#### Sports Medicine Australia Young Investigator Award - The Acute Effect Of Prolonged Intense Cycling And Blackcurrant Extract On Protein Carbonyls In Well-trained Male Cyclists

Simon B. Dannapfel<sup>1</sup>, Tim E. Lowe<sup>2</sup>, Robina A. Cummins<sup>1</sup>. <sup>1</sup>Waikato Institute of Technology, Hamilton, New Zealand. <sup>2</sup>HortResearch, Hamilton, New Zealand.

Email: sdannapfel@yahoo.co.nz

(No relationships reported)

Prolonged intense endurance exercise can induce oxidative stress in athletes when their endogenous antioxidant network is overwhelmed by free radicals and reactive species. Antioxidant supplementation may therefore be of benefit for athletes under those conditions.

**PURPOSE:** To measure acute changes in plasma protein carbonyl concentration, a marker of oxidative stress, in response to prolonged intense cycling with or without a pre-ride dose of blackcurrant extract.

**METHODS:** A randomised, double-blind placebo-controlled crossover design was used. Eight well-trained male cyclists performed a 90-min laboratory-based cycling trial at 55% of peak aerobic power output (67% of  $\text{VO}_{2\text{max}}$ ) under extract-supplemented and placebo conditions. The extract dose contained 480mg of anthocyanins (potential antioxidants). Blood samples were collected prior to, 30 min after and 60 min after the trials for analysis of protein carbonyl concentration. These data were log-transformed and standardised for assessment of magnitude of change. Heart rate, blood lactate and perceived exertion were also measured during the trials.

**RESULTS:** There was little change in protein carbonyl concentration 30-min post-trial in either condition. By 60 min there was an increase of  $13\% \pm 12\%$  (mean  $\pm$  SD) with the placebo but a reduction of  $6\% \pm 14\%$  with the extract, a moderate difference between conditions of 17% (90% confidence limits 8% to 25%). Differences in heart rate, blood lactate and perceived exertion between trials were inconclusive.

**CONCLUSION:** A single dose of blackcurrant extract estimated to contain a quantity of anthocyanins equivalent to 140g of New Zealand blackcurrants may provide a useful acute nutritional intervention for well-trained athletes prior to intense endurance training or competition.

#### Antioxidant Vitamin - Mineral Supplement Effects On Antioxidant And Oxidative Status With Strenuous Exercise

Valerie Duran, Masha Fox-Rabinovich, Lisa S. McNulty, Steven R. McNulty, David C. Nieman, FACSM, Dru A. Henson, Fuxia Jin, Michael Landramm. *Appalachian State University, Boone, NC.*

Email: duranva@appstate.edu

(No relationships reported)

**INTRODUCTION:** Oxidative stress derives from metabolic processes and can cause damage to DNA, lipids, and proteins. Supplementation with antioxidant vitamins A, C, and E, and the mineral selenium, has been suggested to counteract oxidative stress; however, the existing literature has not produced definitive outcomes.

**PURPOSE:** This project investigated the effects of daily supplementation with a vitamin-mineral complex, emphasizing vitamins C (2000 mg), E (800 IU), A (3000 IU) and selenium (200 ug), respectively for 6-wks on the antioxidant and oxidative damage markers of athletes prior to and after strenuous exercise.

**METHODS:** Twenty-four trained cyclists were randomized into vitamin-mineral (VM) (n=12) or placebo (P) (n=12) groups. Blood samples were collected at baseline, immediately pre- and post-exercise, and 12-h post-exercise and examined for indicators of antioxidant status (Oxygen Radical Antioxidant Capacity (ORAC) and Ferric Reducing Antioxidant Potential (FRAP)) and oxidative damage (F2-isoprostanes). The study design allowed examination of supplementation effects during chronic, exercise, and exercise recovery phases. A 2 (treatment) x 4 (times) repeated measures ANOVA was performed and statistical significance was set at  $P < 0.05$ . Values are mean $\pm$ SE.

**RESULTS:** F2-isoprostanes (pg/mL) were not significantly affected during any phase of supplementation and increased 28% from pre-exercise (22.5 $\pm$ 2.1) to post-exercise (28.9 $\pm$ 4.0) in P and 10% from pre-exercise (21.0 $\pm$ 1.8) to post-exercise (23.3 $\pm$ 1.9) in VM. ORAC (ng/mL trolox equivalents) declined significantly in both groups ( $P < 0.001$ ) with a 31% decline from pre-exercise (19.6 $\pm$ 5.5) to post-exercise (13.5 $\pm$ 4.8) in P and 22% from pre-exercise (21.2 $\pm$ 3.4) to post-exercise (16.6 $\pm$ 3.9) in VM but, was not significantly different during any phase of supplementation. FRAP ( $\mu\text{M/L}$  ascorbate equivalents) increased 9% from pre-exercise (401.7 $\pm$ 104.5) to post-exercise (440.2 $\pm$ 85.7) in P versus 19% from pre-exercise (410.4 $\pm$ 110.8) to post-exercise (488.7 $\pm$ 109.1) in VM with a strong trend for a time effect ( $P = 0.063$ ). However, supplementation was not effective during any phase.

**CONCLUSION:** These results do not support use of an antioxidant vitamin-mineral supplement to augment antioxidant status or suppress exercise-induced oxidative damage.

### 1401 Board #3 May 27 9:30 AM - 11:00 AM

#### Moderate Volume And Intensity Aerobic Exercise Training Does Not Attenuate Postprandial Oxidative Stress In Pre-diabetics

Patrick S. Tucker<sup>1</sup>, Kelsey H. Fisher-Wellman<sup>2</sup>, Heather K. Bell<sup>2</sup>, Brian K. Schilling<sup>2</sup>, Richard J. Bloomer<sup>2</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of Memphis, Memphis, TN. (Sponsor: Larry Weiss, FACSM, FACSM)

(No relationships reported)

**PURPOSE:** Exercise training improves glucose and lipid metabolism and increases antioxidant defense. These adaptations may serve to minimize the oxidative stress which typically occurs post feeding, in particular for those with metabolic dysfunction. The purpose of this study was to determine the effects of aerobic exercise training on postprandial oxidative stress in a sample of pre-diabetic subjects.

**METHODS:** Twenty previously sedentary, pre-diabetic subjects were randomly assigned to an eight week aerobic exercise training intervention (3 sessions/week; 30-45 minutes/session; n=10; age: 36 $\pm$ 3yrs; fasting blood glucose: 106 $\pm$ 4mg $\cdot\text{dL}^{-1}$ ; BMI: 34 $\pm$ 2 kg $\cdot\text{m}^{-2}$ ) or a no exercise control group (n=10; age: 31 $\pm$ 2yrs; fasting blood glucose: 101 $\pm$ 4mg $\cdot\text{dL}^{-1}$ ; BMI: 33 $\pm$ 2 kg $\cdot\text{m}^{-2}$ ). Before and within two days following the intervention, subjects consumed a lipid/carbohydrate rich test meal. Blood samples were collected pre meal (fasted), and at 1, 2, 4, and 6 hours post meal and assayed for xanthine oxidase activity (XO), hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), malondialdehyde (MDA), triglycerides (TAG), and glucose. Area under the curve (AUC) was calculated for each variable, both pre and post intervention.

**RESULTS:** Exercise training had no effect on decreasing the AUC for any variable ( $p > 0.05$ ). All variables increased post feeding, with a peak response noted at 4-6 hours post meal.

**CONCLUSION:** Aerobic exercise training performed at the frequency, duration and intensity in the present study has no effect on postprandial oxidative stress or TAG within a sample of pre-diabetic subjects.

---

**1402 Board #4 May 27 9:30 AM - 11:00 AM****Cytokine Alteration Following Antioxidant Supplementation And Anterior Cruciate Ligament Surgery**

Tyler Barker<sup>1</sup>, Scott W. Leondard<sup>2</sup>, Thomas B. Martins<sup>3</sup>, Roy H. Trawick<sup>4</sup>, Harry R. Hill<sup>5</sup>, Carl R. Kjeldsberg<sup>5</sup>, Maret G. Traber<sup>2</sup>. <sup>1</sup>The Orthopedic Specialty Hospital & Oregon State University, Murray, UT. <sup>2</sup>Oregon State University, Corvallis, OR. <sup>3</sup>ARUP, Salt Lake City, UT. <sup>4</sup>The Orthopedic Specialty Hospital & Clinic, Murray, UT. <sup>5</sup>ARUP & University of Utah, Salt Lake City, UT.  
(No relationships reported)

Vitamins E and C display immuno-modulatory properties. Cellular and humoral mediated immune responses are associated with T helper 1 (Th1) and Th2-type cytokines, respectively. Balance disruptions to the interleukin (IL)-6:IL-10 and Th1:Th2-type cytokine ratios indicate a shift in pro-/anti-inflammatory and pattern of adaptive immunity cytokine dominance, respectively. Furthermore, disruptions to the IL-6:IL-10 ratio may provide prognostic potential following severe trauma or surgery. Interleukin (IL)-10 is an anti-inflammatory cytokine that suppresses pro-inflammatory (i.e., TNF- $\alpha$ , IL-1, IL-6, etc.) and Th1-type (i.e., IL-2, IL-12, IFN- $\gamma$ ) cytokines. IL-10 increases during the reperfusion following anterior cruciate ligament (ACL) surgery, which we found is ameliorated with vitamin E and C supplementation.

**PURPOSE:** To identify the influence of vitamins E and C on the IL-6:IL-10 ratio, and Th1- (IFN- $\gamma$ , IL-2, IL-12) - Th2- (IL-4, IL-5, IL-10) type cytokine ratios following ACL surgery.

**METHODS:** A randomized, double-blind, placebo-controlled study was carried out in men undergoing ACL reconstructive surgery, who were randomly assigned to twice daily supplementation with either: 1) antioxidant (AO; 300 mg RRR- $\alpha$ -tocopheryl acetate (400 IU) and 500 mg ascorbic acid (AA),  $n = 13$ ), or 2) matching placebos (PL;  $n = 12$ ). Experimental treatment began ~2-wks prior and continued through 7-d post-surgery. Subjects provided fasting blood draws: 1) Baseline (Bsl, ~2 wk prior to surgery), 2) pre-surgery (Pre, ~90-min pre-surgery), 3) 90-min, 4) 72-h and 5) 7-d post-surgery. Plasma  $\alpha$ - and  $\gamma$ -tocopherols ( $\alpha$ - and  $\gamma$ -T), AA, cytokines, and serum high-sensitivity C-reactive protein (hsCRP) were measured.

**RESULTS:** Following AO supplementation, circulating  $\alpha$ -T and AA increased, while  $\gamma$ -T decreased ( $P < 0.05$ ; treatment X time interaction). Both IL-6 and hsCRP were elevated at 72-h and 7-d ( $P < 0.05$ ). Interestingly, depressions in the IL-6:IL-10, IFN- $\gamma$ :IL-10 and IL-2:IL-10 ratios following ACL surgery were ameliorated with AO supplementation ( $P < 0.05$ ; treatment X time interaction).

**CONCLUSION:** Moderate supplementation levels of vitamin E and C minimize the depression in the IL-6:IL-10, IFN- $\gamma$ :IL-10 and IL-2:IL-10 ratios post-ACL surgery.

---

**1403 Board #5 May 27 9:30 AM - 11:00 AM****Oxidative-Stress, Muscle Forces/Soreness Responses To Eccentric Exercise: Fruit/Vegetable Concentrate Compared To Placebo.**

Allan H. Goldfarb, FACSM, Ryan S. Garten, Changmo Cho, Philip D.M. Chee, Lauren A. Chambers. Univ., of North Carolina, Greensboro, NC.  
(A.H. Goldfarb, Awarded contracted research from NSA, Contracted Research.)

**PURPOSE:** This study was designed to test the efficacy of a fruit/vegetable concentrate (FVC) supplement on oxidative stress, muscle force/work, and muscle soreness (MS) to an acute bout of eccentric exercise (EE) compared to a placebo.

**METHODS:** Forty (18-35 yrs) healthy volunteers were randomly assigned to either a (FVC) or placebo (P) double blind treatment. The subjects took capsules for 28 days (24 days prior to the EE and for the next four days) with compliance = 97.5% FVC; 98.5% P. Subjects arrived in the morning, a resting blood sample was obtained and maximal isometric forces (MIF), and MS (on both arms) were determined prior to the EE (4 sets of 12 repetitions of elbow flexion with their non-dominant arm [ND]). Blood, MIF, and MS were also obtained immediately after EE, 2, 6, 24, 48, and 72 hrs post-exercise. Protein carbonyls (PC), lipid hydroperoxides (LH), and creatine kinase (CK) were determined from plasma.

**RESULTS:** Total work for the EE was similar for the P = 1636.2  $\pm$  172.9 J and FVC = 1784.4  $\pm$  174.4 J. The % decline in work was similar across treatments {1<sup>st</sup> set to 4<sup>th</sup> set for the EE = 35.3  $\pm$  4.2 % (P) and 31.7  $\pm$  3.7 % (FVC)}. MIF decreased immediately post EE for the ND {35.9%  $\pm$  4.0 (P) vs. 31.1%  $\pm$  3.2 (FVC)} reaching its nadir at 2h hrs post EE. CK increased over time and peaked at 72 hrs after EE (292.0  $\pm$  64.6 IU (P); 240.8  $\pm$  66.9 IU (FVC) with no difference across treatments. LH did not demonstrate any changes across time or treatment. PC increased over time ( $p < 0.001$ ) with no time x treatment effect. PC were similar across treatment prior to and immediately post EE. PC increased 2hr post EE in the P group and increased over time with a peak at 48 hrs post EE (0.52 nmol/mg protein<sup>-1</sup>). PC were significantly lower in the FVC treatment compared to P ( $p < 0.034$ ) from 2hr post time through 72 hr post EE.

**CONCLUSIONS:** The data indicates that four weeks of pre-supplementation and continued treatment after EE with a fruit/vegetable concentrate had no apparent effect on the muscle forces and MS but attenuated blood oxidative stress compared to placebo treatment as indicated by protein carbonyls.

Supported by a grant from NSA.

(No relationships reported)

**PURPOSE:** Routine haematological and biochemical monitoring of an Olympic Sailing Squad was undertaken over a 12 month period leading up to the Olympic Games. An aspect of this, plasma total antioxidant capacity (TAC), was considered in more depth for the present study. TAC scores are known to increase during and post-exercise but little is known about changes over the course of a competitive season, particularly in elite athletes.

**METHODS:** The athletes comprised the entire 2008 Great Britain Olympic Sailing Team, as well as the men's 470 2008 World and European Champions who were not selected for the Olympics. Individual blood samples were collected from the sailors (13 Males, 7 females, age 29  $\pm$  3 yrs, weight 70.4  $\pm$  11 kg) on a minimum of three and a maximum of seven occasions as part of routine haematological and biochemical profiling. The frequency of sampling was determined by sailor availability in the U.K. Sailors were sub-divided into illness prone (IP) and non-illness prone (NIP) groups based on the categorisation used by Cox et al (2007). Blood sampling was undertaken with samples drawn between 8-10 am, fasted and 36-48 hours post training. Haematological and biochemical analysis was performed on venous blood samples collected into K3 EDTA tubes and analysed at a clinical laboratory. Plasma total antioxidant capacity (TAC) was determined using a chemiluminescent assay (ABEL<sup>®</sup>, Knight Scientific Ltd, UK). This measured the capacity of EDTA plasma to scavenge the peroxynitrate radical derived from the reaction between superoxide and nitric oxide radical (Nourooz-Zadeh et al 2006). Data are expressed as vitamin E analogue equivalents (umol/L) and presented as mean (SD).

**RESULTS:** Over 12 months a total of 20 sailors were sampled, with 18 from the Olympic Squad. A total of 110 blood samples were drawn. The TAC score for the whole squad was 396 (58), with TAC scores of 364 umol/L (48) and 413 (57) umol/L for the IP and NIP groups respectively. The largest intra-individual athlete variation in TAC score across 12 months was 53 umol/L, and the smallest 11 umol/L, with the range of TAC scores across the squad being from 259-544 (umol/L).

**CONCLUSIONS:** The sailors' TAC scores varied considerably over 12 months, with greater inter than intra variation. The IP sailors showed a trend towards lower mean TAC scores than the NIP group.

**1405 Board #7 May 27 9:30 AM - 11:00 AM**

## Effect On Anti-oxidative Capacity Of California Almond Supplementation In Elite Chinese Cycling

Jinde Fu, *National Institute of Sports Medicine, China, Beijing, China.*

Email: jindef@163.com

(No relationships reported)

**PURPOSE:** The aim of this study was to examine the effect of California almond supplementation on Anti-oxidative capacity of elite Chinese Cycling athletes.

**METHODS:** Using a crossover balance design, 12 Elite Chinese Cycling athletes (age: 22.0±0.6 years; height: 180.1±1.9 cm; weight: 73.7±2.1 kg; VO2max: 69.0±0.9 ml/min/kg BW) were randomly divided into 2 groups. While almonds group was given 75g almond per day for 4 weeks, control group was fed with cookies which energy is equivalent to the almond daily consumed. After 2-week washout, the two groups were crossed and fed with cookies and almonds, respectively for another 4 weeks. The almonds were provided by the Almond Board of California, USA. During the study, all athletes were trained at the same road/facility and dined in the same canteen and they drank a measured amount of sport beverage containing no vitamin E. Performance tests were done before and after the 4-week feeding treatment. Venous blood samples were drawn in the morning of performance test after overnight fast and immediately post-performance and next morning before and after the 4-week feeding treatment to evaluate plasma TAOC, GPx, SOD, XOD, serum MDA, NO, Vit E etc.

**RESULTS:** After 4-week almond supplementation, the TAOC level of Almond Group became significantly higher than that of Cookie Group (15.81±0.80 vs 12.86±1.11, p<0.05). The SOD activity has no significant difference in both Groups (p>0.05), but the SOD level of Almond Group in next morning of performance tests were significantly higher than that of before treatment (62.2±1.3 vs 57.8±0.6, p<0.05) and that of Cookie Group (62.2±1.3 vs 59.8±1.8, p<0.05). Vit E level at each time point in Almond Group was slightly higher than that of Cookie Group, but no statistically significant difference. No significant difference was observed in plasma GPx, XOD serum MDA.

**CONCLUSIONS:** The supplementation of almond in Elite Chinese Cycling athletes elevated TAOC level, SOD activity and vitamin E level. It suggested that almond supplementation could improve the antioxidant capacity of endurance athletes.

Supported by The Almond Board of California (ABC)

### Effect Of Acute Exercise On Lipid Peroxidation And Antioxidant Enzyme Status In Lean And Obese Zucker Rats

Chia-Chen Yang, Hsien-Tang Lin, Tsai-Wei Shen, Tsung-Hsien Lu, Ming-Fen Hsu, Chien-Wen Hou, Mallikarjuna K, Chia-Hua Kuo. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L Ivy, FACSM)

Email: jazellayang@hotmail.com

(No relationships reported)

**PURPOSE:** Exercise performance and its beneficial effects depend on the intensity and duration of exercise and also on the body weight. In this study we made an attempt to examine the effect of acute exercise treatment on antioxidant enzymes status and lipid peroxidation levels in lean and obese Zucker rats.

**METHODS:** Both lean (200±10gms) and obese (450±15gms) rats were divided as control and acute exercise (90min, swimming) groups.

**RESULTS:** In the results, we observed a significant (p<0.05) drop in hepatic superoxide dismutase (SOD) activity and glutathione (GSH) levels with acute exercise in both lean and obese rats. Interestingly, catalase (CAT) activity was significantly increased with acute exercise in obese rats. This is may be the compensatory response to cope with the high amount of free radical toxicity in obese rats. The sister antioxidant enzymes, glutathione peroxidase (GSH-Px) and glutathione reductase (GR) were not significantly altered with acute exercise. All antioxidant enzyme activities are higher in lean control group compare to that of obese control group. However, hepatic MDA levels was significantly elevated with acute exercise treatment in both groups and this elevation was more pronounced in obese than that of lean group.

**CONCLUSIONS:** The lower antioxidant enzyme status and higher MDA values in obese rats suggests that obese rats are more vulnerable to expose oxidative stress. From these findings it is appeared that obese zucker rats have high risk from oxidants and acute exercise has been shown to increase oxidative stress.

1407 Board #9 May 27 9:30 AM - 11:00 AM

### Plasma Antioxidant Capacity And Protein Modification In Adolescent Competitive Athletes

Anja Carlsohn<sup>1</sup>, Sascha Rohn<sup>2</sup>, Frank Mayer<sup>1</sup>, Florian J. Schweigert<sup>3</sup>. <sup>1</sup>University of Potsdam, Potsdam, Germany. <sup>2</sup>Technical University Berlin, Berlin, Germany. <sup>3</sup>University of Potsdam, Potsdam-Nuthetal, Germany.

Email: carlsohn@uni-potsdam.de

(No relationships reported)

**INTRODUCTION:** Exercise is known to increase production of reactive oxygen species, which might impair cell integrity and contractile function of muscle cells. Additionally, it is evident that the endogenous antioxidant defense system is elevated in adult athletes. Studies analyzing the effect of regular exercise on the antioxidant status in adolescent athletes are lacking.

**PURPOSE:** To evaluate the impact of age, gender and exercise on the plasma antioxidant capacity and protein modifications in adolescent athletes.

**METHODS:** Plasma antioxidant capacity was measured in male (MA, n=35, 16±2yrs) and female athletes (FA, n=56, 16.5±1.9yrs) and male (MSC, n=9, 16.5±2.2yr) and female (FSC, n=11, 16.2±2.2yr) sedentary controls (total N= 111, 12-20yrs) using the TEAC-Assay. Protein modifications were assessed by MALDI-tof-MS employing the TTR microheterogeneity model. Exercise related energy expenditure (EEtrain) was calculated based on a 7d-activity protocol. In addition, plasma antioxidants were measured in fasting blood samples. Data were analyzed by two-way ANOVA (α=0.05).

**RESULTS:** Though plasma levels of nutritional antioxidants did not differ between the groups, plasma antioxidant capacity was higher in athletes (MA 1.47±0.2 mmol TE/L; FA 1.45±0.2 mmol TE/L) compared to controls (MSC 1.17±0.04 mmol TE/L; FSC 1.14±0.04 mmol TE/L) and rises with both age (P<0.05) and EEtrain (P<0.05). No differences in TTR microheterogeneity between athletes (MA 0.87±0.3 n/cysTTR; FA 0.73±0.1 n/cysTTR) and controls (MSC 1.39 ±0.2 n/cysTTR; FSC 1.11 ±0.2 n/cysTTR) could be observed considering age (P=0.44), gender (P=0.24) and EEtrain (P=0.55).

**CONCLUSION:** Results of the study suggest that both age and exercise increase plasma antioxidant capacity in young athletes. In addition, exercise does not promote protein modification. Thus, in young athletes beneficial effects of exercise training on antioxidant status rather than oxidative stress may be anticipated.

### Effects Of Oxidative Stress On Glutathione Levels In Patients With Parkinson's Disease

William G. Werner<sup>1</sup>, Joanne DiFrancisco-Donoghue<sup>1</sup>, Ahmed Elokda<sup>2</sup>, Nancy Bono<sup>3</sup>, Eric M. Lamberg<sup>4</sup>. <sup>1</sup>New York Institute of Technology/ NYCOM, Old Westbury, NY. <sup>2</sup>New York Institute of Technology, Old Westbury, NY. <sup>3</sup>NYCOM, Old Westbury, NY. <sup>4</sup>State University at Stony Brook, Stony Brook, NY.

Email: wwerner@nyit.edu

J. DiFrancisco-Donoghue Presenting

(No relationships reported)

Resting glutathione (GSH) levels are lower in people with Parkinson's disease (PD) than any other neurological condition. Levels of GSH are important markers of oxidative stress and protect the body against reactive oxygen species. Oxidative stress causes free radical damage in the body that might result in cell damage and death. Medications used

to treat PD have been shown to further increase oxidative stress. Maximal exercise stress testing has been shown to be an effective tool to determine a healthy individual's ability to handle oxidative stress and measure GSH response.

**PURPOSE:** To understand the response of GSH system as a criterion measure of oxidative stress in people with PD during acute exercise stress both on and off medication.

**METHODS:** Fourteen men with PD and 15 Healthy Controls (HC) underwent a maximal treadmill exercise stress test. Subjects with PD performed the test once off PD medication (PD-Off) for 12 hours and one week later on medication (PD-On). Venous blood was collected at rest and post exercise. The criterion for peak exercise was: 1) attained 90% of target heart rate (HR); 2) RPE 9; 3) unable to maintain pace; 4) RER over 1.3. Outcome measures included HR, V02, GSH, GSSG, GSH: GSSG ratio.

**RESULTS:** At both rest and peak exercise GSH levels were lower in the PD-On group than the PD-Off Group (rest  $p=.0299$ ; peak  $p=.0002$ ), and both groups were lower than HC ( $p<.0001$  for all). GSH decreased more in the PD-On and PD-Off groups compared to the HC (PD-On  $p=.0013$ ; PD-Off  $p=.0321$ ). There was no difference in the GSH change between the PD-On and PD-Off groups. GSSG levels were higher in the PD-On group than PD-Off group, and the PD-Off group was higher than HC. This held true at rest and peak exercise ( $p<.0001$  for all). All groups increased a comparable amount with exercise. As compared to HC, the ratio of GSH:GSSG was less in the PD-On group and the PD-Off group was less than the PD-On group, in both rest and peak exercise ( $p<.0001$  for all except PD-On vs. PD-Off  $p=.0002$ ). With exercise, this ratio decreased the same amount in all groups.

**CONCLUSIONS:** People with PD have higher oxidative stress levels than healthy controls at rest and have a lower tolerance to acute exercise stress. PD medication increases this oxidative stress. Maximal exercise testing is an accurate tool to indicate how subjects with PD respond to oxidative stress.

#### **Systemic Vascular Resistance And Total Vascular Impedance In Multiple Sclerosis**

Christine Frederiksen<sup>1</sup>, Cecilie Fjeldstad, PhD<sup>2</sup>, Anette Fjeldstad, PhD<sup>3</sup>, Michael Bembem, PhD, FACSM<sup>1</sup>, Gabriel Pardo, MD<sup>2</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>Mercy NeuroScience Institute, Oklahoma City, OK. <sup>3</sup>University of Utah, Salt Lake City, UT.

Email: chris\_310r@hotmail.com

(No relationships reported)

**BACKGROUND:** Multiple sclerosis (MS) is a chronic inflammatory autoimmune disease that affects the central nervous system (CNS). It has been reported that autoimmune diseases such as rheumatoid arthritis and systemic lupus erythematosus have reduced arterial compliance and increased resistance to blood flow.

**PURPOSE:** The primary purpose of this study was to examine systemic vascular resistance (SVR) and total vascular impedance (TVI) in patients with Relapse-Remitting MS (RRMS) compared to healthy age-matched controls.

**METHODS:** Fifty-eight men and women between the ages of 18-64 years were separated into 8 different groups; young ( $\leq 40$  years old) control men ( $n=13$ ), old ( $\geq 41$  years old) control men ( $n=8$ ), young men RRMS ( $n=5$ ), old men RRMS ( $n=2$ ), young control women ( $n=14$ ), old control women ( $n=8$ ), young women RRMS ( $n=4$ ), old women RRMS ( $n=11$ ) who volunteered for this study. Total vascular impedance and systemic vascular resistance were measured by using the Pulse Contour Analysis (PCA), which analyzes blood pressure waveforms. A 2-way ANOVA (gender x group) was used to explore differences in the outcome variables with  $p \leq 0.05$  set for statistical significance.

**RESULTS:** A 2-way ANOVA showed there was no significant gender effect, however there was a significant group effect ( $p=0.048$ ). The young controls had a significantly lower TVI than the young and old MS. Where, the young controls showed a significantly lower SVR than the old controls and the old MS.

**CONCLUSION:** TVI and RSV are significantly compromised in individuals with MS, compared to age-matched controls, thus, indicating there is a systemic effect of an inflammatory process with in the CNS.

#### **Evidence For Impaired Exercising Forearm And Leg Muscle Blood Flow At Higher Exercise Intensity In Copd**

Mikhail Kellawan, Katherine Webb, Denis O'Donnell, Michael E. Tschakovsky. *Queen's University, Kingston, ON, Canada.*

Email: 7jmk2@queensu.ca

(No relationships reported)

Chronic Obstructive Pulmonary Disease (COPD) is characterized by extreme exercise intolerance. Patients often report leg discomfort as the reason for stopping, both during a progressive exercise test and during continuous exercise. Given the impact of compromised oxygen delivery on exercise performance it is possible that exercise intolerance is in part due to reduced exercising muscle oxygen delivery.

**PURPOSE:** To test the hypothesis that exercising muscle oxygen delivery in both small (forearm handgrip) and large (leg kicking) muscle mass exercise is compromised in COPD.

**METHODS:** 12 COPD ( $59.4 \pm 2.7$  yrs, forced expiratory volume in 1 s (FEV1)  $42.6 \pm 4.0\%$  predicted) and 12 age and activity matched control subjects ( $60.5 \pm 2.8$  yrs) participated in four exercise protocols on separate occasions: progressive increases in forearm handgrip and knee extension/flexion exercise to exhaustion, and step increases in forearm handgrip and knee extension/flexion to 50% peak work rate. Beat by beat Doppler and Echo ultrasound measures of forearm blood flow (FBF; brachial artery) and leg blood flow (LBF; femoral artery) and mean arterial blood pressure (MAP; arterial tonometry, Colin 5000), arterial oxygen saturation were made. Venous blood samples provided measures of Hb content (StatProfile M Blood Gas Analyzer, Nova Biomedical) **RESULTS:** data are mean  $\pm$  SE. Peak forearm exercise intensity (weight lifted in lbs) for COPD was 83% of control ( $33.7 \pm 2.7$  vs.  $40.7 \pm 3.0$ ). Forearm oxygen delivery (FOD; ml O<sub>2</sub>/min) was similar between COPD and Control until exercise intensity reached 25 lbs (COPD vs. Control FOD  $76 \pm 5$  vs.  $96 \pm 9$ ,  $P=0.058$ ). However, there were no differences in any parameters quantifying blood flow kinetics with step increase to 50% peak (all  $P>0.60$ ). Responses for leg exercise mirrored those for the forearm.

