reported)

In adults, low physical fitness is known to contribute to the early onset and progression of cardiovascular disease. Recent findings have shown a close relationship between metabolic risk factors and physical fitness in children and youth. Whilst these studies mainly focus on the effect of cardiorespiratory fitness (CRF), few studies have examined the independent effect of muscular fitness (MF).

**PURPOSE:** To investigate the associations of MF with clustered metabolic risk score in youth.

**METHODS:** This cross-sectional study included 2299 Norwegian 9- and 15-year-olds. A continuous score representing a metabolic risk profile was derived by computing standardized residuals for HOMA score, waist circumferences, triglycerides, high-density lipoprotein cholesterol, and systolic blood pressure. MF was evaluated by measuring lower limb explosive strength (standing broad jump), upper limb muscle strength (hand grip), abdominal muscular endurance (sit-ups) and endurance of the trunk extensor muscle (modified Biering-Sørensen test). MF score was computed by combining the standardized values of these four tests. CRF was measured directly during a maximal cycle ergometer test. Metabolic risk, MF and CRF were analyzed as continuous variables using multiple linear regression.

**RESULTS:** Metabolic risk was inversely associated with MF, independent of CRF, and after adjustment for age, sex and pubertal stage ( $b = -1.12$ ,  $P < 0.001$ ). CRF was, independent of MF, inversely associated with clustered metabolic risk ( $b = -0.337$ ,  $P < 0.001$ ). However, before adjusting for CRF/MF, the associations of MF and CRF with metabolic risk were almost equally strong ( $b = -0.315$ ,  $P < 0.001$ ;  $b = -0.443$ ,  $P < 0.001$  for MF and CRF, respectively).

**CONCLUSION:** Both MF and CRF were independently associated with metabolic risk in youth. Whilst measuring CRF directly is time-consuming and expensive, determining MF is cheap and feasible. Our results suggest that determination of MF might be a favourable method when investigating the association between physical fitness and metabolic risk in large populations.

**Relationship Between The Development Of Physical Strength And Physical Growth In Preschool Children**

Takahiro Nakano<sup>1</sup>, Kosho Kasuga<sup>2</sup>, Tomohiko Murase<sup>3</sup>, Kayo Kumagai<sup>2</sup>, Kazuo Oguri<sup>4</sup>, Toshiki Tachi<sup>4</sup>. <sup>1</sup>Nagoya Gakuin University, Nagoya, Japan. <sup>2</sup>Gifu University, Gifu, Japan. <sup>3</sup>Aichi University, Nagoya, Japan. <sup>4</sup>Shizuoka Sangyo University, Shizuoka, Japan. (Sponsor: Kiyoji Tanaka, FACSM)  
Email: taka@ngu.ac.jp

(No relationships reported)

A decline in the physical strength of children, observed in Japan in recent times, is becoming a serious problem. For the improvement of physical strength, the action that considered physical growth as well as the acquisition of exercise habit is important. Physical growth is particularly remarkable in preschool children. Further, the development of physical strength is strongly affected by physical growth. Therefore, it seems that education and guidance, which considered physical growth, are effective in improving it.

**PURPOSE:** The purpose of this study was to examine the relationship between the development of physical strength and physical growth in preschool children. In particular, we focused on a change in the variance of data between school years.

**METHODS:** The subjects of this study were 652 preschool children. We measured their stature, body weight, and nine parameters related to physical strength and motor ability. These parameters were grip strength, upright handstanding time, sitting trunk flexion, 25 m run, standing long jump, side step, beam cross jump, softball throw, and ball catch. We confirmed the change in the data between school years by one-way ANOVA. We examined the change in the mean and standard deviation (SD) of each parameter between students of different school years by graph statistics. Furthermore, we calculated the amount of change in these data by dividing the difference in the data by the SD of a school year below. In all analyses, we examined the difference among the states of change in physical growth, physical strength, and motor ability.

**RESULTS:** All parameters improved significantly. The states of change in the means and SDs of upright handstanding time, softball throw, side step, grip strength, ball catch, and body weight were similar. Further, the states of changes in side step and stature were similar. The examination of the amount of change also yielded a similar result.

**CONCLUSIONS:** From these results, these parameters whose states of change are similar to those in body weight and stature may be improved with growth. On the other hand, since changes in the sitting trunk flexion, 25 m run, and beam cross jump are different from those in body weight and stature, it is speculated that a special intervention that affects exercise skill and movement acquisition is necessary.

**Modeling Changes In Gross Motor Coordination Of Portuguese Children: Effects Of Bmi And Physical Activity**

José A. Maia, Renata Coelho, Rui Silva, Andre Seabra, Vitor Lopes. *Faculty of Sport, Porto, Portugal.*

Email: jmaia@fade.up.pt

(No relationships reported)

Adequate levels of gross motor coordination (GMC) are relevant for children to express their motor and cognitive skills. Longitudinal data concerning the influence of BMI and physical activity in GMC is scarce

**PURPOSES:** (1) to model annual changes in GMC of children, and (2) to evaluate the importance of time varying predictors: body mass index (BMI) and physical activity levels (PA).

**METHODS:** sample size comprises 285 children (143 boys; 142 girls) followed longitudinally for 4 years starting at the age of 6. GMC was assessed with the KTK (Körperkoordinations-test für Kinder) comprising 4 items: backward balance (BB), jumping sideways (JS), hopping on one leg (HL), and shifting platforms (SP). PA was evaluated with the Godin and Shephard questionnaire. BMI was computed as the ratio of weight (kg) to height<sup>2</sup>(m). Data analysis was done within the multilevel framework using HLM 6.0. Statistical evaluation of nested models was sequential using Deviance as a test statistic. Reliability estimates for all variables was computed with the intraclass correlation coefficient (R).

**RESULTS:** data showed high reliability for GMC tests (0.75<R<0.91), PA (0.65<R<0.80), height and weight (R=0.99). All GMC tests and BMI showed significant (P<0.05) mean increases with age. PA evidenced a small decline over the 4 years, more evident in girls (from 41.81±2.97 Met/15Min/Week at 6 years to 33.36±1.71 at 9 years). A series of nested models for each GMC test showed that data behaved in a non linear fashion, with baseline values being positively associated with annual changes in motor coordination. Across the 4 years, BMI shows a negative (P<0.05) impact in GMC, but PA showed a significant (p<0.05) positive association.

**CONCLUSIONS:** (1) boys and girls show similar significant increases in GMC from 6 to 9 years of age; (2) BMI is negatively associated with GMC changes; (3) on the contrary, PA is positively associated with motor coordination; (4) baseline values of GMC are positively associated with their changes; (5) even if BMI induces a reduction in GMC performance, a protective effect is evident for those children who are at the upper quartile of the distribution of PA across the 4 years. This shows the importance of promoting moderate to high levels of PA to induce relevant increases in GMC even if one is overweight.

**Construct Validation Of Physical Activity Measures In Adults With Intellectual Disabilities**

Marquell J. Johnson<sup>1</sup>, Joonkoo Yun<sup>2</sup>, Jeff McCubbin<sup>2</sup>. <sup>1</sup>University of Wisconsin - Eau Claire, Eau Claire, WI. <sup>2</sup>Oregon State University, Corvallis, OR.

(Sponsor: Anthony Wilcox, FACSM)

Email: johnmarq@uwec.edu

(No relationships reported)

Self-report measures have been utilized to capture the physical activity (PA) behaviors of adults with Intellectual Disabilities (ID). Despite a lack of validity evidence, researchers have relied on the assistance of secondary sources (e.g. parents, caregiver, etc) to measure levels of PA for individuals with ID.

**PURPOSE:** To examine the validity evidence for self-report with assistance from a secondary source as a measure of PA in adults with ID.

**METHODS:** Thirty-seven individuals with mild to moderate ID participated. Multitrait-Multimethod (MTMM) analysis was used to evaluate the psychometric properties. Convergent validities were determined by evaluating the outcomes of a self-report measure of PA, accelerometry, and pedometry. Results from a self-report measure of fat intake were used for evaluating evidence of discriminant validity. Participants wore an accelerometer and pedometer during waking hours for two 7-day periods. Following each 7-day period self-report measures for PA and fat intake were administered to the participants with assistance from a secondary source. Test-retest reliability using ICC conducted between interview-1 and interview-2 in self-reported PA bouts and fat intake, activity counts by accelerometer, and number of steps taken measured by pedometer. Correlation coefficients (r) were calculated to examine the association between self-reports with assistance measures and objective measures of PA.

**RESULTS:** Examination of the pattern of reliability and validity coefficients of the MTMM analysis revealed strong construct validity evidence. Reliability coefficients ranged from ICC (2, 2) = 0.78 to ICC (2, 2) = 0.96. Self-report with assistance as a measure of PA was ICC (2, 2) = 0.80. Convergent validity coefficients for self-reported PA, accelerometers, and pedometers were r = 0.34 (p ≤ 0.05) and r = 0.52 (p ≤ 0.01), respectively. Discriminant validity coefficients between self-reported fat intake and PA was r = -0.37 (p ≤ 0.05) and between self-reported fat intake and the objective measures of PA (accelerometers and pedometers) were r = 0.00 and r = -0.23, respectively.

**CONCLUSIONS:** The study demonstrated that self-report with assistance from a secondary source as a measure of PA in adults with ID has strong validity evidence.

This project was funded by the Arc of WA Trust Fund.

**Correlations Between Physical Activity, Function, And Self-assessment Of Participation In Children With Duchenne Muscular Dystrophy**

Donovan J. Lott, Roxanna Bendixen, Sunita Mathur, Claudia Senesac, Alicia Kinsey, Krista Vandenborne. *University of Florida, Gainesville, FL*.  
Email: djlottpt@php.ufl.edu  
(No relationships reported)

Duchenne muscular dystrophy (DMD) is a devastating degenerative disease caused from the lack of the muscle protein dystrophin. Boys with DMD experience a gradual decline in their ability to perform functional tasks with disease progression; however, the relationships among functional ability, physical activity, and participation have not been explored.

**PURPOSE:** The purpose of this study was to determine the relationships between physical activity level, functional abilities, and self-assessment of participation in boys with DMD.

**METHODS:** Seven ambulatory boys with DMD (mean age 7.1 + 1.1 years) participated. Physical activity was assessed for seven consecutive days with a GT1M ActiGraph activity monitor to obtain step count, peak step count, activity count, peak activity count (PAC), and METs (determined by the Freedson child energy expenditure prediction equation). Subjects also completed timed functional tests: 30 foot fast walk, rise from supine, rise from sitting, and ascending four stairs. The Children's Assessment of Participation and Enjoyment (CAPE) was administered to determine participation in three activity domains: Physical Activity, Recreational Activity, and Social Activity. Relationships were examined using Pearson correlation coefficients.

**RESULTS:** There were strong correlations found between PAC and the 30 foot walk ( $r = 0.893$ ,  $p < 0.01$ ), METs and Social Activity ( $r = 0.865$ ,  $p < 0.02$ ), Physical Activity and rise from supine ( $r = -0.991$ ,  $p < 0.001$ ), and Recreational Activity and rise from sitting ( $r = 0.893$ ,  $p > 0.01$ ). A trend was noted for an association between Physical Activity and ascending four stairs ( $r = -0.739$ ,  $p = 0.06$ ).

**CONCLUSIONS:** The data from this pilot study demonstrate the presence of inter-relationships among physical activity level, functional ability, and participation in boys with DMD. These findings implicate the importance of including activity level and participation measures in clinical trials for the DMD population. Further research is warranted to better understand the correlations between these variables and how they are impacted with therapeutic interventions for patients with DMD.

**Reviewing Physical Activity Interventions In Latin America: Does Including Conference Abstracts Add Value?**

Jesus Soares<sup>1</sup>, Christine M. Hoehner<sup>2</sup>, Perez P. Diana<sup>2</sup>, Isabela C. Ribeiro<sup>1</sup>, Michael Pratt, FACSM<sup>1</sup>, Mario Bracco<sup>3</sup>, Pedro C. Hallal<sup>4</sup>, Ross C. Brownson<sup>2</sup>. <sup>1</sup>CDC, Atlanta, GA. <sup>2</sup>Washington University, St. Louis, MO. <sup>3</sup>Centro de Estudos do Laboratório de Aptidão Física de São Caetano do Sul, Sao Caetano do Sul, Brazil. <sup>4</sup>Federal University of Pelotas, Pelotas, Brazil.  
Email: jsoares@cdc.gov  
(No relationships reported)

According to a recent systematic review of peer-reviewed articles and theses, there is a shortage of physical activity (PA) interventions taking place in Latin America that have been evaluated and published in the peer-reviewed literature.

**PURPOSE:** The goal of this systematic review of conference abstracts was to describe PA interventions taking place in Latin America and assess the value of including this form of grey literature in a literature review.

**METHODS:** Abstracts from an expert-derived sample from conferences of nine scientific organizations were searched for community-based PA interventions in Latin America. This study (1) described and calculated the yield of conference abstracts focused on PA interventions; (2) classified the interventions by type; (3) assessed the added value of reviewing conference abstracts; and (4) tracked which evaluated interventions were eventually published.

**RESULTS:** From 31 annual conference proceedings, 88 abstracts were identified as community-based interventions focused on increasing PA (23 were informational, 32 were behavioral and social, and 8 were environmental and policy approaches to increase PA; 25 had insufficient information to classify). Only 32 abstracts used a PA outcome and control group. After excluding interventions that were (1) duplicates; (2) published in 2006 or later (ineligible from previous systematic review); or (3) included in the previously review of peer-reviewed articles and theses, the value added by including conference abstracts was 11 PA interventions. None of these 11 interventions were subsequently published.

**CONCLUSIONS:** This review confirmed the limited evidence concerning the effectiveness of community-based PA interventions in Latin America. In addition, it highlighted the challenges and low added value of including grey literature in systematic reviews of community interventions, particularly in regions with limited evidence. There is a need for stronger evaluation design and execution, as well as publication of evaluated interventions, to build the evidence base concerning PA interventions in Latin America.

**Influence Of Socio-economic Status On Habitual Physical Activity In 8- To 10-year-old Children**

Clemens Drenowatz<sup>1</sup>, Joey C. Eisenmann<sup>1</sup>, Karin A. Pfeiffer, FACSM<sup>1</sup>, Douglas Gentile<sup>2</sup>, David Walsh<sup>3</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>Iowa State University, Ames, IA. <sup>3</sup>National Institute on Media and the Family, Minneapolis, MN.  
Email: drenowatz@msu.edu  
(No relationships reported)

In adults, a lower socio-economic status (SES) is generally associated with lower physical activity (PA) levels; however, findings are inconclusive in children.