**CONCLUSIONS:** Oxygen delivery to exercising muscle in COPD may be compromised at higher exercise intensities in both small and large muscle mass exercise. However, the speed with which oxygen delivery adjusts at exercise onset is not.

#### **Venoarteriolar Response Is Unaltered By Beta-adrenergic Blocker Or Exercise Training In Postural Orthostatic Tachycardia Syndrome**

Tiffany B. VanGundy<sup>1</sup>, Shigeki Shibata<sup>1</sup>, M Dean Palmer<sup>1</sup>, Daniel L. Creson<sup>1</sup>, Melyn Galbreath<sup>1</sup>, Benjamin D. Levine, FACSM<sup>2</sup>, Qi Fu<sup>2</sup>. <sup>1</sup>The Institute for Exercise and Environmental Medicine, Dallas, TX. <sup>2</sup>The University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Email: TiffanyVanGundy@TexasHealth.org

(No relationships reported)

Postural Orthostatic Tachycardia Syndrome (POTS) is characterized by excessive tachycardia during orthostasis. We previously found that POTS patients have enhanced

venoarteriolar response (VAR) when compared to healthy sedentary women. Whether a standard pharmacologic treatment for POTS such as beta blockers, or non-pharmacological treatment like exercise training could normalize the VAR in these patients is unknown.

**PURPOSE:** We tested the hypothesis that short-term exercise training would attenuate cutaneous VAR to a greater extent than beta blocker treatment.

**METHODS:** Nineteen patients (18 females, 1 male), age 15-44 years were studied. First, patients were given a random, double-blind assignment to receive either placebo (n=10) or non-selective beta blocker (n=9, propranolol, 80 mg q.d.) treatment for 4 wk, and then patients (n=17) completed a 3-mo exercise training program. Female patients were tested during mid-luteal phases of their menstrual cycles before and after medication treatment, and after exercise training. Skin blood flow (SkBF, laser-Doppler flowmetry), was measured in the calf at heart level (baseline, BL) and during leg dependency of 17-35 cm below the heart for 2 min each while supine.

**RESULTS:** Blood pressure (BP, Portapres) and heart rate (HR, ECG) were monitored continuously. Both HR and BP were not different at BL compared to during leg dependency, except diastolic BP was slightly higher during leg dependency in the pre exercise training group [BL  $62 \pm 11$  (SD) mmHg vs. leg dependency  $63 \pm 12$ ,  $P=0.037$ ]. HR was significantly lower after beta blocker (BL  $86 \pm 16$  bpm vs.  $71 \pm 13$ ,  $P=0.002$ ) and after exercise training ( $81 \pm 14$  bpm vs.  $72 \pm 15$ ,  $P=0.002$ ). Only the group taking beta blocker had significant reductions in systolic and diastolic BP ( $P=0.013$  and  $0.008$ ) after treatment. VAR, determined by the relative decrease in SkBF during leg dependency, was not different after placebo ( $-45 \pm 10\%$  vs.  $-42 \pm 13$ ,  $P=0.571$ ), beta blocker ( $-42 \pm 12\%$  vs.  $-38 \pm 14$ ,  $P=0.471$ ) or exercise training ( $-41 \pm 13\%$  vs.  $-46 \pm 11$ ,  $P=0.314$ ).

**CONCLUSION:** These results suggest that the enhanced VAR observed in POTS patients is not affected by beta blocker or exercise training. However, the pathophysiology for such enhanced VAR and the effective therapy still need to be determined.

Supported by NIH K23 (HL0752 83) and the GCRC grant (RR00633).

(No relationships reported)

Recent evidence indicates the importance of hemodynamic forces on endothelial cell expression, with in vivo shear stress producing beneficial and oscillatory forces producing proatherogenic effects.

**PURPOSE:** (1) To examine the association between vascular conductance, flow velocity patterns, vascular structure/reactivity and physical function; and (2) to determine the possible modifying role of daily physical activity on these associations, in the elderly.

**METHODS:** Participants (n=66; Age:  $83 \pm 11$ , Range: 61 to 98yrs) from the Louisiana Healthy Aging Study (LHAS) were used for these analyses. Carotid artery and brachial dimensions (diameter, arterial mass (CMASS), and brachial artery reactivity (BAR)) were determined using high-resolution ultrasonography. Physical activity status (Total Daily Energy Expenditure (TDEE) and amount of daily physical activity (PAL=TDEE/RMR) were assessed using doubly-labeled water. Physical function (CSPFP-10) was determined from a previously validated instrument used to assess basic and instrumental activities of daily living.

**RESULTS:** Vascular conductance was significantly related to retrograde velocity ( $r=-0.33$ ,  $p=0.008$ ) and the antegrade/retrograde ratio ( $r=0.34$ ,  $p=0.005$ ). The antegrade/retrograde ratio was associated with carotid arterial mass ( $r=-0.27$ ,  $p=0.03$ ), and BAR ( $r=0.24$ ,  $p=0.06$ ). A multivariate prediction model (using vascular conductance, flow velocity measures, and vascular structure/reactivity) accounted for ~25% of the variance in the CSPFP-10 score. TDEE ( $r=0.41$ ,  $p=0.03$ ) and PAL ( $r=0.30$ ,  $p=0.09$ ) were associated with the antegrade/retrograde ratio. Moreover, both TDEE ( $r=0.64$ ,  $p=0.001$ ) and PAL ( $r=0.51$ ,  $p=0.001$ ) were strongly associated with CSPFP-10. A MANOVA revealed those in the higher daily physical activity tertiles had lower CMASS (Low PAL:  $13.91 \pm 1.35$ ; Mod PAL:  $12.76 \pm 2.06$ ; High PAL:  $12.21 \pm 1.96$ ,  $p=0.05$ ), and greater BAFMD (Low PAL:  $2.65 \pm 2.05$ ; Mod PAL:  $3.47 \pm 3.10$ ; High PAL:  $5.36 \pm 2.98$ ,  $p=0.03$ ).

**CONCLUSION:** These data indicate higher vascular resistance is associated with altered flow patterns, and increased carotid arterial mass. These changes contribute to lower physical function. However, higher daily energy expenditures contribute to a positive vascular phenotypic expression and greater physical function.

**Regional Hemodynamics And Calf Venous Compliance During Post-exercise Hypotension In Humans**

Masako Y. Endo, Kazue Shimada, Mizokami Akiko, Masako Yamada, Akira Miura, Yoshiyuki Fukuba, FACSM. Prefectural University of Hiroshima, Hiroshima, Japan. (Sponsor: Yoshiyuki Fukuba, FACSM)

(No relationships reported)

Prolonged dynamic aerobic exercise is associated with a post-exercise reduction in arterial blood pressure. This post-exercise hypotension (PEH) arises from an increase in systemic vascular conductance (TVC), which is thought to be predominantly attributed to increased vascular conductance (VC) within the muscles that were active during the exercise. However, arterial vasodilation does not entirely account for the rise in TVC, and the contribution of distention and vasodilation of the venous system in PEH is not well resolved.

**PURPOSE:** We, therefore, aimed to ascertain the contribution of the VC of the legs, arms, kidneys and viscera to TVC during PEH, as well as blood flow (BF) to the skin and the compliance of the calf vein after exercise.

**METHODS:** Eight subjects performed a single bout of upright cycle ergometry at 60% of resting HR reserve for 60 minutes. Stroke volume was measured by echocardiography, and BF in the right renal, superior mesenteric, right brachial, and right femoral arteries was measured by the pulsed echo-Doppler ultrasonography in supine position before exercise, and twice during recovery (15-30 min and 40-55 min). Heart rate, mean arterial pressure, and skin BF was measured continuously by laser-Doppler flowmetry. VC in each vessel was calculated from BF/MAP. Calf venous compliance was measured by venous congestion plethysmography (Halliwill et al., JAP 87:1555-1563, 1999) before exercise and 40-55 min post exercise.

**RESULTS:** MAP decreased in every subject from ~20 min after exercise cessation. TVC significantly increased (~23 %;  $P<0.05$ ) in the initial post-exercise measurement compared to baseline. This rise resulted from increases in VC in leg (~33 %), arm (~20 %), and kidney and viscera (~2 %). There was no significant change in VC in the skin during this period. Calf venous compliance was unchanged between pre-exercise and recovery ( $P>0.05$ ).

**CONCLUSIONS:** PEH was induced by arterial vasodilation in active and inactive muscles, but not the renal and splanchnic vascular beds. Furthermore, there was no post-exercise increase in venous compliance in the active musculature.

(No relationships reported)

Signals descending from higher brain centers are involved in cardiovascular regulation during exercise. The concept of these descending signals has been incorporated into the widely accepted theory of "central command." However, the extent up to which central command contributes to the regulation of cerebral blood flow responses during exercise remains unknown.

**PURPOSE:** The purpose of the present study was to examine the role of central command in the exercise-induced increase in cerebral blood flow.

**METHODS:** Eleven subjects performed static elbow flexion for 2-min at 30% maximal voluntary contraction (MVC) with the manipulation of central command by vibrations applied to the biceps brachii tendon. The influence of the central command can be decreased without altering the muscle mechanoreflex activation by tendon vibration to assist an exercising muscle in developing a given force. The same subjects also performed static elbow flexion without vibrations (control). We continuously recorded cardiovascular parameters and the mean blood flow velocity of the middle cerebral artery ( $V_{MCA}$ ).  $V_{MCA}$  was measured using an ultrasound system with color-coded representation of blood flow equipped with a 2.0-MHz sector transducer. Cerebrovascular resistance index (CVRI) was calculated by dividing the mean arterial pressure (MAP) by  $V_{MCA}$ . In addition, rating of muscle fatigue sensation (MFS) in exercising muscles was taken after the end of exercise by using 1 - 10 category scale.

**RESULTS:** The MFS at the end of the exercise with vibration was significantly lower as compared to without vibration. The increase in the MAP, heart rate (HR) and  $V_{MCA}$  during exercise with vibration was significantly lower than that during exercise without vibration. However, there was no significant difference in CVRI between with and without vibrations.

**CONCLUSION:** Our results suggested that central command has an indirect effect on the regulation of MCA blood flow resulting from the changes in cerebral perfusion pressure and cardiac output.

Email: KimberlyHubing@texashealth.org

(No relationships reported)

**PURPOSE:** The purpose of this study was to test the hypothesis that local inhibition of nitric oxide and prostaglandin synthesis would attenuate cutaneous vasodilator responses during post-menopausal hot flashes.

**METHODS:** Four microdialysis membranes were inserted into forearm skin (dorsal surface) of 8 post-menopausal women (51±7 yrs). Ringers solution (control), 10mM Ketorolac (Keto), 10mM  $N^G$ -l-arginine methyl ester (L-NAME), and a combination of 10mM Keto + 10mM L-NAME were each infused at the separate sites. Skin blood flow at each site was indexed using laser-Doppler flowmetry. The onset of a flash was defined as an increase of 0.002 mg/cm<sup>2</sup> · minute<sup>-1</sup> per second in sternal sweat rate (capacitance hygrometry). Cutaneous vascular conductance (CVC) was calculated as laser-Doppler flux/mean arterial pressure. CVC is expressed as a percentage of the maximal calculated CVC (CVC<sub>max</sub>) obtained following infusion of 50mM sodium nitropruside at all sites at the end of the study.

**RESULTS:** Data from 13 hot flashes were analyzed. At the control site, the mean peak increase in CVC was 14±5 % CVC<sub>max</sub> units. This value was not different relative to the peak increase in CVC at the Keto site (15±7% CVC<sub>max</sub> units,  $P = 0.77$ ). However, the peak increase in CVC during the flash was attenuated at the L-NAME and L-NAME + Keto sites (7±4 % CVC<sub>max</sub> units and 8±7 % CVC<sub>max</sub> units, respectively,  $P < 0.05$  for both sites) relative to both the control and the Keto sites. There was no difference in sweat rate between any of the sites ( $P = 0.99$ ).

**CONCLUSION:** These data demonstrate that cutaneous vasodilation during a hot flash has a nitric oxide component. Increases in CVC despite the inhibition of prostaglandin synthesis suggest prostaglandins do not contribute to cutaneous vasodilation during a hot flash.

**Superior Mesenteric And Renal Artery Blood Flow During Low And Moderate Intensity Cycling Exercise In Humans**

Masako Yamada<sup>1</sup>, Masako Y. Endo<sup>1</sup>, Nozoe Matsuda<sup>1</sup>, Akira Miura<sup>1</sup>, Shunsaku Koga<sup>2</sup>, Yoshiyuki Fukuba, FACSM<sup>1</sup>. <sup>1</sup>*Prefectural University of Hiroshima, Hiroshima, Japan.* <sup>2</sup>*Kobe Design University, Kobe, Japan.* (Sponsor: Yoshiyuki Fukuba, FACSM)

(No relationships reported)

Sympathetic induced-vasoconstriction is known to induce a reduction in the abdominal (e.g. splanchnic and renal) blood flow (BF) during exercise. The degree of this vasoconstriction is typically suggested to be proportional to exercise intensity. However, increased sympathetic nerve activity is not a simple linear function of intensity, but rather increases only once work rates eliciting a heart rate (HR) response of about 100 bpm are exceeded. As such, the degree to which sympathetic nerve activity contributes to the regulation of abdominal blood flow during low and moderate intensity exercise is not well understood (Am J Physiol 294:H2322-H2326, 2008).

**PURPOSE:** We, therefore, aimed to determine BF in the superior mesenteric artery (SMA) and renal artery (RA) during exercise above and below this 'threshold' of sympathetic nervous activation.

**METHODS:** Twelve subjects performed 4 minutes of cycle ergometer exercise in a semi-supine position followed by 3 minutes rest, at two work intensities: low-intensity exercise (L) at ~90 bpm (n=12) and moderate-intensity exercise (M) at ~130 bpm (n=7). Mean blood velocity (MBV) in the right RA and SMA were measured by pulsed echo-Doppler ultrasonography throughout, and HR and mean arterial pressure (MAP) were measured beat-by-beat using Finapres. Vascular resistance index (RI) in each artery was calculated from MAP/MBV.

**RESULTS:** Steady states were achieved in all measurements by the 4th minute of L and M exercise. MAP was unchanged in L (82±6 vs 85±8 mmHg), and increased in M (82±5 vs 113±9 mmHg;  $P < 0.05$ ) compared to rest. During L exercise MBV was lower (-9.7±9.8 %;  $P < 0.05$ ) in the RA and unchanged in SMA, compared to rest. During M exercise MBV in both RA (-22±11 %) and SMA (-21±13 %) were significantly decreased ( $P < 0.05$ ) compared to rest; responses which were mirrored in RI.

**CONCLUSION:** Even low intensity exercise with a heart rate maintained below 100 bpm caused a significant vasoconstriction in the kidney, but not in upper visceral area, i.e. regulation of abdominal blood flow appears to be regionally dependent.

**Blood Flow In The Inferior Vena Cava At The Onset Of Cycling Exercise In Humans**

Yoshiyuki Fukuba, FACSM<sup>1</sup>, Rie Kogata<sup>1</sup>, Masako Yamada<sup>1</sup>, Akira Miura<sup>1</sup>, Shunsaku Koga<sup>2</sup>, Masako Y. Endo<sup>1</sup>. <sup>1</sup>*Prefectural University of Hiroshima, Hiroshima, Japan.* <sup>2</sup>*Kobe Design University, Kobe, Japan.*

Email: fukuba@pu-hiroshima.ac.jp

(No relationships reported)

At the onset of exercise, the stroke volume (SV) is typically augmented through the Frank-Starling mechanism by increased venous return (V-Return) from blood storage regions such as the lower limbs and viscera. However, the influence of the respiratory pump in effecting this increased V-Return is not well understood.

**PURPOSE:** We, therefore, aimed to measure blood flow (BF) in the inferior vena cava (IVC) at the onset of cycle ergometry, during modulation of respiratory and muscle pumps.

**METHODS:** Seven healthy females (19-32 yrs) sat at rest in a semi-supine position before the onset of 10 seconds of low-intensity cycling exercise (40 W). BF in the IVC (2-3 cm below the renal vein bifurcation) and the portal vein (PV; as an index of BF of the visceral organs) was measured by echo-Doppler ultrasonography for 30 s, across the rest (20 s) - exercise (10 s) transition. HR and blood pressure were measured continuously by Finapres. As a control, subjects breathed spontaneously throughout (C condition). To reduce the influence of respiratory pump, the subjects did a 20 s breath-hold (at end-expiration) from 10 s before exercise onset (non-RP condition). In addition, muscle pumped BF was reduced by inflating a cuff (80 mmHg) on the upper thighs from 10 s before exercise onset (non-MP condition).

**RESULTS:** The time course of BF in the IVC was not different ( $P>0.05$ ) between C and non-RP conditions: an abrupt increase at exercise onset (C; from rest 639 to 2035 at first 2 s after exercise onset, non-RP; 565 to 1848 ml/min,  $P<0.05$ ) followed by a rapid reduction to a constant level (approx. 1500-1600 ml/min during 5-10 s). BF in the PV was also similar between C and non-RP, decreasing rapidly after exercise onset. The exercise-induced increase BF in IVC was completely ablated in the non-MP condition (averaged 440 ml/min throughout exercise).

**CONCLUSION:** The offsetting of positive and negative effects on BF during inspiration and exhalation appeared to provide no net gain to V-Return, suggesting that the respiratory pump has little influence on the dynamics of cardiac output at exercise onset. In contrast V-Return was determined predominantly by muscle pump - even during low-intensity cycling exercise.

**Fluid Replacement And Heat Stress During Exercise Alters Postexercise Cardiac Hemodynamics In Endurance Trained Men**

Brenna M. Lynn, John R. Halliwill, FACSM. *University of Oregon, Eugene, OR.*

Email: brenna.l@ubc.ca

(No relationships reported)

Endurance exercise-trained men have decreases in cardiac output with no change in systemic vascular conductance during postexercise hypotension, which differs from sedentary and normally active populations.

**PURPOSE:** As inadequate hydration may explain these differences, we tested the hypothesis that fluid replacement prevents this postexercise fall in cardiac output, and further, exercise in a warm condition would cause greater decreases in cardiac output.

**METHODS:** We studied 14 trained men ( $63.5 \pm 4.7$  ml kg<sup>-1</sup> min<sup>-1</sup>) before and through 90 min after cycling at 60%  $\dot{V}O_{2peak}$  for 60 min under three conditions: (1) fluid replacement and thermoneutral, (2) no fluid replacement and thermoneutral, and (3) no fluid replacement and exercise in a warm environment. Arterial pressure and cardiac output were measured pre and postexercise in a thermoneutral environment.

**RESULTS:** The fall in mean arterial pressure following exercise was not different between conditions ( $P = 0.453$ ). Postexercise cardiac output ( $P = 0.027$ ), systemic vascular conductance ( $P = 0.001$ ), stroke volume ( $P < 0.001$ ), and heart rate ( $P < 0.001$ ) were different between conditions, as higher cardiac output ( $D 0.4 \pm 1.6$  l/min;  $P = 0.023$ ), systemic vascular conductance ( $D 6.0 \pm 2.2$  ml min<sup>-1</sup> mmHg<sup>-1</sup>;  $P = 0.008$ ), and stroke volumes ( $D 9.1 \pm 2.1$  ml/beat;  $P = 0.002$ ) were seen in the fluid condition compared to the no fluid condition, but there was no difference between the fluid condition versus the no fluid and warm condition (all  $P > 0.05$ ).

**CONCLUSION:** These data suggest that fluid replacement mitigates the postexercise decrease in cardiac output in endurance-exercise trained men. Surprisingly, exercise in a warm environment also mitigates the fall in cardiac output postexercise. Funding by AHA 555623Z and The Evonuk Foundation.

Wilson<sup>1</sup>, Kate Thomas<sup>1</sup>, Michael J.A Williams<sup>1</sup>, Philip N. Ainslie<sup>1</sup>. <sup>1</sup>University of Otago, Dunedin, New Zealand. <sup>2</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>3</sup>Brunel University, Uxbridge, United Kingdom. <sup>4</sup>Leeds General Infirmary, Leeds, United Kingdom.

Email: carissa.murrell@stonebow.otago.ac.nz

(No relationships reported)

Ageing and prolonged exercise independently affect the cerebral blood flow (CBF) response to orthostatic stress (e.g. standing). The extent to which prolonged exercise affects the CBF response to orthostatic stress in older people is unknown.

**PURPOSE:** To determine the effect of age and prolonged exercise on blood pressure and CBF responses to orthostatic stress.

**METHODS:** Measures were obtained before and within 45 min after 4 h of continuous running at 70-80% of maximal heart rate in nine (7 male, 2 female) young (Y;  $27 \pm 4$  y;  $\dot{V}O_{2max}$   $59.0 \pm 9.6$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and twelve (10 male, 2 female) older (O;  $65 \pm 5$  y;  $\dot{V}O_{2max}$   $45.5 \pm 7.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) athletes. Middle cerebral artery blood flow velocity (CBFv; transcranial Doppler ultrasound) and blood pressure (BP; Finometer) were measured continuously whilst supine and during 60° head-up tilt for 15 min or to pre-syncope).

**RESULTS:** Prior to exercise, CBFv was 25% higher in the young [Y:  $67 \pm 7$  cm.s<sup>-1</sup>; O:  $50 \pm 9$  cm.s<sup>-1</sup>;  $P=0.00$ ]. Following exercise, mean arterial blood pressure (MAP) whilst supine was lowered [Pre:  $90 \pm 9$  mm Hg; Post:  $82 \pm 8$ ;  $P=0.00$ ], with similar responses between age groups ( $P=0.38$ ). Following exercise, orthostatic tolerance was reduced [Tilt completed, Pre:  $14:39$  (min:s)  $\pm 0:55$ ; Post:  $5:59 \pm 4:53$ ;  $P=0.00$ ] and the tilt-induced drop in MAP was greater [ $-10 \pm 11\%$ ;  $-31 \pm 15\%$ ;  $P=0.00$ ], but responses were similar between age groups ( $P=0.74$ ). Heart rate rose more with tilt in the young post-exercise [Y:  $+47 \pm 25\%$ ; O:  $+16 \pm 10\%$ ; (at 60 s pre-syncope)  $P=0.00$ ], but was similar between groups at pre-syncope ( $P=0.94$ ). Pre-syncope developed in 17/21 athletes post exercise vs. 3/21 pre exercise. Although the pre-syncope-induced reduction in CBFv was greater in the young [Y:  $43 \pm 18$  cm.s<sup>-1</sup>; O:  $21 \pm 12$  (vs. supine);  $P=0.01$ ], at the point of pre-syncope, absolute CBFv was similar across groups [Y:  $34 \pm 10$  cm.s<sup>-1</sup>; O:  $32 \pm 13$ ;  $P=0.77$ ].

**CONCLUSION:** Despite older athletes having lower basal CBFv and similar exercise-induced hypotension to young adult athletes, age does not appear to be a risk factor for the marked orthostatic intolerance and syncope following prolonged exercise. Interestingly, the similar CBFv at pre-syncope suggests there may be an age-independent critical CBFv threshold at which syncope occurs.

Email: fabriciajunqueira@gmail.com

(No relationships reported)

The presence of endothelial nitric oxide synthase (eNOS) gene polymorphism on exon 7 (894G>T) may decrease the bioavailability of nitric oxide and has been associated with endothelial dysfunction, but the impact of exercise on vascular reactivity is still unknown.

**PURPOSE:** To investigate the influence of this polymorphism on the post-exercise effect of maximal dynamic exercise on vascular reactivity.

**METHODS:** Fifty three healthy sedentary volunteers (35±9years; 26%male) were studied - 22 with (GT or TT genotypes) and 31 without (GG genotype; controls) 894G>T polymorphism. Vascular reactivity was assessed by forearm venous occlusion plethysmography during 3 min recording before and after 5 min of circulatory arrest (3 min recording; reactive hyperemia - HR). The measurements were performed before and immediately after a maximal cardiopulmonary exercise test on a treadmill. Blood flow was determined as the area under the curve and conductance derived from blood flow/mean arterial pressure. The kinetics of the blood flow during HR was analyzed based on the time-constant (tau) after adjusting the data to a mono-exponential model. ANOVA-Newman-Keuls was used to compare groups along time (Ethics Committee-005/07).

**RESULTS:** Groups were similar for anthropometry, biochemical, and exercise variables. Subjects with 894G>T polymorphism (GT+TT) presented lower basal blood flow and conductance before exercise (GT+TT: 2.27±0.17 AU; GG: 2.74±0.20 AU; P=0.049), but increased to control values after exercise (GT+TT: 2.57±0.27 AU vs. GG: 2.72±0.23 AU; P=0.57). Blood flow during HR increased after exercise in both groups, but the kinetics was slower only for subjects with 894G>T polymorphism as time-constant was higher when compared to controls (GT+TT: 46.0±5.8s vs. GG: 33.3±4.9s; P=0.043).

**CONCLUSIONS:** Healthy young subjects with 894G>T polymorphism present lower forearm blood flow due to lower conductance before exercise that was normalized after effort. Reactive vasodilation increased after exercise regardless of the genotype for eNOS on exon 7, but in subjects with GT+TT polymorphism the phenomenon was slower suggesting altered control of blood flow after exercise.

---

**The Effect Of Atropine On Cerebral Perfusion During Systemic Hypotension**

Peizhen Zhang, Kevin Formes, Nancy Tierney, Xiangrong Shi, FACSM. UNT HEALTH SCIENCE CENTER, Fort Worth, TX.

(No relationships reported)

**PURPOSE:** The aim of this study was to seek the importance of reflex control of heart rate (HR) in maintaining cerebral perfusion during systemic hypotension.

**METHODS:** Eight healthy subjects (28.4±1.9 yr) gave the written consent to participate in the study that was approved by IRB at UNTHSC. Systemic hypotension was elicited by cuff deflation (CD) following 3-min bilateral supra-systolic occlusion at rest and during lower-body negative pressure (LBPN).

**RESULTS:** Atropine increased baseline HR from 63±2 to 103±3 bpm. However, neither middle cerebral arterial blood flow velocity ( $V_{MCA}$ , Doppler) nor mean arterial pressure (MAP, Tonometry) was significantly altered by atropine (before vs after: 66.3±4.0 vs 70.1±4.8 cm/s and 84±4 vs 87±4 mmHg). Though CD elicited hypotension was greater after atropine, the decreases in  $V_{MCA}$  were not different (see Table 1). Nonetheless, MAP recovery time following CD was not different before and after atropine despite significant diminution of the tachycardiac response.  $V_{MCA}$  recovery time had a trend (P = 0.10) to be longer after atropine.

**CONCLUSION:** MAP recovery remained fully compensated after atropine, whereas  $V_{MCA}$  recovery was partially dependent on HR reflex.

Table 1. Response to cuff deflation after 3-min supra-systolic occlusion

LBPN	Drug	DMAP mmHg	DV <sub>MCA</sub> cm/s	DT <sub>MAP</sub> sec	DT <sub>V<sub>MCA</sub></sub> sec	DHR bpm
0	Control	-11±2	-7.6±1.7	12.3±2.5	6.6±2.3	+18±3
	Atropine	-16±2	-8.4±1.6	12.3±2.1	9.0±1.9	+6±1 <sup>†</sup>
-15	Control	-16±2	-10.1±2.5	13.2±1.7	5.8±0.9	+23±3
	Atropine	-23±2	-10.9±1.9	11.1±2.7	6.7±0.7	+10±1 <sup>†</sup>
-40	Control	-21±2*	-14.2±2.1	11.2±1.5	4.9±0.9	+26±3
	Atropine	-25±2*	-12.7±1.8	7.8±0.7	6.4±0.7	+13±2* <sup>†</sup>
P	Drug	0.0001	0.9774	0.2178	0.1039	0.0001
	LBPN	0.0001	0.0005	0.2391	0.1703	0.0082

DT<sub>MAP</sub> and DT<sub>V<sub>MCA</sub></sub>: recovery time for DMAP and DV<sub>MCA</sub>, respectively. P indicates the outcome of two-way ANOVA. \* And † denote a significant change from 0 Torr LBPN and a significant difference before and after atropine, respectively.

**Skeletal Muscle Blood Flow During Limb Movement: The Role Of Joint Angle.**

Stephen J. Ives<sup>1</sup>, John McDaniel<sup>2</sup>, Anette S. Fjeldstad<sup>1</sup>, Melissa A. Hayman<sup>1</sup>, David W. Wray<sup>1</sup>, Russell S. Richardson<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Veterans Affairs Hospital, Salt Lake City, UT.

Email: ives.stephen@utah.edu

(No relationships reported)

Although it is clear that blood flow varies across a duty cycle, thought to be predominately a consequence of changing intramuscular pressure, there is also an unknown contribution of joint angle.

**PURPOSE:** To isolate the effects of joint angle on skeletal muscle blood flow in humans by adopting a reductionist approach.

**METHODS:** Six apparently healthy male volunteers (32±7 yr, 89±19 kg, 180±10 cm) participated in 1 trial of passive supine knee extensor exercise. Each trial consisted of 4 complete oscillations from approximately 180° of knee extension to 90° knee flexion at a rate of 5 degrees \* sec<sup>-1</sup>. Blood flow was assessed using Doppler ultrasonography, and was analyzed second by second. The lower leg was occluded at a supra-systolic pressure (250 mmHg), at the level of the tibial tuberosity during all measurements. Joint angle was measured using a modified knee brace instrumented with a digital goniometer, and heart rate was measured using ECG output from the Doppler system. All variables were collected at a frequency of 200 Hz on an A-D system.

**RESULTS:** No differences were observed between antegrade and retrograde femoral blood flows across joint angle. In contrast net blood flow was progressively attenuated ( $p < .01$ ) between the high (180°), mid (135°), and low (90°) joint angles, irrespective of heart rate. Full knee extension facilitated a 52% greater flow (272.6 mL\*min<sup>-1</sup>); as compared to the flexed joint angle (178.6 mL\*min<sup>-1</sup>). Additionally, when the systolic pulse and optimal joint angle align (systole + full extension), joint angle and systolic pulse acted synergistically and blood flow was optimized. The magnitude of the effect is quite remarkable, such that optimal joint angle can acutely raise skeletal muscle blood flow equal to that of a systolic pulse.