**PURPOSE:** The purpose of this study is to examine whether physical activity and/or sedentary behavior differs in children by SES.

**METHODS:** Subjects included 275 (119 males; 156 females) children 8-10 years of age. Height and body mass were assessed according to standard procedures and body mass index (BMI, kg/m<sup>2</sup>) was calculated. Self-reported household income was used to determine SES and create 5 groups ( \$100,000). Habitual, free-living PA was assessed by a pedometer. Participants recorded time worn and the number of steps accumulated on each day over a 7-day period. Measures of screen time (TV, computer use, video games) were determined by self-report. Differences in physical activity levels and sedentary behavior by SES were initially tested using ANOVA. Further analyses used ANCOVA controlling for leg length, sex, and BMI.

**RESULTS:** No significant SES group differences were observed for age (total sample 9.6 ± 0.9 years), height (total sample 138.5 ± 8.1 cm), and leg length (total sample 65.7 ± 5.1 cm); however, lower SES individuals had higher body mass and BMI compared to higher SES groups. Mean daily steps also differed significantly among SES groups with lower SES groups approximating 10,500 steps/day compared to about 12,000 steps/day in the higher SES groups. These differences remained significant ( $p < 0.05$ ) when controlling for leg length, but were not significant when further controlling for sex and BMI. Significant differences between SES groups were shown for sedentary behavior as well ( $P < 0.05$ ) with higher SES groups approximating 20 hrs/wk compared to almost 40 hrs/week of TV in lower SES groups and these differences remained significant when controlling for sex and BMI.

**CONCLUSIONS:** Children from a low SES display lower PA levels and spend more time in sedentary behavior; however, differences in PA were influenced by BMI. The higher BMI in these children might be another factor contributing to increased health risks among low SES individuals.

## Physical Activity During Pregnancy And Offspring Characteristics At 8-10 Years

Lanay M. Mudd, Erin E. Kuffel, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.*

Email: muddlana@msu.edu

(No relationships reported)

Few investigators have examined the influence of pregnancy physical activity (PA) on offspring characteristics in childhood.

**PURPOSE:** To evaluate the relationships between perinatal factors (birth weight, pregnancy PA) and offspring systolic blood pressure (SBP), body mass index (BMI), and aerobic fitness ( $VO_{2max}$ ) at age 8-10 years while also considering childhood PA.

**METHODS:** Study participants (n=16 mother/child pairs) were members of a cohort who were studied previously during pregnancy 8-10 years ago. Resting SBP (Dinamap), height, weight, and percent fatness (BodPod) were measured on both the mother and her child. Women and children performed treadmill tests to maximum voluntary exhaustion to determine  $VO_{2max}$ . Birth weight was abstracted from previous records. Pre-pregnancy, trimester-specific and average pregnancy PA (kcal/kg/wk) were calculated from historical recall surveys. Mothers rated their children's PA level (0-10 scale) at age 4 yrs, 6 yrs, and currently. Relationships between perinatal factors and offspring characteristics were evaluated via Spearman correlations and linear regression analyses.

**RESULTS:** Child SBP was related to third trimester PA ( $r_s = -0.622$ ,  $p=0.016$ ), child PA at 4 yrs ( $r_s = -0.498$ ,  $p=0.050$ ), and current child PA ( $r_s = -0.735$ ,  $p=0.001$ ). In multivariable regression analyses, child PA at 4 yrs and current PA remained significantly related to child SBP ( $R^2=0.637$ ). Second trimester ( $r_s = -0.534$ ,  $p=0.033$ ), third trimester ( $r_s = -0.501$ ,  $p=0.048$ ), and average pregnancy PA ( $r_s = -0.502$ ,  $p=0.048$ ) were significantly related to child BMI, as were maternal  $VO_{2max}$  ( $r_s = -0.526$ ,  $p=0.036$ ), and maternal BMI ( $r_s = 0.532$ ,  $p=0.034$ ); however, none of these were significant predictors in multivariable regression. Child  $VO_{2max}$  was related to pre-pregnancy PA ( $r_s = 0.506$ ,  $p=0.046$ ) and child percent fat ( $r_s = -0.596$ ,  $p=0.016$ ). Neither remained significant in multivariable regression. Birth weight was related to child SBP ( $r_s = -0.752$ ,  $p=0.031$ ) only among children of mothers who did not meet PA recommendations during pregnancy (n=8; < 7.5 kcal/kg/wk).

**CONCLUSIONS:** These pilot data suggest that PA during pregnancy may be related to child SBP and BMI at 8-10 years of age. Pregnancy PA may also disrupt associations between birth weight and child SBP.

### 3039 Board #186 May 30 9:30 AM - 11:00 AM

#### Hierarchical Model Related To Adolescents Physical Activity: Environmental, Social And Personal Issues

Aylton J. Figueira Junior<sup>1</sup>, Maria Beatriz Rocha Ferreira<sup>2</sup>, Fabio L. Ceschini<sup>1</sup>, Luciene D. Alvares<sup>1</sup>. <sup>1</sup>University of São Caetano do Sul - USCS, São Caetano do Sul - São Paulo, Brazil. <sup>2</sup>State University of São Paulo - UNICAMP, São Caetano do Sul - São Paulo, Brazil.

Email: aylton.figueira@uscs.edu.br

(No relationships reported)

Physical activity is considered an important health related lifestyle for adolescents; however the comparison of place of living (rural or metropolitan area) is not well determined.

**PURPOSE:** Analyze the prevalence of physical inactivity (PI) in adolescents living at countryside (CS) and at the metropolitan area (MA) of São Paulo City - Brazil and the hierarchical factors that should explain PI behavior.

**METHODS:** 262 adolescents were evaluated (14.9±1.2 (male); 14.3±1.3 years old female) living in a countryside (4,000 inhabitants) of São Paulo State and at MA of São Paulo city (1 million inhabitants). All adolescents answered the São Paulo Lifestyle Survey that has questions related physical activity practice, television-DVD watching, computer, videogames, internet access and sleeping habits. Statistic analysis used was the hierarchical model (Poison Regression Analysis Prevalence Ratio - PR) ( $p<0.05$ ) to determine the strength among variables and PI level. Qui-Square Test was assessed to determine the significant prevalence. Three sets of independent variables were chosen to explain the relationship of PI, environmental, social-demographic and personal behavior, classified as: weak influence (gender, age, number of sibling, house type); medium (transport to/back from school, physical education class (PE) participation, barriers to physical activity); strong influence (time of TV watching, time of computer, videogames and sleeping time).

**RESULTS:** Significant values ( $p<0.05$ ) were found for PI (54.2%-MA and 33.3%-CS). Multivariate Regression analysis indicated that distance from house-school, transportation type to go-back from school, PE participation, barriers number were related to PI ( $p<0.05$ ). Adolescent PR showed that inactive transportation (bus/car) to / from school correlated to inactivity (RP:1.64 [IC95%:1.04-2.59]), as well low PE classes attendance (RP:2.05 [IC95%: 1.22- 3.44]) and over two barriers (RP:1.46 [IC95%: 1.00-2.15]). No interference on PI was related to total seating time for TV watching, computer and videogame.

**CONCLUSIONS:** Data evidence the necessity of positive intervention in adolescents to use active transportation; promote interesting program at PE classes and reduce the barriers perception.

#### Contribution Of Youth Sports, School Physical Education And Socioeconomic Position To Adulthood Leisure Time Physical Activity

Tomi Mäkinen<sup>1</sup>, Katja Borodulin<sup>1</sup>, Tuija Tammelin<sup>2</sup>, Ossi Rahkonen<sup>3</sup>, Tiina Laatikainen<sup>1</sup>, Ritva Prättälä<sup>1</sup>. <sup>1</sup>National Public Health Institute, Helsinki, Finland. <sup>2</sup>Finnish Institute of Occupational Health, Oulu, Finland. <sup>3</sup>University of Helsinki, Helsinki, Finland.

Email: tomi.makinen@ktl.fi

(No relationships reported)

**PURPOSE:** To examine how participation in youth sports, attitude towards school physical education, parental socioeconomic positions (SEP), and adulthood SEP contribute to leisure-time physical activity (LTPA) in adulthood.

**METHODS:** The data derived from the National FINRISK 2002 sub-study which examined past and present self-reported physical activity among women (N=2813) and men (N=2362) aged 25-64-years. Gender-specific analyses were conducted by structural equation modelling. Results are presented as age-adjusted standardized regression coefficients (b). Participation in youth sports comprised a latent variable including participation in competitive sports and leisure-time exercise. Attitude towards school physical education formed a latent variable including five statements about school physical education. Parental SEP was measured with parental occupation. Adulthood SEP formed a latent variable including education and household income. Occupational physical activity (OPA) measured in metabolic equivalents (METhours/wk) was examined. Outcome variable was adulthood overall LTPA (METhours/wk).

**RESULTS:** The median value for overall LTPA was 19.3 METhours/wk in women and 19.0 METhours/wk in men. Adulthood SEP (women b=0.14, men b=0.08) had a positive association with overall LTPA in adulthood and a negative association with OPA (women b=-0.09, men b=-0.14). Participation in youth sports had a negative association with attitude towards school physical education (women b=-0.52, men b=-0.50) but positive association with overall LTPA in adulthood in men (standardized b=0.13). Attitude towards school physical education and OPA was not associated with overall LTPA.

**CONCLUSIONS:** SEP in both genders and participation in youth sports in men play a prominent role in overall LTPA in adulthood.

#### Physical Activity Levels Of Elementary Aged Children In Early Morning Care: Differences By Age And Gender

Meghan M. Senso, Jessica Thomas, Kodi Howard, Stewart G. Trost, FACSM. *Oregon State University, Corvallis, OR.*

Email: sensom@onid.orst.edu

(No relationships reported)

The prevalence of childhood obesity in the US has increased from 6.5% in 1980 to 18.8% in 2004. Low physical activity (PA) is a probable contributor to this increase in obesity. Numerous studies have examined PA levels in children during or after school. However, little is known about PA behavior before school, during early morning care (EMC).

**PURPOSE:** The purpose of this study was to describe the PA behaviors of elementary-aged children during EMC and examine any gender or age differences.

**METHODS:** All children participating in EMC (kindergarten through 5th grade) at two elementary schools were invited to participate. Those who consented wore an Actigraph GT1M accelerometer while attending EMC for one week ( $n=13$ , mean age =  $7.8 \pm 1.7$ , 31% male, mean BMI =  $17.4 \pm 1.9$ , mean BMI percentile =  $65.8 \pm 22.5$ ). Data was analyzed from the time children arrived at school until the first morning bell. Each child completed 3-5 monitoring sessions. The percentage of time spent in sedentary behavior (SB), light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA) was calculated using the Freedson child equation. Age group and gender differences were analyzed using a generalized linear model in SAS PROC GLIMMIX. Pair-wise comparisons were evaluated for significance using pre-planned single degree freedom contrasts.

**RESULTS:** For all participants, the average percentage of time spent in SB, LPA, and MVPA was 38% (95% CI, 34.7, 42.2), 34% (95% CI, 30.9, 38.1), and 27% (95% CI, 24.4, 30.7), respectively. On average, girls spent significantly more time in SB and less time in MVPA than boys. No gender difference was observed for LPA. Younger children (5-6 yrs) spent significantly less time in LPA and more time in MVPA than older children (10+ yrs). The middle age group (7-9 yrs) spent more time in LPA than the younger age group, but showed no other differences.

**CONCLUSIONS:** There were significant gender and age differences in PA levels during early morning care. The overall percentage of time spent in MVPA was low suggesting that EMC is a possible time to improve PA behavior among elementary-aged children.

#### Concurrent Mental And Physical Stress: Cardiorespiratory And Neuroendocrine Responses

Kelly A. McLeod<sup>1</sup>, Supatchara E. Tangsilsat<sup>1</sup>, Gary H. Kamimori, FACSM<sup>2</sup>, Edmund O. Acevedo, FACSM<sup>3</sup>, Heather E. Webb<sup>4</sup>. <sup>1</sup>University of New South Wales, Sydney, Australia. <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD. <sup>3</sup>Virginia Commonwealth University, Richmond, VA. <sup>4</sup>Mississippi State University, Mississippi State, MS.

Email: hwebb@colled.msstate.edu

(No relationships reported)

Military personnel, law enforcement officers, firefighters, and rescue workers are often presented with concurrent physical and psychological challenges while performing occupational duties. Activation of the sympathetic-adrenal (SA) and hypothalamic-pituitary-adrenal (HPA) axes during concurrent mental and physical challenge may result in negative health consequences.

**PURPOSE:** To examine cardiorespiratory (CR), stress hormone and perceptual responses to a combination of acute physical and mental stress.

**METHODS:** Sixteen participants completed a  $\dot{V}O_{2max}$  test followed by two experimental conditions. The dual stress condition (DSC) consisted of moderate-intensity cycling at 60%  $\dot{V}O_{2max}$  for 37 minutes with a modified Stroop Color Word (SCW) task and Mental Arithmetic (MA task) from 12 min to 32 min, whilst in the exercise alone condition (EAC), the participants rode at the same intensity without the mental challenge. CR measures included heart rate (HR), respiratory rate (RR), minute ventilation ( $\dot{V}_E$ ), ventilatory efficiency ( $\dot{V}_E/\dot{V}O_2$ ), oxygen consumption ( $\dot{V}O_2$ ), and respiratory exchange ratio (RER). Blood samples were collected prior to, during, and after exercise to measure cortisol (CORT), epinephrine (EPI) and norepinephrine (NE). The State Anxiety Inventory (SAI), the Ratings of Perceived Exertion (RPE) scale, and the NASA Task Load Index (NTLX) were used as psychometric measures.

**RESULTS:** The DSC resulted in significant elevations in SAI and NTLX scores at the conclusion of the dual-stress portion of the protocol. The DSC also elicited significantly greater responses in CR measures of HR, RR,  $\dot{V}_E$  and  $\dot{V}_E/\dot{V}O_2$  measures. CORT and EPI were significantly elevated in the DSC when compared to the EAC, and area-under-the-curve (AUC) calculations revealed greater overall releases of CORT, EPI, and NE in the DSC.

**CONCLUSION:** These results suggest that combined mental and physical challenge have a greater impact on the body's cardiorespiratory, hormonal and psychological stress response than a physical stress alone. This may have harmful implications for those exposed to such conditions on a regular basis.

---

#### Aerobic Fitness Impacts Cardiorespiratory And Stress Hormone Responses To Concurrent Mental And Physical Stress

Supatchara E. Tangsilsat<sup>1</sup>, Kelly A. McLeod<sup>1</sup>, Gary H. Kamimori, FACSM<sup>2</sup>, Edmund O. Acevedo, FACSM<sup>3</sup>, Heather E. Webb<sup>4</sup>. <sup>1</sup>University of New South Wales, Sydney, Australia. <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD. <sup>3</sup>Virginia Commonwealth University, Richmond, VA. <sup>4</sup>Mississippi State University, Mississippi State, MS.

Email: hwebb@colled.msstate.edu

(No relationships reported)

Studies have demonstrated that a combination of mental and physical challenge can elicit exacerbated cardiorespiratory (CR) and stress hormone responses above a single stimulus. However, an analysis of the effects of aerobic fitness on the CR and neuroendocrine responses to concurrent mental and physical stress between below average (Low-fit) and above average (High-fit) fitness individuals, has not been conducted.

**PURPOSE:** To examine the effect of aerobic fitness on cardiorespiratory and stress hormone (cortisol [CORT], epinephrine [EPI], and norepinephrine [NE]) responses to concurrent mental and physical stress.

**METHODS:** Eight above average (high-fit [HF],  $\dot{V}O_{2max} = 51.18 \pm 2.09$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) and eight below-average fitness (low-fit [LF],  $\dot{V}O_{2max} = 36.58 \pm 3.36$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) participants completed two experimental conditions. An exercise-alone condition (EAC) consisted of cycling at 60%  $\dot{V}O_{2max}$  for 37 minutes, while a dual-stress condition (DSC) included concurrent participation in a mental challenge for 20 minutes while cycling.

**RESULTS:** Heart rate, respiration rate, minute ventilation, and ventilatory efficiency were exacerbated in the DSC. The DSC elicited greater overall CORT, EPI, and NE responses. Additionally, LF participants had a greater overall release of CORT in the DSC. However, HF demonstrated greater EPI and NE responses, paralleled with elevated cardiorespiratory responses.

**DISCUSSION:** LF individuals seem to demonstrate unnecessary and possibly unfavorable CORT responses to the DSC compared to HF individuals. The higher levels of EPI and NE in HF participants may explain the elevated cardiorespiratory responses compared to LF participants.

### 3044 Board #191 May 30 8:00 AM - 9:30 AM

#### Validation Of A Pattern-recognition Activity Monitor In Older Adults During Daily Living Activities

Pedro De Saint-Maurice, Andres M. Calabró, Gregory J. Welk, FACSM. *Iowa State University, Ames, IA.*  
Email: pmaduro.exsa@gmail.com  
(No relationships reported)

The pattern-recognition capabilities of the Intelligent Device for Energy Expenditure and Activity (IDEEA) monitor offer advantages to assess complex daily living activities in older adults, compared to traditional accelerometry-based activity monitors.

**PURPOSE:** The purpose of the study was to evaluate the accuracy of the IDEEA for assessing daily living activities in older-adults.

**METHODS:** Twenty-six participants (14 men and 12 women, age= 74.1±4.0, BMI= 26.5 ±3.8) completed 9 light intensity occupational activities (sitting motionless, sitting/fidgeting, transferring from sitting to standing, dressing with a lab coat, stacking boxes, stepping, bending down and folding clothes, sweeping and walking) for 3 minutes each. Participants wore concurrently the IDEEA and a portable metabolic analyzer (Oxycon Mobile, OM). Data from both instruments IDEEA monitor and the OM, were processed on a minute-by-minute basis and merged by time. Mixed model analyses of variance were used to evaluate the accuracy of group level estimates of EE from the IDEEA. Tukey-Kramer paired comparisons tests were used to test for differences among levels of fixed effects as well as the interaction term.

**RESULTS:** The overall EE was overestimated ( $p<0.001$ ) by the IDEEA by 0.23kcal/min. The IDEEA monitor overestimated EE during sitting motionless (24.6%), fidgeting while sitting (46.0%), stepping (45.8%), folding clothes (0.1%), sweeping (5.4%) and walking (70.3%). The IDEEA underestimated transferring from sitting to standing (16.2%), dressing (19.6%) and stacking boxes (16.7%). Differences were significant for sitting/fidgeting ( $p=0.02$ ), transferring from sitting to standing ( $p=0.04$ ), dressing ( $p=0.04$ ), stepping ( $p<0.001$ ) and for walking ( $p<0.001$ ). Sitting motionless ( $p=0.09$ ), stacking boxes ( $p=0.13$ ), folding clothes ( $p=0.78$ ) and sweeping ( $p=0.04$ ) were non-significant.

**CONCLUSION:** Even though the overall method effect was significantly different, data showed agreement in variability across stages. The IDEEA demonstrated ability to detect subtle changes in EE associated with household tasks in older adults.

**3045 Board #192 May 30 8:00 AM - 9:30 AM**  
**Maximal Heart Rates And Body Mass In Male Police Officers Participating In Authentic Shooting Range Maneuvers.**

Robert B. Pankey, Melissa Kemp, Stacia Miller, Allie Campbell. *Texas State University, San Marcos, TX.* (Sponsor: John Walker, FACSM)  
Email: rp20@txstate.edu  
(No relationships reported)

**PURPOSE:** The purpose was to explore the relationship of elevated heart rates on law enforcement officers from normal (NOR), overweight (OVR) and obese (OBS) BMI groups who participated in deadly force encounter scenarios during authentic shooting range maneuvers. It was hypothesized that there would be significant differences in maximum heart rate (MXHR) between officers.

**METHODS:** Certified male law enforcement officers ( $n=41$ , ht.=70±3.2 in., wt.=201±38.1 lbs., age=35±7.3 yr.) from the Advance Law Enforcement Rapid Response Training (ALERT) program volunteered for this investigation. Heart Monitors were used to capture MXHR of each individual officer participating in the force-on-force scenario before and after their maneuvers. Each maneuver lasted approximately five minutes.

**RESULTS:** A single factor ANOVA was used to determine if maximal heart rates differed between groups participating in authentic shooting range maneuvers. A significant difference was found in BMI among subjects in NOR (22.5±1.84,  $n=8$ ), OVR (27.3±1.41,  $n=20$ , ) and OBS (34.1±3.90,  $n=13$ ) groups ( $p<.05$ ,  $F_{2,38}=56.1$ ). 31% of the subjects were classified OBS and 80% of the subjects were considered OVR and OBS, according to BMI categories (Powers, 2007). No significant difference was found in MXHR between groups NOR (178±12.61 bpm), OVR (177±35.45 bpm) and OBS (174±22.63 bpm) groups ( $p>.05$ ,  $F_{2,38}=.052$ ).

**CONCLUSIONS:** A non-significant finding in MXHR among groups in this investigation could be attributed to external factors such as good preparation, experience, as well as internal factors such as self control and good conditioning. High subject BMI levels did not seem to affect average maximal heart rates during shooting range maneuvers. In order to increase accuracy and decrease any chance of false reaction or inaccuracies, one should strive to maintain low heart rate while in a shooting scenario. Lower MXHR among subjects participating in the authentic shooting scenarios was perceived as a positive finding in this investigation. Investigations as this should serve to identify individuals with cardiovascular risk factors while maintaining vigilance over individuals who exhibit physiological or psychological changes on occasions of lethal force type maneuvers.

**Longitudinal Comparison Of Body Mass Index And Percent Fat Changes In Charlotte Mecklenburg Police Department**

Matthew S. Boulous<sup>1</sup>, Robert W. Boyce, FACSM<sup>1</sup>, Glenn R. Jones<sup>2</sup>, Edward L. Boone<sup>3</sup>. <sup>1</sup>University of North Carolina at Wilmington, Wilmington, NC. <sup>2</sup>City of Charlotte, Charlotte, NC. <sup>3</sup>Virginia Commonwealth University, Richmond, VA.  
Email: msl1190@uncw.edu  
(No relationships reported)

Body composition is of primary concern in careers with high physical demands, such as police, and is commonly measured by body mass index (BMI) and percent body fat (BF). BMI uses height and weight ( $\text{kg/m}^2$ ), and the BF test measures subcutaneous fat (skinfolds). Little has been done in police organizations showing how these two methods differ in classifying police as they age and how the changes over time differ between genders.

**PURPOSE:** To compare BMI classifications of obesity with BF in police over 12 years with gender comparisons.

**METHODS:** Police recruit and in-service fitness tests were used to track changes in mass, BMI, BF, fat and lean body mass, and obesity in police. Comparisons were made between genders at recruit and in-service testing and the changes in these variables over time.

**RESULTS:** Sample included 286 police; 24 females, 262 males. Average number of years between tests is 12.6 ± 2.1 years. Mean age of initial recruit 24 ± 3 yrs and at in-service was 37 ± 3 yrs. Significant differences were found between genders in all body composition variables, except fat mass at both testing periods,  $p \leq 0.001$ . Comparing females vs. males at both testing periods BMI was significantly higher (initial-recruit 21.3 ± 2.1 vs. 25.5 ± 3.6; in-service 24.4 ± 3.3 vs. 29.4 ± 4.7) and percent body fat was significantly lower (initial 20.7 ± 4.5% vs. 14.7 ± 5.8%; in-service 26.0 ± 6.5% vs. 19.5 ± 6.2%) in males. There were significant differences,  $p \leq 0.05$ , between females vs. males in the amount of change that occurred from recruit to in-service tests in body mass (8.3 ± 6.3 kg vs. 12.6 ± 9.2 kg) and lean mass (2.8 ± 3.2 vs. 5.9 ± 4.9); males showed greater increases. Both genders increased in all body composition variables from initial-recruit to in-service tests,  $p \leq 0.001$ . A greater percentage of males (39%) than females (8%) were classified as obese at in-service by BMI, the gender percentages were similar with BF (females 25% vs. males 21%). There was considerable disagreement in those classified as obese between the two classification systems at in-service; showing 55 people that were classified as obese in BMI were classified as non-obese in BF.

**CONCLUSIONS:** BMI and BF showed considerable disagreement as to who was classified as obese. It is suspected that the increase in lean mass over time in these police influences this disagreement, especially in males.

**3047 Board #194 May 30 8:00 AM - 9:30 AM**  
**Race Comparisons Of Longitudinal Changes In Strength Of Police Officers**

Steven M. Nusca<sup>1</sup>, Robert W. Boyce, FACSM<sup>1</sup>, Shelley C. Joye<sup>1</sup>, Glenn R. Jones<sup>2</sup>, Edward L. Boone<sup>3</sup>. <sup>1</sup>University of North Carolina at Wilmington, Wilmington, NC. <sup>2</sup>City of Charlotte, Charlotte, NC. <sup>3</sup>Virginia Commonwealth University, Richmond, VA.  
Email: smn0189@uncw.edu  
R. Boyce presenting  
(No relationships reported)

Strength profiles of police officers from recruitment to in-service, especially when considering gender, race and age, provides a basis for designing effective training, hiring, and retention procedures. No longitudinal police research was found that compared strength changes over time relative to race.

**PURPOSE:** To identify differences in strength scores from initial-recruit to in-service tests and to compare racial differences using a retrospective longitudinal design.

**METHODS:** Strength variables included bench press, bench press/lean weight and bench press/weight. Body weight, percent body fat, and bench press scores were retrieved for the 1990 to 1995 recruit classes and were paired to the most recent scores on 2006 in-service fitness log. Sample included 309 police officers: 30 females (13 black, 17 white) and 279 males (41 black, 238 white).

**RESULTS:** Mean age at initial-recruit was  $24.6 \pm 3.4$  years and for in-service was  $37.1 \pm 3.7$  years. Average time between tests was  $12.5 \pm 2.0$  years. Bench press strength significantly increased ( $p \leq 0.05$ ) for all gender and racial groups from initial-recruit to in-service tests. Black males vs. white males were significantly ( $p \leq 0.01$ ) stronger in bench press strength at initial-recruit ( $95.1 \pm 24.6$  kg vs.  $84.1 \pm 21.1$  kg) and at in-service ( $109.5 \pm 20.3$  kg vs.  $97.5 \pm 20.6$  kg). No significant differences in the amount of change were found between genders and between races for all strength variables. All racial and gender groups increased in bench press/lean weight, however the increase in white females was not significant. No differences were found between black and white females in all strength variables at both testing periods. Black males were significantly stronger than white males in bench press/weight only at the initial-recruit test ( $1.12 \pm 0.27$  vs.  $1.03 \pm 0.23$ ,  $p \leq 0.05$ ). White males showed a significant increase in bench press/weight over time ( $1.03 \pm 0.23$  to  $1.06 \pm 0.22$ ,  $p \leq 0.05$ ) but they did not reach the strength level of the black males at in-service ( $1.09 \pm 0.20$ ).

**CONCLUSIONS:** Police departments, with the implementation of a properly designed physical fitness program, can expect to see increases in the strength of their personnel over the first half of their careers; however, there are gender and racial differences related to strength gain.

---

**3048 Board #195 May 30 8:00 AM - 9:30 AM**  
**Age-related Decline In Physical Performance Capacity Is Offset By Aerobic Fitness.**

Miranda K. Udem<sup>1</sup>, Bryant A. Stamford, FACSM<sup>2</sup>, Robert J. Moffatt<sup>1</sup>. <sup>1</sup>Florida State University, Tallahassee, FL. <sup>2</sup>Hanover College, Hanover, IN.  
(No relationships reported)

Maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ), muscle mass and strength decline with age. This loss with age commonly leads to a decrease in human physical performance and may have serious implications for occupations where maximal or near maximal effort is critical.

**PURPOSE:** To examine the effect of age and  $\text{VO}_{2\text{max}}$  on work decrement of a maximal "all out" task.

**METHODS:** Fifty-six males, ages 20 to 59 yrs were selected from a larger pool of subjects. Based on age and  $\text{VO}_{2\text{max}}$  subjects were assigned to one of four age groups: 20-29 yrs ( $\text{VO}_{2\text{max}}=44.8 \pm 2.8$  ml/kg/min; n=13), 30-39 yrs ( $\text{VO}_{2\text{max}}=43.4 \pm 4.1$  ml/kg/min; n=8), 40-49 yrs ( $\text{VO}_{2\text{max}}=41.7 \pm 4.0$  ml/kg/min; n=20) and 50-59 yrs ( $\text{VO}_{2\text{max}}=39.4 \pm 5.3$  ml/kg/min; n=15). Subjects performed a graded exercise test on a treadmill to determine  $\text{VO}_{2\text{max}}$  and on a separate day a one minute maximal arm ergometry test (AET) to determine anaerobic capacity. The experimental session entailed a performance run for 0.35 miles at a pace of 8.75 min/mile. Immediately following the run a second maximal AET was completed. The decrement in performance of anaerobic capacity tests (the difference between AET#1 and AET#2) was determined and examined by age and  $\text{VO}_{2\text{max}}$  ( $\text{FIT} = >42$  ml/kg/min;  $\text{LOWFIT} = <42$  ml/kg/min).