**CONCLUSIONS:** During supine passive knee extensor exercise, skeletal muscle blood flow was joint angle dependent and likely due to the associated mechanical deformation of the vasculature.

(No relationships reported)

**PURPOSE:** We sought to examine the potential role of oxidative stress on skeletal muscle function with advancing age.

**METHODS:** Nuclear magnetic resonance (NMR) was employed to simultaneously assess muscle perfusion (arterial spin labeling, ASL) and energetics (31P NMR spectroscopy) in the lower leg of young ( $26 \pm 5$  yrs,  $n = 6$ ) and older ( $70 \pm 5$  yrs,  $n = 6$ ) healthy volunteers following consumption of either placebo (PL) or an oral antioxidant (AO) cocktail (Vitamins C, E, and alpha lipoic acid) previously documented to decrease plasma free radical concentration. NMR measurements were made during and after 5-min of moderate intensity ( $\approx 5W$ ) plantar flexion exercise.

**RESULTS:** AO administration significantly improved end-exercise perfusion ( $50 \pm 5$  ml $\cdot$ 100g $\cdot$ 1 $\cdot$ min $\cdot$ 1, AO;  $43 \pm 4$  ml $\cdot$ 100g $\cdot$ 1 $\cdot$ min $\cdot$ 1, PL) and post-exercise perfusion area-under-the-curve ( $1286 \pm 236$  ml $\cdot$ 100g $\cdot$ 1, AO;  $866 \pm 144$  ml $\cdot$ 100g $\cdot$ 1, PL) in older subjects, while AO administration did not alter hemodynamics in the young group. Concomitantly, muscle oxidative capacity (time constant of PCr recovery) was improved following AO in the older ( $43 \pm 1$ s, AO;  $51 \pm 7$ s, PL) but not the young ( $54 \pm 5$ s, AO;  $48 \pm 7$ s, PL) group.

**CONCLUSIONS:** These findings support the concept that oxidative stress is partially responsible for the age-related decline in skeletal muscle perfusion. Acute antioxidant administration restored perfusion toward that of the young and consequently improved oxidative capacity in the elderly, demonstrating the functional consequence of free-radical-mediated hypoperfusion on skeletal muscle energetics in this cohort.

#### Transfer Function Characteristics Of The Arterial Baroreflex Neural And Peripheral Arcs At Rest And During Muscle Metaboreflex Activation In Humans

Colin N. Young<sup>1</sup>, James P. Fisher<sup>2</sup>, Shigehiko Ogoh<sup>3</sup>, Paul J. Fadel<sup>1</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>University of Birmingham, Birmingham, United Kingdom. <sup>3</sup>University of North Texas Health Science Center, Fort Worth, TX. (Sponsor: Peter B. Raven, FACS)M

Email: cny5db@mizzou.edu

(No relationships reported)

Previous studies have demonstrated an increase in the sensitivity of arterial baroreflex (ABR) control of muscle sympathetic nerve activity (MSNA) in humans during isolated activation of the muscle metaboreflex with post exercise muscle ischemia (PEMI). However, this increased ABR-MSNA control does not appear to enhance the ABR control of arterial blood pressure (BP), suggesting potential alterations in the transduction of MSNA into a peripheral vascular response and a subsequent ABR-mediated change in BP.

**PURPOSE:** To examine the neural and peripheral arcs of the ABR and their interactive relationship at rest and during muscle metaboreflex activation.

**METHODS:** Graded isolation of the muscle metaboreflex was achieved by PEMI following isometric handgrip performed at 15 and 30% maximal voluntary contraction (MVC) in nine healthy subjects. BP, MSNA and femoral artery blood velocity were continuously recorded. To assess the sensitivity (i.e. gain) of the ABR neural and peripheral arcs, the transfer function from BP to MSNA and MSNA to femoral vascular conductance index, respectively were analyzed.

**RESULTS:** Compared to rest no changes were observed in the ABR neural or peripheral arcs during PEMI following 15%MVC handgrip. However, PEMI after 30%MVC handgrip increased the low frequency (LF) transfer function gain between BP and MSNA (ABR neural arc;  $+58 \pm 28\%$ ,  $P=0.036$ ), whereas the LF gain between MSNA and femoral vascular conductance index (ABR peripheral arc) was decreased from rest ( $-36 \pm 8\%$ ,  $P=0.017$ ).

**CONCLUSION:** The gains of both the neural and peripheral ABR arcs were altered during muscle metaboreflex activation in an intensity-dependent manner. Indeed, during high intensity muscle metaboreflex activation an increased ABR gain of the neural arc appears to offset an attenuation of the peripheral arc gain to help maintain the overall ABR control of systemic blood pressure.

#### Lower Body Negative Pressure Shifts The Volume Indifferent Point

Sara S. Jarvis, James A. Pawelczyk, FACS)M. Penn State University, University Park, PA.

Email: ssj120@psu.edu

(No relationships reported)

During head-up tilt, gravity redistributes  $\sim 700$  mL of blood to the legs, abdomen, and pelvis. We have developed a quantitative approach to examine how splanchnic pooling influences orthostatic tolerance. The volume indifferent point (VIP) is the point where blood volume does not change, regardless of posture. Its location is influenced by regional compliances and should be coincident with the hydrostatic indifferent point (HIP). Thus, a more inferiorly located HIP/VIP should result in less venous return and lower orthostatic tolerance. We hypothesized that excessive splanchnic pooling induced with lower body negative pressure (LB)NP would result in a more inferior VIP.

**PURPOSE:** To determine the location of the VIP during a control period and during  $-20$  mmHg LB)NP.

**METHODS:** Four segments (xyphoid process-iliac crest, umbilicus-iliac crest, iliac crest-mid thigh, manubrium-xyphoid process) were identified; their distance was referenced to the floor. Segmental bioelectrical impedance from each segment was collected continuously while subjects were tilted ( $0^\circ$ ,  $15^\circ$ ,  $30^\circ$ , and  $50^\circ$ ) for 6 min each and repeated during  $-20$  mmHg LB)NP. D)Segmental blood volume ( $15-0^\circ$ ,  $30-0^\circ$ ,  $50-0^\circ$ ) was calculated from impedance and non-linear regression was used to determine the distance from the floor in which segmental blood volume did not change (the VIP).

**RESULTS:** The VIP was located  $64 \pm 4\%$  of an individual's height during control measurements. LB)NP induced an inferior shift in the location of the VIP ( $-5.3 \pm 6.2$  cm,  $p=0.02$ ).

**CONCLUSIONS:** The VIP is located roughly at the level of the diaphragm in healthy individuals. Application of  $-20$  mmHg LB)NP induces splanchnic pooling and shifts the VIP toward the feet.

#### Effects Of Kaatsu Training On Haemostasis In Healthy Subjects

Haruhito Takano<sup>1</sup>, Toshiaki Nakajima<sup>1</sup>, Miwa Kurano<sup>1</sup>, Nami Kubota<sup>1</sup>, Haruko Iida<sup>1</sup>, Tomohiro Yasuda<sup>1</sup>, Yoshiaki Sato<sup>1</sup>, Hiroshi Ohshima<sup>2</sup>, Takashi Abe<sup>1</sup>, Naokata Ishii<sup>1</sup>, Toshihiro Morita<sup>1</sup>. <sup>1</sup>University of Tokyo, Tokyo, Japan. <sup>2</sup>Japan Aerospace Explosion Agency, Tokyo, Japan.

Email: masamasa@pb4.so-net.ne.jp

(No relationships reported)

The KAATSU training is performed under the reduction of muscle blood flow by a specially-designed belt (KAATSU belt), which induces blood pooling in capacitance vessels by restricting venous return. However, no prior studies have examined the effects of KAATSU training on haemostasis.

**PURPOSE:** We investigated acute effects of KAATSU training on haemostasis including fibrinolytic responses under several conditions. in healthy subjects.

**METHODS:** Two protocols have been performed. (1) 6 healthy men (mean age,  $48 \pm 5$  yr) performed KAATSU ( $160$  mmHg) of both thighs for 15 minutes and then KAATSU

training combined with low-intensity leg and foot aerobic exercises for ~10 minutes in hypobaric chamber, which mimics 8000 feet in airflight. (2) Another 7 men (mean age,  $30 \pm 4$  yr) performed leg press exercises (30 % 1 RM) with and without KAATSU of both thighs 24 h after bed rest. Blood samples were taken at rest, immediately after KAATSU, and exercises with or without KAATSU, and after exercise. For the investigation of blood fibrinolysis, determinations of tissue-type plasminogen activator (tPA) activity or antigen, plasminogen activator inhibitor (PAI)-1 activity or antigen, fibrin degradation product (FDP) and D-dimer were used. Prothrombin time (PT) and platelet counts were also measured.

**RESULTS:** (1) In hypobaric chamber, KAATSU by itself significantly increased tPA activity, while PAI-1 activity was unchanged. Furthermore, immediately after the exercise, tPA activity increased significantly. (2) During the exercises combined with KAATSU 24 h after bed rest, tPA antigen significantly increased, compared with control exercises, but PAI-1 antigen was unchanged. In both cases, KAATSU training did not induce fibrin formation as assessed by fibrin D-dimer and FDP.

**CONCLUSIONS:** This study indicates that potentially favorable changes occur in fibrinolytic factors after KAATSU and KAATSU training in healthy subjects.

**1427 Board #29 May 27 11:00 AM - 12:30 PM**  
**Coagulation And Fibrinolytic Responses To Exercise In Hot And Cold Temperatures**

Paul R. Nagelkirk, Joanna M. Hoare, Kyla B. Hogan. *Ball State University, Muncie, IN.*

(No relationships reported)

Most adverse cardiovascular events are the result of an occlusive blood clot. During exercise, ischemic risk transiently increases, possibly due to exertion-related changes in coagulation and fibrinolytic activity. Previous research suggests ambient temperature affects resting coagulation and fibrinolytic potential, but the effect of heat and cold on hemostasis during exercise is unknown.

**PURPOSE:** To assess changes in coagulation and fibrinolysis during maximal exercise in hot and cold temperatures, and to compare those responses to exercise under normal, temperate conditions.

**METHODS:** Fifteen healthy male subjects ( $25.3 \pm 4.3$  years) completed maximal cycle ergometer exercise tests in hot ( $30^\circ\text{C}$ ), temperate ( $20^\circ\text{C}$ ) and cold ( $5^\circ$  or  $8^\circ\text{C}$ ) temperatures. Blood samples were obtained before and immediately after exercise and analyzed by ELISA to determine plasma concentrations of thrombin-antithrombin complex (TAT), tissue plasminogen activator (tPA) and plasminogen activator inhibitor-1 (PAI-1). Results were analyzed with a two-factor ANOVA using temperature and time (pre-, post-exercise) as within-subjects factors. Post-hoc pairwise comparisons were made using Fisher's LSD method.

**RESULTS:** VO<sub>2</sub>peak was not different among the three temperatures (temperate =  $40.7 \pm 8.7$ , hot =  $41.8 \pm 9.4$ , cold =  $41.2 \pm 9.2$  ml/kg/min,  $p > 0.05$ ). A main effect of time was observed for TAT (temperate =  $0.45 \pm 0.26$  -  $1.04 \pm 0.44$  ng/ml, hot =  $0.64 \pm 0.55$  -  $1.18 \pm 0.95$  ng/ml, cold =  $0.88 \pm 0.57$  -  $1.34 \pm 0.79$  ng/ml, PRE to POST, respectively,  $p < 0.01$ ) and tPA activity (temperate =  $0.72 \pm 0.44$  -  $2.71 \pm 0.55$  IU/ml, hot =  $0.72 \pm 0.38$  -  $2.64 \pm 0.61$  IU/ml, cold =  $0.86 \pm 0.45$  -  $2.65 \pm 0.77$  IU/ml, PRE to POST, respectively,  $p < 0.01$ ). A non-significant trend was observed for the PAI-1 response to exercise (temperate =  $14.5 \pm 23.7$  -  $12.3 \pm 20.2$  IU/ml, hot =  $15.1 \pm 26.5$  -  $10.0 \pm 15.1$  IU/ml, cold =  $10.5 \pm 10.4$  -  $7.9 \pm 9.7$  IU/ml, PRE to POST, respectively,  $p = 0.08$ ). Cold temperature resulted in significantly higher TAT concentrations than temperate conditions ( $p = 0.05$ ). No other main effects of temperature or time x temperature interactions were observed.

**CONCLUSIONS:** The potential for clot formation is elevated during exposure to cold temperatures. These data suggest that risk of an ischemic event may be elevated in the cold.

**Effects of Covert Subject Actions on Percent Fat by Air Displacement Plethysmography**

R. Randall Clark<sup>1</sup>, Michelle H. Tegenkamp<sup>2</sup>, Greg L. Landry<sup>3</sup>, Dale A. Schoeller<sup>2</sup>. <sup>1</sup>UW Hospital Sports Medicine Center, Madison, WI. <sup>2</sup>University of Wisconsin-Madison, Madison, WI. <sup>3</sup>University Hospital and Clinics, Madison, WI.

(No relationships reported)

Athletes in weight classification sports may engage in rapid weight loss methods to "make weight" prior to competition. Distance runners and endurance athletes, where there is a perception of improved performance at a lower body weight, may also engage in excessive weight loss methods prior to competition. Such practices may cause poor athletic performance and can be harmful to the body. Some trainers and coaches, and in the case of wrestling, the NCAA have adopted programs aimed at reducing unhealthy weight loss behaviors by measuring body fat using hydrostatic weighing, skinfolds or air-displacement plethysmography (ADP). Athletes, however, may use covert methods during body composition testing to artificially increase their percent body fat allowing them to reach a lower minimum weight.

**PURPOSE:** The goal of this study was to examine the accuracy of ADP under altered conditions. This study examined the susceptibility of the Bod Pod ADP instrumentation to intentional manipulation of body composition measures by subjects.

**METHODS:** Subjects underwent body composition analysis in the Bod Pod following the standard procedure previously validated. They then underwent eight more measurements while performing the following: four breathing patterns altering lung volume, foot movement, hand cupping to trap air, and heat and cold exposure.

**RESULTS:** Increasing and decreasing lung volume during thoracic volume measurement and during body density measurement altered the apparent percent body fat assessment ( $p < 0.001$ ). High lung volume during thoracic gas measures (HLV-TG) overestimated fat by  $3.7 \pm 2.1\%$ . Lowered lung volume during body volume measures (LLV-BV) overestimated body fat by an additional  $2.2 \pm 2.1\%$ . The summation effect of the covert manipulation resulted in an overestimation of the athletes' body composition by 5.9 percent body fat. The heat and cold exposure, tapping and cupping treatments were not significantly different from control.

**CONCLUSION:** These results demonstrate that athletes can covertly alter their body composition measurement to obtain a lower competition weight when measured by ADP. It is therefore important that technicians monitor for intentionally altered breathing when using ADP that could artificially increase percent body fat and invalidate the test result.

**Self-perception Of Body Composition In Lean Pole Vault Athletes**

Michael G. Coles, Tim R. Anderson, Jacobo O. Morales, Lisa J. Leininger. *California State University, Fresno, Fresno, CA.*

Email: mcoles@csufresno.edu

(No relationships reported)

Research has shown that certain individuals may have a distorted self-perception of body size, shape, and weight. Most studies in this area do not include very lean athletes and are not focused specifically on body composition.

**PURPOSE:** This investigation was done in order to determine if there is a difference between self-perceived and actual estimated body fat percentages in lean pole vault athletes.

**METHODS:** A cohort of 168 men and women pole vaulters from 3 competitive categories, pre-collegiate, collegiate, and post-collegiate, participated in the investigation. Each participant was asked to self-predict his or her percent body fat ( $BF_{pred}$ ) before having their body composition estimated using a 7-site skinfold technique ( $BF_{skf}$ ). Paired t-tests were used to determine if the  $BF_{pred}$  value differed from the  $BF_{skf}$  result for each combination of gender and competitive category.

**RESULTS:** Table 1 contains the mean ( $\pm$  SD) for descriptive data,  $BF_{pred}$ , and  $BF_{skf}$  for men and women grouped by competitive level.

**CONCLUSION:** These results indicate that there was a significant difference ( $p<0.05$ ) between  $BF_{pred}$  and  $BF_{skf}$  for all men, regardless of competitive level, and pre and post collegiate women. All of these groups overestimated their percent body fat. There was no significant difference ( $p>0.05$ ) between  $BF_{pred}$  and  $BF_{skf}$  for collegiate level women pole vaulters. These results suggest that these lean female pole vault athletes have a more accurate self-perception of their percent body fat than other groups in this study. Reasons for this could be that they have more knowledge and/or experience with the construct of percent body fat and/or put more emphasis on monitoring this component of fitness.

Competitive Level & Gender	Age (y)	HT (m)	BM (kg)	%Fat Self-Predicted	% Fat Skin Fold Estimate
Pre-Collegiate Male	16.9 $\pm$ 1.13 N = 35	1.79 $\pm$ 0.07	69.76 $\pm$ 7.15	9.23 $\pm$ 3.99	5.66 $\pm$ 2.78

#### 1430 Board #32 May 27 9:30 AM - 11:00 AM Validity And Reliability Of Skinfold Measurement In Assessing Body Fatness Of Hong Kong Chinese Children

Daniel C. S. Yeung, Stanley Sai-chuen Hui, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Email: danyeu@indiana.edu

(No relationships reported)

The prevalence of childhood obesity in Hong Kong has increased closed to 70% in the past 13 years. For tracking the childhood obesity level effectively, there is an urgent need to evaluate the obesity level of children in Hong Kong using objective and practical measurement.

**PURPOSE:** Using Air Displacement Plethysmography (ADP) as a criterion, we evaluated the validity and reliability of skinfold (SKF) measurement in predicting percent body fat of Chinese children in Hong Kong.

**METHODS:** A heterogeneous sample of healthy voluntary Chinese children (142 boys and 88 girls) with a wide age range (9-19 years) and body composition was recruited through stratified purposeful sampling.

**RESULTS:** The internal consistency of SKF and ADP measurements were very high ( $r \geq .988$ ). Repeated t-test showed no significant difference between %fat measured by ADP (%fatADP) and that measured by dual X-ray absorptiometry in a sub-sample (N = 41), and significant difference was found between percent fat estimated by the Slaughter equations (%fatSlaughter) and %fatADP. The Slaughter equations slightly underestimated %fat of Hong Kong children, in which 1.52% for boys and 1.84% for girls. Despite the high R squares (.81 for boys and .64 for girls), the slope of the regression line for boys was significantly different from the line of identity. Subsequent stepwise regression analyses found three alternative SKF prediction models for estimating percent body fat of Chinese children in Hong Kong, which combining waist circumference, height and children's age. The most accurate model for boys was %fat = 22.091 - 0.147 (height) + 0.760 ( $\Sigma$ 3SKF) - 0.003 ( $\Sigma$ 3SKF)<sup>2</sup> (R square = .88, SEE = 3.70%), and that for girls was %fat = 17.539 + 0.303 ( $\Sigma$ 2SKF) + 0.516 (height) - 0.175 (waist circumference) (R square = .71, SEE = 3.38%). The third model for boys and girls was the convenient model, as only triceps SKF and age is required for the estimation. The equation for boys was %fat = 14.405 + 1.479 (triceps) - 0.856 (age) (R square = .81, SEE = 4.67%), and the equation for girls was %fat = 13.936 + 1.170 (triceps) - 0.502 (age) (R square = .63, SEE = 3.77%).

**CONCLUSION:** The accuracy of these models is comparable to the Slaughter equations, but the estimated %fat by these new models were less deviated from %fatADP than that estimated by the Slaughter equations.

#### 1431 Board #33 May 27 9:30 AM - 11:00 AM Comparison Of Somatotype Measurements Of Physical Education Students From Singapore And India

Nidhi Gupta<sup>1</sup>, Govindasamy Balasekaran<sup>1</sup>, Savan Jainpurkar<sup>2</sup>, Visvasuresh Victor Govindaswamy<sup>3</sup>. <sup>1</sup>National Institute of Education, Nanyang Technological University, Singapore, Singapore. <sup>2</sup>Northern Illinois University, Dekalb, IL. <sup>3</sup>Texas A&M University, Texarkana, TX.

Email: nidhi\_scholar@hotmail.com

(No relationships reported)

Somatotype measurements provide accurate descriptive information of athlete's physique than anthropometric measurements. Somatotype measurements describe the relative muscularity, fatness, and slenderness of the physique. There are few studies on somatotypes of Asian population and the comparison of somatotypes between two Asian cohorts has not been investigated.

**PURPOSE:** The purpose of this study was to measure and compare somatotypes of Physical Education (PE) students in Singapore and India.

**METHODS:** 13 healthy males (age, 26.8 $\pm$ 0.8 yrs; BMI, 22.7 $\pm$ .67 kg•m<sup>-2</sup>) and 8 females (age, 24.1 $\pm$ .6 yrs; BMI, 19.7 $\pm$ .66 kg•m<sup>-2</sup>) from Singapore and 16 healthy males (age, 26.3 $\pm$ .78 yrs; BMI, 23.2 $\pm$ .81 kg•m<sup>-2</sup>) and 7 females (age, 19.3 $\pm$ .64 yrs; BMI, 21.8 $\pm$ 1.56 kg•m<sup>-2</sup>) from India were selected for this investigation. Somatotype components [Endomorphy (END), Mesomorphy (MES), and Ectomorphy (ECT)] were calculated according to the procedure by Heath and Carter (2002) for all subjects. Somatotype software was used to calculate the somatotypes of subjects. Data was plotted using probability-probability (P-P plot) and Box-and-Whisker plot. Shapiro-Wilk statistics was utilized to assess the data's goodness of fit to the normal distribution. As the data was not normally distributed, Kruskal-Wallis non-parametric statistical test was employed to compare MES, END, and ECT among both countries according to gender.

**RESULTS:** The Singapore females (mean somatotype: 3.66-3.15-3.19; SD: 0.81-1.22-1.09) were balanced endomorph while Indian females (mean somatotype: 4.71-4.03-2.16; SD: 1.48-0.92-1.25) were mesomorphic endomorph. In addition, Singapore males (mean somatotype: 3.43-4.65-2.49; SD: 1.27-1.31-1.43) and Indian males (mean somatotype: 2.76-4.31-2.00; SD: 1.53-1.33-1.18) had similar endomorphic mesomorph body type. There were no significant differences in somatotypes between Indian and Singapore males ( $p>0.05$ ) and between Indian and Singapore females ( $p>0.05$ ).

**CONCLUSIONS:** Results indicated similarities in somatotypes among Singapore and Indian PE students. The male students of both countries were muscle framed and female students were generally endomorph. Results suggest that students of Asian origin with similar somatotypes may be currently enrolled as PE students in India and Singapore.

**Is Body Mass Index Useful In Sports Medicine ?**

Bruno Sesboue<sup>1</sup>, Steven PROVYN<sup>2</sup>, Aldo SCAFOGLIERI<sup>2</sup>, Jan Pieter CLARYS<sup>2</sup>. <sup>1</sup>IRMS, CAEN, France. <sup>2</sup>Vrije Universiteit Brussel, Brussels, Belgium.

Email: sesboue-b@chu-caen.fr

(No relationships reported)

**PURPOSE:** The Body Mass Index (BMI) is very often used in sports medicine to evaluate obesity/leanness and to guide athletes to a particular sport. Is this index relevant ?

**METHODS:** We studied the morphological characteristics of 563 soccer players involved in the French soccer 1st league championship. These players are divided into forwards (F, n=127), backs (B, n=176), goalkeepers (G, n=60) and midfielders (M, n=200) by soccer journals. We compared mean values to see if each position on the field of play was associated to a particular morphological profile.

**RESULTS:** Soccer players are  $27 \pm 4.27$  years old,  $1.81 \pm 1.81$  m tall and weigh  $75.0 \pm 6.5$  Kg ( $165.0 \pm 14.3$  lbs). Their BMI is  $22.9 \pm 1.2$ . Forwards are younger than backs and goalkeepers ( $p<0.05$ ) and they are as old as midfielders. They are smaller than backs and taller than midfielders ( $p<0.01$ ); they are as tall as goalkeepers. They are lighter than backs and goalkeepers but a little heavier than midfielders. Their BMI is only different from the BMI of midfielders. Backs are older than midfielders and they as old as midfielders. They are smaller than goalkeepers and midfielders. They are lighter than goalkeepers and heavier than midfielders. Their BMI is lower than that of goalkeepers but higher than that of midfielders. Goalkeepers are older, higher and heavier than midfielders with a higher BMI.

**CONCLUSIONS:** The best data to characterize soccer players are simply height and weight : we know that goalkeepers have to be large and need explosive power. They are taller than other players. If we look at BMI, we lose information : there is no difference in BMI between goalkeepers, forwards or backs, but height and weight are very significantly different. "Overweight" could reflect musculature rather than obesity. So, BMI is not useful for the evaluation of sportsmen. Moreover, the BMI does not permit any notion of the distribution of regional adiposity, or health risks that are associated with visceral obesity.

**Associations Between Body Composition And Measures Of Physical Activity**

Sara Fleet Michaliszyn, Ellen Cussler, Joshua Farr, Rob Blew, Vinson Lee, Scott Going. *University of Arizona, Tucson, AZ.*

Email: smichaliszyn@nursing.arizona.edu

(No relationships reported)

The prevalence of obesity in adolescent girls continues to rise worldwide. The increase in obesity is often attributed to low levels of physical activity although large inconsistency exists between reported levels of physical activity and level of fatness. These inconsistencies may be related to methodological variation in assessing measures of body composition.

**PURPOSE:** The purpose of this investigation was to determine if adjusting for height relative to body composition would improve the association between body composition and levels of physical activity.

**METHODS:** A cross-sectional analysis was conducted in 328 female adolescents aged 9-15yrs (age,  $11.0 \pm 1.0$  years; BMI,  $27.6 \pm 6.2$  kg/m<sup>2</sup>). Youth were asked to wear a pedometer during waking hours to get an objective measure of physical activity (steps/day) for seven consecutive days. Body weight and standing height were measured to the nearest 0.1 kilograms and centimeters, respectively. Body composition was assessed via dual energy x-ray absorptiometry. To adjust for body size, fat mass (FM) and lean mass (LM) were normalized for height and expressed as fat mass index (FMI) and lean mass index (LMI). All regression analyses were controlled for age and race.

**RESULTS:** We found that 2.6% of the variance in physical activity was accounted for by FM ( $R = .16$ ;  $P = 0.04$ ) and this association was not strengthened after adjusting for height (FMI,  $R = .16$ ;  $P = 0.04$ ). LM ( $R = .120$ ;  $p > 0.05$ ) and LMI ( $R = .122$ ;  $p > 0.05$ ) were not significantly associated with physical activity. When expressing FM and LM as a percentage of body mass, percent fat mass predicted 2.8% ( $R = .17$ ;  $P = 0.03$ ) of the variance in physical activity whereas percent lean mass explained 2.7% ( $R = .16$ ;  $P = 0.03$ ) of the variance in physical activity.

**CONCLUSION:** Adjusting for height does not increase the association between measures of body composition and levels of physical activity. All measures of FM and percent LM are similarly related to physical activity in adolescent girls.

**1434 Board #36 May 27 9:30 AM - 11:00 AM**  
**An Intracellular Water Reduction Before A Competition Decreases Upper-body Power Output In Elite Judo Athletes**

Analiza M. Silva, Catarina Matias, Ana L. Quitério, Susana Oliveira, Diana Santos, Maria J. Valamatos, Luís B. Sardinha. *Faculty of Human Movement, Lisbon, Portugal.*

(No relationships reported)

**PURPOSE:** To analyze the effect of body composition changes, from a period of weight maintenance to before a competition (nearly 1-month apart), on upper-body power output (PO) in male judo athletes.

**METHODS:** A total of 23 men, top-level athletes (age:  $22.8 \pm 2.7$  yrs), were evaluated at baseline [weight:  $73.0 \pm 7.3$  kg; percent fat mass (%FM):  $11.7 \pm 2.4$  %] and before a competition (Weight:  $72.0 \pm 7.2$  kg; %FM:  $11.2 \pm 2.3$  %). Before the competition some of these athletes lost weight through self-determined means while others remained or increased their weight. A 7-day recall of dietary food intake was recorded at baseline and before the competition. At both moments, and after an overnight fasting, total body water (TBW), extracellular (ECW), and intracellular water (ICW) were estimated by bioelectrical impedance spectroscopy while FM, fat-free mass (FFM), lean soft tissue (LST), and arms LST were assessed by dual-energy x-ray absorptiometry (DXA). At baseline, a power-load spectrum was used to assess upper-body PO in a bench-press position while, before the competition, and after a standardized warm-up, only the individual load where the peak PO value was obtained at baseline was used to assess PO changes. Changes are expressed as a percentage of the baseline value; comparisons of means, bivariate and partial correlations were used.

**RESULTS:** A significant mean reduction ( $p<0.05$ ) in weight was observed [ $-1.3 \pm 2.5$  %,  $-6.2$  to  $2.8$  % (mean  $\pm$  SD, range)] while no significant mean changes were found in FM ( $-4.3 \pm 10.1$  %,  $-21.9$  to  $14.0$  %), FFM ( $-0.8 \pm 2.3$  %,  $-5.4$  to  $3.1$  %), LST ( $-0.9 \pm 2.5$  %,  $-5.8$  to  $3.2$  %), arms LST ( $-1.8 \pm 4.4$  %,  $-9.9$  to  $4.1$  %), TBW ( $-0.9 \pm 3.9$  %,  $-9.2$  to  $5.9$  %), ECW ( $-0.5 \pm 5.0$  %,  $-15.8$  to  $5.9$  %), ICW ( $-1.0 \pm 5.4$  %,  $-10.9$  to  $8.6$  %), energy intake ( $-4.3 \pm 29.0$  %,  $-54.1$  to  $54.9$  %), and PO ( $2.9 \pm 12.3$  %,  $-24.0$  to  $41.3$  %). Changes in PO were only related with changes in TBW ( $r=0.711$ ,  $p<0.001$ ) and ICW ( $r=0.605$ ,  $p=0.002$ ); these associations remained after controlling for weight and arms LST changes ( $r=0.658$ ,  $p=0.001$  and  $r=0.633$ ,  $p=0.002$ , respectively) which means that those athletes that lost TBW, specifically the ICW compartment, were those that reduced PO.