**RESULTS:** No differences in mean  $\text{VO}_{2\text{max}}$  were observed between the age groups. Percent decrements in performance of the subsequent maximal AET occurred within each age group. Performance decrements were seen in the 20-29, 30-39 and 40-49 yr groups (13.4, 11.8 and 17%, respectively) and were significantly ( $p < 0.05$ ) less when compared to the 50-59 yr group (31.2%). Both LOWFIT and FIT individuals in their 20's and 30's had a significantly lower percent decrement of anaerobic capacity than those in their 40's and 50's ( $p < 0.05$ ). Regardless of age, LOWFIT subjects had significantly greater percent decrements in performance on the post-run maximal AET ( $p < 0.05$ ) when compared with FIT subjects.

**CONCLUSION:** There appears to be an age related effect on maximal anaerobic tasks which is, to a large degree, offset when aerobic capacity levels, independent of age are maintained above 42 ml/kg/min.

---

**3049 Board #196 May 30 8:00 AM - 9:30 AM**  
**Assessing Knowledge Of Cardiovascular Disease Risk Factors And Risk In Volunteer Firefighters**

Hye Lim Yoo, Warren D. Franke, FACSM. Iowa State University, Ames, IA.  
Email: rimiduck@iastate.edu  
(No relationships reported)

Firefighting has one of the highest occupational fatality rates in the United States. Heart disease is responsible for 45% of these on-duty deaths with most occurring in volunteer rather than career firefighters. Most decedents had predisposing risk or pre-existing disease.

**PURPOSE:** The purpose of this study was to assess knowledge of cardiovascular disease (CVD) risk factors and trends of risk screening in volunteer firefighters.

**METHODS:** Participants included in this analysis were 227 volunteer firefighters. Self reported data were obtained on the presence of CVD, CVD signs and symptoms, risk factors (age, diabetes, obesity, hypertension, hyperlipidemia, and tobacco use), timing of blood pressure and blood lipid check-ups, and demographic and occupational data.

**RESULTS:** The mean age of participants was  $37 \pm 11$  years, BMI =  $29.5 \pm 5.9$ , and most of them were either overweight (34%) or obese (40%). Over 31% were current tobacco users but only 4% had been diagnosed as diabetic. Among firefighters who knew their blood pressure, systolic and diastolic blood pressures were  $124 \pm 15$  and  $79 \pm 10$  mmHg, respectively. Among firefighters who knew their blood lipids, total cholesterol, low density lipoprotein cholesterol, high density lipoprotein cholesterol, and triglycerides were  $189 \pm 49$ ,  $132 \pm 53$ ,  $50 \pm 26$ , and  $187 \pm 62$  mg/dl, respectively. The majority of firefighters were unaware of their risk for either hypertension (46%) or hyperlipidemia (86%). Most participants had had their blood pressure measured within the past year (93%), although 2% of them had never done so. In contrast, only 34% of them had their blood lipids checked within the past year while 39% had never done so.

**CONCLUSIONS:** Firefighters who had had blood pressure and lipids assessed did not have markedly elevated values. The prevalence of overweight, obesity, and smoking among this group were higher when compared with general population data. However, many volunteer firefighters are not aware of their risk for CVD and risk screening appears inadequate.

---

**3050 Board #197 May 30 8:00 AM - 9:30 AM**  
**Differences Between Fire-instructors And Recruit Firefighters Pre-, During And Post Flashover Training**

Lieneke P.J. Schellekens<sup>1</sup>, Florentina J. Hettinga<sup>2</sup>, Tim van Ommen<sup>1</sup>, Eric Mo<sup>2</sup>. <sup>1</sup>Vrije Universiteit, Amsterdam, Netherlands. <sup>2</sup>TNO Defence, Security and Safety, Soesterberg, Netherlands. (Sponsor: Jos. J. de Koning, FACSM)  
(No relationships reported)

**INTRODUCTION:** Identifying differences in responses to the stressful demands of FOT between experienced fire-instructors (INSTR) and recruit firefighters (RFF) is important to achieve safe task performance.

**PURPOSE:** To identify differences between RFF and INSTR pre-, during and post FOT.

**METHODS:** 8 FF and 6 INSTR of the Amsterdam Fire Service performed a regular FOT in a wood burned flashover container. During FOT, subjects wore standard turnout gear including SCBA. Mean heart rate (HR; Polar S810i, Finland) and core temperature ( $T_{\text{core}}$ ; CoreTemp<sup>TM</sup>, HQInc., USA) were obtained at the start of FOT (PRE), during FOT (Exp1@10min and Exp2@20min), directly after FOT (POST) and during recovery (Rec1@5min and Rec2@10min). Workload was expressed as percentage heart rate reserve (%HRR) as derived from HR. Anxiety (ANX) was recorded PRE and POST using a Visual Analogue Scale.

**RESULTS:** RFF and INSTR differed in years of experience ( $0.3 \pm 0.7$  vs  $18.8 \pm 4.9$  yrs) and number of FOTs ( $2 \pm 5$  vs  $107 \pm 44$ ).

Table 1: %HRR,  $T_{core}$ , and  $T_{skin}$  of RFF and INSTR during FOT.

	%HRR		$T_{core}$ ( $^{\circ}\text{C}$ )		ANX	
	RFF	INSTR	RFF	INSTR	RFF	INSTR
Pre	$38.9 \pm 14.4$	$37.4 \pm 5.5$	$37.86 \pm 0.30$	$37.40 \pm 0.46$	$0.65 \pm 0.91$	$0.00 \pm 0.00$
Exp1	$45.9 \pm 12.1$	$41.0 \pm 15.0$	$37.86 \pm 0.29$	$37.44 \pm 0.51$		
Exp2	$72.5 \pm 8.2$	$60.7 \pm 13.2$	$37.95 \pm 0.30$	$37.52 \pm 0.49$		
Post	$81.7 \pm 17.3$	$76.4 \pm 23.0$	$38.45 \pm 0.42$	$37.85 \pm 0.40$	$1.38 \pm 1.36$	$0.10 \pm 0.25$
Rec1	$59.5 \pm 15.8$	$68.5 \pm 11.7$	$38.74 \pm 0.48$	$38.06 \pm 0.35$		
Rec2	$57.1 \pm 14.8$	$52.4 \pm 7.8$	$38.79 \pm 0.55$	$37.91 \pm 0.83$		

During FOT,  $T_{core}$  was higher for RFF. No main effects were found for %HRR. No difference was found for PRE-ANX. POST-ANX was higher for RFF. A significant negative correlation was found between experience and  $T_{core}$  for POST ( $r = -0.55$ ), REC1 ( $r = -0.55$ ) and REC2 ( $r = -0.58$ ).

**CONCLUSIONS:**  $T_{core}$  and POST-ANX are higher for RFF, associated with a lower level of experience. Based on the higher  $T_{core}$ , the response to heat exposure seems to be less adequate in RFF. This should be taken into account in determining FOT training load and duration. The higher POST-ANX of RFF, where PRE-ANX was similar to INSTR, may indicate an underestimation of FOT, supporting the necessity of an adequate preparation of RFF prior to FOT.

### 3051 Board #198 May 30 8:00 AM - 9:30 AM Professional Firefighter Physical Fitness And Dietary Practices

Matt Beekley, FACSM<sup>1</sup>, Elizabeth Gwaltney<sup>1</sup>, Heather Kranenburg<sup>1</sup>, Josh Bixler<sup>1</sup>, James B. Brown<sup>2</sup>. <sup>1</sup>University of Indianapolis, Indianapolis, IN.

<sup>2</sup>Indiana University, Bloomington, IN.

Email: beekley@uindy.edu

(No relationships reported)

Professional firefighters encounter unique physical fitness demands. Typically, the job consists of working one day at the firehouse and two days off duty. Nutritional intake data are scarce in the professional firefighter population.

**PURPOSE:** The purpose of this study was to examine Indianapolis professional firefighters' physical fitness, and compare nutritional intakes on and off duty.

**METHODS:** 43 Indianapolis professional firefighters age 44 yrs (SD 8; 2 female, 41 male) from two firehouses completed physical fitness testing.  $\text{VO}_{2\text{max}}$  was predicted from Queen's step test. Body fat was predicted from sum of three skinfolds. Food dairies were analyzed by computer from 15 of these firefighters.

#### RESULTS:

Physical Fitness Results		
N = 43	Mean	SD
Height (cm)	180.9	4.8
Weight (kg)	93.1	15.0
Blood Pressure (mm Hg)	129/84	11/9
Predicted Body Fat Percentage	23.2	5.9
Predicted $\text{VO}_{2\text{max}}$ (ml.kg.min)	53.6	6.4
Sit and Reach Results (in.)	12.9	3.0
Grip Strength (kg; R+L combo)	104.8	18.6
Push-ups (1 minute)	30.9	14.3
Curl-ups (1 minute)	49.1	13.1

Dietary Analysis Results				
N = 15	On Duty Mean	SD	Off Duty Mean	SD
Calories	2216.5	686.4	2786.7*	828.9
Calories from fat	835.3	320.1	1212.8*	532.8
Total fat (g)	86.1	30.8	122.3*	44.7
Saturated fat (g)	26.0	8.3	40.0*	18.4
Cholesterol (mg)	261.0	155.3	397.8	264.1

\* = significantly different from On Duty Mean,  $p < 0.05$

**CONCLUSIONS:** Although the physical fitness of Indianapolis firefighters appears excellent, firefighters ate significantly more calories, calories from fat, total fat, and saturated fat off duty compared to on duty. Nutritional interventions to decrease the risk of heart disease in this population should consider both on and, particularly, off duty dietary changes.

Supported in part by a Fire Act grant

### 3052 Board #199 May 30 8:00 AM - 9:30 AM

## Day To Day Differences In Periodic Cortisol Measurements Seen In Professional Firefighters

Nathan Eckert, David A. Tanner, James B. Brown. *Indiana University, Bloomington, IN.* (Sponsor: Mathew D. Beekley, FACSM)

(No relationships reported)

**INTRODUCTION:** Professional firefighters (PF) are routinely exposed to life-threatening environments. As a result, PF are at risk for the development of both psychological and physical stress related disorders.

**PURPOSE:** This study sought to assess day to day changes in the diurnal cycle of eight PF (age:  $45 \pm 7$  yrs &  $21.8 \pm 7.27$  yrs experience) Cortisol.

**METHODS:** Saliva samples were collected from eight PF at 09:00, 12:00, 18:00, and 22:00 hours during nine on-duty days and two off-duty days. Cortisol concentration was measured in saliva samples using ELISA.

**RESULTS:** Despite a downward trend in Fig. 1, ANOVA did not reveal a significant trend ( $P > .05$ ) for time and a main effect for days. The interaction between the on-duty and off-duty assessments also failed to reach significance. Lastly, the interaction between test day and time period was not significant ( $p > .05$ ).

**CONCLUSION:** Cortisol levels did not differ from day to day at any time point for PF. However, the non-significant trend of Cortisol levels throughout the day reflects a normal diurnal pattern. The data suggests that future research is needed to probe for Cortisol level differences between on-duty and off-duty days as well as Cortisol levels in response to emergency dispatch.

Figure 1. Mean Periodic Cortisol Concentration

### 3053 Board #200 May 30 8:00 AM - 9:30 AM

#### Effect Of Wearing Thermal Protective Clothing On Functional Balance In Male Firefighters

Pui W. Kong, David Hostler, Joe Suyama, Rakié Cham. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Robert L Robertson, FACSM)

Email: venikong@yahoo.com

(No relationships reported)

The incidence of fall related injuries among firefighters is high. During fire suppression, firefighters wear thermal protective clothing (TPC) which typically includes heavy fire-resistant outer garments, safety boots, gloves, a helmet, fire-resistant hood, and a self-contained breathing apparatus (SCBA). This protective equipment may impair balance by reducing visibility and adding mass on the body.

**PURPOSE:** We investigated the effect of wearing firefighting TPC on functional balance and the influence of morphometrics and physical activity on balance.

**METHODS:** Twenty-three male firefighters (age= $28.2 \pm 6.7$ yr, height= $177 \pm 1.2$ cm, mass= $91.3 \pm 21.2$ kg) provided informed consent to participate in this study. Subjects were surveyed about physical fitness: 12 reported performing resistance training and 11 reported no such training. All subjects performed a functional balance test under four conditions: 1) regular clothing, 2) TPC, 3) TPC with SCBA while carrying facemask, and 4) TPC with SCBA while wearing facemask. The balance test required subjects to walk forward and backward on a beam with a 180° turn half-way. The average walking time and number of errors made (e.g. falling off beam) were compared between conditions using a mixed design ANOVA (within-group factor = equipment condition; between-group factor = self-reported resistance training). Correlations between balance and physical characteristics were explored.

**RESULTS:** A significant main effect of equipment condition was found for the time to complete the task ( $p < 0.001$ ) and errors committed during the task ( $p = 0.003$ ). Subjects walked more slowly in the three TPC conditions compared with regular clothing ( $p < 0.001$ ). Overall, subjects reporting resistance training made 36.4% fewer errors than those without ( $p = 0.047$ ). Errors increased with the demands of TPC among subjects who did not participate in resistance training but remained unchanged among resistance trained subjects (equipment  $\times$  resistance training interaction  $p = 0.026$ ). No significant correlations between balance and age, height, mass or body mass index were identified.

**CONCLUSION:** Firefighters walk more slowly during a beam walking task as a strategy to maintain balance when wearing TPC. Resistance training may have a positive influence on functional balance when wearing TPC.

### 3054 Board #201 May 30 8:00 AM - 9:30 AM

#### Temperature Monitoring In Firefighters During And Following Exercise In Thermal Protective Clothing

David Hostler, Sarah Kerin, James C. Bednez, Joe Suyama. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Fredric L Goss, FACSM)

Email: hostlerdp@upmc.edu

(No relationships reported)

**PURPOSE:** Accurate monitoring of firefighter temperature is important to assure safety during operations. Multiple devices exist to monitor core and skin temperature but little is known about their utility in firefighters. We compared multiple, commercially available thermometers during, and following, work in thermal protective clothing (TPC) to a gold standard core temperature.