**CONCLUSIONS:** To avoid upper-body power reductions before a competition, athletes should not decrease TBW and ICW. Together, these findings highlight the need of assessing hydration changes in Judo athletes.

**Prone Vs. Supine Dxa Scans In Ambulatory Subjects: A Pilot Study**

Joshua M. Miller, Ashraf S. Gorgey, David R. Gater, Jr. *Hunter Holmes McGuire VA, Richmond, VA.*  
Email: Joshua.Miller@va.gov  
(No relationships reported)

Dual energy X-ray absorptiometry (DXA) is widely used technique for bone mineral density as well as body composition, since it provides an accurate estimation in healthy adults and clinical population. In clinical population, supine position may not be feasible due to medical complications such as pressure ulcers.

**PURPOSE:** To determine if there is an agreement in bone mineral content (BMC) and body composition (Fat Free Mass (FFM) and Fat Mass (FM)) in supine versus prone positioning on the Lunar Prodigy DXA scanner.

**METHODS:** Thirteen (7 males and 6 females; aged  $33.7 \pm 8.7$  yrs;  $26.0 \pm 5$  kg/m<sup>2</sup>) subjects were recruited to perform two full body scans while on the DXA (1 prone and 1 supine). Each scan took approximately 6 minutes to perform and had about one-minute between scans in order to reposition into either a supine or prone position.

**RESULTS:** Pearson correlations demonstrated strong agreement between supine and prone position in BMC ( $r = .99$ ,  $p = .0001$ ), FFM ( $r = .98$ ,  $p = .0001$ ), FM ( $r = .99$ ;  $p = .0001$ ). Paired T-test revealed significant differences in supine vs. prone in BMC ( $3.0 \pm 0.5$  vs.  $3.1 \pm 0.5$ ,  $p = .0001$ ) and FM ( $20.9 \pm 10.0$  vs.  $20.3 \pm 9.9$ ,  $p = .002$ ); however, there was no significant difference in FFM ( $53.9 \pm 10.0$  vs.  $53.7 \pm 9.8$ ,  $p = .412$ ).

**CONCLUSIONS:** The current study suggests that prone can be used as an alternative position during DXA scans to measure BMC and body composition.

**Four Models For Predicting Pediatric Body Composition For Anglo And Hispanic Youth**

David K. Wittenburg, Murat Karabulut. *University of Texas at Brownsville, Brownsville, TX.*  
Email: david.wittenburg@utb.edu  
(No relationships reported)

Body composition is becoming recognized as a critical component in the reporting of health-related measures in children due to the increase in metabolic disorders. However, measuring body composition is often difficult due to lack of training, privacy issues and cost of accurate measuring devices. Therefore, it may be advisable to develop a prediction equation that can be used to accurately determine body composition in youth.

**PURPOSE:** To develop a body composition prediction equation for elementary age youth.

**METHODS:** A stratified sampling method was used to select volunteer children for this study. Height, weight, BMI, age, and skinfold were collected on 886 Anglo ( $n = 445$ ) and Hispanic ( $n = 441$ ) children between the ages of 7 and 12 ( $9.1 \pm 2.1$ ). Body composition was determined by using a standard two site procedure that is common in most schools. Group body fat means were examined through two-way ANOVA. Correlation matrices were run with each group on the variables of height, weight, BMI, age, and body fat percent. Regression prediction models were developed using stepwise regression techniques. Cook's D and Mahalanobis D distances were examined to determine outlier affects.  $R^2$  and standard error of the estimate (SEE) were examined for each resulting model.

**RESULTS:** The data was split by gender and ethnicity after two-way ANOVA revealed a significant difference between males and females and between Anglo and Hispanic groups. Prediction models were established with the following variables for the following groups: Anglo Females: BMI, Weight, Age ( $R^2 = .555$ ,  $SEE = 4.34$ ); Hispanic Females: Weight, Height ( $R^2 = .478$ ,  $SEE = 4.52$ ); Anglo Males: BMI, Weight, Age ( $R^2 = .561$ ,  $SEE = 5.83$ ); Hispanic Males: Weight, Age ( $R^2 = .403$ ,  $SEE = 5.32$ ). All models indicated acceptable means and ranges for Cook's and Mahalanobis distances.

**CONCLUSIONS:** The results indicate that reasonable field-based prediction models can be used as a general assessment tool when clinical methods are not available or practical within Anglo and Hispanic youth populations. The prediction variables also indicated consistency within ethnicities. Weight, age and BMI are consistent body fat prediction variables for Anglo youth while weight is a consistent body fat prediction variable for Hispanic youth. Future studies should examine these variables more closely.

**Validity Of Equations For Total And Regional Skeletal Muscle Mass By Ultrasound In Japanese Prepubertal-boys**

Taishi Midorikawa<sup>1</sup>, Megumi Ohta<sup>2</sup>, Yuki Hikiyama<sup>3</sup>, Yoshitake Oshima<sup>4</sup>, Shigeo Tanaka<sup>5</sup>, Shizuo Sakamoto<sup>1</sup>. <sup>1</sup>Waseda University, Saitama, Japan. <sup>2</sup>Kanazawa Seiryō University, Kanazawa, Japan. <sup>3</sup>Chiba Institute of Technology, Chiba, Japan. <sup>4</sup>Omron Healthcare Co., Ltd., Kyoto, Japan. <sup>5</sup>National Institute of Health and Nutrition, Tokyo, Japan.  
Email: taishi@aoni.waseda.jp  
(No relationships reported)

At the present time, there are very few effective methods to accurately and non-invasively estimate skeletal muscle (SM) mass in children. Recently, we developed ultrasound-derived prediction equations for estimating total and regional (i.e. arm, trunk and leg) SM mass in adults males and females (Eur J Appl Physiol 96: 24-31, 2006). However, it is unknown whether these equations are a valid method to estimate SM mass in prepubertal children.

**PURPOSE:** To investigate whether ultrasound-derived prediction equations for estimating total and regional SM mass in adults are applicable for prepubertal children.

**METHODS:** Sixty-one healthy Japanese prepubertal boys (mean age 10yr) volunteered for the study. Contiguous MRI images with a 1-cm slice thickness were obtained from the first cervical vertebra to the ankle joints as reference data. The volume of SM was calculated from the summation of digitized cross-sectional area. The volume units were converted into mass by an assumed SM density of 1.041g/cm<sup>3</sup>. The regional SM mass was determined by anatomical landmarks visible in the scanned images. Muscle thickness was measured by B-mode ultrasound (5 MHz scanning head) at 9 sites on different muscles (lateral forearm, anterior and posterior upper arm, abdomen, subscapular, anterior and posterior thigh, anterior and posterior lower leg). Total and regional SM mass were estimated using prediction equations for adult males, which were developed based on the relationship between ultrasound-measured muscle thickness and MRI-measured SM mass.

**RESULTS:** The measured SM mass by MRI was  $11.3 \pm 2.8$  kg for total,  $1.1 \pm 0.3$  kg for arm,  $4.6 \pm 1.2$  kg for trunk,  $4.2 \pm 1.2$  kg for thigh and  $1.4 \pm 0.5$  kg for lower leg, and were significantly different from the predicted total and regional SM mass by ultrasound (total  $8.0 \pm 3.6$ kg, arm  $0.9 \pm 0.3$ kg, trunk  $5.9 \pm 1.1$ kg and lower leg  $0.9 \pm 0.4$ kg, respectively,  $p < 0.01$ ) except for thigh ( $4.2 \pm 1.3$ kg).

**CONCLUSIONS:** The ultrasound-derived prediction equations for adults are not applicable for prepubertal boys. The specialized equation for estimating total and regional SM mass in prepubertal children is needed.

**Body Mass Index For Women's National Basketball Association Players**

Jeff G. Konin, Kenzo Koike. *University of South Florida, Tampa, FL* (Sponsor: Sandra Hoffman, FACSM)  
(No relationships reported)

**PURPOSE:** Body Mass Index (BMI) has been proposed as a method to assess the body type of individuals in a relatively simple manner by taking into account one's height and weight. Categories of described body type include underweight, normal weight, overweight, obese class 1, obese class 2, and extreme (morbid) obesity. One of the

inaccuracies of using BMI as a screening tool for obesity is that it does not take into account lean body mass versus adipose tissue. Despite this challenge, it remains a popular and widely-used screening tool. The purpose of this study was to assess the body mass index of women's professional basketball players. The authors have previously identified patterns of BMI for competitive athletes in sports inclusive of football, baseball, ice hockey, soccer, and others. Previous work has been successful in identifying patterns for male athletes whereby a higher percent of the recorded BMI's have typically been noted to fall in the overweight category. It was assumed that similar trends would be noted with competitive female athletes, in particular professional basketball players.

**METHODS:** Height and weight were recorded for 164 females currently playing in the Women's Professional Basketball Association (WNBA). This data was obtained from publicly available team websites during 2008 and used to calculate the body mass index for team averages and by player position throughout the league.

**RESULTS:** Body mass index by player position ranged between 22.5 - 23.8, falling within the acceptable BMI range. Specifically, by player position, BMI outcomes were 22.5 (Guards, N = 75), 22.6 (Forwards, N = 61), and 23.8 (Centers, N = 28). Overall team averages for the 14 teams ranged from 21.9 - 23.4, all within normal acceptable ranges. Analysis of variance showed no significant difference between BMI's by position.

**CONCLUSIONS:** The overall difference between the position players of guard, center and forward were not significant and did not reveal an overweight classification based upon average BMI. As expected, the average of players in the position of center had slightly higher BMI's. Future studies should continue to assess how BMI is utilized with female athletic populations.

**1439 Board #41 May 27 9:30 AM - 11:00 AM**  
**Characteristics Of Body Mass Index For Women's Professional Volleyball Players**

Kenzo Koike, Jeff G. Konin. *University of South Florida, Tampa, FL* (Sponsor: Sandra Hoffman, FACSM)  
 (No relationships reported)

**PURPOSE:** Body Mass Index (BMI) is a commonly used measurement tool for assessing the body type of individuals in a relatively simple manner by taking into account one's height and weight. The lack of complexity and required equipment contribute to the high utilization of this method. Categories of described body type include underweight, normal weight, overweight, obese class 1, obese class 2, and extreme (morbid) obesity. One of the inaccuracies of using BMI as a screening tool for obesity is that it does not take into account lean body mass versus adipose tissue. The purpose of this study was to assess the body mass index of women's professional volleyball players. The authors have previously identified patterns of BMI for competitive athletes in sports inclusive of football, baseball, ice hockey, soccer, and others. The majority of the previously published findings report BMI's of male athletes who readily make their body weight available for public knowledge. Attempts to locate disclosed body weight measurements for female professional athletes have not been made as readily available. It was hypothesized that trends would be noted with competitive female professional volleyball players that might be indicative of an overweight BMI despite participating at an elite level of International athletic performance.

**METHODS:** Height and weight were recorded for 124 females currently playing Women's Professional Volleyball. This data was obtained from publicly available team websites during 2008 and used to calculate the body mass index for team averages and by player position throughout the league.

**RESULTS:** Body mass index by player position averages ranged between 20.1 - 21.4, falling within the acceptable BMI range. Specifically, by player position, BMI outcomes were 21.4 (Liberio, N = 11), 20.9 (Middle Blocker, N = 36), 20.8 (Setter, N = 20), 20.1 (Universal, N = 18), and 21.4 (Wing Spiker, N = 35). Analysis of variance showed no significant difference between BMI's by position.

**CONCLUSIONS:** The overall difference in BMI between the position players for women's professional volleyball players were not significant and did not reveal an overweight classification based upon average BMI. Future studies should continue to assess how BMI is utilized with female athletic populations.

**1440 Board #42 May 27 9:30 AM - 11:00 AM**  
**Comparison Of Body Composition Measurement Methods In Female Soccer Players**

Mariana Pencheva, Laura Kruskall, FACSM, John Young, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV*.  
 Email: jack.young@unlv.edu  
 (No relationships reported)

Optimal body size is important for peak performance in sport. Assessment of body composition provides the coach and athlete with insight into the optimal body weight for performance in a given sport. Laboratory techniques for determining body composition are often not generally available for coaches and athletes because of the complex equipment required for the assessment. Consequently, several techniques have been developed which are more suited for use in the field. However, the accuracy of these techniques has not been fully established in an athletic population.

**PURPOSE:** to compare commonly used techniques for determining body composition against densitometry to determine their accuracy in a specific athletic population.

**METHODS:** Subjects were 18 members of a division I university women's soccer team (164.5 ± 1.1 cm; 63.0 ± 1.5 kg). Body composition was determined by dual-energy X-ray absorptiometry (DEXA), air plethysmography (BodPod), bioelectrical impedance analysis (BIA), near infrared reactance, ultrasound, and skinfold fat thickness (3, 4, and 7 site), and compared with the results obtained by densitometry (hydrostatic weighing).

**RESULTS:** Correlations ( $r^2$ ) between densitometry and the other techniques were

DEXA	BodPod	BIA	Near IR	Ultrasound	SF 3 site	SF 4 site	SF 7 site
.85	.68	.08	.35	.48	.85	.88	.37

**CONCLUSION:** These results suggest that measures of skinfold thickness, either 3 site (triceps, abdomen, suprailiac) or 4 site (triceps, abdomen, suprailiac, thigh), assuming a competent administrator, provide the most accurate field technique for assessing body composition. Despite the ease of measurement provided by the other field techniques, the accuracy of such techniques is questionable in this population.

**1441 Board #43 May 27 9:30 AM - 11:00 AM**  
**Role Of Body Mass Index And Race On Two And Three Component Percent Fat Of Young Adults: Tiger And Heritage Family Studies**

Andrew S. Jackson, FACSM<sup>1</sup>, Brian K. McFarlin<sup>1</sup>, Mary H. Sailor<sup>2</sup>, Jack Wilmore, FACSM<sup>3</sup>, Tuomo Rankinen<sup>4</sup>, Molly S. Bray<sup>2</sup>. <sup>1</sup>University of Houston, Houston, TX. <sup>2</sup>Baylor College of Medicine, Houston, TX. <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA., LA. <sup>4</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
 Email: udde@mac.com  
 (No relationships reported)

Much of the classic body composition research used a two-component (2C) model to estimate percent body fat (BF%) from body density determined by underwater weighting (U-BD). Dual-energy X-ray absorptiometry (DXA), a three-component model, is becoming the laboratory method of choice to measure BF%.

**PURPOSE:** To compare the effects of race and body mass index (BMI) on BF% measured by U-BD, 2-C and DXA methods.

**METHODS:** The subjects included white (W) and African-American (AA) men and women from the HERITAGE family (n=385) and TIGER studies (n=826). The young

adults ranged in age from 17 to 35 y. The subjects underwent in an exercise intervention and had their BF% measured 1 to 3 times over 9 months. The BF% of the TIGER subjects was measured by DXA. Sex and race specific 2-C equations were used to calculate BF% from U-BD of the HERITAGE subjects. Linear mixed models (LMM) regression was used to analyze the all observations, which were 1,266 for women and 820 for men. The independent variables were BMI, BF% method (2-C vs. DXA) and race (W vs. AA) and the dependent variable was BF%. The men and women's data were analyzed separately.

**RESULTS:** The LMM results for women and men were similar. A significant BMI by method showed that below a BMI of about 25 kg/m<sup>2</sup>, the Siri BF% for a given BMI was lower than DXA BF%, but above 25 kg/m<sup>2</sup> the 2-C BF% was higher than DXA BF%. Adding race to the LMM improved model fit ( $p < 0.001$ ) for both men and women. Graphic examination of the trends showed that for a given BMI, the DXA BF% of AA men was about 4.6% lower than W. The DXA BF% of AA women was nearly 2% lower than W women.

**CONCLUSIONS:** These results showed there is both a race and method effect for young men and women when using the DXA and U-BD, 2-C laboratory methods to measure BF%. The method effect is a function of BMI level.

**Serum Levels Of Human Angiopoietin-related Growth Factor In Human Body**

Byung Il Yeh, Jun Namkung, *Wonju College of Medicine, Yonsei University, Wonju, Gangwondo, Republic of Korea.*

Email: mia1@yonsei.ac.kr

(No relationships reported)

The angiopoietin-related growth factor (AGF) is a novel hepatokine that increases energy expenditure and insulin sensitivity. Animal models demonstrated AGF as a candidate for treatment of obesity and diabetes; however, no human study has been reported.

**PURPOSE:** To determine the serum levels of AGF in human body and the correlations with biochemical markers or body measurement data.

**METHODS:** From Korean Rural Genomic Cohort (KRG) study, 195 subjects were enrolled (age  $56.1 \pm 8.015$ , 98 were male, 97 were female). Sandwich ELISA was performed to measure the serum levels of AGF; biochemical markers and body measurement data collected in KRG study were used for correlation analysis.

**RESULTS:** Serum AGF levels were significantly increased in the people with metabolic syndrome ( $328.48 \pm 16.28$  ng/mL) compared to those of healthy people ( $276.65 \pm 10.72$  ng/mL). Among the components of metabolic syndrome, people with high waist circumferences showed significant higher serum AGF than in control group. Correlations with significance were observed between serum AGF and weight, waist, hip, body mass index, total body fat, visceral fat, LDL, AST, ALT, fasting insulin, or 1 hour insulin level of oral glucose tolerance test (OGTT) in positive, and age in negative.

**CONCLUSIONS:** Serum levels of human AGF were diametrically opposed to hypotheses from animal models. Further study is needed to investigate the AGF resistance. This is the first report of serum levels of AGF in human.

The impact of physical conditioning on body composition is determined by performance requirements, training regimen, and training history. However, in some instances meeting competition weight class requirements may dictate the relationship between fat-free mass (FFM) and fat mass (FM) with an emphasis on low fat mass and limited, perhaps minimal, muscle mass.

**PURPOSE:** To examine the relationship and limits of FFM and FM accumulation in individuals with a history of physical conditioning and competition.

**METHODS:** Males (age:  $21.2 \pm 3.1$  yrs) and females (age:  $21.8 \pm 4.4$  yrs) were divided into two groups: Controls (CON) were military personnel participating in high-level of physical conditioning (males:  $n=52$ ; females:  $n=24$ ) and Athletes (ATH: males:  $n=379$ ; females:  $n=32$ ) were competing at the NCAA, national, international, or Olympic level. Body composition was determined by hydrostatic weighing, BodPod, or ultrasound.

**RESULTS:** Height and body mass were greater in ATH. The relationship between height and weight was significant in all groups; with the slopes of the regression lines (males: 2.17 kg cm; females 1.07 kg cm) being greater and intercepts (males: -298 kg; females 112 kg) being less in ATH ( $R^2=0.596$  and  $0.398$ ). The relationship between body mass and % fat ( $R^2=0.76$ ) and FM ( $R^2=0.87$ ) was significant in male ATH, but only FM ( $R^2=0.44$ ; %Fat  $R^2=0.05$ ) was related to body mass in female ATH. There was a strong, curvilinear relationship between FFM and FM in male ATH ( $y=0.599^{0.0391x}$ ;  $R^2=0.71$ ), but not female ATH ( $y=0.16x+8.2$ ;  $R^2=0.07$ ) or C. In males there appears to be a threshold such that athletes with  $> 80$  kg FFM have significantly greater height (8-13 cm), body mass (30-41 kg), % fat (~8%), and fat mass (13-15 kg). The difference in body mass between female ATH and CON is almost entirely due to FFM accumulation as % fat (CON:  $26.9 \pm 4.5\%$ ; ATH:  $23.3 \pm 4.9\%$ ) and FM (CON:  $17.9 \pm 3.9$  kg; ATH:  $16.9 \pm 4.9$  kg) are similar.

**CONCLUSION:** ATH are taller with greater body mass than CON. Male athletes who compete in "weight class" sports carry less FFM but similar FM at the same height and body mass as non-weight class athletes. Accumulation of FM appears to accompany FFM in males, whereas females appear to carry a constant, larger component of FM throughout the body mass range.

**Appendicular Lean Soft Tissue Can Be Well Predicted From Simple Anthropometric Measurements**

Sigurbjörn Á. Arngrímsson, Ágústa Tryggvadóttir, Andrés T. Eyjólfsson, Gunnar A. Davíðsson, Erlingur B. Richardsson, Kári Jónsson, Anna S.

Ólafsdóttir, *University of Iceland, Laugarvatn, Iceland.* (Sponsor: Ellen M. Evans, FACSM)

Email: samgrim@hi.is

(No relationships reported)

Anthropometric measurements of the upper arm have been used to assess skeletal muscle (SM) and nutritional status. However, these assessments have never been validated.

**PURPOSE:** To evaluate the strength of the Frisancho equation (upper arm SM area) for predicting SM and to predict appendicular lean soft tissue (ALST) from simple anthropometric measurements.

**METHODS:** Height, weight, upper arm circumference, and seven (subscapular, triceps, chest, midaxillary, abdomen, suprailiac, and thigh) skinfolds (7SKF) were measured in 96 (50 women,  $169.0 \pm 6.5$  cm,  $63.5 \pm 7.4$  kg,  $26.2 \pm 2.5$  cm,  $118.3 \pm 31.4$  mm, 46 men,  $182.9 \pm 7.3$  cm,  $75.9 \pm 11.4$  kg,  $28.9 \pm 2.8$  cm,  $83.7 \pm 38.8$  mm) healthy 18 year-olds. Estimates of whole body and regional body composition were obtained via dual energy X-ray absorptiometry and ALST was used to calculate whole body SM. Subjects were randomized into prediction equation developmental (DEV,  $n=66$ ) and cross-validation (C-V,  $n=30$ ) groups.

**RESULTS:** No differences were found in the physical characteristics between the DEV and C-V groups ( $p=0.097-0.858$ ). The upper arm SM area from the Frisancho equation predicted ALST ( $22.5 \pm 5.4$  kg,  $r=0.74$ ,  $SEE=3.8$  kg,  $p<0.001$ ), whole body SM ( $26.3 \pm 6.3$  kg,  $r=0.73$ ,  $SEE=4.5$  kg,  $p<0.001$ ), and upper arm LST ( $2.8 \pm 0.9$  kg,  $r=0.69$ ,  $SEE=0.7$  kg,  $p<0.001$ ) moderately well in the whole group. An equation predicting ALST from weight, 7SKF and gender cross-validated well ( $R=0.97$ ,  $SEE=1.5$  kg,  $p<0.001$ ) as did equations based on weight, sum of 3 SKF (triceps, abdomen and thigh), and gender ( $R=0.97$ ,  $SEE=1.6$  kg,  $p<0.001$ ), and weight, suprailiac, and gender ( $R=0.96$ ,  $SEE=1.7$  kg,

p<0.001). In all these prediction equations, the slope and intercept did not differ from the line of identity (p>0.05). The final prediction equations were based on the whole sample: 1)  $ALST = -0.7638 + 0.3763 \times \text{weight} - 0.0423 \times 7SKF + 2.9097 \times \text{gender}$ , 2)  $ALST = 0.9065 + 0.3608 \times \text{weight} - 0.0741 \times 3SKF + 2.3748 \times \text{gender}$ , and 3)  $ALST = -1.7776 + 0.3628 \times \text{weight} - 0.1649 \times \text{suprailiac} + 3.8679 \times \text{gender}$ . The error scores from all the final equations were normally distributed, homoscedastic, and not related to predicted scores ( $r=0$ ,  $p>0.997$ ).

**CONCLUSION:** Although the Frisancho equation does indicate ALST and whole body SM, simple anthropometric measurements better predict ALST, which can then be used to estimate whole body SM.

(No relationships reported)

The Jackson-Pollock-Ward (JPW) generalized equations for men and women (1978, 1980) were developed primarily with lean, non-Hispanic white (NHW) subjects. Our research (2008) confirmed that the JPW equations give biased percent fat (BF%) estimates when applied to ethnically diverse young men and women with higher levels of obesity.

**PURPOSE:** To develop valid prediction equations to estimate BF% measured with dual-energy X-ray absorptiometry (DXA) in diverse, contemporary young adults.

**METHODS:** The subjects included 435 men and 712 women from the TIGER study who ranged in age from 17 to 35 y. The racial/ethnic composition for men and women, respectively, was: NHW, 43.5% and 32.9%; Hispanic, 28.1% and 30.8%; and African-American (AA), 39.0% and 25.7%. The subjects BF% was measured from 1 to 3 times over 9 months (total observations = 701 for men and 1,144 for women). Linear mixed models (LMM) regression was used to develop two different equations using DXA BF% as the dependent variable. Model 1 included sum of skinfolds (SS; chest, abdomen, and thigh for men; triceps, suprailium and thigh for women). Model 2 included BMI and waist (WC, men) or hip circumference (HC, women). Race/ethnic group was included as a categorical variable in each model with NHW as the referent.

**RESULTS:** For men, both the SS and BMI equations resulted in a regression weight for AA men that was statistically significant compared to NHW men, while the regression weight for Hispanic men was within chance variation of NHW men. The standard errors of estimate were 3.08% for the SS model and 3.98% for the BMI model in men. For women, DXA BF% of Hispanic women was 2.5% higher than NHW for a given SS, while the regression weight for AA women was within chance variation of NHW women. The relation between BMI and BF% was quadratic, and hip circumference was related to BF% independent of BMI. Controlling for BMI and HC, the BF% of AA women was 1.7% lower and the Hispanic BF% was 1.7% higher compared to NHW women. The standard errors of estimate were 4.0% for the SS model and 3.8% for the BMI model in women.

**CONCLUSIONS:** The LMM results confirmed that race/ethnicity accounted for significant BF% variance beyond that accounted for by SS or the combination of BMI and WC or HC. The developed SS and BMI equations provide accurate models to estimate DXA BF% in ethnically diverse young men and women.

**Does Body Mass Index Effectively Categorize Body Composition In American Men And Women?**

L. Jerome Brandon, FACSM, Jurine Owen. Georgia State University, Atlanta, GA.  
Email: lbrandon@gsu.edu  
(No relationships reported)

Over the last 30 years, obesity, typically assessed by body mass index (BMI), has increased steadily in Americans. A major question is whether or not the increase represents an increase in body fat?

**PURPOSE:** Therefore, the purpose of this study was to evaluate the relationship between BMI and body fat in American men (M) and women (W).

**METHODS:** One hundred and forty-two adult volunteers with a mean age of 36.1 years (69 M; 73 W) were measured for height, weight, ten skinfolds, waist (WC) and hip circumferences (HC) and percent body fat (%fat) using a Lunar DPX-L dual-energy X-ray absorptiometer (DXA). Data analyses included descriptive assessment, correlations and multiple regression analyses (stepwise).

**RESULTS:** The M and W differed on measures of BMI (W 23.0 and M 25.3 kg/m<sup>2</sup>), DXA %fat (W 30.0, M 19.3%), skinfolds (SF) %fat (W 23.6, M 20.9%), and waist C (W 73.5, M 85.5 cm), but not abdomen SF (W 22.4, M 23.5 mm). When BMI was included in a stepwise regression equation to estimate DXA %fat, an R of 0.75 was observed for the W. Adding abdomen SF to the equation increased R to 0.85 and the SEE decreased from 5.5 to 4.4%. When BMI was used to estimate DXA %fat for the M the R was 0.74. When abdomen SF was added to the equation the R increased to 0.87 and the SEE decreased from 4.7 to 3.5 %. When BMI was used to estimate body fat, it accounts for approximately 55% of the variability in %fat in both M and W with a prediction error of 4.7 to 5.5%. When abdomen SF was added to the regression equation with BMI, the prediction equation accounted for approximately 74% of the variability and the error of estimate decreased by approximately 20%.

**CONCLUSIONS:** These data indicate that adding a simple anthropometric variable (abdomen SF) to BMI increases its prediction of body fat and thus improves estimates of obesity with an inexpensive and easy to use procedure.

**Effects Of Three Months Of Pilates-based Exercise In Women On Body Composition**

Ana Isabel Carvalho Cruz-Ferreira, Catarina Lino Neto Pereira, FACSM, Jorge Azevedo Fernandes. University of Évora, Évora, Portugal.  
Email: anacruzferreira@gmail.com  
C. Pereira Presenting  
(No relationships reported)

**PURPOSE:** Body Composition is one of the indicators of the health problems. The role of physical activity on the effects on Body Composition has been investigated. However, studies regarding Pilates, a popular physical activity, are rare. The purpose is to analyze the effects of three months of the Pilates-based mat exercise program (PME) on Body Composition.

**METHODS:** Sixty eight women, aged 25-55 yrs, were randomly assigned to either an exercise group (n=43, 41.0±7.2 yrs) to participate in a PME in a 12-week classes of 60 minutes, 2 times per week, or to a control group (n=25, 40.0±7.7). Dual-energy x-ray Absorptiometry (DXA), evaluated Fat Mass (g) (FM), the Lean Mass (g) (LM) and the Percentage Fat Mass (%) (PF) from upper and lower limbs, and Total Body Mass (g) were measured variables. All variables were measured at baseline and again after 12 weeks. Repeated measures of ANOVA, were run in SPSS version 15.0.

**RESULTS:** Comparison revealed significant increases on LM: upper body left limb (63.8 g, p=0.001), upper body right limb (75.4g, p=0.002), lower body left limb (88.6 g, p=0.030), lower body right limb (116.3g, p=0.014) with significant decreases on FM: upper body right limb (-75.8 g, p=0.045) and on PF: upper body right limb (-2 %; p=0.008), lower body right limb (-0.9 %; p= 0.015) on the exercise group. Related to Total Body Mass, the exercise group did not show statistically significant differences. Control group did not showed significant differences between baseline and after 12 weeks in any variables. There were no statistically significant differences between exercise group and control group at baseline.

**CONCLUSION:** This study demonstrates that the exposure of women to PME during 12 weeks, for two 60-minutes sessions per week improve Body Composition, namely

(No relationships reported)

Previous research has shown that body mass index (BMI), waist circumference (WC) and race were independent sources of abdominal adiposity variation measured by computed tomography. When BMI and WC are controlled for, African-Americans had less abdominal adiposity than Caucasian men and women.

**PURPOSE:** We examined as a function of gender the relationship between race/ethnicity (White-W, Hispanic-HH, and African-American-AA) and abdominal adiposity.

**METHODS:** Subjects (age 18-30 y) were randomly selected from the Training Interventions and Genetics of Exercise Response (TIGER) Study. The sample included 128 subjects split into six groups based on gender and race/ethnicity (W, H and AA men and women). Dual energy x-ray absorptiometry (DXA) was used to measure both whole body fat and abdominal fat (L1 to L4) using a whole body scan. Data was analyzed using general linear models (GLM). The dependent variable was DXA abdominal fat and the independent variables were gender, race/ethnicity and gender by race/ethnicity interaction. WC and BMI were covariates.

**RESULTS:** The full GLM accounted for 87% of DXA abdominal fat. An examination of the GLM results showed that gender, WC and BMI were significantly related ( $p < 0.001$ ) with DXA abdominal fat. Using W subjects as the referent group, an analysis of race/ethnicity showed that the H ( $p = 0.643$ ) and H by gender interaction ( $p = 0.215$ ) terms were not statistically significant. In contrast, both the AA ( $p < 0.001$ ) and AA by gender interaction ( $p = 0.041$ ) were statistically significant. The GLM analysis showed that, controlling for WC and BMI, DXA fat was significantly lower in AAs compared to W men and women, and the difference tended to be greater for females.

**CONCLUSIONS:** These results are consistent with the published data from The HERITAGE Family study. With WC and BMI statistically controlled, the adiposity of AA men and women is less than W men and women. These results extend the generalizability to H men and women and show they are not different from W men and women in abdominal adiposity. The consistency between the TIGER and HERITAGE results with W and AA subjects supports the value of using DXA to measure abdominal adiposity.

**The Effects Of Jogging Versus Walking Training On Bone Mineral Density In Obese Japanese Men.**

Hiroyuki Ohkubo<sup>1</sup>, Hiroyuki Sasai<sup>1</sup>, Yasutomi Katayama<sup>2</sup>, Miki Eto<sup>1</sup>, Takehiko Tsujimoto<sup>1</sup>, Kiyoji Tanaka, FACSM<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Ibaraki, Japan. <sup>2</sup>Kogakkan University, Ise, Mie, Japan.

Email: hiro0621@stat.taiiku.tsukuba.ac.jp

(No relationships reported)

**BACKGROUND:** Jogging is more effective for increasing bone mineral density (BMD) than walking, even though both modes can increase BMD. High-impact exercise is known to be beneficial for bone health. A previous study has reported that seven-months of walking with exercise intensities above the anaerobic threshold (AT) is more effective than below-AT intensity in preventing bone loss among postmenopausal women. However, it remains unclear whether shorter-term (3 months) exercise is effective for maintaining BMD in men.

**PURPOSE:** The purpose of this study was to compare the effects of 3 months jogging versus walking training on BMD in obese men.

**METHODS:** Twenty-eight Japanese men participated in this study. They were non-randomly divided into a jogging group ( $n = 14$ , age:  $44.3 \pm 9.6$  yr, body mass index [BMI]:  $28.9 \pm 2.0$  kg/cm<sup>2</sup>) or walking group ( $n = 14$ , age:  $49.0 \pm 8.1$  yr, BMI:  $28.2 \pm 1.7$  kg/cm<sup>2</sup>). Both groups participated in 90-minute supervised exercise sessions (mild jogging or brisk walking plus light strength training) on 3 d/wk for 3 months. The participants attempted to keep exercise heart rate above the AT (jogging group) or near the AT (walking group). Fat mass, lean mass and BMD were measured using dual-energy X-ray absorptiometry (DXA) at pre and post exercise training. A limitation of this study is that DXA instruments used were QDR4500 (Hologic) for the jogging group and DPX-NT (Lunar) for the walking group.

**RESULTS:** Attendance rate at the exercise sessions was 74.4% in jogging group and 79.3% in walking group (no significant difference). Exercise training significantly reduced body weight (jogging group:  $-2.8 \pm 2.6$  kg, walking group:  $-2.5 \pm 2.6$  kg), BMI (jogging group:  $-1.0 \pm 0.9$  kg/cm<sup>2</sup>, walking group:  $-0.8 \pm 0.9$  kg/cm<sup>2</sup>) and fat mass (jogging group:  $-2.6 \pm 1.8$  kg, walking group:  $-2.5 \pm 1.7$  kg). Although BMD remained unchanged in both groups, two-way (group by time) repeated ANOVA revealed a significant interaction in BMD (jogging group:  $0.01 \pm 0.02$  g/cm<sup>2</sup>, walking group:  $-0.01 \pm 0.02$  g/cm<sup>2</sup>,  $P < 0.05$ ). Similar results were found by using analysis of covariance (ANCOVA) even after adjustments for age, baseline BMI, fat mass and lean mass ( $P < 0.01$ ).

**CONCLUSIONS:** These results suggest that jogging is a more effective mode of exercise for maintaining BMD than walking, despite the short duration of only 3 months.

**Differences In Physical Activity Levels Of Young Adults Using Percent Fat Cut-points Versus Body Mass Index**

Michael Zhanovec<sup>1</sup>, GEORGIANNA TUURI<sup>2</sup>, J.M. LOFTIN, FACSM<sup>3</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>LSU AgCenter, Baton Rouge, LA. <sup>3</sup>University of Mississippi, University, MS.

Email: mzanovec@agcenter.lsu.edu

(No relationships reported)

**PURPOSE:** Use of universal cut-points to categorize overweight and obesity based on the body mass index (BMI; in kg·m<sup>-2</sup>) is controversial. The BMI assumes that after adjusting weight for height, all individuals have the same relative body fatness independent of age, gender, race, and level of physical activity (PA). The purpose of this study was to examine self-reported levels of PA using percent body fat (%BF) cut-points versus BMI cut points in college students.

**METHODS:** Subjects ( $n = 278$ ; 50% male, 60% White) completed the International Physical Activity Questionnaire (IPAQ), were measured for height and weight, and completed a total body DXA scan to determine percent body fat. Physical activity levels were quantified in total, vigorous, moderate, and walking MET-minutes per week (MET-min·wk<sup>-1</sup>). Excess body fatness was defined as  $\geq 25\%$  in males and  $\geq 39\%$  in females. Overweight/obesity was defined as a BMI  $\geq 25$  kg·m<sup>-2</sup>. Descriptive statistics were calculated for males and females separately. Independent  $t$  tests were used to compare means by %BF or BMI category. Level of significance was set at  $p < 0.05$ .

**RESULTS:** Mean values of BMI, %BF, and MET-min·wk<sup>-1</sup> were:  $26.1 \pm 3.9$ ,  $18.4 \pm 7.6$ , and  $2927 \pm 1513$  in males; and  $23.2 \pm 3.9$ ,  $30.5 \pm 7.4$ , and  $1873 \pm 1150$  in females. When PA levels were compared using %BF cut points, significant differences were observed in total activity (males only) and vigorous activity in males and females. Conversely, when categorized by BMI, no differences were observed between groups.

**CONCLUSION:** These results suggest that %BF cut-points, rather than BMI, should be used to more accurately reflect PA levels of young adults.

**Who Attempts To Lose Weight? A Study Using The Health Information National Trends Survey (hints)**

Michelle Y. Martin, Maria Pisu, Polly Kratt, Young Kim. *University of Alabama at Birmingham, Birmingham, AL.*  
Email: mymartin@uab.edu  
(No relationships reported)

**PURPOSE:** In 2001, the Surgeon General issued a "Call to Action to Prevent and Decrease Overweight and Obesity." Yet in 2007, an estimated 37% Americans were overweight and 26% obese. Identifying the characteristics of individuals who attempt weight loss and those who do not may provide important information for weight loss interventions.

**METHODS:** Data from the 2005 HINTS was used to explore weight loss attempts among the general population. Participants with BMI  $\geq 25$  (N=3193) were stratified by their report of weight loss attempts in the past year (73% Yes vs. 27% No). We used t-tests and chi-square analysis to compare group characteristics and logistic regression to identify independent predictors of weight loss attempts.

**RESULTS:** Participants were primarily white (83%), obese (Mean BMI  $30.3 \pm 5.2$ ) and middle-aged (Mean age:  $53.12 \pm 16.7$  years.) Groups did not differ in weight loss behaviors such as hours of weekly exercise, fruits or vegetables consumed per day, or time spent watching television (all p values  $> .05$ ). Logistic results suggested that those more likely to report weight loss attempts were 1) younger (OR 1.79 for those 18-34; OR 1.77 for those 35-49; OR 1.80 for those 50-64, and OR 1.51 for those 65-74 compared to those 75+); 2) spoke to friends/family about their health (OR 2.20; CI 1.83-2.66); 3) had a college degree (OR 1.64 CI 1.23-2.19 compared to those with  $<$  high school); and reported poorer health (OR 2.16 for those in poor health; 2.54 for fair health; 2.27 for good health; and 1.82 for very good health, compared to those in excellent health) and 5) were separated (OR 2.09 CI 1.02- 4.29 compared to widowed). Additional marital status categories were not significant. Minorities were less likely than whites (OR 0.70; CI 0.59-0.84) to report weight loss attempts.

**CONCLUSIONS:** Although reporting attempts to lose weight, overweight and obese individuals did not show any difference in weight loss behaviors compared to those who do not attempt. Weight loss programs may be especially needed for minority, less educated, older individuals, and those who perceive better health. Social support for health may also play a key role.

### 1452 Board #54 May 27 11:00 AM - 12:30 PM Impact Of Gender On Substrate Utilization During Treadmill Walking At A Self-selected Pace

Cosme F. Buzzachera<sup>1</sup>, Hassan M. Elsangedy<sup>2</sup>, Heriberto Colombo<sup>2</sup>, Kleverton Krinski<sup>2</sup>, Bruno V. Santos<sup>2</sup>, Wagner Campos<sup>2</sup>, Carlo Baldari<sup>3</sup>, Laura Guidetti<sup>3</sup>, Sergio G. DaSilva<sup>2</sup>, Fredric L. Goss, FACSM<sup>4</sup>. <sup>1</sup>Università Degli Studi di Roma "Foro Italico", Rome, Italy. <sup>2</sup>Federal University of Parana, Curitiba, Brazil. <sup>3</sup>Università Degli Studi di Roma, Rome, Italy. <sup>4</sup>University of Pittsburgh, Pittsburgh, PA.  
Email: franklin\_buzza@hotmail.com  
(No relationships reported)

**PURPOSE:** To determine the impact of gender on substrate utilization during exercise at a self-selected pace.

**METHODS:** Healthy male (n = 17) and female (n = 17) subjects performed a maximal exercise grade test and a 20-min bout of treadmill walking at a preferred pace in order to determine fat and carbohydrate (CHO) oxidation rates. Gas exchange measurements were performed throughout the tests and stoichiometric equations were used to calculate substrate oxidation rates. For each individual, a best-fit polynomial curve was constructed of fat oxidation rate ( $\text{g} \cdot \text{min}^{-1}$ ) vs exercise intensity ( $\% \text{VO}_{2\text{max}}$ ) and used to obtain the following variables: (a) the maximal rate of fat oxidation (MFO) measured over the entire range of exercise intensities; (b) the exercise intensity at which the MFO was observed ( $\text{Fat}_{\text{max}}$ ); and (c)  $\text{Fat}_{\text{max}}$  zone, a range of exercise intensities with fat oxidation rates equal to  $\pm 10\%$  of  $\text{Fat}_{\text{max}}$ . Independent t-tests were used to examine gender differences in substrate oxidation rates during the maximal exercise test and 20-min bout of walking at a preferred pace.

**RESULTS:** The MFO was similar between men ( $0.41 \pm 0.22 \text{ g} \cdot \text{min}^{-1}$ ) and women ( $0.39 \pm 0.14 \text{ g} \cdot \text{min}^{-1}$ ). However, the  $\text{Fat}_{\text{max}}$  was lower ( $P < 0.01$ ) in men ( $36.7 \pm 6.5\% \text{VO}_{2\text{max}}$ ) than in women ( $44.5 \pm 5.4\% \text{VO}_{2\text{max}}$ ). Similarly, the "low" ( $28.4 \pm 5.2$  and  $33.3 \pm 3.6\% \text{VO}_{2\text{max}}$ ) and "high" ( $45.1 \pm 8.2$  and  $56.0 \pm 7.5\% \text{VO}_{2\text{max}}$  for men and women, respectively) borders of the  $\text{Fat}_{\text{max}}$  zone were lower ( $P < 0.05$ ) in men than in women. During treadmill walking at a preferred pace, the CHO oxidation rates were greater ( $P < 0.01$ ) in men ( $1.40 \pm 0.65 \text{ g} \cdot \text{min}^{-1}$ ) than in women ( $0.87 \pm 0.51 \text{ g} \cdot \text{min}^{-1}$ ), but there were no gender differences in the fat oxidation rates ( $0.24 \pm 0.13$  and  $0.24 \pm 0.08 \text{ g} \cdot \text{min}^{-1}$  for men and women, respectively). However, the contribution of fat oxidation to total energy expenditure (EE) was greater ( $P < 0.05$ ) in women ( $45.5 \pm 12.6\%$ ) than in men ( $32.7 \pm 16.4\%$ ), despite no differences in the relative exercise intensity between the men ( $37.5 \pm 10.7\% \text{VO}_{2\text{max}}$ ) and women (and  $40.3 \pm 7.2\% \text{VO}_{2\text{max}}$ ).

**CONCLUSION:** Although men and women self-selected similar relative exercise intensity, the contribution of fat oxidation to total EE is significantly greater in women than in men. Interestingly, both genders self-selected an exercise intensity that falls within the  $\text{Fat}_{\text{max}}$  zone.

---

### 1453 Board #55 May 27 11:00 AM - 12:30 PM Effects Of Exercise Intensity On Post-prandial Glucose Disposal In Abdominally Obese Adults

Nathan Y. Weltman, Corey A. Rynders, Glenn A. Gaesser, FACSM, Eugene J. Barrett, Arthur Weltman, FACSM. *University of Virginia, Charlottesville, VA.*  
(No relationships reported)

**INTRODUCTION:** The effects of acute exercise on post-prandial glucose disposal are equivocal.

**PURPOSE:** To examine the impact of exercise intensity on the blood glucose and insulin responses to an oral glucose tolerance test (OGTT).

**METHODS:** Eleven abdominally obese adults (n=11; age,  $25.2 \pm 1.3$  yrs; BMI,  $38.5 \pm 1.5 \text{ kg/m}^2$ ; % body fat,  $43.9 \pm 2.1\%$ ; waist circumference,  $114.2 \pm 4.1 \text{ cm}$ ;  $\text{VO}_{2\text{peak}}$ ,  $17.7 \pm 1.1 \text{ ml/kg/min}$ ) completed a  $\text{VO}_{2\text{peak}}$ /lactate threshold (LT) protocol plus 4 randomly assigned exercise sessions; 1) rest (C; no exercise); 2) low, (L; 50% of difference between LT and rest); 3) moderate (M; @ LT); and 4) high, (H; 50% of difference between LT and  $\text{VO}_{2\text{peak}}$ ). Sessions were calorically equivalent to 200kcal, calculated from min-by-min energy expenditure by open circuit spirometry. One hour after the onset of exercise, subjects received a 75-g OGTT. Glucose and insulin were assayed from blood samples collected before (-30 to 0 min), during (0 to 60min) and after exercise (60 to 240min) at 5-10min intervals.

**RESULTS:** There were no significant differences among conditions in post OGTT 1) area under the glucose concentration curve ( $\text{mg/dl}/180\text{-min}$ ; C,  $21690 \pm 1288$ ; L,  $21691 \pm 1192$ ; M,  $22502 \pm 1369$ ; H,  $21748 \pm 1152$ ;  $p=.80$ ) and 2) area under the insulin response curve ( $\mu\text{IU/ml}/180\text{-min}$ ; C,  $9936 \pm 1091$ ; L,  $10222 \pm 778$ ; M,  $9823 \pm 876$ ; H,  $9771 \pm 894$ ;  $p=.97$ ,  $n=9$ ). Blood glucose concentrations returned to baseline by 180-min after OGTT in all experimental conditions ( $\text{mg/dl}$ ; baseline, C=89, L=92, M=94, H=93; 180-min, C=84, L=94, M=90, H=89;  $p=.887$ ).

**CONCLUSIONS:** In abdominally obese adults a single bout of exercise did not affect post-prandial glucose and insulin responses.

### 1454 Board #56 May 27 11:00 AM - 12:30 PM

## Effects Of Carbohydrate Supplementation On The Ratings Of Perceived Exertion- Blood Lactate Relationship

Jennifer Steiner, Alyssa Curmaci, Jim Patrie, Glenn Gaesser, FACSM, Arthur Weltman, FACSM. *University of Virginia, Charlottesville, VA.*

(No relationships reported)

**PURPOSE:** To examine the effects of carbohydrate (CHO) ingestion on the RPE-blood lactate relationship during incremental and constant effort exercise.

**METHODS:** Six male and three female subjects (mean age=27.2±8.2yrs; ht=174.5±13.5cm; wt=68.9±12.5kg; body fat=18.5±8.3%), completed two incremental cycling LT/VO<sub>2</sub>peak tests followed by two 45-minute production trials. Either ~240 ml of a carbohydrate or placebo (PL) was ingested before and every 15 min during exercise.

**RESULTS:** No differences were observed between conditions at LT, 2.5 and 4.0 mM and peak. Within the CHO condition: VO<sub>2</sub>= 25.0, 32.6, 37.5, 47.2 ml/kg\*min<sup>-1</sup>; poweroutput=123.3, 170.7, 200.1, 241.7 watts; RPE= 12.8, 15.4, 17.2, 19.3; and HR= 137.4, 156.8, 168.7, 187.7 bpm at LT, 2.5mM, 4.0mM and peak, respectively. Within PL VO<sub>2</sub>= 24.7, 32.5, 36.8, 45.7 ml/kg\*min<sup>-1</sup>; power output= 130.0, 175.4, 201.9, 240.0 watts; RPE= 12.1, 15.0, 17.0, 19.3; and HR= 134.9, 157.9, 169.6, 187.2 bpm, respectively. In the CHO condition blood glucose was higher (P < 0.001) and a trend was observed for lower RPE over time (P = 0.07). During the production trials (RPE of 16) in the CHO condition higher blood glucose area under the curve (AUC) (PL: 204.1±79.3; CHO: 220.6±18.5 mM, P=0.039) and a trend for greater total work (PL: 448.5±73.8; CHO 470.5±65.6 kJ, P=0.089) were observed.

**CONCLUSION:** We conclude that: 1) CHO ingestion does not alter the blood lactate-RPE relationship during incremental LT/VO<sub>2</sub>peak cycling; and 2) carbohydrate supplementation during exercise eliciting high RPE may increase work output during training sessions.

1455 Board #57 May 27 11:00 AM - 12:30 PM

### Maltodextrin Supplementation Enhanced Performance In Elite Athletes Of Mountain Biking During Competition

Raul Osiecki<sup>1</sup>, Carlos Ricardo Maneck Malfatti<sup>2</sup>, Erivelton Fontana de Laat<sup>2</sup>, Larissa T. Soler<sup>2</sup>, Irene W. Bronkhorst<sup>2</sup>, Ana Karina Hlatiki<sup>2</sup>, Gabrielle Seidl Juruena<sup>3</sup>. <sup>1</sup>Universidade Federal do Paraná, Curitiba, Brazil. <sup>2</sup>Universidade Estadual do Centro-Oeste, Irati, Brazil. <sup>3</sup>Hospital Santa Casa, Irati, Brazil.

Email: raulk@ufpr.br

(No relationships reported)

The observed improvements in performance with CHO ingestion have been attributed to maintenance of plasma glucose and glycogen availability. However, the supplementation with maltodextrin-induced modifications in heart rate intensity and performance in different moments of competition for Mountain Biking has not been reported.

**PURPOSE:** Therefore the aim of this study was to analyze the effect of maltodextrin supplementation in heart rate intensity and time competition spent in each lap; cardiorespiratory and blood glucose response in maximal test performed in laboratory in elite Mountain Biking athletes. **METHOD:** A total of seven male bikers [age (years): 28.4 ± 10.6; body fat (%): 9.46 ± 3.76; VO<sub>2</sub>max (mL/kg/min): 61.13 ± 8.4], participated in double-blind type study. The athletes received supplementation with maltodextrin (1g/kg) or placebo (light tangerine juice) dissolved in distilled water 20 min before competition (7 laps with 2 Km each) or laboratory maximal test. A incremental exercise test on a cyclo-ergometer at 60 rpm, starting at 50 W with increases by 25 W every 3 min until exhaustion with maltodextrin or placebo use was performed (cycloergometer Biotec 1800-CEFISE®) to determined alterations in maximal heart rate, Wattsmax, VO<sub>2</sub>max, VEmax, VO<sub>2</sub> in the ventilatory threshold (VT) using a gas exchange analyzer (ParvoMedics TrueOne® 2400). The heart rate was monitored each 5 s during the entire competition (Polar Team System®). The comparisons between time spent in each lap (7 laps) during competition and laboratory variables comparisons (maltodextrin vs. placebo) were made using two-way ANOVA.

**RESULTS:** In the competition, the maltodextrin supplementation enhanced performance, reducing 26 s in mean time spent for all laps (CHO: 549 ± 56.3 s vs. Placebo: 575 ± 69.5 s; p<0.05). In laboratory test, maltodextrin increase the blood glucose during exercise (CHO: 104.1 ± 20.9 mg/dL vs. Placebo: 88.2 ± 5.3 mg/dL; p<0.05) but has no effect in cardiorespiratory variables.

**CONCLUSION:** Maltodextrin enhanced performance during Mountain Biking competition, showing that maltodextrin supplementation is a good strategy for these competitors. The maintenance in blood glucose associated with maltodextrin use suggests improvements in performance through reduction of muscle glycogen use.

1456 Board #58 May 27 11:00 AM - 12:30 PM

### Carbohydrate Oxidation From A Carbohydrate Gel Compared To A Drink During Exercise

Asker E. Jeukendrup, FACSM<sup>1</sup>, Beate Pfeiffer<sup>1</sup>, Trent Stellingwerf<sup>2</sup>, Eric Zaltas<sup>2</sup>. <sup>1</sup>University of Birmingham, Birmingham, United Kingdom. <sup>2</sup>Nestlé Research Center, Lausanne, Switzerland.

(No relationships reported)

Studies investigating exogenous carbohydrate (CHO) oxidation from CHO drinks during exercise have revealed that ingestion of a mixture of glucose (GLU) and fructose (FRU) leads to 20-50% higher CHO oxidation rates as compared to GLU alone. However, athletes often ingest CHO in the form of gels (semi-solid form). It is currently not known if CHO ingested in the form of a gel is oxidised as effectively as a drink.

**PURPOSE:** To investigate exogenous CHO oxidation from CHO provided in either semi-solid (GEL) or solution (DRINK) form, when delivered at relatively high rates during cycling exercise.

**METHODS:** Eight well trained cyclists (34±3yrs; 76±3kg; 1.78±0.02m; VO<sub>2</sub>max: 61±3ml/kg/min) performed three exercise trials in random order. The trials consisted of cycling at 59±1% VO<sub>2</sub>max for 180min while receiving one of the following three treatments: GEL plus plain water, DRINK, or plain water. Both CHO treatments delivered GLU plus FRU in a ratio of 2:1 at a rate of 1.8g/min. Fluid intake was matched between treatments.

**RESULTS:** Exogenous CHO oxidation from both treatments showed a similar time course with peak exogenous CHO oxidation rates being reached at the end of 180min exercise. Peak exogenous CHO oxidation rates were not different between GEL and DRINK (1.44±0.1g/min vs. 1.42±0.08g/min, respectively, p=0.40). Oxidation efficiency was also similar between the GEL and DRINK trial (71±5% vs. 69±5%, respectively, p=0.36).

**CONCLUSIONS:** This study demonstrated that a GLU+FRU mixture is oxidised to the same degree when administered as a semi-solid GEL or liquid DRINK. Both forms of CHO administration led to similarly high peak oxidation rates and showed similar oxidation efficiencies.

### Gastrointestinal Discomfort In Moderate Running: Effect Of Body Mass Adjusted Carbohydrate-electrolyte Drink Volume

Rafael Pires Silva, Janaina Lubiana Altoé, Mônica Ribeiro Saldanha, Felipe Tadeu Melo Reis, Dayane Graciele Jesus Miranda, Fabrícia Geralda Ferreira, João Carlos Bouzas Marins. *Federal University of Viçosa, Viçosa, MG, Brazil.*

Email: rafael.pires@ufv.br

(No relationships reported)

Especially in endurance exercise such as marathon and triathlons, is not uncommon to see an increased incidence of GI symptoms associated with food and beverage intake before and during exercise.

**PURPOSE:** To investigate the effect of two volume of carbohydrate-electrolyte (CHO) drink according to the body mass (BM) during one-hour running performance on the gastrointestinal (GI) tract and to verify if BM could be an optional parameter of fluid replacement.

**METHODS:** Thirty-two individuals; 16 men ( $23.3 \pm 1.3$  years) and 16 women ( $21.7 \pm 1.7$  years) performed three runs on a treadmill at 75%  $\dot{V}O_{2max}$  during 60 min. In this time, the subjects drank a 6% CHO solution in set volumes of 2 or 3 mL  $\cdot$  kg<sup>-1</sup> BM (LV and HV; respectively) every 15 minutes. GI complaints were evaluated by a short questionnaire requested to verbally answer at every 15 minutes. Glycemia, ratings of perceived exertion (RPE), and thirst sensation were also evaluated at this same period of time.

**RESULTS:** The most occurrences of GI complaints were observed in men than women. The most frequency of GI complaints was related at 45 and 60 min. The most frequent symptom in HV was urging to urinate indicated by 75% men at 60 min and 81.2% women at 45 min. In LV this perceptual were of 62.5% and 50% for men and women respectively. There were no register of severe symptoms for women in all the trials and for men during LV trial. Only one man in HV indicated a score 6 for severe symptoms (stomach problems, bloated feeling and stomach cramps) from 30 minutes. At 15 min both in HV and in LV was observed the lower glycemic mean for men ( $5.19 \pm 0.57$  mmol.L<sup>-1</sup>;  $5.16 \pm 0.72$  mmol.L<sup>-1</sup> respectively) and women ( $5.06 \pm 0.61$  mmol.L<sup>-1</sup>;  $4.83 \pm 0.46$  mmol.L<sup>-1</sup>). At 60-min LV women presented a light lower thirst sensation than men ( $p = 0.02$ ). In all the trials RPE was higher ( $p < 0.001$ ) at 60 min than at 15 min and at 45 min than at 30 min.

**CONCLUSION:** The data demonstrate that ingestion of 2 or 3 mL.kg<sup>-1</sup> BM of a 6% CHO drink at every 15-min during 60-min run is effective in maintenance of blood glucose and did not caused severe GI symptoms that would compromise performance and health, presuming that, the use of body mass as an optional parameter of fluid replacement is rising such as practical and nonaggressive method for studies involving the GI tract.

**1458 Board #60 May 27 11:00 AM - 12:30 PM**  
**Effect Of Issued Meals On Muscle Glycogen Levels In Wildland Firefighters**

Tyler J. Tucker, John S. Cuddy, Dustin R. Slivka, Walter S. Hailes, Brent C. Ruby, FACSM. *The University of Montana, Missoula, MT.*  
(No relationships reported)

Wildland fire suppression offers a unique opportunity to study physiological stress during arduous job tasks (hiking steep terrain, digging, sawing, and watering) in extreme environmental conditions with low food availability. The energy demands of wildland firefighters (WLFF) during fire suppression have been well documented. However, previous studies have yet to determine the effect of laborious wildfire suppression on muscle substrate use.

**PURPOSE:** The purpose was to determine the effects of wildfire suppression on muscle glycogen utilization in WLFFs.

**METHODS:** Interagency Hot Shot WLFFs (n=12) participated in the study (n=6 on two separate days, days 1, 2). Muscle biopsies were obtained from the *vastus lateralis* pre and post work shift. Activity was measured using activity monitors strategically positioned on the chest and boot. Food was consumed *ad-libitum*, and recorded using a food log.

**RESULTS:** Body weight decreased on Day 1 ( $89.6 \pm 8.4$  to  $89.0 \pm 8.3$  pre and post, respectively,  $p < 0.05$ ), but was similar pre to post work shift on Day 2 ( $83.3 \pm 9.0$  to  $83.5 \pm 8.9$  pre and post work shift, respectively). Muscle glycogen decreased on Day 1 ( $115 \pm 14$  to  $82 \pm 23$  mmol.kg<sup>-1</sup> wet wt.,  $p < 0.05$ ), but was similar pre to post work shift on Day 2 ( $83 \pm 16$  and  $82 \pm 14$  mmol.kg<sup>-1</sup> wet wt.). Muscle glycogen was higher pre-shift Day 1 compared to pre-shift Day 2 ( $115 \pm 14$  versus  $83 \pm 16$  mmol.kg<sup>-1</sup> wet wt., respectively,  $p < 0.05$ ). Activity patterns were similar between the two days. Total energy and carbohydrate intake was greater on Day 1 compared to Day 2.

**CONCLUSION:** Muscle glycogen was different at the beginning of the work shift on consecutive days when participants self-selected work and energy intake patterns. These data suggest that the availability and palatability of provisions, and the potential of inadequate rations may compromise muscle performance during multiple work shifts.