**METHODS:** On three separate occasions, 18 euhydrated firefighters (16 males) aged  $28.2 \pm 11.3$  years wearing TPC, completed two consecutive bouts of exercise in a hot room separated by a 20-minute rest and rehydration period that mimicked the National Fire Protection Administration (NFPA) work-rest guidelines. During exercise in TPC, four-site skin temperature and an ambulatory monitor worn on the arm was compared to an ingested core temperature capsule. Between and following exercise periods, temperature was measured with four commercially available thermometers (temporal artery, tympanic, oral, and an adhesive thermometer applied to the forehead). The different techniques were compared to core temperature using the Bland-Altman test of agreement.

**RESULTS:** Core temperature ranged from 36.7 to 39.7°C. During exercise, the mean (95%CI) difference between core and four-site mean skin temperature was 1.2°C (-0.8, 3.2) and was 3.0°C (0.1, 5.8) between core and the ambulatory one-site temperature monitor. When comparing external thermometers to core temperature following exercise, confidence intervals around the agreement greater than 0.5°C made all devices unsuitable for clinical use. The smallest bias was 0.4°C (tympanic) and the largest was 1.5°C (temporal artery).

**CONCLUSIONS:** Clinically significant biases and wide 95% CIs were seen with all temperature monitoring techniques when compared with core temperature in realistic situations. Caution should be used when employing any of these techniques to estimate core temperature on the fireground.

### 3055 Board #202 May 30 8:00 AM - 9:30 AM

#### Effects Of Chronic Consumption Of Electrolyte Beverages By Mill Workers On Markers Of Metabolic Syndrome

Delia Roberts, FACSM<sup>1</sup>, Kelly Dinsmore<sup>2</sup>. <sup>1</sup>Selkirk College, Castlegar, BC, Canada. <sup>2</sup>University of Calgary, Calgary, AB, Canada.  
Email: droberts@selkirk.ca  
(No relationships reported)

Electrolyte carbohydrate (ECHO) beverages have been shown to be more effective than water at maintaining euhydration and physical and cognitive performance during athletics. Given the consequences of loss of performance in the workplace, the use of said beverages may be warranted in occupations with hydration challenges due to high work rates, heat exposure and the use of personal protective equipment. However, occupational populations tend to be older with risk factors for hypertension, diabetes and cardiovascular disease, contraindicating the salt and sugar in hydration beverages.

**PURPOSE:** To investigate the effect of chronic consumption of ECHO on hydration and health in veneer mill workers.

**METHODS:** Blood lipid profile, fasting insulin and glucose, high sensitivity C-reactive protein (Hs-CRP) and blood pressure (BP) were monitored in 17 males (age 45 ± 11 yrs, height 168 ± 34 cm, weight 90 ± 18 kg, 23.0 ± 4.8% body fat). Workers were provided with ECHO (3 mEq/L K<sup>+</sup>, 18 mEq/L Na<sup>+</sup> and 6% sucrose-glucose mixture) or EB (identical in composition, appearance and taste except for artificial sweetener instead of sugars) ad libitum for 5 weeks in a double-blind random cross over design with 4 weeks of washout between treatments.

**RESULTS:** Workers were able to maintain a euhydrated state with both beverages, changes in body mass pre-post work shift were less than 0.5%.

Table 1. Mean ± SD for Metabolic Syndrome markers

	Pre-treatment		Post-Treatment	
	Baseline	Washout	EB	ECHO
Fasting Insulin (pmol/L)	67 ± 48	82 ± 62	64 ± 61	59 ± 55
Fasting Glucose (mmol/L)	5.6 ± 0.6	5.0 ± 0.8	5.4 ± 0.6	5.3 ± 0.5
Hs-CRP (mg/L)	3.0 ± 2.2	3.0 ± 2.3	3.1 ± 2.3	3.0 ± 2.4
Systolic BP (mmHg)	132 ± 16	134 ± 13	130 ± 12	132 ± 13
Diastolic BP (mmHg)	79 ± 9	81 ± 10	78 ± 7	78 ± 8
Total Cholesterol (mmol/L)	5.3 ± 1.0	5.2 ± 0.2	5.1 ± 1.1	5.1 ± 1.0
Triglycerides (mmol/L)	1.5 ± 1.1	1.4 ± 0.6	1.6 ± 0.9	1.5 ± 1.0
HDL (mmol/L)	1.2 ± 0.3	1.1 ± 0.2	1.2 ± 0.3	1.2 ± 0.4
LDL mmol/L)	3.3 ± 0.9	3.4 ± 0.9	3.2 ± 0.8	3.2 ± 0.7

**CONCLUSION:** Neither beverage caused any change in the measured markers of Metabolic Syndrome. It appears that in this population of workers, 5 weeks of consumption of approximately 2.5 L of EB or ECHO/day did not have any adverse effect on blood pressure, blood lipids or glucose tolerance.

### 3056 Board #203 May 30 8:00 AM - 9:30 AM Exercise Performance And Heat Stress In Paper Mill Employees

Markus Stark<sup>1</sup>, Günter Schwaberg<sup>2</sup>, Serge P. von Duvillard, FACS<sup>3</sup>, Peter Hofmann<sup>1</sup>. <sup>1</sup>Karl-Franzens University and Medical University Graz, Graz, Austria. <sup>2</sup>Medical University Graz, Graz, Austria. <sup>3</sup>University of Salzburg, Salzburg, Austria.  
Email: markus.stark@uni-graz.at  
(No relationships reported)

Exercise Performance and Heat Stress in Paper Mill Workers

Heat Stress is a daily component of work stress in industrial workers such as paper mill workers. The World Health Organization provides reference values for the upper limit of tolerance for working in hot and humid conditions such as a HR of 110 bpm, independent of age and fitness level.

**PURPOSE:** The aim of the study was to investigate the relationship between exercise performance and heart rate (HR) response during several work shifts in the heat in workers of different age and fitness level.

**METHODS:** Seven companies from Paper Mill Industry participated in the project. 187 workers (age: 36.4±9 yrs, Ht: 177±6 cm, Wt: 82.5±12 kg) took part in the study. Exercise performance was determined by means of an incremental submaximal cycle ergometry (Daum Electronic 8008) exercise test measuring HR (S 610, Polar Electro, Finland), oxygen uptake (VO<sub>2</sub>) (Metamax I, Cortex Biophysik, Germany) and power output (P) and VO<sub>2</sub>max and Pmax were calculated. HR was measured for 8 h during each of 817 work shifts with a total of 6.000 h.

**RESULTS:** Mean values for Pmax (226±22 W, 2.23±0.45 W.kg<sup>-1</sup>) and VO<sub>2</sub>max (35.4±14.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>) were within the limits of normal age related fitness level. The average HR during 8 h work shift was 92±11 bpm and well below the WHO limit of 110 min<sup>-1</sup>. However, some workers had an elevated HR of up to 200 min<sup>-1</sup> due to work specific heat stress and humidity (55±15°C WBGT, 10-60% humidity) performing specific tasks (e.g. disruption of normal paper production, cleaning the basement of the machine). There was a significant influence of age, fitness level, and task specific HR increase in the heat. The older and the less fit (R=0.288, P<0.05) the workers, the higher was the HR during 8 h shift, and in the short term (accumulated 60 min) task specific maximal HR (160±12bpm), challenges the fixed target HR of 110 bpm due to age related decline in HR is not provided for in WHO guidelines. The number of workers presenting HR above threshold increased with age and decreased with fitness level.

**CONCLUSION:** Our study suggest that the HR response during work in the heat and humidity was dependent on age and fitness level with some workers exhibiting low exercise performance level and eliciting elevated HR above the WHO recommendation.

### 3057 Board #204 May 30 8:00 AM - 9:30 AM West Virginia Games For Health: Implementing Dance Dance Revolution Into Public Schools

Justine Vosloo<sup>1</sup>, Linda Carson<sup>1</sup>, Nidia Henderson<sup>2</sup>, Emily Murphy<sup>1</sup>. <sup>1</sup>West Virginia University, Morgantown, WV. <sup>2</sup>Public Employees Insurance Agency, Charleston, WV.  
Email: justine.vosloo@mail.wvu.edu

(No relationships reported)

Dance Dance Revolution (DDR) has been found to be a powerful tool in the fight against obesity that researchers believe can have a profound long-term impact on the health and lifestyle habits of a new generation. In January of 2006, the state of West Virginia (WV) and Konami Digital Entertainment, Inc., announced the placement of DDR systems into all WV public schools. To date 364 (50%) physical education (PE) teachers have received DDR training and equipment. The training schedule began with the 180 middle schools of which 166 (88%) have been trained, followed by 93 (83%) of the 112 high schools, and 105 (24%) of the 438 elementary schools.

**PURPOSE:** The purpose of this study was to determine the trained PE teachers' perceptions regarding the utility of DDR in a school setting.

**METHODS:** Surveys were sent out to all 364 trained teachers and 167 (46%) completed and returned the surveys.

**RESULTS:** 100% of the teachers surveyed felt that their students enjoyed DDR. The majority of the teachers first introduced DDR in PE as a whole class, but then most commonly use it as a station/circuit with other activities. 57% reported incorporating DDR into other school activities. The most common other activities included at lunch/recess, school dances, and as a reward activity. 29% reported concerns about implementing DDR into the school setting. The most frequent concerns were: maintenance of the equipment, theft, and lack of additional equipment. 32% reported having bought additional equipment from other sources. 28% were interested in developing a DDR club for social affiliation.

**CONCLUSIONS:** Implementing DDR into the school environment has been viewed positively by the majority of WV physical educators. These results support expansion of the project, with the goal of engaging public school students, including those not normally predisposed to exercise, in a fun physical activity that helps improve overall health at an impressionable age.

**3058 Board #205 May 30 8:00 AM - 9:30 AM**  
**Field Evaluation Of Physical Activity In Wristband Type Motion Monitor**

Shinji Takahashi<sup>1</sup>, Koya Suzuki<sup>1</sup>, Tomohiro Kizuka<sup>2</sup>, Yosuke Sakairi<sup>2</sup>. <sup>1</sup>Tohoku Gakuin University, Sendai, Japan. <sup>2</sup>University of Tsukuba, Tsukuba, Japan.

Email: shinji@izcc.tohoku-gakuin.ac.jp

(No relationships reported)

**BACKGROUND:** To assess physical activity during daily free-living, objective methods are necessary. Recently, many type of accelerometer were developed and used for assessment of physical activity energy expenditure. In Japan, a multi sensor wristband (ViM sports memory) that includes a uniaxial accelerometer and a gyro-sensor has been developed. However, until now, no studies have been reported concerning the validity of this device in field situation.

**PURPOSE:** To examine the validity of the ViM for evaluation of physical activity by comparing with an indirect calorimeter (IC) during non-regulative activities in the field situation.

**METHODS:** Nine males (age: 20.6 +/- 0.7 yrs; body mass, 62.0 +/- 9.2 kg; height, 170.3 +/- 4.9 cm) and 8 females (age, 20.5 +/- 0.6 yrs; body mass, 55.7 +/- 6.7 kg; height, 158.7 +/- 5.3 cm) performed each 10 min of five type non-regulative activities (sitting rest, standing household task, video game (Wii sports), dance, and rope jump). The ViM was placed on non-dominant wrist position. During all activities, the IC (MetaMax 3B) measured energy expenditure (METs). The ViM recorded body motion, then the manufacture's software predicted energy expenditure (predicted EE, kcal/min) from outputs of the device. We calculated predicted METs by predicted EE values. To ensure steady state METs by the IC and the ViM, only the averaged values for final 7 min of each activity were used for data analysis. Data were analyzed with two-way ANOVA with repeated measurements; within-subjects factors were 2 measurement methods (IC and ViM) and 5 activity types. The criterion validity of the ViM was tested by correlation coefficients for each activity.

**RESULTS:** Two-way ANOVA results showed significant interaction ( $F(4, 56) = 26.3, p < 0.001$ ). There were significant differences between the IC and the ViM in all activities ( $p < 0.010$ ). Especially, the ViM fairly underestimated the IC at jump rope (IC: 7.9 +/- 1.6 METs; ViM: 5.1 +/- 0.4 MET,  $p < 0.001$ ). For the criterion validity of the ViM, there were no significant correlation coefficients for each five activity ( $r < 0.30, p \geq 0.25$ ) although correlation coefficient was significant for pooled data ( $r = 0.91, p < 0.001$ ).

**CONCLUSIONS:** The ViM significantly underestimates METs measured by the IC, and the criterion validity is low in field situation.

**Rating Of Perceived Exertion With Various Modes Of Video Game Interaction**

Amanda Dye, Katie Schwisow, Kim Aszklar, Anna Willard, Justin Ulbright, W. Matthew Silvers. Eastern Washington University, Cheney, WA.

(Sponsor: Wendy Repovich, FACSM)

(No relationships reported)

Novel interaction modes for video games potentially offer a way to meet daily physical activity standards during game play.

**PURPOSE:** This study compared perceived exertion (RPE) during various modes of game play.

**METHODS:** Twenty-nine healthy, active college students (male: n=13, female: n=16) volunteered for participation. Each participant completed five game conditions in 5-min bouts: (CTRL) Super Mario Bros. 3 seated; (STAND) Super Mario Bros. 3 standing; (GH3) Guitar Hero 3 standing; (WII) Wii Sports Tennis standing; and (DDR) Dance Dance Revolution. Participants were taught how to use the Borg 15-point RPE scale prior to testing. Immediately following each condition participants indicated an RPE score that best represented their exertion level. Repeated measures ANOVA were used to investigate differences in RPE between game conditions.

**RESULTS:** Mean data for RPE are provided in Table 1. There was a statistically significant multivariate difference ( $p < 0.01$ ) for RPE. Pairwise comparisons indicated significant differences ( $p < 0.01$ ) between conditions, except for WII and GH.

Table 1. Mean $\pm$ SD values for RPE are summarized for each condition.						
	CONDITION					
VARIABLE	Rest	CTRL	STAND	WII	GH	DDR
RPE	7.1 $\pm$ 0.8	7.8 $\pm$ 1.1	8.7 $\pm$ 1.7	10.2 $\pm$ 1.4	9.6 $\pm$ 2.1	11.5 $\pm$ 1.6

**CONCLUSION:** DDR yielded the highest RPE scores, ranging from 10 to 13. ACSM recommendations indicate that RPE scores around 13 are representative of 40-50%  $\text{VO}_{2\text{max}}$ , which may be enough to elicit health benefits. Difficulty level for all game conditions was low and pilot data suggests that playing WII, GH, and DDR at higher difficulty levels increases RPE scores and associated cardiorespiratory responses. Therefore, the present findings indicate that DDR game play, even at novice levels, may be intense enough to maintain or improve health. Furthermore WII, GH, and DDR at expert levels may be intense enough to improve physical fitness.