**Effect Of Hyperoxia Recovery After Different Intensity Training On Glucose Tolerance.**

Wen-Chih Lee<sup>1</sup>, Hsin-Yi Hsu<sup>2</sup>, Cheng-Feng Ho<sup>1</sup>, Sun-Chin Yang<sup>1</sup>, John L. Ivy, FACSM<sup>3</sup>, Chia-Hua Kuo<sup>4</sup>. <sup>1</sup>Shih Hsin University, Taipei, Taiwan. <sup>2</sup>Aletheia University, Taipei, Taiwan. <sup>3</sup>University of Texas at Austin, Austin, TX. <sup>4</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)  
Email: wjlee2411@yahoo.com.tw  
(No relationships reported)

**PURPOSE:** To investigate the effects of hyperoxia recovery on glucose tolerance and insulin response after high intensity interval training (HIIT) and moderate aerobic training (MIT).

**METHODS:** The exercise intervention period was 20 min. Subjects ( $20.3 \pm 1.3$  yrs,  $182.5 \pm 5.8$  cm,  $76.6 \pm 13.8$  kg) were exercised at two different intensities on separated days: HIIT (repeating 2 min under 90%  $\dot{V}O_{2max}$  - 1 min rest for 7 times) and MIT (repeating 5 min under 70%  $\dot{V}O_{2max}$  - 5 min under 50%  $\dot{V}O_{2max}$  for 2 times), respectively. After training, each subjects recovered under either normoxic (21%O<sub>2</sub>) or hyperoxic (100%O<sub>2</sub>) conditions for 90 min. Oral glucose tolerance test, insulin, and cortisol were measured at baseline and during the recovery phase. Heart rate variability was recorded at baseline and 30 min after exercise.

**RESULTS:** A significant lower glucose level was noted under HIIT condition with hyperoxia recovery comparing to normoxia ( $p < .05$ ). Insulin levels during OGTT were not different under all conditions. For those subjects after HIIT, but not MIT, lower cortisol level with hyperoxia was found at 60 and 90 min after exercise. Vagal activity significantly decreased at 30 min after both exercises, yet no group difference was found.

**CONCLUSION:** This study demonstrated that hyperoxia can improve insulin sensitivity for glucose disposal during post-exercise recovery. This effect appears to be due to a reduced cortisol response during recovery, and was not associated with autonomic nervous activity.

**Insulin-assisted Glycogen Supercompensation Abolished The Exercise-induced Increase In Glut4 Protein**

Mu-Tsung Chen<sup>1</sup>, Li-Chen Lee<sup>2</sup>, Chia-Hua Kuo<sup>3</sup>. <sup>1</sup>Shin-Chien University, Taipei, Taiwan. <sup>2</sup>Shih-Shin University, Taipei, Taiwan. <sup>3</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)  
Email: fish0510@msn.com  
(No relationships reported)

**PURPOSE:** The purpose of the study was to investigate the interactive effect of exogenous insulin on post-exercise glycogen supercompensation in skeletal muscle.

**METHODS:** Forty eight rats were weight-matched and divided into following 6 groups: control (C), insulin treated (INS), immediately after exercise with previous glycogen supercompensation by exercise (EX0), immediately after exercise with previous glycogen supercompensation by exercise and insulin injection (EX0+INS), exercise followed a 16-hr recovery (EX16), and exercise followed a 16-hr recovery with insulin injection (EX16+INS).

**RESULTS:** Glucose intubation with insulin treatment (INS groups) significantly elevated glycogen storage in various skeletal muscles. Insulin treatment further elevated exercise-induced glycogen supercompensation level (EX16+INS). We also found that residual glycogen content in EX0+INS group was significantly greater than EX0 group after exercise. In addition, we also observed that exercise-increased GLUT4 protein expression was attenuated by insulin-assisted glycogen supercompensated muscle during recovery.

**CONCLUSIONS:** We demonstrated that our glycogen supercompensation protocol by exogenous insulin treatment further elevated glycogen supercompensation in exercised rats. This result has ensured a greater residual muscle glycogen when they performed the same exercise protocol. Furthermore, the amount of intramuscular glycogen storage appears to be a

**Effect Of Resistance Exercise On Dehydroepiandrosterone Sulfate Concentration And Glycemia During Recovery**

Hsien-Chin Yu, Yi-Min Tsai, Chia-Hua Kuo. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L. Ivy, FACSM)

Email: yu6857@tp.edu.tw

(No relationships reported)

Serum dehydroepiandrosterone sulfate (DHEA-S) concentration is known to associate with the whole-body insulin sensitivity.

**PURPOSE:** The main purpose of the study was to investigate the effect of resistance exercise on DHEA-S concentration during a 72-h postexercise recovery, and its relation to glucose tolerance and insulin sensitivity.

**METHODS:** Serum samples was obtained from 19 male volunteers (aged  $21.2 \pm 0.4$  years) 24 h before the onset of exercise and 24 h, 48 h, and 72 h following exercise for measurements of DHEA-S, cortisol, and TNF- $\alpha$ . Oral glucose tolerance test (OGTT) and insulin response were determined 24 h before and 48 h after exercise.

**RESULTS:** We found that exercise significantly suppressed serum DHEA-S levels during recovery (48 h and 72 h). The resistance exercise did not affect glucose tolerance, but insulin response during OGTT was significantly elevated. The increased insulin level was not associated with serum levels of cortisol and TNF- $\alpha$ .

**CONCLUSIONS:** The present study found that resistance exercise has a DHEA-S lowering effect persisted for 72 h. This change appears to be related to the elevated insulin concentrations during OGTT.

**Influence Of Mouth-rinsing A Carbohydrate Solution On 1 Hour Running Performance**

Ian Rollo, Matthew Cole, Richard Miller, Clyde Williams, FACSM. *Loughborough University, Leicestershire, United Kingdom.*

Email: I.Rollo@lboro.ac.uk

(No relationships reported)

**PURPOSE:** The aim of this study was to investigate the influence of mouth-rinsing a CHO solution on 1 h running performance.

**METHODS:** Following a prolonged fast (13-15 h), ten endurance-trained male runners completed two 1 h performance runs on an automated treadmill that allowed changes in running speed without manual input. Runners either mouth-rinsed a 6.4% carbohydrate (C) or placebo (P) solution immediately before and at 15 min intervals during the 1 h run. Solutions were rinsed for 5 s before being expectorated into pre-weighed containers.

**RESULTS:** The mean running speed was  $13.1 \pm 1.6$  km/h for trial P and  $13.3 \pm 1.6$  km/h for trial C. Running speed was significantly faster between 25-30 min, 35-40 min and 55-60 min on trial C ( $p < 0.05$ ). Total distance covered for trial P was  $13063 \pm 1638$  m; and  $13328 \pm 1596$  m for trial C ( $p = .052$ ). Carbohydrate oxidation and RER were no different between trials ( $P > 0.05$ ). No difference was reported in perceived exertion (RPE), felt arousal (FAS) or pleasure-displeasure (FS) between trials ( $p > 0.05$ ).

**CONCLUSIONS:** In conclusion mouth-rinsing a 6.4% CHO solution significantly increased self-selected running speed during a 1 h performance run.

**Effect Of The Glycemic Index Of A Pre-exercise Meal On Metabolism And Cycling Time Trial Performance**

Laura J. Moore, Adrian W. Midgley, Gemma J. Thomas, Simon Keatley, Lars R. McNaughton, FACSM, Jason Siegler. *University of Hull, Hull, United Kingdom.*

Email: lmoore@hull.ac.uk

(No relationships reported)

**PURPOSE:** The aim of this study was to investigate the effects of low or high glycaemic index (GI) foods consumed prior to a 40-km time trial (TT) on metabolism and subsequent endurance performance.

**METHODS:** Ten male cyclists consumed either a high GI or low GI meal, providing  $1 \text{ g} \cdot \text{kg}^{-1}$  body mass of carbohydrate, 45 min prior to a 40 km TT on a Velotron cyclePro $\text{\textcircled{C}}$ .

**RESULTS:** The TT performance was significantly improved in the low GI trial ( $93 \pm 8$  min) compared to the high GI trial ( $96 \pm 7$  min) ( $p = 0.009$ ). Whole blood glucose concentration at the point of exhaustion was significantly higher in the low GI trial ( $5.04 \pm 0.97 \text{ mmol} \cdot \text{L}^{-1}$ ) compared to the high GI trial ( $4.90 \pm 0.75 \text{ mmol} \cdot \text{L}^{-1}$ ) ( $p = 0.001$ ). Low GI carbohydrate oxidation rate ( $2.51 \pm 1.71 \text{ g} \cdot \text{min}^{-1}$ ) was significantly higher ( $p = 0.003$ ) than the HGI carbohydrate oxidation rate ( $2.14 \pm 1.5 \text{ g} \cdot \text{min}^{-1}$ ). Fat oxidation rate was significantly higher ( $p = 0.002$ ) for the high GI trial ( $0.27 \pm 0.17 \text{ g} \cdot \text{min}^{-1}$ ) than the low GI trial ( $0.16 \pm 0.14 \text{ g} \cdot \text{min}^{-1}$ ). Insulin rose significantly following the high GI meal compared to the low GI meal ( $p = 0.008$ ) but dropped significantly to similar values throughout the TT. No significant differences in either TGA or FFA concentration were observed between the trials.

**CONCLUSION:** The greater carbohydrate oxidation and glucose concentration in the low GI trial may have produced a glucose-sparing effect, maintaining energy production towards the end of exercise and a subsequent improvement in time trial performance in the low GI trial.

**Insulin Sensitivity And Heart Rate Variability For Former Elite Basketball Player With Regular Exercise**

Li-Yen Tsao, Chu-Chun Fang, Mei-Chih Chen, Chia-Hua Kuo. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L. Ivy, FACSM)

Email: Tsao@webmail.ntcb.edu.tw

(No relationships reported)

**PURPOSE:** Insulin sensitivity is known to reduce with advancing aging. This age-dependent metabolic deterioration, to some extent, is associated with reduced vagal activity and increased sympathetic activity. The present study was undertaken to determine insulin sensitivity and heart rate variability (which reflects the autonomic activity) for former elite basketball players.

**METHODS:** Oral glucose tolerance test (OGTT), insulin response, and heart rate variability were determined for both young basketball players (Young, age  $17.88 \pm 0.42$ ,  $N = 9$ ) and former basketball players with regular recreational exercise training (Middle aged, age  $57.23 \pm 1.22$ ,  $N = 13$ ).

**RESULTS:** We found that HF (vagal activity) and LF/HF was not different between the young and middle-aged groups. Weight, BMI, waist circumference, and glucose concentration on OGTT for the middle aged group were significantly greater than the young subjects. Insulin level was not significantly different between groups.

**CONCLUSIONS:** Previous study reported that insulin sensitivity and vagal activity was concurrently reduced with age. The present study demonstrated that vagal activity was well maintained, but glucose tolerance was lower for the middle-aged basketball players with regular exercise.

**PURPOSE:** To determine whether endurance exercise performance and blood glucose, insulin were altered when consuming a carbohydrate-soypeptide beverage.

**METHODS:** Using a crossover balanced design, 12 Elite Chinese male cycling athletes (22.6±2.8 yrs, 73.5±5.7 kg, 184.6±4.2 cm, 69.3±6.4 VO<sub>2</sub>max) after signing informed consent were randomly divided into 2 groups, consuming carbohydrate-soypeptide (6% and 1 %) beverage and commercial carbohydrate-containing (6%) sports beverage at the same rate during 4 weeks. After 2-week washout, two groups were crossed and supplemented with two beverages for another 4 weeks. During the performance test, each athlete was asked to ride on a cycling training facility for 2h at average 60% VO<sub>2</sub>max, then to exert oneself to ride for 20min (time trial). The cycling distance, pedaling rate, etc.were recorded. Venous blood samples were drawn for biochemical tests.

**RESULTS:** The results showed that no significant difference was observed in the cycling distance, Pedaling rate, average speed, total energy expenditure and power output between two groups. Blood glucose level at different time points (before, 60min, 120min, 135min of performance test) showed no significant difference in both groups, but blood glucose and insulin level elevated in CHO-Peptide group immediately post-exercise compared to CHO group (93.4±22.8 vs 84.6±17.4, 13.9±18.3 vs 4.6±2.1 respectively). Blood glucose level of CHO-Peptide group were higher than that of CHO group before and after training at different training type (from 100 to 210 km cycling distance), but no statistically significant difference.

**CONCLUSION:** Our data indicated that carbohydrate-soypeptide and carbohydrate treatment showed no statistically significant difference in the cycling performance, but appeared to increase blood glucose and serum insulin levels at immediately post-exercise.

(No relationships reported)

**INTRODUCTION:** Inactivity physiology studies have raised the concern that too much sitting is a distinct and increasingly prevalent health hazard, including associations between sitting and risk for metabolic syndrome, type 2 diabetes, and coronary heart disease. Excessive postprandial plasma insulin and impaired insulin action are potentially induced by sitting down for too long independent of body fat or obesity.

**PURPOSE:** To determine if inactivity caused by prolonged sitting directly increases postprandial plasma insulin.

**METHODS:** Nine men (n=5) and women (n=4) who were relatively lean (22 ± 6% body fat) were studied on 3 different days preceded by a similar baseline. Plasma glucose and insulin were measured before and after the exact same standardized mixed supper on the 3 days of testing. Two of the trials involved a day of routine sedentary activities most commonly associated with sitting, with the only difference being the caloric intake during the breakfast and lunch preceding the test meal. A third trial consisted of less sitting (~25% of the day) and more physical activity due to upright non-exercise activities.

**RESULTS:** Despite no difference in plasma glucose concentrations, plasma insulin concentration after the test meal was significantly greater (32-41%, p<0.05) after both of the sitting trials than the low sitting trial.

**CONCLUSION:** Sitting can rapidly trigger postprandial hyperinsulinemia in healthy humans.

**Energy Status And Amp-activated Protein Kinase In Human H460 Lung Cancer Cells**

Mei Yin Su<sup>1</sup>, Jia Ming Chang<sup>2</sup>, Sandy S. Hsieh, FACSM<sup>1</sup>, Ming Chuan Chang<sup>2</sup>, Thomas Ta-Tung Yuan<sup>2</sup>. <sup>1</sup>National Taiwan Normal University, Taipei City, Taiwan. <sup>2</sup>Development Center for Biotechnology, Taipei County, Taiwan.

Email: 895300100@ntnu.edu.tw

(No relationships reported)

According to the Warburg Effect, glucose provides a major source of energy at a high rate of glycolysis in cancer cells. However, serum which includes many growth factors also plays a crucial role in supporting the proliferation of cancer cells. AMP-activated protein kinase (AMPK), a key energy sensor in energy homeostasis, in regulating ATP levels and enzyme expression is involved in the proliferation of cancer cells. Thus to find a strategy to treat cancer, it would be beneficial to determine the different patterns between energy metabolism and the signaling system in cancer cells.

**PURPOSE:** To investigate the effects of glucose or serum on the energy status and AMPK activity in H460 cancer cells.

**METHODS:** H460 cancer cells were starved with glucose-free or serum-free medium for 16 h. Then glucose and serum, respectively, were added to analyze for levels of ATP and Lactate, and the activities of AMPK and LDH at 1, 3, 6, 12, 24 h.

**RESULTS:** In the glucose treatment, the activity of AMPK was activated by glucose and showed a biphasic phenomenon with a peak at 1 h and a maximal activity at 24 h. The intracellular ATP was gradually increased up to 2 fold at 24 h and the intracellular lactate was decreased to approximately 60%. The activity of LDH also showed a biphasic phenomenon which was increased to a peak at 6 h and raised at 24 h. In the serum treatment, the phosphorylation of AMPK was suppressed which started at 1 h and sustained to 12 h. The intracellular ATP showed a dramatic increase of 50 % at 1 h, and the intracellular lactate was gradually increased to a peak at 3 h and then decreased to the background level at 24 h. The activity of LDH was decreased at 12 h and returned to normal levels at 24 h.

**CONCLUSION:** The activation of AMPK by glucose showed a biphasic phenomenon, and the levels of ATP were gradually increased in accordance with the decrease in lactate. Serum inhibited the phosphorylation of AMPK, but the levels of ATP were persistently increased. It is suggested that cancer cells show a different pattern in energy status in response to serum and glucose and that exercise might change the supply of energy to cancer cells, thus affecting the characteristics of cancer cells.

**Muscle Metabolic Status During Repeated Very Short Work-to-Rest Transitions**

Glen R. Belfry<sup>1</sup>, Graydon R. Raymer<sup>2</sup>, Don H. Paterson, FACSM<sup>1</sup>, Tom J. Overend<sup>1</sup>, Greg D. Marsh<sup>1</sup>, Scott G. Thomas<sup>3</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>Nipissing University, North Bay, ON, Canada. <sup>3</sup>University of Toronto, Toronto, ON, Canada.

Email: gbelfry@uwo.ca

(No relationships reported)

Little is known about the muscle metabolic status during repeated bouts of very short work-to-rest transitions.

**PURPOSE:** : In the present study, we measured gastrocnemius muscle [PCr] and [H<sup>+</sup>] using phosphorus-31 magnetic resonance spectroscopy (<sup>31</sup>P-MRS) during repeated bouts of 10 s heavy-intensity exercise and 5 s rest compared to continuous (i.e. no rest) heavy-intensity exercise.

**METHODS:** Recreationally active male subjects ( $n=8$ ,  $27\text{yr}\pm\text{SE}3.3$ ) performed on separate occasions 12 min of isotonic plantar flexion (contraction rate 0.75 Hz) continuously (CON) and intermittently (INT) 10 s exercise 5 s rest. Heavy-intensity exercise workload in both CON and INT was set at 150% of the power output associated with the onset of intracellular acidosis determined from a prior incremental plantar flexion exercise protocol. Intracellular concentrations of  $[\text{H}^+]$  and  $[\text{PCr}]$  were calculated at 4 s and 9 s of the work period and 4 s of the rest period in INT, and at similar intervals during CON. ATP synthesis and oxidative flux were estimated from changes in those concentrations.

**RESULTS:** Metabolite concentrations (mean  $\pm$ SE) were increased at 4 s of the rest periods vs 9 s of exercise averaged over the course of the intermittent exercise bout:  $[\text{PCr}]$  ( $19.09\text{ mM}\pm0.59$  vs  $17.33\text{ mM}\pm0.5$ ;  $p<0.01$ );  $[\text{H}^+]$  ( $324.5\text{ nM}\pm13.50$  vs  $284.0\text{ nM}\pm13.6$ ;  $p<0.05$ ). Average  $[\text{H}^+]$  was greater for continuous exercise vs interval exercise ( $252.6\text{ nM}\pm5.6$  vs  $217.18\text{ nM}\pm6.5$ ,  $p<0.001$ ) during the exercise bout.

**CONCLUSIONS:** A 5 s recovery period is sufficient duration to increase  $[\text{PCr}]$  and  $[\text{H}^+]$  between repeated 10 s bouts of heavy-intensity exercise. We therefore suggest a rapid shift of the creatine kinase reaction occurs during a very short rest period ( $<5$  s) following a brief bout of heavy intensity exercise. We also observe that the lower average  $[\text{H}^+]$  during short interval exercise suggests reduced production or increased buffering vs continuous exercise of a similar duration and intensity.

#### Antioxidative Effect Of Exercise Training Combined With Losartan Treatment In The Infarcted Rat Hearts

John Q. Zhang<sup>1</sup>, Xiaohua Xu<sup>1</sup>, Weiyan Zhao<sup>1</sup>, Wenhan Wen<sup>1</sup>, Bryan S. Wilson<sup>1</sup>, Lisa L. Ji<sup>2</sup>. <sup>1</sup>University of Texas at San Antonio, San Antonio, TX.

Email: john.zhang@utsa.edu

(No relationships reported)

Increased oxidative stress and decreased antioxidant capacity are involved in myocardial remodeling after myocardial infarction (MI). Angiotensin II (AngII) plays a major role in oxidative stress. Our previous study demonstrated that exercise training reduced MI-induced elevation of AngII. Whether exercise training and losartan treatment would reduce MI-induced oxidative stress and improve antioxidant status needs to be elucidated.

**PURPOSE:** To investigate post-MI exercise and losartan treatment induced changes in enzymatic antioxidants and oxidative stress.

**METHODS:** MI was surgically induced in 7-wk-old rats. The survivors were assigned to 5 groups: Sham (no MI, no exercise), MISed (MI, no exercise), MI+Ex (MI with exercise), MISed+Los (MI treated with losartan), and MI+Ex+Los (MI treated with losartan and exercise). Treadmill exercise training (16m/min, 50min/d, 5d/wk) and losartan treatment (20 mg/kg/d) began 1 wk post-MI and lasted for 8 wks.

**RESULTS:** Glutathione peroxidase (GPx) and catalase mRNA levels of the surviving left ventricle were comparable among all the groups, while the mRNA level of superoxide dismutase (SOD) was significantly increased in exercise training with/without losartan treatment ( $2.95\pm0.82/1.75\pm0.4$  fold compared to the control) as compared to MISed rats ( $1.40\pm0.18$ ,  $P<0.05$ ). The protein levels for MnSOD and GPx were not significantly different among all the groups. However, the protein level for catalase was significantly increased in MI+Ex+Los rats ( $1.51\pm0.18$ ) compared to Sham group ( $1.0\pm0.16$ ,  $P<0.05$ ). Thiobarbituric acid-reactive substances (TBARS) in plasma were significantly increased in the MI rats, but robustly decreased by exercise training and/or losartan treatment ( $P<0.05$ ), indicating that both exercise and losartan may reduce lipid oxidative damage. In addition, cardiac function (fractional shortening) was significantly improved in rats receiving exercise training and/or losartan treatment compared to the MI rats without the treatments ( $p<0.05$ ).

**CONCLUSION:** Our results suggest that exercise training and losartan treatment exert antioxidative effects and reduce oxidative stress in the MI rats. These improvements may, in turn, attenuate the adverse myocardial remodeling and improve post-MI cardiac function.

#### Exercise Ameliorates The Adhesiveness Of Bone Marrow-derived Endothelial Progenitor Cells Post Acute Myocardial Infarction.

Mickey Scheinowitz<sup>1</sup>, Anat Dayan<sup>2</sup>, Sofia Auslander<sup>3</sup>, Jacob George<sup>3</sup>. <sup>1</sup>Tel-Aviv University, Washington DC, 20010, DC. <sup>2</sup>Tel-Aviv University, Tel-Aviv, Israel. <sup>3</sup>Tel-Aviv University, Tel-Aviv Sourasky Medical Center, Israel.

Email: mickey.scheinowitz@medstar.net

(No relationships reported)

Previously it has been shown that exercise stimulate the production and the availability of Bone-marrow derived endothelial progenitor cells (BM-EPCs) and thus may contribute to cell surface reparation and angiogenesis.

**PURPOSE:** To investigate the role of exercise training initiated either prior to or post acute myocardial infarction (AMI) on BM-EPCs production, properties, and bioavailability.

**METHODS:** Sprague Dawley male rats ( $n=56$ ) were randomly assigned to 7 weeks of swimming exercise and sedentary groups. At the end of the exercise program, both groups were subjected to AMI, and there after were again divided into sedentary or exercise groups for the following 4 weeks period. Upon sacrificing, femur bone marrow were flushed out, washed and centrifuged for the isolation of mononuclear cells. The cells were resuspended in growth medium, plated on dishes coated with human fibronectin, and incubated in  $37^{\circ}\text{C}$ . Following 10 days of incubation, cells were phenotyped by Dil-acLDL and BS-1 lectin and FLK-1 and CD-31. For the EPC adhesion assay, cells were detached from origin culture dishes, and placed again onto fibronectin coated cultured dishes. After incubation, adherent cells were stained and evaluated by Elisa.

**RESULTS:** Immunostaining with Dil-acLDL and BS-1 lectin showed that prior-AMI exercised rats had more, yet, not countrified BM-EPC than the prior-AMI sedentary group. Fibronectin adhesion assay indicated a significantly greater adherence potential of BM-EPC originated from prior-AMI exercised and/or continued post-AMI compared to prior-AMI sedentary and/or sedentary-non AMI groups ( $p<0.001$ ).

**CONCLUSIONS:** Exercise training enhanced BM-EPC's adhesive properties. The greater adhesiveness seen in the exercise continued post-AMI group, signify the role of exercise training in both preventive and rehabilitation of cardiac disease.

#### The Effects Of Endurance Exercise Training On Cardiac-related Factors In Type 2 Diabetic Mice

Libby E. McCurley, Molly Muck, Gun Soo Han, Tiffany Akins, Charles Riggs, FACSM. University of Arkansas, Fayetteville, AR.

Email: mcurley.libby@mcm.edu

(No relationships reported)

Type 2 diabetes is rapidly becoming a major health threat in the United States. The disease, if not controlled, alters energy metabolism and frequently leads to the development of a diabetes-specific cardiomyopathy and increased oxidative stress levels in the heart. Endurance exercise training has been reported to improve cardiac function as well as reduce oxidative stress.

**PURPOSE:** To examine the effects of endurance exercise training on cardiac left-ventricular function and cardiac oxidative stress level in type 2 diabetic mice.

**METHODS:** 28 db/db mice and 29 control mice were randomly assigned to either endurance (ED) (EC) or sedentary groups (SD) (SC). Trained mice ran on the treadmill at 18-24 m/min, 30 min. per day, 5 days per week for 5-8 weeks, while sedentary animals were limited to cage activity. Data collection following the training period included measurement of cardiac dimensions using echocardiography and isolation of cardiac whole homogenate for measurement of oxidative stress through GSH:GSSG measurement.

**RESULTS:** Ejection fraction (%) and fractional shortening (%) respectively, were greater in endurance trained groups ( $0.89 \pm 0.012$  vs.  $0.85 \pm 0.012$ ,  $p < 0.05$ ) and ( $54.5 \pm 1.7$  vs.  $49.0 \pm 1.5$ ,  $p < 0.05$ ). Lower cardiac oxidative stress was observed in the endurance trained mice represented by higher GSH:GSSG ratios ( $0.261 \pm 0.09$  vs.  $0.122 \pm 0.08 \mu\text{M} \cdot \text{g} \cdot \text{min}^{-1}$ ,  $p = 0.05$ ).

**CONCLUSIONS:** Endurance exercise training had a positive effect on both cardiac function and cardiac oxidative stress levels in db/db and control mice

**Heart Rate Recovery Following Maximal Arm And Leg Ergometry**

Sushant Ranadive, Chris Fahs, Lindy Rossow, Stamatis Agiovlasis, Humin Yan, Bo Fernhall, FACSM. *University of Illinois, Champaign, IL*  
Email: sushantranadive@gmail.com

(No relationships reported)

**INTRODUCTION:** Heart rate recovery (HRR) has been shown to be a predictor of mortality and morbidity. HRR is a reflection of autonomic nervous system (ANS) function and particularly of vagal reactivation. Maximal heart rate and aerobic capacity ( $\text{VO}_2\text{max}$ ) differs between arm and leg exercise. However, it is unknown if heart rate recovery pattern are similar between arm and leg exercise.

**PURPOSE:** The main purpose of the present study is to examine the difference in the heart rate recovery pattern following maximal arm and leg ergometry.

**METHODS:** 9 healthy subjects (5 males and 4 females;  $26 \pm 5.8$  yrs) performed graded maximal arm and leg ergometry tests in a randomized, crossover design. Breath by breath gas was collected to measure  $\text{VO}_2\text{max}$ . After the maximal tests HR at 1 and 2 mins of recovery was recorded. HRR was calculated from each graded maximal exercise test, as maximal HR attained during the test minus the HR at 1 min (HRR1) and maximal HR minus the HR at 2 min after exercise (HRR2). HR reserve was calculated as maximum HR - resting HR

**RESULTS:** The HRR1 following arm ergometry was significantly higher than HRR1 post leg ergometry ( $p < 0.05$ ). The HRR % as function of maximum HR in 1<sup>st</sup> min. after arm test was also significantly lower than HRR% following leg ergometry ( $p < 0.05$ ).

**CONCLUSION:** HRR following maximal arm ergometry was greater than HRR following maximal leg ergometry, suggesting that ANS function differs between exercise modes. Based on our results it appears that vagal reactivation is greater in the first minute following arm compared to leg ergometry. This finding may have implications for the clinical utility of HRR following arm ergometry.

Table:

Variable	Arm	Leg
$\text{VO}_2\text{max}$ (ml/kg/min)	30.67 (7.01)	43.12* (5.98)
HRR1 (bpm)	37 (14.41)	26.44* (8.3)
HRR2 (bpm)	49.89 (16.28)	47.11 (12.50)
HRR% 1 min	77.67 (7.95)	85.59* (4.17)
HRR % 2 min	70 (8.69)	74.26 (6.7)

\* Significantly different from arm ergometry ( $p < 0.05$ )

---

**1474 Board #76 May 27 9:30 AM - 11:00 AM**  
**Circadian Variation In The Reactivity Of The Rate-pressure Product To Everyday Physical Activities In Hypertensive Patients**

Greg Atkinson<sup>1</sup>, Helen Jones<sup>1</sup>, Andrew Leary<sup>2</sup>, Michael Murphy<sup>3</sup>, Keith George, FACSM<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>Shandon Clinic, Cork, Ireland. <sup>3</sup>National University of Ireland, Cork, Ireland.

Email: G.Atkinson@ljmu.ac.uk

(No relationships reported)

It has been suggested that the exercise-related response of the rate-pressure product (RPP) is a prognostic marker of cardiovascular mortality. Given that out-of-hospital sudden cardiac events are more common in the morning and, to a lesser extent, in the late afternoon, it is pertinent to examine whether RPP and its reactivity to physical activity vary with time of day.

**PURPOSE:** To use a novel RPP 'reactivity index' to investigate whether the RPP response to everyday physical activities changes over a normal sleep-wake cycle.

**METHODS:** Two hundred and eighteen male, and 222 female, hypertensive patients (aged 15-81 yrs) underwent 24-h monitoring of systolic blood pressure and heart rate (both recorded every 20 min). Wrist movement was recorded every 10 s and summed over the 15 min that preceded a BP measurement. The product of systolic BP and HR was calculated, and RPP reactivity indices were derived by regressing the change in RPP against the change in activity for twelve 2-h data bins. These indices were then analysed for time-of-day differences using a covariate-controlled general linear model.

**RESULTS:** The RPP showed circadian variation ( $P < 0.0005$ ), with a peak of  $11004$  (95%CI =  $10757$  to  $11250$ )  $\text{beat} \cdot \text{min}^{-1} \cdot \text{mmHg}$  occurring at 10:00 h. The reactivity of RPP to physical activity showed two distinct peaks between 08:00-10:00 and between 18:00-20:00 ( $P < 0.0005$ ) which were  $>3$  times greater than the RPP reactivity during the nocturnal period. This circadian variation in RPP reactivity was not moderated by wake-time, medication use, age or gender ( $P > 0.30$ ).

**CONCLUSION:** Under conditions of normal living, the reactivity of the rate-pressure product to a given unit change in physical activity is substantially higher in the morning and early evening compared with other times of day. These times are consistent with the peak times of day for out-of-hospital sudden cardiac events and, therefore, add weight to the notion that the response of the rate-pressure product to exercise could be a useful prognostic marker of cardiovascular mortality.

**Effect Of Voluntary Exercise On Bcl-2 And Bax In Rat Cardiac And Skeletal Muscles**

Xiao M. Pei<sup>1</sup>, Bee T. Teng<sup>1</sup>, Joann W. Ng<sup>1</sup>, Iris Benzie<sup>1</sup>, Yajun Chen<sup>2</sup>, Stephen H. Wong, FACSM<sup>2</sup>, Parco M. Siu<sup>1</sup>. <sup>1</sup>The Hong Kong Polytechnic University, Kowloon, Hong Kong. <sup>2</sup>The Chinese University of Hong Kong, Shatin, Hong Kong.

Email: peixiaomeng@sina.com

(No relationships reported)

Regular physical activity is an effective lifestyle factor that reduces the risk of many chronic diseases. However, the underlying mechanisms of this protective effect have not been fully understood. It is demonstrated that apoptosis plays a role in aging, cardiovascular diseases, skeletal muscle insulin resistance, muscle wasting.

**PURPOSE:** To examine the effect of 2-month voluntary exercise on the expression of Bcl-2 and bax in cardiac and skeletal muscles in a rat wheel running model.

**METHODS:** Eighteen young adult female Sprague Dawley rats were randomly assigned to sedentary control (CON) and exercise (EX) groups. The EX animals were housed individually in cages with 24h free access to a running wheel. The daily running distance for each rat was recorded by a magnetic digital counter equipped with the running wheel. The CON animals were housed in cages without the running wheel. The bodyweight gain and amount of food intake of rats were recorded weekly. After 8 weeks exercise training, rats were sacrificed and the cardiac ventricle and soleus muscles were harvested and processed for real time PCR and Western blot analyses.

**RESULTS:** The average daily running distance of EX animals was 4-6 km during the 8-week experimental period. EX animals showed higher weekly food intake than CON animals but similar change in bodyweight was observed in EX and CON animals. According to RT-PCR analysis, the gene expression of apoptotic signaling factors Bax, Bcl-2 did not show significant change between EX and CON groups in ventricle and soleus muscles ( $P>0.05$ ). In the Western analyses, although Bax protein content was similar in soleus muscles of EX group compared with CON group ( $P>0.05$ ), Bcl-2 protein content in the ventricle of EX group significantly increased by 19% ( $P<0.05$ ) when compared with CON group. No difference was found in Bax protein content in both ventricle and soleus muscles between CON and EX groups ( $P>0.05$ ).

**CONCLUSIONS:** These results showed that two months voluntary exercise can up-regulate Bcl-2 protein expression level in rat heart. These finding suggested that short-term voluntary mode of exercise, which is a more usual and practical form of physical activity in humans can induce anti-apoptotic Bcl-2 adaptation in cardiac muscle.

### Effects Of Exercise Training On Cardiac Fas-dependent Apoptosis In Ovariectomized Rats

Chih-Chau Hsu<sup>1</sup>, Ai-Lun Yang<sup>2</sup>, Chia-Hua Kuo<sup>3</sup>, Chih-Yang Huang<sup>1</sup>, Shin-Da Lee<sup>1</sup>. <sup>1</sup>China Medical University, Taichung, Taiwan. <sup>2</sup>National Cheng Kung University, Tainan, Taiwan. <sup>3</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: e751028t@hotmail.com

(No relationships reported)

**BACKGROUND:** Cardiac apoptosis were found in ovariectomized rats but very limited information regarding the effects of exercise training on cardiac apoptosis in menopausal or bilateral oophorectomized women was available. The purpose of this study was to evaluate the therapeutic effects of exercise training on cardiac Fas-dependent apoptotic pathways. Method. Nine sham-operated rats and nine ovariectomized rats at 7-8 months of age were served as negative (Sham) and positive (OVX) control. Nine ovariectomized rats underwent treadmill running exercise 1 hour daily for 10 weeks. After exercise training or sedentary status, the excised hearts were measured by heart weight index, positive TUNEL assays and Western Blotting. Result. The whole heart weight, the left ventricular weight, the ratios of whole heart weight to tibia length, and the ratios of left ventricle to tibia length were significantly increased in OVX relative to Sham. Abnormal myocardial architecture and more cardiac TUNEL-positive apoptotic cells were observed in OVX. Cardiac Fas ligand, Fas death receptors, FADD, activated caspase 8, and activated caspase 3 in OVX were significantly increased, compared to Sham. Exercise training decreased OVX-induced cardiac TUNEL-positive apoptotic cells. Exercise training decreased OVX-induced Fas ligand, Fas death receptors, Fas-associated death domain (FADD), activated caspase 8, and activated caspase 3.

**CONCLUSION:** Exercise training suppressed ovariectomy-induced cardiac Fas-dependent apoptotic pathways in rat models. The findings may provide one of possible therapeutic approaches for preventing cardiac apoptosis in menopausal or bilateral oophorectomized women.

(No relationships reported)

**PURPOSE:** The aim of this case study was to examine changes in hemodynamic variables in a single trained male cyclist during a 24h cycle ergometer exercise test.

**METHODS:** The subject was monitored throughout 24h at a constant workload at the first lactate turn Point (200 Watt). Heart rate (HR) and respiratory gas exchange measures were analyzed continuously [oxygen consumption ( $\text{VO}_2$ ), carbon dioxide production ( $\text{CO}_2$ )]. Every hour systolic blood pressure (SBP), cardiac output (CO) and stroke volume (SV) were determined non-invasively (Innocor) as well as 2-D echocardiograms over the left parasternal area. Using VINGMED's Anatomical M-Mode it was possible to extract M-mode sweeps from stored 2-D-loops and perform the M-mode measurement [left atrial (LAD), ventricular end-diastolic (EDD) and end-systolic (ESD) diameters]. In addition, we also measured N-terminal pro-brain natriuretic peptide (NT-proBNP). Venous blood sample collection and body weight were obtained every 6 h.

**RESULTS:** After an initial increase after 1 h,  $\text{VO}_2$  was ( $41 - 43 \text{ ml} \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$ ) and CO ( $19 - 18.7 \text{ l} \cdot \text{min}^{-1}$ ) were unchanged during 24h. HR increased at the end of the 5<sup>th</sup> h from 58-143 bpm and decreased constantly during the following 19 h (125 bpm). From the 5<sup>th</sup> h on SV (109 ml) increased steadily throughout the 24<sup>th</sup> h exercise test up to 150 ml. ESD was unchanged (32 mm) but EDD increased from 47 to 51 mm. LAD increased from 37 mm to 45 mm and body weight increased from 71 kg to 74 kg. Hematocrit decreased from 44% to 41%. NT-proBNP increased from 23 at rest to 306  $\text{pg} \cdot \text{ml}^{-1}$  at the end of exercise.

**CONCLUSIONS:** Our study suggests that the decrease in HR during a 24 h aerobic exercise was due to hypervolemia and the associated ventricular workload that resulted in SV increase as a consequence of increases in left ventricular diastolic dimensions.

### Effects Of Enalapril On Ventilatory Responses To Exercise In Older Diastolic Heart Failure Patients

(No relationships reported)

**BACKGROUND:** The primary chronic symptom of diastolic heart failure in the elderly (DHF) is severe exercise intolerance. There are several measures acquired from metabolic exercise stress testing that can help guide treatment and evaluate prognosis. Specifically, measures of ventilatory efficiency have been shown to significantly predict morbidity and mortality in heart failure patients. Therefore, it was the purpose of this study to determine if the ACE-Inhibitor, enalapril, will improve measures of ventilatory function and prognosis in older patients with DHF.

**METHODS:** Seventy-two patients over age 60 with DHF were enrolled in a randomized, double-blind trial of enalapril 20mg per day (E) vs. placebo (P). DHF was defined by HF symptoms with a normal ejection fraction ( $>50\%$ ) with exclusion of other co-morbidities (ischemia, anemia, pulmonary, or valvular disease). Maximal exercise testing was

conducted on an upright cycle ergometer using a staged protocol. Metabolic gas exchange values were collected continuously during exercise and peak values were averaged from the final 30 seconds of exercise. Outcomes were collected and analyzed by staff members blinded to study drug assignment. Assessments were completed at baseline, prior to randomization, and at 4 and 12 month follow-up. Repeated measures ANOVA with adjustments for age, gender, and baseline values were employed to detect statistical changes.

**RESULTS:** Compliance by pill count was 94% in the enalapril group and 96% in the placebo group. At 12-month follow-up, there was no significant difference observed in  $V_E/V_{CO_2}$  ( $31.2 \pm 3.3$  vs.  $31.5 \pm 4$ ;  $p=.845$ ), OUES ( $1.29 \pm .33$  vs.  $1.36 \pm .35$ ;  $p=.603$ ), nor in  $V_E/V_{CO_2}$  slope ( $33.1 \pm 4.5$  vs.  $33.3 \pm 5.2$ ;  $p=.606$ ).

**CONCLUSION:** Enalapril was well tolerated with minimal side effects and adverse events in this population. There was no significant improvement in  $V_E/V_{CO_2}$ ,  $V_E/V_{CO_2}$  slope, or OUES at the 12 month follow-up.

**Effects Of Endurance Training On Amp-activated Protein Kinase (ampk) Activity In The Heart**

Edward Waggy, Jingying Wang, Casey Armstrong, Heng Ma, Ji Li, D. Paul Thomas, FACSM. *University of Wyoming, Laramie, WY.*

Email: [wager23@uwyo.edu](mailto:wager23@uwyo.edu)

(No relationships reported)

AMPK phosphorylation (p-AMPK) in the heart in response to the physiologic stress of an acute bout of exercise has been documented previously. Phosphorylation of the AMPK  $\alpha_2$  subunit at the Thr<sup>172</sup> residue is thought to be responsible for the majority of cardiac AMPK activation. However, whether exercise training modulates either total AMPK or phosphorylation of its two catalytic  $\alpha$  subunits ( $\alpha_1$ ,  $\alpha_2$ ) in response to exercise has not been documented.

**PURPOSE:** To measure and compare the effects of 8 wk daily treadmill exercise on total left ventricular (LV) AMPK levels and AMPK activation (p-AMPK) to an identical bout of exercise between sedentary (SED) and trained (TR) mice.

**METHODS:** TR adult (4-7 mo) C57B6 mice were ramp-test exercised for ~ 17 min, which corresponded to the point of exhaustion for SED mice. Immediately post-exercise, LV tissue from both groups was rapidly excised, freeze-clamped, homogenized, and proteins were extracted for immunoblotting analysis. LV tissue was also obtained from resting controls.

**RESULTS:** Maximal treadmill running speed was increased 28% in TR vs. SED mice ( $46 \pm 1$  vs.  $36 \pm 1$  m/min;  $P < 0.001$ ). Changes in the ratio of p-AMPK/ total AMPK in response to exercise were not significantly affected by training. However, exercise increased AMPK activity associated with the  $\alpha_2$ -catalytic subunit in both SED and TR animals, but to a greater degree in the TR group (40 vs. 86%  $\uparrow$ ;  $P < 0.1$ ,  $P < 0.02$  vs. resting controls respectively).

**CONCLUSION:** Training results in significantly greater exercise-induced activation of AMPK in the mouse LV even at an exercise workload that is sub-maximal for the TR animals. This finding suggests cardiac AMPK activation may be enhanced by chronic endurance exercise.

(No relationships reported)

The description of left ventricular morphology in athletes is common place but the assessment of ventricular function is more limited. Further, with recent advances in ultrasound imaging we can interrogate both local and regional cardiac function.

**PURPOSE:** To assess global and regional cardiac function during systole and diastole in ultra-marathon runners compared to age matched sedentary controls.

**METHODS:** A total of 89 [22 female] ultra-marathon runners at the 2007 and 2008 Western States 100 mile race (UM: mean $\pm$ SD age =  $41 \pm 5$  years, range 24-76 years) and 19 age-matched sedentary controls (CON: mean $\pm$ SD age =  $44 \pm 10$  years, range 23-72 years) underwent M-mode, 2D and Doppler echocardiography to assess global systolic (ejection fraction [EF]) and diastolic function (early/atrial filling velocity ratio [E/A]). 2D speckle-tracking echocardiography facilitated the assessment of longitudinal, radial and circumferential strain and peak systolic and early diastolic strain rates (data reported are septal wall at mitral annulus). Participants with known cardiovascular disease were excluded.

**RESULTS:** On average, the UM ran  $92 \pm 32$  km/week and had trained for  $15 \pm 10$  yrs whereas CON performed less than 120 min of recreational activity per week. EF was  $67 \pm 4$  % in UM and  $64 \pm 6$  % in CON ( $P > 0.05$ ). E/A was  $1.66 \pm 0.36$  in UM and  $1.34 \pm 0.53$  in CON ( $P < 0.05$ ). Longitudinal peak strain (UM:  $-21.2 \pm 3.5$  %, CON:  $-16.3 \pm 3.7$  %), peak systolic strain rate (UM:  $-1.63 \pm 0.34$  .s<sup>-1</sup>, CON:  $-0.94 \pm 0.23$  .s<sup>-1</sup>) and peak diastolic strain rate (UM:  $1.86 \pm 0.39$  .s<sup>-1</sup>, CON:  $1.29 \pm 0.32$  .s<sup>-1</sup>) were significantly augmented in athletes. There were no differences between groups for strain and strain rates assessed in radial and circumferential planes.

**CONCLUSIONS:** Global diastolic function was augmented in UM as was regional strain and strain rates in the longitudinal plane. These changes in deformation likely underpin the global Doppler-flow data.

**Determinants Of Peak Work Capacity Reduction Following 5 Weeks Of Head-down Tilt Bed Rest**

Dean Palmer<sup>1</sup>, Jeff Hastings<sup>1</sup>, Felix Krainski<sup>1</sup>, Eric Pacini<sup>1</sup>, Shigeki Shibata<sup>1</sup>, Qi Fu<sup>1</sup>, Tiffany VanGundy<sup>1</sup>, Chelsie Rowell<sup>1</sup>, Manish Jain<sup>1</sup>, Dan Creson<sup>1</sup>, Tony Babb<sup>1</sup>, Peter Snell<sup>2</sup>, Benjamin Levine, FACSM<sup>1</sup>. <sup>1</sup>IEEM, Dallas, TX. <sup>2</sup>UTSW, Dallas, TX.

Email: [DeanPalmer@TexasHealth.org](mailto:DeanPalmer@TexasHealth.org)

(No relationships reported)

Without an exercise counter measure, 5 weeks of head-down tilt bed rest (HDTBR) results in a dramatic reduction in peak work capacity.

**PURPOSE:** Examine the contributing factors to the reduction of work capacity during sedentary HDTBR and its preservation with exercise training using rowing ergometry.

**METHODS:** 26 subjects (23 m/3 f, age 20-55 yr) were studied before and after 5 weeks of -6° HDTBR. The subjects were divided into 2 groups: (1) HDTBR without exercise, but sitting upright 45 min/d quietly on the ergometer (n=9); (2) HDTBR with exercise (30-45 min/d, 6 d/wk of exercise on a rowing ergometer plus 2 d/wk of supine resistance training; n=17). Endurance training included 3 days of exercise at a moderate, base pace and 2 days of high intensity interval training followed by a low intensity, longer duration recovery day.  $VO_2$  was measured via Douglas Bags and cardiac output (Qc) by C<sub>2</sub>H<sub>2</sub> rebreathing. LV mass and volume were measured via MRI and muscle strength using an isokinetic dynamometer.

**RESULTS:** (see table): Trained subjects experienced virtually no change in work capacity; a small decrease in maximal Qc was balanced by a small increase in a-vO<sub>2</sub>diff; sedentary subjects suffered reductions of 15% in peak work rate and 21% in  $VO_{2max}$ ; (both  $p < 0.01$ ). The sedentary group experienced a 31% reduction in maximal SV after

HDTBR compared to only a 11% decrease among the exercisers. Knee extension peak torque decreased by 14% only in the sedentary group, though this was not clearly related to the reduction in maximal exercise capacity (same peak a-vO<sub>2</sub> diff).

**CONCLUSIONS:** The marked reduction in work capacity following 5 weeks of HDTBR is due principally to cardiac atrophy and a diminished LV mass, chamber volume, and maximal Q<sub>c</sub>.

Group	Exercisers				Sedentary

##### Effects Of Short-term Exercise Training On Autonomic Circulatory Control In The Postural Orthostatic Tachycardia Syndrome

Melyn Galbreath, Shigeki Shibata, Tiffany VanGundy, Dan Creson, Dean Palmer, Qi Fu, Benjamin Levine, FACSM. *IEEM, Dallas, TX.*

Email: MelynGalbreath@texashealth.org

(No relationships reported)

**BACKGROUND:** Postural Orthostatic Tachycardia Syndrome (POTS) is characterized by excessive tachycardia during orthostasis. It affects ~500,000 young American women, but the underlying mechanisms are unclear, though such patients are presumed to have a “dysautonomia”. We tested the hypothesis that patients with POTS have impaired autonomic circulatory control, while short-term exercise training normalizes their autonomic function.

**METHODS AND RESULTS:** Seventeen female POTS patients aged 30±10 (mean±SD) yr underwent an “optimized” exercise training program for 3 mo. Autonomic circulatory control was assessed by spectral and transfer function analysis of R-R interval (RRI) and beat-to-beat blood pressure (BP) variability in the supine position during spontaneous and fixed breathing (0.2 Hz, 12 breaths/min) for 6 min each, before and after training. Data were compared with those obtained in 16 healthy sedentary women matched for age and body mass index. We found that indexes of RRI variability did not differ between patients and healthy women. Transfer function gain (BP to RRI), used as an index of arterial-cardiac baroreflex sensitivity was similar between patients and healthy women in both low- (0.05-0.15) and high-frequency (HF, 0.15-0.30) ranges. Short-term exercise training increased baroreflex gain modestly in POTS patients (GainHF 20.4±15.0 pre- vs 23.7±19.6 ms/mmHg post-training, *P*=0.06), though the gain remained within the normal range compared with healthy women (13.4±9.4 ms/mmHg, *P*=0.10).

**CONCLUSION:** These data suggest that patients with POTS have normal autonomic circulatory control in the supine position with no evidence of dysautonomia, and short-term exercise training can improve the arterial-cardiac baroreflex sensitivity in these patients.

Supported by NIH K23 (HL0752 83) and the GCRC grant (RR00633).

##### Physiological Responses To Resistance Training In Cardiac Patients: Impact Of Differing Warm-up Procedures

Jenna Brinks, Barry Franklin, FACSM, Tom Spring, Roger Hardy, Judith Boura, Adam deJong. *William Beaumont Hospital, Royal Oak, MI.*

Email: jennabrinks@yahoo.com

(No relationships reported)

Resistance training (RT) is typically performed following aerobic exercise in the cardiac rehabilitation setting.

**PURPOSE:** To determine the physiological responses to performing moderate intensity RT following a stretching (ST) versus an aerobic exercise (AE) warm-up.

**METHODS:** Low-risk cardiac patients (n = 17) in a Phase 3 exercise program performed 6 resistance exercises at 70% of their estimated 1-repetition maximum following either an aerobic exercise bout at 60-80% of heart rate reserve or a stretching warm-up. Subjects were randomized to treatment order, with a ≥ 3-day recovery period between sessions. Heart rate, rhythm and electrocardiographic (ECG) responses were monitored via telemetry, and blood pressure and rating of perceived exertion (RPE; 6-20 scale) were assessed during the completion of each resistance exercise. Muscle soreness was rated after each session and 24 hours post-exercise.

**RESULTS:** Heart rate was significantly higher during all resistance exercises following AE. Conversely, systolic blood pressure was significantly lower during 4 of 6 resistance exercises, generally resulting in comparable rate pressure products (RPP) for the two warm-up procedures. Somatic demands (RPE) were slightly higher following 2 resistance exercises after AE. Mean ± SD for the RPP and RPE responses for the 6 resistance exercises are summarized in the table. There were no differences in the frequency of ischemic ECG responses, ectopic activity, or muscle soreness between the two warm-up procedures.

	RPP-AE	RPP-ST	p-value	RPE-AE	RPE-ST	p-value
Leg Press	14379 ± 3764	12854 ± 3980	0.028	12.2 ± 1.6	11.1 ± 1.5	0.043
Chest Press	15254 ± 4292	14302 ± 4710	0.313	12.5 ± 1.5	12.0 ± 1.8	0.144
Leg Extension	16390 ± 4344	16083 ± 5549	0.651	13.0 ± 1.8	12.5 ± 1.6	0.165
Seated Row	17699 ± 4694	16976 ± 5439	0.280	12.5 ± 1.7	12.1 ± 1.8	0.253
Shoulder Press	16040 ± 3485	15068 ± 4920	0.170	13.0 ± 1.7	12.2 ± 1.7	0.045
Lat Pull Down	15530 ± 3633	15172 ± 4856	0.590	12.3 ± 1.2	11.8 ± 1.5	0.123

**CONCLUSION:** Low-risk coronary patients can safely perform RT following a stretching warm-up. Findings suggest that the type of warm-up has little influence on the cardiac and somatic demands of RT in selected cardiac patients.

**Heart Rate Complexity During Upright Tilt Throughout the Normal Menstrual Cycle**

Eren R. Sanborn, Steven A. Romero, Donovan L. Fogt, William H. Cooke. *University of Texas at San Antonio, San Antonio, TX.*

Email: erensanbo@gmail.com

(No relationships reported)

Autonomic neural control of the circulation is fundamental for maintenance of orthostatic stability. Because reproductive hormones influence a wide variety of variables that may affect autonomic function, circulatory control during orthostasis may be altered by menstrual phase. To our knowledge, the effects of menstrual phase on complex interactions among various autonomic regulatory variables and their impact on orthostatic responses have not been studied.

**PURPOSE:** To test the hypothesis that heart rate complexity varies during the normal menstrual cycle during upright tilt.

**METHODS:** Nine healthy eumenorrheic women (mean age  $24 \pm 1$  yr, height  $166 \pm 3$  cm, weight  $68 \pm 2$  kg; mean  $\pm$  SE) were studied during the early follicular (EF; days 1-2 determined by end of menses), late follicular (LF; days 12-13), early luteal (EL; day 22), and late luteal (LL; days 27-28) phases of the menstrual cycle. Blood plasma concentrations were analyzed for estradiol, progesterone, luteinizing hormone (LH), and follicle stimulating hormone (FSH). Subjects were instrumented for ECG and breathed in time with a metronome for 10 min in the supine position (15 breaths/min). Subjects were then tilted head-up to  $70^\circ$  for an additional 10 min of controlled breathing. Heart rate complexity was assessed with non-linear statistics including sample entropy (SampEn; a measure of complexity, or the degree of randomness within a signal) and short-term detrended fluctuations (DFA-s; quantifies fractal-like correlation properties).

**RESULTS:** Progesterone was elevated during EL compared with LF ( $14.3 \pm 7$  vs  $.8 \pm .3$  pg/ml;  $P=.03$ ), and FSH was elevated during EL compared with LL ( $4.1 \pm .9$  vs  $2.6 \pm .3$  pg/ml;  $P=.05$ ). Estradiol tended to be higher during LF and EF ( $P=0.1$ ). No tendencies were detected for LH across menstrual phases ( $P=.4$ ). SampEn decreased ( $P<.03$ ) and DFA increased ( $P<.001$ ) with tilt, but these changes were not different between menstrual phases (all  $P>.05$ ).

**CONCLUSIONS:** These findings suggest that female reproductive hormones do not affect heart rate regulation during an orthostatic challenge. Specifically, the degree of randomness, as well as the fractal nature of cardiac rhythms during orthostasis are not affected by menstrual phase.

**Cardiac Denervation Does Not Effect Exercise Limitation After Heart Transplant**

Jeremy A. Patterson<sup>1</sup>, Nick G. Walton<sup>1</sup>, Kaelin C. Young<sup>2</sup>, Hussam Farhoud<sup>3</sup>. <sup>1</sup>Wichita State University, Wichita, KS. <sup>2</sup>University of Oklahoma, Norman, OK. <sup>3</sup>Cypress Heart, Wichita, KS. (Sponsor: Michael Rogers, FACSM)

Email: jeremy.patterson@wichita.edu

(No relationships reported)

It has been well documented that for heart transplant recipients (HTRs), post-transplantation physical work capacity (PWC) normally does not exceed 60% of the value for healthy age-match controls and peak HR is significantly reduced (66% of predicted). The reduced PWC has been linked to the blunted HR at peak exercise due to complete denervation of the heart causing a loss of autonomic innervation of the SA node. **CASE SUMMARY:** A 37 year-old, professionally trained male cyclist suffered an AMI immediately following a road race and received a heart transplant four months following the AMI. The participant resumed training one month following surgery.

**METHODS:**  $VO_{2max}$  was determined during a symptom-limited graded exercise test on an electronically-braked cycle ergometer, starting at 75 Watts and increasing by 25 Watts / 3 min. at 6 and 12 months post surgery.

**RESULTS:** Peak PWC ( $33.8 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ , 250 Watts;  $44.2 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ , 275 Watts) and peak heart rates (165 bpm and 163 bpm).  $VO_2$  was 92% and 121% of predicted and HR was 97% and 96% of max pre AMI, respectively. These results were similar to the participants in a study (Richard et al., 1999) who had been training regularly for  $36 \pm 24$  months prior to testing and PWC evaluations occurred  $43 \pm 12$  months following HTR.

**CONCLUSION:** This individual showed a normal HR response to workload at 6 months and 12 months post HTx. This is likely due to the short duration in heart failure prior to transplantation. This unique case suggests that maximum HR cannot be a limiting factor to the exercise tolerance of HTRs and chronotropic competence can return to normal. The limiting factor to exercise capacity is likely due to peripheral function (vascular and muscular). Thus, lifestyle prior to HTR positively affects post-transplantation PWC and a more aggressive approach to heart transplant recovery focusing on peripheral dysfunction would benefit patients.

**Therapeutic Effect Of Exercise Training On Cardiac Apoptosis In Streptozotocin-induced Diabetic Rats**

Yi-fan Liu<sup>1</sup>, Fen-Ni Wu<sup>1</sup>, Wei-Wen Kuo<sup>1</sup>, Chia-Hua Kuo<sup>2</sup>, Ai-Lun Yang<sup>3</sup>, Chih-Yang Huang<sup>1</sup>, Shin-Da Lee<sup>1</sup>. <sup>1</sup>China Medical University, Taichung, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>3</sup>National Cheng Kung University, Tainan, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: loveelfa@gmail.com

(No relationships reported)

**BACKGROUND:** Cardiac apoptosis was found in diabetes but very limited information regarding the effects of exercise training on cardiac apoptosis in diabetes was available. The purpose of this study was to evaluate the therapeutic effects of exercise training on cardiac apoptotic pathways.

**METHODS:** Eight Wistar rats and Streptozotocin-induced diabetic rats at 4 months of age were served as negative (Control) and positive (DM) control. Eight Streptozotocin-induced diabetic rats underwent running exercise on treadmill 1 hour daily, 5 sections per week, for 8 weeks (DM-EX). After exercise training or sedentary status, the excised hearts were measured by positive TUNEL assays and Western Blotting.

**RESULTS:** Citrate synthase activity in skeletal muscle in DM-EX is significantly increased compared with sedentary group (Control and DM). Protein levels of mitochondria dependent pathway, including cytochrome c, activated caspase 9, and activated caspase 3 were increased in DM group compared with control. Protein levels of death receptor dependent pathway, including TNF-alpha, Fas ligand, Fas death receptors, Fas-associated death domain (FADD), activated caspase 8, and activated caspase 3 were increased in DM group compared with control. Exercise training decreased diabetes-induced cardiac TUNEL-positive apoptotic cells. Exercise training decreased protein levels of cytochrome c, activated caspase 9, activated caspase 3 (mitochondria pathway) and TNF-alpha, Fas ligand, Fas death receptors, FADD, activated caspase 8, and activated caspase 3 (Fas pathway) in DM-EX group compared with DM group.

**CONCLUSIONS:** Exercise training suppressed diabetes-induced cardiac mitochondria and Fas receptor dependent apoptotic pathways. The findings may provide one of possible therapeutic approaches for preventing cardiac apoptosis in diabetes.

## Influence Of Left Ventricular Diastolic Function On Ventilatory Responses During Exercise In Healthy Individuals

Sophie Lalande, Wayne L. Miller, Bruce D. Johnson. *Mayo Clinic, Rochester, MN.* (Sponsor: James Christopher Baldi, FACSM)

Email: lalande.sophie@mayo.edu

(No relationships reported)

Healthy aging is associated with changes in left ventricular (LV) diastolic function, namely a prolongation of LV relaxation and increased filling pressures. This could influence ventilation through afferent cardiac pulmonary receptors sensitive to stretch or pressure and/or to changes in lung compliance. Such cardio-pulmonary interdependence may be accentuated with exercise.

**PURPOSE:** To determine if indices of LV diastolic function influence ventilation, breathing pattern and gas exchange during exercise in healthy adults, and to determine if these associations are age related.

**METHODS:** 103 adults (age:  $50 \pm 2$ , range 22-76yr, 42 females,  $VO_{2peak}$ :  $34.8 \pm 0.8$  ml/kg/min,  $FEV_1$ :  $105 \pm 1$  %pred) underwent echocardiography and cardiopulmonary exercise testing. Isovolumic relaxation time (IVRT) and the ratio of peak early mitral inflow velocity to peak early mitral annular velocity ( $E/E'$ ) were used as indices of LV relaxation and filling pressure. Respiratory rate (RR), tidal volume ( $V_T$ ), ventilation ( $V_E$ ), all indexed to individual vital capacities (VC), as well as ventilatory efficiency ( $V_E/VCO_2$ ) and  $V_T/Ti$ , an index of  $V_E$  drive, were obtained during exercise.