**3060 Board #207 May 30 8:00 AM - 9:30 AM**  
**Internet Delivered Active Living Every Day Efficacy: More Than Means And Goals**

Derek T. Smith<sup>1</sup>, Christopher M. Dorozynski<sup>1</sup>, Lucas J. Carr<sup>2</sup>. <sup>1</sup>University of Wyoming, Laramie, WY. <sup>2</sup>Brown University and Miriam Hospital, Providence, RI. (Sponsor: D. Paul Thomas, FACSM)  
(No relationships reported)

Active Living Every Day via internet-delivery is a theory-based physical activity (PA) behavior change program with demonstrated efficacy. The internet-delivery (ALED-I) medium recently underwent revision/advancement to include an interactive and optional goal setting feature and real-time PA reporting/graphics from pedometer-measured PA. It is unclear how these recent advances may influence the PA efficacy of ALED-I and whether dominating PA measurement practices for pedometer studies may be missing important efficacy evidence.

**PURPOSE:** To determine the PA efficacy to include mean(s), minimum(s), and maximum(s) of the revised ALED-I PA behavior change program in sedentary and predominantly overweight middle-aged adults.

**METHODS:** Thirty-five participants completed the 16-week ALED-I program, of which 20 were randomly assigned to receive a monthly progressive step goal (G-group; +625 steps/day/month) over the 4-month study (2500 steps/day total increase). The remaining 15 participants were not assigned a goal (NG-group), but had access to the self-actuated goal setting feature inherent within the ALED-I program. At baseline and 16-weeks, PA was measured by pedometer as well as descriptive variables. Participants logged/reported their PA for at least 5 of 7 days per week including one weekend day. Multiple day data allowed calculation of weekly means as well as weekly minimum and maximum PA.

**RESULTS:** Participants (N=35) were 51.4±8.3 years and overweight (BMI: 29.4±6.7 kg/m<sup>2</sup>). In the total sample, the ALED-I program increased PA by 1157 steps/day (8359±2487 to 9517±2676; *p*<0.01). After 16-weeks, there was no difference between the NG and G-groups with respect to change in PA (*p*=0.44). Complimenting the overall increase in PA, the least physically active day (minimum) increased 25% (4684±2061 to 6182±2807 steps; *p*<0.01), and the most physically active day (maximum) increased 10% (*p*<0.05).

**CONCLUSIONS:** A 16-week program using the revised ALED internet-delivery features, with or without prescribed PA goals, shows increases in PA similar to but not greater than those previously reported in overweight and sedentary adults. Multiple day PA reporting elucidated complimentary findings of reduced weekly physical inactivity (increased minimum) and increased peak PA (maximum). NIH Grant # P20 RR016474

**3061 Board #208 May 30 8:00 AM - 9:30 AM**  
**Validity And Reliability Of A Multi-sensor Board For Measuring Common Physical Activities**

Carl Hartung, Rohit Chaudhri, Jorming Goh, Jonathan Lester, Sean Migotsky, Gaetano Borriello, Glen E. Duncan. *University of Washington, Seattle, WA.*

(No relationships reported)

Measuring physical activity is an important component of health-related research. However, none of the currently available methods are fully satisfactory because of problems related to cost, convenience, and measurement error. Furthermore, available methods only capture a portion of the needed information. We developed a novel, portable multi-sensor board (MSB) to overcome these limitations.

**PURPOSE:** To establish the validity and reliability of a multi-sensor board (MSB) that infers common physical activities and estimates the associated energy expenditure.

**METHODS:** Data were obtained from 33 adults (17 female) aged 39.0 ± 15.1 years with body mass index 26.1 ± 4.4 kg/m<sup>2</sup>. Subjects walked/jogged on a treadmill over a select range of speeds and grades for 3 min. each (6 stages in random order) while being connected to a metabolic cart; 3 min. of sitting and 2 min. of standing preceded while 5 min. of sitting followed each bout. A single MSB was worn at the waist attached to a fanny pack for all sessions. Random subjects repeated the experiment on a separate occasion. The MSB uses a decision stumps classifier and Hidden Markov Models to infer activities, and the ACSM prediction equation and the subject's body weight to estimate energy expenditure based on the classified activity.

**RESULTS:** Accuracy of inferred activities compared with the ground truth (correctly identified activities / total activities \* 100) was 92.6 ± 4.5% with test-retest reliability *r* = 0.60. Accuracy of total caloric expenditure estimates (kcal MSB / kcal metabolic cart \* 100) was 97.1 ± 16.6%. Estimates were 88.5 ± 12.1% and reliability *r* = 0.48 when calculating accuracy from the absolute percentage error (kcal MSB - kcal metabolic cart / kcal metabolic cart \* 100).

**CONCLUSION:** The MSB provides valid and reliable measures of accuracy for inferring physical activities and estimating energy expenditure under laboratory conditions based on our preliminary data. Field experiments are underway where subjects perform a short routine (e.g., sitting, standing, walking, riding an elevator up/down, walking up/down steps, etc.) while being connected to a portable metabolic system to more closely mimic real-world conditions.

**Heart Rate Response To Interactive Video Games In Young Adults**

Mika Z. Johnson<sup>1</sup>, Darren E.R. Warburton<sup>1</sup>, Ryan E. Rhodes<sup>2</sup>, Shannon S.D. Bredin<sup>1</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada.

<sup>2</sup>University of Victoria, Victoria, BC, Canada. (Sponsor: Keith George, FACSM)

Email: jmika@interchange.ubc.ca

(No relationships reported)

Interactive video games are increasingly becoming a popular activity among young adults. We have previously shown that interactive gaming (in a laboratory setting) leads to marked health benefits. However, little is known about the exercise intensities engaged in during free play, and whether these intensities meet international physical activity guidelines for health benefits.

**PURPOSE:** To determine the exercise intensities exhibited during free play of interactive video games.

**METHODS:** Five males (24 ± 2 yr) and five females (22 ± 1 yr) were observed during six one-hour sessions (one session/wk). During each session, participants were given the choice of playing with video games in either an interactive medium (i.e., while exercising) or an inactive medium (i.e., traditional video gaming). Participant behaviour was recorded via video cameras and sessions were coded according to the type of activity displayed. Coded behaviours were then grouped and analyzed in three behavioural clusters: interactive gaming (IG), non-gaming physical activity (NG), and sedentary behaviour (SB). Beat-by-beat heart rate was also recorded throughout each session.

**RESULTS:** Young adults spent the majority of their time engaging in IG (61 ± 14% of the total time), with little time spent in traditional sedentary video game play (6 ± 16%). Females spent 60 ± 21% of total IG time at a heart rate which met or exceeded a level associated with the accrual of health benefits according to Health Canada/CSEP's guidelines. Approximately, 38 ± 9% was spent in "light effort" (i.e., 50-63% of heart rate max), 10 ± 5% was spent in the "moderate effort" zone (i.e., 64-76% of heart rate max) and 12 ± 25% was spent in the "vigorous effort" zone or above (i.e., 77-100% of heart rate max). In comparison, males spent 34 ± 28% of total IG time at a heart rate that met or exceeded the health benefit zone (14 ± 5% in "light effort", 11 ± 12% in "moderate effort", and 9 ± 14% in "vigorous effort").

**CONCLUSION:** Average heart rates attained during free play involving interactive video games are sufficient to meet international physical activity guidelines for health benefits. These findings have important implications for the design of physical activity interventions, specifically for young adults. **FUNDING:** Hampton Endowment Research Funds.

**Physiological Cost Of An Active Video Game Versus Other Exercise Modes In University Students**

Jo M. Welch, Justin White, Nicole A. Nixon. *Dalhousie University, Halifax, NS, Canada.*  
Email: jo.welch@dal.ca  
(No relationships reported)

Physically interactive video games require the movement of large muscle groups and therefore may potentially provide enough physical activity to produce health benefits. A few studies have evaluated their potential for caloric expenditure in children but little is known about their effects in young adults.

**PURPOSE:** The purpose of this study was to determine if a physically interactive video game can provide enough exercise for health benefits in comparison to walking and participating in a fitness boxing video.

**METHODS:** University students were randomly assigned to 6 possible intervention sequences in which all participants completed one 30 min session of each of 3 interventions: Nintendo Wii Sport boxing, brisk walking, and a fitness boxing video. Height, weight, resting heart rate, and maximum heart rate were measured before the intervention. Based on the ACSM Positions Stands for cardiorespiratory and weight management benefits, two target heart rate ranges were calculated for each subject to evaluate possible health benefits associated with cardiorespiratory fitness (65-90%  $\text{VO}_2$  max) and weight management (55-69%  $\text{VO}_2$  max). During each intervention, heart rate (HR) and ratings of perceived exertion (Borg RPE) were recorded. A significant difference among the groups was assessed by repeated measures ANOVA. LSD pairwise comparisons were used to perform post hoc evaluations of differences between treatments.

**RESULTS:** 23 subjects (15 women) mean age 21 y, height 172 cm, weight 71 kg, and BMI  $24 \text{ kg}\cdot\text{m}^{-2}$  completed the study. Differences among and between the mean HR values of the walking ( $120 \pm 17$  bpm), Wii ( $134 \pm 21$  bpm) and fitness video ( $163 \pm 13$  bpm) interventions were all significant. Mean RPE was also significantly different among the walking, Wii, and fitness video interventions ( $9.6 \pm 2.6$  vs.  $11.5 \pm 2.7$  vs.  $14.4 \pm 1.8$ ). The Wii intervention placed 40.9% of the subjects within their weight management target ranges and 27.3% within the more stringent cardiorespiratory fitness benefit range.

**CONCLUSION:** Nintendo Wii Boxing provided marginal physiological stimulus in fit university students. We suggest that benefits may be greater in a less fit population.

**Energy Expenditure Of An Interactive Video Game: A Preliminary Study**

Miyoung Lee, E. Andrew Pitchford. *Oregon State University, Corvallis, OR.*  
(No relationships reported)

Interactive video games (e.g., Dance Dance Revolution) have been utilized to increase energy expenditure (EE) and to change health-related behavior. A recent popular interactive game, Wii (Nintendo, Japan), is more skill-free and age- and user-friendly; however, the feasibility as a potential intervention tool to increase EE with moderate intensity physical activity (MPA) has not been examined.

**PURPOSE:** To determine EE and intensity of Wii Sports game activities.

**METHODS:** As a pilot study, eight healthy adults ( $M \pm SD$ :  $29.13 \pm 7.39$  yrs old & participating in MPA  $3.57 \pm 2.76$  times/week) were recruited (height, weight, & age:  $176.80 \pm 5.33$  cm &  $80.25 \pm 8.61$  kg in 3 males;  $166.24 \pm 4.61$  cm &  $59.94 \pm 4.24$  kg in 5 females). Experience of playing Wii was varied: never ( $n=3$ ), 1-10 times ( $n=4$ ), and more than 10 times ( $n=1$ ). Energy expenditure (EE;  $\text{VO}_2$ ) of individuals was measured by indirect calorimetry and heart rate (HR) monitor during quiet sitting and playing Wii (Tennis, Bowling, and Boxing) for about 10 minutes each, respectively. Between activities, participants rested 2-3 minutes to simulate a real life setting. A counter-balanced design was employed to avoid carry-over effect of the 3 game activities from the previous activity. Descriptive analysis was applied to determine EE and HR of each activity. Independent  $t$ -test with Bonferroni correction when needed and repeated measures ANOVA were employed to investigate the difference between sitting and the 3 activities and differences among the 3 activities, respectively. All alpha level was set .05.

**RESULTS:** Mean  $\pm$  SD of observed EE (MET-min) and HR was as follows (MET/HR):

Sitting  $1.05 \pm 1.11 / 68.85 \pm 9.78$

Bowling  $2.67 \pm 4.7 / 86.97 \pm 12.53$

Tennis  $3.43 \pm .86 / 98.93 \pm 11.07$

Boxing  $4.56 \pm 1.62 / 111.81 \pm 13.00$

MET scores and HR of all three activities were statistically different from sitting quietly,  $t = -3.52$  to  $-9.49$  with  $p < .001$  &  $p < .01$ , respectively. After repeated measures ANOVA, MET and HR were also significantly different among activities,  $F = 9.85$  &  $17.96$  with  $p = .013$  &  $p = .001$ , respectively.

**CONCLUSION:** Tennis and boxing of Wii games were determined as MPA, which is 3.0-5.9 MET. Larger sample size is needed to generalize the findings; however, results indicate that a well-designed intervention applying Wii may be able to increase MPA of individuals.

**3065 Board #212 May 30 8:00 AM - 9:30 AM**  
**Oxygen Consumption With Various Modes Of Video Game Interaction**

Hennig Lydia, Olsen Christine, Felderman Kristin, Justin Ulbright, Rees Sara, John Harshman, W. Matthew Silvers. *Eastern Washington University, Cheney, WA.* (Sponsor: Wendy Repovich, FACSM)  
Email: lhennig@eagles.ewu.edu  
(No relationships reported)

Novel interaction modes for video games potentially offer a way to meet daily physical activity standards during game play.

**PURPOSE:** This study compared mean and peak oxygen consumption ( $\text{VO}_2$ ) during various modes of video game play.

**METHODS:** Twenty-nine healthy, active college students (male:  $n=13$ , female:  $n=16$ ) volunteered for participation. Each participant completed five game conditions in 5-min bouts: (CTRL) Super Mario Bros. 3 seated; (STAND) Super Mario Bros. 3 standing; (GH3) Guitar Hero 3 standing; (WII) Wii Sports Tennis standing; and (DDR) Dance Dance Revolution.  $\text{VO}_2$  was measured continuously during each condition with mean ( $m\text{VO}_2$ ) and peak ( $p\text{VO}_2$ ) 1-min values recorded for analysis. Mean resting  $\text{VO}_2$  also was measured. Repeated measures ANOVA were used to investigate differences in  $m\text{VO}_2$  and  $p\text{VO}_2$  between game conditions.

**RESULTS:** Mean data for  $m\text{VO}_2$  and  $p\text{VO}_2$  are provided in Table 1. There was a statistically significant multivariate difference ( $p < 0.01$ ) for  $m\text{VO}_2$  and  $p\text{VO}_2$ . Pairwise comparisons indicated significant differences ( $p < 0.05$ ) between conditions, except for CTRL and STAND ( $m\text{VO}_2$ :  $p = 0.16$  and  $p\text{VO}_2$ :  $p = 0.20$ ).

Table 1. Mean $\pm$ SD values for $m\text{VO}_2$ and $p\text{VO}_2$ are shown for each condition.						
	CONDITION					
VARIABLE	Rest	CTRL	STAND	WII	GH	DDR
mean $\text{VO}_2$ (ml/kg/min)	$4.22 \pm 0.57$	$4.76 \pm 0.79$	$4.93 \pm 0.79$	$7.77 \pm 2.34$	$5.45 \pm 0.76$	$11.88 \pm 3.49$
peak $\text{VO}_2$ (ml/kg/min)	--	$5.38 \pm 0.95$	$5.60 \pm 0.98$	$8.86 \pm 2.88$	$6.15 \pm 1.17$	$14.59 \pm 2.68$

**CONCLUSION:** DDR yielded the highest  $m\dot{V}O_2$  and  $p\dot{V}O_2$  corresponding to 3.4 and 4.2 METS of intensity, respectively. ACSM recommendations for physical activity indicate 450-750 met-minutes should be accumulated weekly to elicit health benefits. It appears then that 2-3 hours of DDR play per week, even at a novice level of difficulty, could meet these recommendations. Wii and GH, however, would require almost double the weekly time to elicit health benefits similar to DDR.

**3066 Board #213 May 30 8:00 AM - 9:30 AM**  
**Blood Pressure Responses With Various Modes of Video Game Interaction**

Kaitlyn Emmett, Karen Hartman, Justin Ulbright, Malin Orcutt, Jessica Sullivan, Martha Chew, W. Matthew Silvers. *Eastern Washington University, Cheney, WA.* (Sponsor: Wendy Repovich, FACSM)  
 Email: kemnett@eagles.ewu.edu  
 (No relationships reported)

Novel interaction modes for video games potentially offer a way to meet daily physical activity standards during game play.

**PURPOSE:** This study compared blood pressure responses during various modes of video game play.

**METHODS:** Twenty-nine healthy, active college students (male: n=13, female: n=16) volunteered for participation. Each participant completed five game conditions in 5-min bouts: (CTRL) Super Mario Bros. 3 seated; (STAND) Super Mario Bros. 3 standing; (GH3) Guitar Hero 3 standing; (WII) Wii Sports Tennis standing; and (DDR) Dance Dance Revolution. Immediately following each condition systolic (SBP) and diastolic (DBP) blood pressures were measured. Resting SBP and DBP also were obtained. Repeated measures ANOVA were used to investigate statistical differences in SBP and DBP between game conditions.

**RESULTS:** Mean data for SBP and DBP are provided in Table 1. There was a statistically significant multivariate difference ( $p=0.038$ ) for DBP, but not for SBP ( $p=0.658$ ).

Table 1. Mean $\pm$ SD values for SBP and DBP are shown for each condition.						
	CONDITION					
VARIABLE	Rest	CTRL	STAND	WII	GH	DDR
SBP (mm Hg)	118.7 $\pm$ 6.5	119.1 $\pm$ 9.4	118.3 $\pm$ 9.1	120.3 $\pm$ 7.2	119.2 $\pm$ 9.8	118.9 $\pm$ 17.3
DBP (mm Hg)	72.3 $\pm$ 8.0	76.8 $\pm$ 6.2	76.2 $\pm$ 6.7	76.1 $\pm$ 9.3	76.6 $\pm$ 9.2	79.3 $\pm$ 9.6

**CONCLUSION:** Blood pressure responses, as a whole, were similar across conditions, except for DDR, which elicited significantly higher DBP ( $p=0.01-0.05$ ) compared to REST, STAND, WII, and GH. The expected blood pressure responses across conditions were increases in SBP and no change/decreases in DBP due to vasodilation. It is possible that the observed increases in DBP may be attributed to testing error. Further study is warranted to verify these findings and the blood pressure implications for video game play in multiple populations.

**3067 Board #214 May 30 8:00 AM - 9:30 AM**  
**Heart Rate Responses With Various Modes of Video Game Interaction**

Kyle Sasser, Shane Eller, Ken Dragoo, Justin Ulbright, Taylor Robinson, W. Matthew Silvers. *Eastern Washington University, Cheney, WA.* (Sponsor: Wendy Repovich, FACSM)  
 Email: kyle.sasser@gmail.com  
 (No relationships reported)

Novel interaction modes for video games potentially offer a way to meet daily physical activity standards during game play.

**PURPOSE:** This study compared heart rate (HR) responses during various modes of video game play.

**METHODS:** Twenty-nine healthy, active college students (male: n=13, female: n=16) volunteered for participation. Each participant completed five game conditions in 5-min bouts: (CTRL) Super Mario Bros. 3 seated; (STAND) Super Mario Bros. 3 standing; (GH3) Guitar Hero 3 standing; (WII) Wii Sports Tennis standing; and (DDR) Dance Dance Revolution. Mean ( $HR_{mean}$ ) and peak ( $HR_{peak}$ ) HR values were recorded during each condition, as well as resting HR. Repeated measures ANOVA were used to investigate differences in  $HR_{mean}$  and  $HR_{peak}$  between game conditions.

**RESULTS:** Mean data for  $HR_{mean}$  and  $HR_{peak}$  are provided in Table 1. There was a statistically significant multivariate difference ( $p<0.01$ ) for  $HR_{mean}$  and  $HR_{peak}$ . Pairwise comparisons indicated significant differences ( $p<0.05$ ) between conditions, except for WII and GH.

Table 1. Mean $\pm$ SD values for $HR_{mean}$ and $HR_{peak}$ are summarized for each game condition.						
	CONDITION					
VARIABLE	Rest	CTRL	STAND	WII	GH	DDR
$HR_{mean}$ (beats/min)	72.4 $\pm$ 9.5	77.0 $\pm$ 8.9	86.7 $\pm$ 12.5	90.0 $\pm$ 13.0	90.3 $\pm$ 12.8	114.1 $\pm$ 18.2
$HR_{peak}$ (beats/min)	--	86.1 $\pm$ 10.0	91.7 $\pm$ 13.5	100.5 $\pm$ 14.1	99.3 $\pm$ 14.5	121.7 $\pm$ 16.5

**CONCLUSION:** DDR yielded the highest  $HR_{mean}$  and  $HR_{peak}$  scores compared to other conditions. DDR HR scores represent approximately 60% of age-predicted  $HR_{max}$  for the sample population, which is in line with ACSM recommendations for fitness development. Additionally, it appears that WII and GH HR scores represent approximately 50% of age-predicted  $HR_{max}$ , which may not be intense enough for fitness development, but may elicit improvements in health.

**3068 Board #215 May 30 8:00 AM - 9:30 AM**  
**Heart Rate Response To Free Play Of Active Video Games**

Jeremy Richter, Stephen J. Kinzey, Shanon R. Siegel, Linda D. Wilkin, Brent Lukacs, Bryan L. Haddock. *California State University, San Bernardino, San Bernardino, CA.*  
 Email: richterj@csusb.edu  
 (No relationships reported)

Although the prevalence of overweight in children has remained stable between NHANES 2003-2004 data and the 2005-2006 data, the prevalence remains high, with 33.3% of

6-11 year olds having a BMI greater than the 85<sup>th</sup> percentile based on CDC recommendations. The popularity of video games has often been blamed for this high prevalence of overweight in children.

**PURPOSE:** The purpose of this study was to determine if children were given the opportunity to play active video games whether they would exercise at a level that would be conducive to increasing fitness and to compare this response in overweight and lean children.

**METHODS:** Thirty four participants had their height and weight measured at baseline. The mean BMI was 22.7 ( $\pm$  8.6) kg/m<sup>2</sup>, 13 of the participants had a BMI that was <85<sup>th</sup> percentile based on CDC recommendations, while 21 participants were >85<sup>th</sup> percentile. All participants were provided access to a wide variety of active video games once a week for 45 minutes, over a 7-week period. Each participant was connected to a HR monitor upon arriving and their average amount of time played and average HR were calculated. If a participant arrived late or left early, less time was available to play.

**RESULTS:** The average HR did not significantly vary between the exercise sessions ( $p>0.05$ ) or between BMI classification ( $p>0.05$ ). The number of participants who achieved an average HR that was at or above 70% of their predicted max HR varied between 6.2% and 26.6 %.

**CONCLUSIONS:** When given free access to playing a wide variety of active video games, children aged 6-11 years of age exercised at an intensity that was great enough to moderately increase their HR. However, most participants did not achieve a HR that would put them in the ACSM's training HR zone. There were no significant differences in response to the exercise sessions based on BMI category. It is important to continue to investigate methods of increasing physical activity in children.

**3069 Board #216 May 30 8:00 AM - 9:30 AM**  
**Energy Cost Of Physically Active Video Gaming Against A Human Or Computer Opponent**

Jessica McWha<sup>1</sup>, Sarah Horst<sup>1</sup>, Gregory A. Brown, FACSM<sup>1</sup>, Brandon S. Shaw<sup>2</sup>, Ina Shaw<sup>3</sup>. <sup>1</sup>*the University of Nebraska at Kearney, Kearney, NE.*  
<sup>2</sup>*Tshwane University of Technology, Pretoria, Gauteng, South Africa.* <sup>3</sup>*Vaal University of Technology, Vanderbijlpark, South Africa.*  
(No relationships reported)

Playing a physically active video game increases energy expenditure above that of sedentary video game play. And anecdotal reports suggest that people play harder against other people than against the computer system. However, the energy expenditure of playing a physically active video game against another person has not been evaluated. Furthermore, most of the research on energy expenditure during physically active video game play has been conducted in children even though young adults represent a large portion of the video game market.

**PURPOSE:** To determine if there is a difference in energy expenditure while playing *Nintendo Wii Boxing* against a Human or Computer opponent, and to evaluate the energy expenditure in young adults.

**METHODS:** Twenty college-aged adults (10 males, 22.5  $\pm$  0.5 y :10 females, 21.0  $\pm$  0.4 y) were measured for body composition and maximal aerobic capacity (VO<sub>2</sub>max) before playing *Nintendo Wii Boxing* for 15 minutes against a human or computer opponent, in a randomized manner, while heart rate, oxygen consumption, and energy expenditure were measured.

**RESULTS:** Heart rate, oxygen consumption, and energy expenditure were all higher ( $P<0.05$ ) at VO<sub>2</sub>max than any other condition. Heart rates (beats/min) while playing the video game were higher ( $P<0.05$ ) for both the Human (103.8  $\pm$  4.3) and Computer (104.6  $\pm$  4.6) opponent than at rest (75.4  $\pm$  2.9), with no differences between gender or video game opponent. Oxygen consumption (ml/kg/min) while playing the video game was higher ( $P<0.05$ ) for both the Human (14.6  $\pm$  1.80) and Computer (14.4  $\pm$  1.66) opponent than at rest (4.4  $\pm$  0.51), with no differences between gender or video game opponent.

**CONCLUSIONS:** The present data support previous investigations indicating that playing a physically active video game increases heart rate, oxygen consumption, and energy expenditure, but the magnitude of increase is not sufficient to classify physically active video game play as even moderate intensity exercise. These data also indicate that the magnitude of increase in energy expenditure while playing a physically active video game is similar in children and young adults. The present data further suggest that playing against a computer or human opponent does not alter the magnitude of increase in energy expenditure associated with physically active video game play.

**3070 Board #217 May 30 8:00 AM - 9:30 AM**  
**Salivary Cortisol And Blood Lactate Responses To Physically Active Video Gaming In Young Adults**

Sarah Horst<sup>1</sup>, Jessica McWha<sup>1</sup>, Gregory A. Brown, FACSM<sup>1</sup>, Brandon S. Shaw<sup>2</sup>, Ina Shaw<sup>3</sup>. <sup>1</sup>*the University of Nebraska at Kearney, Kearney, NE.*  
<sup>2</sup>*Tshwane University of Technology, Pretoria, Gauteng, South Africa.* <sup>3</sup>*Vaal University of Technology, Vanderbijlpark, South Africa.*  
(No relationships reported)

Physically active video games require the use of more body movement, and hence greater energy expenditure, than do traditional sedentary video games. Wang and Perry reported that blood lactate concentrations were not changed by playing a traditional sedentary video game, but the blood lactate and salivary cortisol response to a physically active video game have not been measured. Furthermore, informal statements by those who play physically active video games indicate that they put more effort into playing when they are competing against another person.

**PURPOSE:** To compare the blood lactate and salivary cortisol responses, as measures of physiological stimulation, when playing a physically active video game against a computer and human opponent.

**METHODS:** 20 healthy, college aged adults (10 males, 22.5  $\pm$  0.5 y: 10 females, 21.0  $\pm$  0.4 y) were assessed for body composition and maximal oxygen consumption (VO<sub>2</sub>max), with measurements of blood lactate and salivary cortisol concentrations before and after the VO<sub>2</sub>max assessment. On another day, the subjects engaged in 15 minutes of playing a physically active video game (*Wii Boxing*, Nintendo inc.) in a randomized manner against a human opponent or against the computer system with blood lactate and salivary cortisol concentrations measured before and immediately after each gaming session.

**RESULTS:** There were no differences in resting blood lactate concentrations between the males (1.2  $\pm$  0.2 mmol/L) and females (1.1  $\pm$  0.1 mmol/L). Blood lactate concentrations following the VO<sub>2</sub>max assessment were higher in the males (10.4  $\pm$  0.6 mmol/L) than in the females (8.4  $\pm$  0.4). Playing the physically active video game did not alter blood lactate in either gender or condition. The females had higher ( $P<0.05$ ) salivary cortisol concentrations than the males. However, there were no changes in salivary cortisol concentrations due to any intervention.

**CONCLUSIONS:** These data suggest that playing a physically active video game against a human opponent does not produce greater physiologic stimulation than when playing against the computer. Furthermore, the level of physical activity when playing a physically active video game is insufficient to result in changes in blood lactate or salivary cortisol, further indicating that physically active video game play is not vigorous exercise.

**Do Active Video Games Help Children Lose Weight?**

Bryan L. Haddock, Linda D. Wilkin, Shannon R. Siegel, Stephen J. Kinzey. *California State University, San Bernardino, San Bernardino, CA.*  
Email: bhaddock@csusb.edu  
(No relationships reported)

Active video games have been suggested as a possible alternative to exercise for helping solve the issue of obesity in youth. Currently, 33.3% of children aged 6-11 are classified as "at risk for overweight" or "overweight" according to the CDC guidelines.

**PURPOSE:** The purpose of this study was to determine if a 7 week class on health, with time given to play active video games, would lead to changes in BMI and body fat levels in children aged 6-11.

**METHODS:** Thirty one children aged 6-11 years completed at least 5 of the 7 training sessions and had their height, weight, BMI, and % body fat analyzed. Participants were instructed on basic health and nutrition for 45 minutes per week and were given access to playing a wide variety of active video games for 45 minutes at each weekly session. Height, Weight, BMI, and Body Fat (via skin fold measurements) were measured prior to beginning the class, following the completion of the class, and at 6 and 12 weeks after the completion of the class.

**RESULTS:** ANOVA revealed no significant differences existed in BMI during the follow up period ( $p>0.05$ ). Body Fat % was lower at 12 weeks post intervention compared to any other time point ( $p<0.05$ ).

**CONCLUSIONS:** Although 7 weeks of access to active video games did not impact BMI, there was a statistically significant drop in % body fat based on skinfolds 12 weeks after the intervention. Since the only decrease was shown 12 weeks post, it is likely that the active video games did not directly lead to a decrease in % body fat, but that the 7 week class and exercise session led to a lifestyle improvements which decreased body fat %. The results of this work and other work in this area would suggest that an intervention of active video games alone may not be sufficient to combat overweight in children. Active video games could be a component of a successful program.

**3072 Board #219 May 30 8:00 AM - 9:30 AM**  
**Energy Expenditure And Cardiopulmonary Responses To Sedentary And Physically-interactive Video Gaming In College Males**

Julie A. Pray Walton. *Calvin College, Grand Rapids, MI.*

Email: jwalton@calvin.edu

(No relationships reported)

There has been a simultaneous rise in obesity and sedentary leisure activity rates in youth over the past three decades. The video gaming industry has responded to this by introducing physically-active video games meant to counter the more sedentary nature of their products.

**PURPOSE:** The purpose of this study was to compare energy expenditure and cardiopulmonary response patterns during sedentary vs. physically-interactive video tennis.

**METHODS:** Ten college-age males underwent maximal exercise treadmill testing to determine maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ), ventilatory factors ( $\text{VE}_{\text{max}}$ ,  $\text{TV}_{\text{max}}$ ) and heart rate ( $\text{HR}_{\text{max}}$ ). One week later subjects played seated, sedentary video tennis (SVT) for 18 minutes, rested 10 min. then played an 18-minute round of interactive video tennis (IAVT) while  $\text{VO}_2$ , kcal, HR, VE, TV, and breathing frequency (BF) were monitored. Mean values for all variables were compared using an ANOVA posthoc paired  $t$  test,  $p=.05$ .

**RESULTS:** Mean  $\text{VO}_2$ , HR, VE, TV, and kcal expenditure during IAVT ( $7.61 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ , 93.14 bpm, 13.46 L/min, .684L, 2.99 kcal/min) were significantly higher than SVT ( $4.88 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ , 80.07 bpm, 10.18 L/min, .583L, 1.88 kcal/min). There was no significant effect from either game format on BF. Mean VE and TV in both game situations were significantly lower than both resting and maximal VE and TV. When reported as % $\text{VO}_{2\text{max}}$ , % $\text{HR}_{\text{max}}$ , and % $\text{VE}_{\text{max}}$ , IAVT play elicited rates of 17.25%, 48.3%, and 15.25% respectively, whereas SVT rates were 11.22%, 41.57%, and 11.42%. Subjects reached a significantly higher Peak  $\text{VO}_2$  on IAVT ( $9.86 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) compared to SVT ( $6.51 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ).

**CONCLUSIONS:** IAVT elicited significantly higher values compared to SVT for all reported variables except BF, leading to the conclusion that IAVT gamers worked at a higher % $\text{VO}_{2\text{max}}$ , % $\text{HR}_{\text{max}}$ , % VE, and calorie cost compared to playing a similar, but seated, handheld video game. Ventilatory data indicated a ventilatory relaxation response in both game situations. Neither game elicited values to cause a training effect or burn significant calories. IAVT was comparable in energy expenditure to folding laundry or driving a car, suggesting that interactive video games touted as physically-active are still a low-active endeavor.

**3073 Board #220 May 30 8:00 AM - 9:30 AM**  
**Assessment Of Cardiovascular Response And Metabolic Cost Of Speaking While Using An Active Workstation**

Ronald Cox, Jared Guth, Christopher Reed, Helaine Alessio, FACSM, Susan Brehm, Briana Kellems, Leah Siekemeyer. *Miami University, Oxford, OH.*

Email: coxrh@muohio.edu

(No relationships reported)

**PURPOSE:** To assess indicators of speech quality and document the heart rate, blood pressure and metabolic requirement ( $\text{VO}_2$ ) of speaking while sitting, standing and walking.

**METHODS:** Thirty adults aged 37 $\pm$ 14 years participated in all conditions. Heart rate and  $\text{VO}_2$  were obtained continuously with a Parvomedics metabolic system and expressed as ml/kg/min while subjects read silently, and aloud, or engaged in spontaneous conversation in a sitting, standing or walking (1 mph) condition. Blood pressure and rating of perceived exertion (RPE) were obtained during the last minute of the respective tasks. Expert listeners, blinded to the purpose of the study and the protocol assessed randomized samples of the participants reading and spontaneous speech tasks during the 3 conditions.

**RESULTS:** Standing elevated metabolic rate 10-15% over the sitting position ( $3.3 \pm .7$  vs.  $3.6 \pm .9 \text{ ml/kg/min}$ ). Walking 1 mph while performing the respective tasks resulted in physical activity level of 2.0-2.3 MET. The ranges for heart rates for the tasks performed under sitting-standing-walking conditions were 78-83, 87-91, and 90-96 bpm respectively. RPE across conditions varied from .4 to 1.6. There was no significant difference in the average number of syllables included in each breath group across the conditions ( $p = .945$ ). The number of ungrammatical pauses that occurred when the participants were reading aloud was minimal (0 -1 ungrammatical pause per reading) and the occurrence of these ungrammatical pauses did not differ across the conditions. No dysfluencies (e.g., unusual speech patterns, stuttering) were detected.

**CONCLUSION:** The significant elevation in metabolic rate in the absence of any deterioration in speech quality or RPE support the utility of using active work stations to significantly increase PA in the work environment and thereby enhancing health.

(No relationships reported)

**PURPOSE:** The investigation of the recruitment methods for programs and the characteristics of participants, along with the program contents, would lead to more effective operation of physical activity promotion programs. The purpose of the present study was to identify the determinants of the participation in walking program with the e-mail function of cellular phone.

**METHODS:** The sample was collected from the registrants of Japanese social research company. The company sent their registrants (30-49 years old) the requests for answering the questionnaire. The recruitment of the program was in the end of the questionnaire. In about 13,000 registrants receiving the requests, 4935 who answered all questions were identified as the subjects in the present investigation. The intervention program with e-mail newsletter was offered to all applicants.

**ANALYSIS:** Kraemer's signal detection analysis (Kraemer. *The American Statistician*, 1988; 42: 37-49) was used for selecting predictor of applicant from potential variables (gender, age, marital status, number of family, educational background, occupation, family income, hour per day spent in television watching, and hour per day spent in internet using, stage of

change for walking behavior, and self-efficacy for regular walking).

**RESULTS:** In all subjects, 1268 (25.7%) of them applied for the program. Signal detection analysis revealed that the predictors of applicant were stage of change, self-efficacy, and hour in internet using. As these variables, people were classified 6 groups: 1) precontemplation (N=1285, 9.9%), 2) contemplation (N=1197, 26.4%), 3) over-preparation, self-efficacy<11, Internet use<3 hours (N=958, 24.8%), (4) over-preparation, self-efficacy<11, Internet use≥3 hours (N=450, 34.4%), (5) over-preparation, self-efficacy 11-13 (N=567, 36.5%), and (6) over-preparation, self-efficacy≥14 (N=478, 47.1%).

**CONCLUSIONS:** The present study indicates that those who engage in walking, have higher self-efficacy for regular walking, or use internet more frequently tends to participate in the walking program using information technology.

**ACNOWLEDGEMENT:** The present study was Supported by a Grant-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (16300197).

**Effects Of E-mail Based Walking Program On Weekly Walking Time And Behavior**

Yoshio Nakamura, Kanako Yamawaki, Koichiro Oka. *Waseda University, Tokorozawa, Japan.* (Sponsor: Mitsuru Higuchi, FACSM)

Email: nakamura@waseda.jp

(No relationships reported)

**PURPOSE:** The effectiveness of physical activity intervention mediated information technology has been highlighted. The purpose of the present study was to examine whether walking program with the e-mail function of cellular phone promotes walking behavior among Japanese people in 30-49 years.

**METHODS:** The participants were registrants in an internet monitor system, who concerned about a walking program for their health. One thousand one hundred eleven (male: N=554, female: N=557, 30-49 years) participants joined in this study as an intervention group. On the other hand, 1190 subjects (male: N=598, female: N=592, 30-49 years) were served as an age- and gender-matched control group. The participants in the intervention group were encouraged to execute a walking behavior with e-mails using their cellular phones twice a week for one month (8 times in total). The contents of the e-mail were depended on the level of participants' walking behavior investigated before this intervention. The primary outcome was time (in minute) of walking per week. The stage of changes in the walking behavior was measured as the secondary outcome.

**RESULTS:** ANCOVA adjusting baseline walking time and demographic variables showed an improvement in the walking time for the intervention group in comparison with that of control group after the intervention [Mean inter-group difference in change: 70.1 min/week, (P<0.05)]. Percentage of improved the stage of changes in the walking behavior was higher in intervention group (38.5%) than that of control group (22.3%) ( $\chi^2 = 61.19$ , P<0.05).

**CONCLUSIONS:** These results indicate that the walking program with the e-mail function of cellular phone promotes for the walking behavior in selected subjects for one month. Further research examining long term effect on walking behavior after the program would be needed.

**ACNOWLEDGEMENT:** The present study was Supported by a Grant-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (16300197).

**3076 Board #223 May 30 8:00 AM - 9:30 AM**  
**Effectiveness Of A Tailored Wellness Program On Biometricirics**

Kaileigh A. Russo<sup>1</sup>, Steven M. Schwartz<sup>2</sup>, Richard B. Parr, FACSM<sup>1</sup>, Roop C. Jayaraman<sup>1</sup>. <sup>1</sup>Central Michigan University, Mt. Pleasant, MI. <sup>2</sup>Health Media Inc., Ann Arbor, MI.

(No relationships reported)

The rising cost of healthcare has driven employers to invest in effective health education and communication strategies to reduce morbidity associated with behavioral and biometric risk factors. There is growing evidence for the use of computer-tailored, online behavioral health interventions.

**PURPOSE:** To determine whether a computer-tailored, online wellness program had an effect on body mass index (BMI), cholesterol, blood pressure, blood glucose, and waist circumference.

**METHODS:** We recruited subjects from a large mid-western college campus to participate in the computer-tailored wellness program. Information collected based on epidemiological need, stage of change, motivation, self-confidence, barriers and demographics, the automated system recruits participants into follow-up behavior change interventions. Self-reported baseline and follow-up biometric data (total cholesterol, high density lipoprotein (HDL), systolic (SBP) and diastolic blood pressure (DBP), fasting glucose, height, weight and waist circumference) either CHI squared ( $\chi^2$ ) for categorical variables or *t* tests for continuous variables.

**RESULTS:** Of the 432 employees enrolled, 23.8% (n = 129) completed the one-year follow up health risk assessment. The participants in this study were predominately women (78%), middle-aged, white/non-Hispanic and college graduates. At one year follow up, proportionally more men reported a HDL ≥ 40 mmol/L (+12%), waist circumference ≤ 40 in (+10%), and fasting blood glucose ≤ 100 mg/dL (+23%). Favorable trends were not noted for women at year-end. Although, hypertension was the second most common self-reported chronic condition, only 5% reported DBP >90mmHg and SBP >140mmHg. Body mass index (BMI) data showed proportionally fewer men in extremely obese (-5.6%), and overweight categories (-5.5%) and more men in the obese category (+5.6%). Women showed little proportional change in the BMI risk category expect for the significant increase in the extremely obese category (4.6%, p<0.05).

**CONCLUSION:** Participation in the computer-tailored wellness program resulted in a moderate positive shift towards healthier biometric data in men but not in women participants. The low program retention contributed to the suboptimal program performance on risk modification.

This study was designed to test the efficacy of an internet-based physical activity intervention program (IPAIP) that consisted of website components and e-mail tip sheets. The IPAIP was based on behavioral theory, and emphasized physical activity information. Some reports indicate that an internet-based physical activity intervention increases physical activity. Some intervention programs are composed of website components and e-mail tip sheets similar to this study; however, it has been unclear whether components of the program had much effect on attitudes toward physical activity.

**PURPOSE:** To examine changes in physical activity, and to evaluate the contribution of the components to the attitudes toward physical activity.

**METHODS:** A total of 81 college students (52 intervention: group I and 29 control: group C) in Japan completed a 14-week randomized controlled trial during the first semester. All participants answered the International Physical Activity Questionnaire (IPAQ). Group I responded to a questionnaire which was designed to measure the effects of the components and e-mail tip sheets, and the attitudes (interest, belief, and intention) toward physical activity.

**RESULTS:** Group I exhibited a significant increase (+270 kcal/day) in total physical activity compared with group C (+13 kcal/day). Group I exhibited a significant decrease (-77.1 min/day) in the average time spent sitting on weekdays compared with group C (+55.9 min/day). Factor analysis confirmed the existence of four factors underlying the questions to measure the effects of the components and e-mail tip sheets: choose and schedule for strength and stretching (factor 1), goal setting and schedule for physical activity (factor 2), learn about physical activity, strength and stretching (factor 3), and energy expenditure (factor 4). In a pass analysis, factor 1 (b = 0.33) and factor 3 (b = 0.33), factor 1 (b = 0.40) and factor 4

( $b = 0.36$ ), factor 2 ( $b = 0.58$ ) had significant direct effects on the interest ( $R^2 = 0.36$ ), the belief ( $R^2 = 0.42$ ), the intention ( $R^2 = 0.34$ ) respectively.

**CONCLUSION:** The IPAIP increased total physical activity and decreased minutes sitting on weekdays. It also seemed to have positive effects on attitudes toward physical activity. Factor analysis revealed that a part of IPAIP had direct effects on the interest and belief.