**RESULTS:** Age was positively correlated with IVRT and  $E/E'$  ( $r=0.32$ ,  $0.58$ ,  $p<0.001$ ). An increase in LV filling pressure was positively associated with  $V_E/VC$  at a matched submaximal workload ( $r=0.21$ ,  $p<0.05$ ), and with RR/VC and  $V_E/VCO_2$  at peak exercise ( $r=0.21$ ,  $0.26$ ,  $p<0.05$ ). Prolonged LV relaxation was associated with  $V_E/VC$ ,  $V_E/VCO_2$  and  $V_T/Ti$  at the matched workload ( $r=0.35$ ,  $0.26$ ,  $0.21$ ,  $p<0.05$ ), and with RR/VC,  $V_T/VC$  and  $V_E/VCO_2$  at peak exercise ( $r=-0.22$ ,  $0.23$ ,  $0.22$ ,  $p<0.05$ ). The relationship between diastolic function and ventilatory function was not independent of age at the submaximal workload. The associations between RR/VC and LV filling pressure and relaxation, as well as the association between  $V_E/VC$  and filling pressure were independent of age at peak exercise.

**CONCLUSION:** Resting measures of LV diastolic function are associated with breathing pattern, gas exchange and ventilation, however only measures of breathing pattern at peak exercise appeared to be associated with diastolic function independently of age. NIH Grant HL71478.

#### Cardiorespiratory Responses To Aquatic Vs. Traditional Treadmill Exercise: Implications For Exercise Prescription

C Ozemek, P.H. Brubaker, FACS, A Gonzales, S Wiley, G Collins. *Wake Forest University, Winston Salem, NC.*

Email: ozemc8@wfu.edu

(No relationships reported)

**PURPOSE:** Recently, there has been an increased use of aquatic treadmills (AT) for injury rehabilitation, however little is known regarding the response of the cardiorespiratory system to this modality of exercise. The purpose is to determine the cardiorespiratory responses of AT vs. traditional treadmill (TT) exercise, particularly with respect to the heart rate/oxygen consumption (HR/ $VO_2$ ) relationship.

**METHODS:** Eleven Wake Forest University student-athletes ( $20.8 \pm 0.6$  years, 6 females and 5 males), completed similar exercise testing protocols on the AT and TT. Both protocols began with 5 minutes of standing rest followed by four exercise stages of increasing belt speed (1.5, 3.0, 4.5, and 6.0 mph). Thereafter, the AT protocol incorporated three exercise stages at 6.0 mph with water jet resistance (@ 30, 40, and 50% of jet capacity) while the TT protocol included three exercise stages at 6.0 mph with incline gradients of 1.0, 2.0, and 4.0% grade. A Cosmed K4b2 device with Polar monitor was used to collect heart rate (HR), ventilation (VE), tidal volume (TV), breathing frequency (Bf), and oxygen consumption every minute. Ratings of Perceived Exertion (RPE) were also obtained each minute.

**RESULTS:** There was no significant differences between AT and TT for  $VO_2$  at rest or during any stage of exercise, with exception to stage 3. Furthermore, there were no significant differences between AT and TT for HR, VE, Bf, and RPE on any exercise stage. Tidal volume was significantly lower during AT than TT at stage 3 only. Furthermore, bivariate plots of HR and  $VO_2$ , across all stages of exercise, indicates a similar relationship in these variables during AT ( $r = .94$ ,  $y = .269x - 10.86$ ) and TT ( $r = .95$ ,  $y = .291x - 12.98$ ).

**CONCLUSION:** These data indicate that AT and TT exercises elicit similar cardiorespiratory responses in collegiate athletes. Furthermore, the similarity in the relationship between HR and  $VO_2$  observed in AT and TT suggests that HR can be used to regulate appropriate levels of exercise intensity on AT.

#### Assessment Of Cardiac Structure/function And Risk Factors In Collegiate Football Players: Does Body Size Matter?

Benjamin Wooster, Peter H. Brubaker, FACS, J. Brian Moore, Devon A. Dobrosielski, Daryl Rosenbaum. *Wake Forest University, Winston-Salem, NC.*

(No relationships reported)

More than fifty thousand men play American football at the collegiate level. The unique demands of this sport may alter cardiac function and increase risk for cardiovascular disease (CVD). Interior lineman (IL) may be especially vulnerable due to ingestion of hypercaloric diets to support heavy frames or facilitate additional weight gain.

**PURPOSE:** To evaluate cardiac structure/function and CVD risk factors in collegiate football players.

**METHODS:** Twenty-six players from Wake Forest University were recruited to participate; including interior lineman ( $n=13$ ) and skill position (SP) players ( $n=13$ ). BMI, % body fat and resting blood pressure were measured according to established guidelines. Fasting blood samples were obtained to determine serum lipids and glucose levels. End-diastolic volume (EDV) and end-systolic volume (ESV) were evaluated using echocardiography.

**RESULTS:** In addition to higher mean ( $\pm$  SD) BMI ( $36.0 \pm 3.6$  vs.  $26.3 \pm 1.5$  m/kg<sup>2</sup>) and % body fat ( $24.9 \pm 4.6$  vs.  $9.9 \pm 2.7$  %) IL showed significantly elevated Triglycerides and VLDL, with a corresponding decrease in HDL ( $37.8 \pm 3.2$  vs.  $48.6 \pm 5.8$  mg/dl) compared to SP. Mean SBP ( $134 \pm 12$  vs.  $121 \pm 5$  mmHg) and DBP ( $79 \pm 6$  vs.  $72 \pm 7$  mmHg) was significantly higher in IL. Interior linemen also demonstrated significantly greater EDV and ESV compared to SP, although there is no difference between groups after adjusting for body size (fig. 1).

**CONCLUSION:** These results suggest that collegiate IL may be at considerable risk for developing CVD compared to SP due to potential abnormalities in cardiac structure/function. Future research is necessary expand on these observations including the inclusion of an age & size matched "control" group of non-football players.

G. White Presenting

(No relationships reported)

**PURPOSE:** Myocardial inflammation may be a potential mechanism for the release of troponin and NTproBNP following a Marathon. CMR has not been previously used to detect and quantify myocardial inflammation and fibrosis pre- and post-Marathon.

**METHODS:** CMR was performed in 18 athletes 24hrs pre and 6 hours post a Marathon run. Each scan was performed on a 1.5T Siemens Avanto scanner using a 4 channel body array coil. Myocardial structure and function was assessed using breath hold SSFP cine imaging in long and short axis views. The presence of myocardial inflammation and oedema was assessed using STIR imaging and a 3-4 minute spin echo sequence immediately post 0.1mmol intravenous gadolinium-DTPA to assess relative gadolinium enhancement. Inversion recovery segmented-FLASH imaging with TI adjusted to null normal myocardium to highlight regions of fibrosis was used to image delayed enhancement. Each participant had bloods drawn for TnI, NT-proBNP, and CRP at baseline, immediately post and 6 hours after the run. Each CMR scan was analyzed for wall thickness per segment, volumes and function, myocardial oedema. Delayed enhancement images were analysed using Medis software.

**RESULTS:** Biventricular volumes, stroke volume, ejection fraction, and mass were unchanged pre and 6 hrs post marathon. The majority of subjects were found to have a rise in BNP levels immediately and 6 hours after the race as well as elevations in TnI above the level of cut off for myocardial infarction (P=0.001). There were no focal regions of visual signal increase on the STIR images in any of the 18 subjects. Global myocardial oedema was predefined using a cut off ratio of 1.9 comparing SI of myocardium to skeletal muscle on STIR imaging, and a relative 45% increase in the SI myocardium/skeletal muscle immediately post intravenous gadolinium on relative gadolinium enhancement imaging (rGE). No subject reached these cut off values. None had any visual myocardial fibrosis on late enhancement imaging or using automated software.

**CONCLUSIONS:** Serum markers of myocardial cell damage post ultra endurance exercise are not associated with CMR detectable levels of myocardial oedema, inflammation or scarring, suggesting lower degrees of myocardial damage than in patients with acute myocardial infarction, in spite of similar levels of troponin elevation.

**Parasympathetic Modulation Of The Autonomic Nervous System In Individuals With Down Syndrome**

George H. Echols<sup>1</sup>, Kevin S. Heffernan<sup>2</sup>, Arturo Figueroa<sup>3</sup>, Scott Collier<sup>3</sup>, Tracy Baynard<sup>1</sup>, Ifigenia Giannopoulou<sup>3</sup>, Styliani Giannopoulou<sup>3</sup>, Bo Fernhall, FACS<sup>1</sup>. <sup>1</sup>University of Illinois Urbana-Champaign, Urbana, IL. <sup>2</sup>Tufts Medical Center, Boston, MA. <sup>3</sup>Syracuse University, Syracuse, NY.

Email: gechols@illinois.edu

(No relationships reported)

Individuals with Down syndrome (DS) are known to have autonomic dysfunction at rest and exercise in comparison to a healthy population. Autonomic dysfunction has been associated with early mortality.

**PURPOSE:** To examine the autonomic responses to perturbations in persons with Down syndrome in comparison to similar non-disabled controls.

**METHODS:** Static hand-grip (HG) was performed by 38 participants (controls: n=13; DS: n=25) were examined. Autoregressive power spectral analysis was used to investigate R-R interval variability during 2 min of rest and 2 min of HG exercise at 30% of maximum. 29 participants (controls: n=11, DS: n=18) also performed head-up upright tilt. Autoregressive power spectral analysis was used to investigate R-R interval variability during 5 min of rest and 5 min of tilting, and all data were log transformed before analyses. Total power, LF, HF and LF/HF were analyzed using 2x2 (group by condition) ANOVA.

**RESULTS:** There were interactions for total power, low frequency (LF), high-frequency (HF) and the LF/HF ratio (p<0.05), showing that individuals with DS exhibited a lesser change in response to both HG and upright tilt. For the HG, HF decreased from 6.25 at rest and to 5.04 during exercise, but the persons with DS went from 5.84 to 5.43. The LF/HF ratio increased during HG, from 5.55 to 5.95 for controls, whereas the persons with DS changed from 5.45 to 5.62. During the tilt test, HF decreased from 6.45 to 4.99 in controls, and from 5.77 to 4.01 in subjects with DS. The LF/HF ratio went from 4.80 at rest to 6.65 during tilt in controls, whereas the persons with DS changed from 5.52 to 6.35.

**CONCLUSIONS:** Individuals with DS exhibited reduced heart rate variability responses to both HG and upright tilt, suggesting global autonomic dysfunction in response to sympathetic stress. This is manifested by both reduced vagal withdrawal, and reduced alteration in sympathovagal balance.

**Histologic Evaluation Of Doxorubicin-induced Cardiotoxicity In Exercise Trained Rats**

Traci L. Parry<sup>1</sup>, Greg Wilkerson<sup>2</sup>, David S. Hydock<sup>1</sup>, Brock T. Jensen<sup>1</sup>, Chia-Ying Lien<sup>1</sup>, Carole M. Schneider, FACS<sup>1</sup>, Reid Hayward<sup>1</sup>. <sup>1</sup>University of Northern Colorado, Greeley, CO. <sup>2</sup>Colorado State University, Fort Collins, CO.

Email: traci.parry@unco.edu

(No relationships reported)

The value of exercise in attenuating doxorubicin (DOX)-induced cardiotoxicity is becoming increasingly evident. While exercise has been shown to attenuate DOX-induced declines in cardiac function, little is known about the effects of exercise training on the formation of myocardial lesions that accompany DOX treatment.

**PURPOSE:** To evaluate the effects of exercise training on the myocardial lesions associated with DOX exposure using a qualitative/quantitative scale specifically designed for the assessment of anthracycline toxicity.

**METHODS:** Female Sprague Dawley rats were randomly assigned to one of four experimental groups: sedentary (SED)+saline (SAL), SED+DOX, wheel run (WR)+SAL, WR+DOX. SED animals remained sedentary for the entire study. Animals in WR groups were individually housed in cages equipped with running wheels and allowed to voluntarily exercise. Animals in DOX groups received a 15 mg/kg cumulative dose of DOX (2.5 mg/kg/wk, i.p.) and animals in SAL groups received saline injections of equivalent volume using the same dosing schedule. DOX/SAL injections began on day one of the protocol. After the 10 week period, hearts were removed, flushed using an isolated working heart system, fixed in 10% buffered formalin. Myocardial lesions were scored on two categories: severity degree (0 - 2 scale) and extension degree (0 - 5 scale). The product of the severity and extension scores gave the total cardiotoxicity score (0 - 10 scale).

**RESULTS:** DOX treatment significantly increased the mean total score from 0.1 in SED+SAL to 5.6 in SED+DOX (p<0.01), which is consistent with previous studies showing that DOX elicits myocardial lesions at this dose. However, while similar exercise protocols have shown to preserve cardiac function, this does not appear to be the case in terms of the histologic appearance of myocardial lesions. Mean total score for WR+DOX (6.0) was significantly different from SED+SAL (p<0.01) and not different from SED+DOX.

**CONCLUSIONS:** Utilizing a well-established scoring system for DOX cardiotoxicity in rodent models, pathologic changes to the myocardium were clearly evident between saline-treated groups and those receiving DOX. No significant differences were noted, however, between the myocytes in sedentary versus exercised hearts utilizing the parameters of this scoring system.

## Therapeutic Effect Of Exercise Training On Cardiac Fibrotic Pathway In Obesity

Shin-Da Lee<sup>1</sup>, Ching-Yi Tasi<sup>1</sup>, Chia-Hua Kuo<sup>2</sup>, Chih-Yang Huang<sup>1</sup>. <sup>1</sup>China Medical University, Taichung, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: shinda@mail.cmu.edu.tw

(No relationships reported)

**Background.** No information regarding transforming growth factor beta (TGF $\beta$ ) and connective tissue growth factor (CTGF) in obese heart as well as no information regarding the effects of exercise training on cardiac fibrosis in obesity was available. The purpose of this study was to evaluate TGF- $\beta$ -CTGF-related fibrotic pathway in obese heart and the effects of exercise training on cardiac fibrosis. **METHODS:** Twelve lean Zucker rats (LZR) and twelve obese Zucker rats (OZR) at 5-6 months of age were served as sedentary lean group and sedentary obese group as well as twelve obese rats underwent swimming exercise 3 hour daily for 1 month (OZR-EX). After exercise training or sedentary status, the excised hearts were measured by Hematoxylin and Eosin (H&E) staining, Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay, Masson trichrome staining and Western Blotting. **RESULTS:** Myocardial architecture abnormality, more cardiac TUNEL-positive apoptotic cells, and minor cardiac fibrosis were found in OZR, compared to LZR. The protein levels of TGF- $\beta$ , mitogen-activated protein kinase/extracellular signal-regulated kinase (MEK), extracellular signal-regulated kinase (ERK), CTGF, matrix metalloproteinase (MMP)-9, and MMP2 were significantly increased in OZR relative to LZR. Exercise training decreased OZR-induced myocardial architecture abnormality, cardiac TUNEL-positive apoptotic cells, and cardiac fibrosis as well as exercise training decreased OZR-induced fibrosis-related protein levels of TGF- $\beta$ , MEK, ERK, CTGF, MMP-9, and MMP2.

**CONCLUSIONS:** Exercise training prevented cardiac fibrosis and cardiac TGF- $\beta$ -CTGF fibrotic pathway in obese models. Our findings imply that exercise therapy could be one of possible therapeutic approaches to prevent delirious cardiac fibrosis in obesity.

### 1494 Board #96 May 27 9:30 AM - 11:00 AM Does Bariatric Surgery Reverse Obesity-associated Sympathoexcitation?

Cornelius B. Groenewald, Nisha Charkoudian, Nicholas A. Strom, Jessica R. Sawyer, Timothy B. Curry. *Mayo Clinic, Rochester, MN.*

(No relationships reported)

Obesity is associated with an increase in resting levels of muscle sympathetic neural activity (MSNA) and a decrease in reflex sympathetic neural and cardiovascular responsiveness. Exercise and diet induced weight loss reverse these changes, however the potential effects of bariatric surgery induced weight loss are unknown.

**PURPOSE:** We hypothesize that bariatric surgery will decrease baseline levels of MSNA and increase baroreflex sensitivity.

**METHODS:** We measured MSNA (peroneal microneurography), R-R interval (ECG) and arterial pressure (arterial catheter) in three groups of subjects: (1) subjects > 12 months post bariatric surgery (N = 2) (2) obese subjects BMI > 35 kg/m<sup>2</sup> (N = 7) (3) lean control subjects BMI < 25 kg/m<sup>2</sup> (N = 5). MSNA, ECG and arterial blood pressure were measured continuously during intravenous vasodilator (sodium nitroprusside) and pressor (phenylephrine) boluses. Baroreflex control of sympathetic outflow and of the heart were determined by the relationships of arterial pressure with MSNA and R-R interval, respectively, during blood pressure fluctuations (modified Oxford technique).

**RESULTS:** Our preliminary results indicate that chronic resting levels of MSNA were lower in post bariatric subjects [19 +/- 4 (SE) bursts/min vs 28 +/- 4 bursts/min in obese subjects] with values no different from non-obese control individuals (21 +/- 3 bursts/min). Bariatric surgery also appeared to increase the responsiveness of baroreflex control of the heart [14.23 msec/mmHg (RRI) vs 8.50 msec/mmHg for obese subjects (p < 0.004)].

**CONCLUSION:** Preliminary results indicate bariatric surgery may reverse both obesity associated increases in chronic resting levels of MSNA and improve sensitivity of the baroreflex.

Supported by NIH UL1 RR024150 (to the Mayo Clinic).

## A-27 Free Communication/Poster - Clinical Exercise Testing

MAY 27, 2009 7:30 AM - 12:30 PM

ROOM: Hall 4F

---

### 1495 Board #97 May 27 11:00 AM - 12:30 PM Clinical Measurement Of Sit-to-stand Performance In People With Painful Vertebral Degenerative Disease

Jin Jong Chen<sup>1</sup>, Ying Po Hsu<sup>1</sup>, Kung Chia Li<sup>2</sup>. <sup>1</sup>National Yang-ming University, Taipei, Taiwan. <sup>2</sup>Chiayi Yang-Ming Hospital, Taipei, Taiwan.

Email: jjchen@ym.edu.tw

(No relationships reported)

**PURPOSE:** People with painful vertebral degenerative disease are characterized as having difficulty with transitional movements, such as the sit-to-stand movement. A valid and feasible tool is needed to help clinicians quantify the ability of people with painful vertebral degenerative disease to perform transitional movements. Few studies have been conducted to evaluate patients' performance during different phases of sit-to-stand. The purpose of this study was to develop a three-phase sit-to-stand testing (3PSST) instrument for PVDD patients and to investigate the PVDD impacts on the elderly subjects.

**METHODS:** Forty-one elderly subjects (67.1 $\pm$ 9.0 years) from an orthopedic clinic with PVDD were examined before the surgery or other treatments. Thirty age-matched community healthy elderly dwellers (72.5 $\pm$ 5.4 years) were included in this study as control group volunteers (CG). Sit-to-stand performance tests were conducted using a force plate to measure the ground reaction force (GRF) and center of pressure (COP). Switches mounted on chair back and chair seat were used to separate the whole sit-to-stand course into three phases: (1) reaction time (RT), from start signal (SS) to trunk left chair back (TL), (2) trunk movement time (TMT), from TL to buttock left the chair seat (BL), and (3) stand movement time (SMT), from BL to the maximum GRF (MGRF). MGRF were normalized with individual body weight (BW) before group comparison.

**RESULTS:** The results demonstrated that PVDD group subjects had significant poor sit-to-stand performance than the CG subjects: slower RT (0.89 $\pm$ 0.49 vs. 0.70 $\pm$ 0.30 sec, P<.05), slower TMT (0.90 $\pm$ 0.97 vs. 0.40 $\pm$ 0.12 sec, P<.05), and slower SMT (0.40 $\pm$ 0.95 vs. 0.10 $\pm$ 0.12 sec, P<.05). PVDD subjects also demonstrated significant smaller MGRF than CG (1.20 $\pm$ 0.08 vs. 1.29 $\pm$ 0.10BW, p< 0.05).

**CONCLUSIONS:** The 3PSST displays validity properties at discriminating between subjects with and subjects without PVDD that make this test potentially useful in clinical decision making. The subjective variables from the 3PSST could be established to identify RT, TMT and SMT physical function impairment for treatment planning and effectiveness evaluation.

---

### 1496 Board #98 May 27 11:00 AM - 12:30 PM Is Hand Grip Strength A Valuable Tool In Order To Assess Physical Performance In Athletes?

Ulla M. Svantesson<sup>1</sup>, Frode Slinde<sup>2</sup>, Cecilia Elam Edwén<sup>3</sup>, Lena Hulthén<sup>4</sup>. <sup>1</sup>Institute of neurosciences and physiology, University of Gothenburg, Gothenburg, Sweden. <sup>2</sup>Department of Clinical Nutrition, University of Gothenburg, Gothenburg, Sweden. <sup>3</sup>Institute of Neurosciences and physiology, University of Gothenburg, Gothenburg, Sweden. <sup>4</sup>Department of Clinical Nutrition, University of Gothenburg, Gothenburg, Sweden.

Email: ulla.svantesson@neuro.gu.se

(No relationships reported)

The assessment of physical performance in elite athletes is very important in order to design an optimal training protocol for the athlete. The assessment tools must have high reliability and high validity for the sport activity. Hand grip strength is used to evaluate hand function and may be used to assess generalized upper extremity strength. However, reliability values for younger subjects and test-retest reliability of hand grip strength is scarce in the literature.

**PURPOSE:** The study aimed to investigate hand grip strength in elite athletes and to evaluate test-retest reliability of hand grip strength.

**METHODS:** Sixty-nine elite athletes between 20-34 years (29 women (W)) and 75 control subjects (61 W) participated in the study. Ice hockey (17 men (M)), soccer (16 W, 18 M), sailing (3W, 5M) and high jumpers/throwers (10W) participated. Hand grip strength was measured with the Grippit® instrument recording MVC (maximal voluntary strength). Body composition (fat mass (FM), fat free mass (FFM), lean mass (LM), bone mineral density/content (BMD/C)) was assessed using the DEXA® apparatus.

**RESULTS:** Women throwers showed hand grip strength values of 458 N/395 N for right and left hand respectively, the high jumpers showed 413 N/342 N, soccer players showed 402 N/358 N and women sailors 407 N/360 N. The women athletes did not show any significant differences in hand grip strength between sport activities. The women control subjects showed 331 N/303 N. Male soccer players showed 529 N/479 N, ice hockey players 614 N/563 N and sailors 680 N/655 N being significantly ( $p < 0.05$ ) different between sport activities. The men control subjects registered 542 N/518 N. Test-retest reliability was very high ( $ICC = 0.94$ ). Whole body FFM correlated very well with hand grip strength ( $r = 0.62-0.67$ ) as well as FFM for the right and left hand respectively ( $r = 0.72$ ). BMC showed very high correlation with hand grip strength ( $r = 0.69-0.71$ ).

**CONCLUSIONS:** Hand grip strength values give important information when assessing the overall physical performance. Hand grip strength values show very high reliability and correlate very well with body composition, especially fat free mass and bone mineral content of the athlete. Being easy to perform, hand grip strength can be highly recommended as a measuring tool when assessing overall performance.

1497 Board #99 May 27 11:00 AM - 12:30 PM

### Comparing The Shuttle Walk Test And Chester Step Test In Cardiac Rehabilitation Patients In Scotland

Siobhan Gallanagh<sup>1</sup>, Paul MacIntyre<sup>2</sup>. <sup>1</sup>University of Glasgow, Scotland, United Kingdom. <sup>2</sup>Royal Alexandra Hospital, Paisley, United Kingdom.

(No relationships reported)

**PURPOSE:** Cardiac rehabilitation involving exercise reduces all cause mortality following a cardiac event. Current guidelines recommend initial assessment of baseline cardiovascular fitness prior to exercise-based cardiac rehabilitation. The shuttle walk test (SWT) and Chester step test (CST) are currently used in the UK for this **PURPOSE**: This study aims to compare the physiological responses to the CST and SWT in order to determine which test is more effective at measuring cardiovascular fitness.

**METHODS:** 10 cardiac rehabilitation patients were subjects in this randomized cross-over study. The submaximal CST and SWT were extended linearly to maximal tests to ensure true  $VO_{2PK}$  was achieved. The tests were extended (E-CST and E-SWT) by adding levels to each test.  $VO_{2PK}$  was the primary outcome; measured by a portable breath-by-breath cardiorespiratory gas analyzer. Peak heart rate ( $HR_{PK}$ ), peak perceived exertion ratings ( $RPE_{PK}$ ), subjects' preferences and reasons for stopping the tests were recorded as secondary outcomes.

**RESULTS:**  $VO_{2PK}$  measurements were higher in the E-SWT than in the E-CST in 60% of subjects ( $p < 0.607$ ). Mean  $VO_{2PK}$  values were 24.9 and 24.4 ml/kg/min for the E-SWT and E-CST respectively.  $HR_{PK}$  measurements were higher in the E-SWT than in the E-CST in 80% ( $p < 0.199$ ). Mean  $HR_{PK}$  values were 130 and 128 bpm for the E-SWT and E-CST respectively.  $RPE_{PK}$  values were higher in the E-CST than the E-SWT in 60% ( $p < 0.057$ ). 60% of subjects preferred the E-SWT to the E-CST ( $p < 0.022$ ). The commonest reason for terminating the E-CST was leg pain. The commonest reason for terminating the E-SWT was shortness of breath.

**CONCLUSIONS:** The trend for a higher  $VO_{2PK}$  in the E-SWT suggests that it provides a more accurate assessment of aerobic capacity than the E-CST in cardiac rehabilitation patients. The CST exercises an individual muscle group where as the SWT involves the use of several muscle groups throughout the body, reducing the likelihood of local muscle fatigue. Walking is generally a more familiar activity than stepping. As patients are more likely to have higher  $VO_{2PK}$  values in the SWT than in the CST we conclude that the SWT is more suitable for use in cardiac rehabilitation.

1498 Board #100 May 27 11:00 AM - 12:30 PM

### Utility Of The RPE To Assess Walking Intensity Following Traumatic Lower Extremity Amputation

Benjamin Darter, Jason Wilken. Brooke Army Medical Center, Fort Sam Houston, TX.

Email: benjamin.darter@amedd.army.mil

(No relationships reported)

#### PURPOSE:

The purpose of this preliminary study was twofold: 1) to establish the test-retest reliability of the Rating of Perceived Exertion (RPE) as a measure of walking intensity in persons with or without traumatic lower extremity amputation; 2) to confirm validity of the RPE through its association with energy cost (EC).

**METHODS:** Eight men and women (26.4±3.9 yr) with (n=3) and without (n=5) a traumatic lower extremity amputation volunteered to complete a multiple speed treadmill walking test with a repeat test an average of 12 days later. Each participant walked at 5 height-normalized walking speeds and one matching the overground self-selected walking velocity (SSWV). Perception of walking intensity [modified Borg RPE scale (6-20)] and steady state EC (mlO<sub>2</sub>/kg/min) were assessed at each speed. Reliability of the RPE between tests 1 and 2 was analyzed using two-factor (test, speed) ANOVA and, at each speed, an Intraclass Correlation Coefficient (ICC). Pearson correlation coefficients between the RPE and EC were used to determine validity.

**RESULTS:** RPE values (see below) were not different between tests for either group. ICCs for both groups demonstrated good reliability ( $ICC > 0.75$ ) for walking speeds above 1.2 m/s for persons with an amputation and 1.3 m/s in non-amputees. Slower walking speeds produced ICC values in the moderate to poor range ( $ICC < 0.53$ ) for each group. Strong associations ( $r > 0.85$ ) between RPE and EC were observed for each test except test 1 in the amputee group ( $r = 0.78$ ).

RPE					
Amputee			Non-Amputee		
Speed (m/s)	Test 1	Test 2	Speed (m/s)	Test 1	Test 2
0.7	9.7±2.8	8.0±1.0	0.7	7.0±0.0	6.8±0.5
1.0	11.7±0.6	10.7±0.6	1.0	9.0±1.2	7.6±1.1
1.2	12.7±0.6	13.0±1.0	1.2	10.8±0.8	9.6±1.5
1.4	14.3±1.2	15.3±1.5	1.4	12.2±1.6	11.6±2.1
1.6	17.0±0.0	17.0±0.0	1.7	13.4±1.5	12.8±1.9
SSWV (1.2)	12.5±0.6	12.6±0.6	SSWV (1.3)	11.2±1.5	10.8±1.8

**CONCLUSIONS:** Preliminary results suggest the RPE is reliable for measuring the walking intensity at speeds at or above SSWV in persons with or without lower extremity amputation. Reliability and validity may be reduced, however, at slower walking speeds.

---

**1499 Board #101 May 27 11:00 AM - 12:30 PM**  
**Impact Of Painful Vertebral Degenerative Disease On The Elderly Subjects' Dynamic And Static Balance Performances**  
Ying Po Hsu<sup>1</sup>, Kung Chia Li<sup>2</sup>, Jin Jong Chen<sup>1</sup>. <sup>1</sup>National Yang-ming University, Taipei, Taiwan. <sup>2</sup>Chiayi Yang-Ming Hospital, Chiayi, Taiwan.  
Email: ptober1971@hotmail.com  
(No relationships reported)

**PURPOSE:** Significant impacts of painful vertebral degenerative disease (PVDD) on the elderly subjects' physical function have been noted. But only few studies conducted before the surgery to evaluate patients' balance capacity due to severe intolerable pain. The purpose of this study was to investigate the impacts of PVDD on static and dynamic balance performance.

**METHODS:** Forty-one elderly subjects (67.1±9.0 years) from an orthopedic clinic with PVDD were examined before the surgery treatment. Thirty age-matched community healthy elderly dwellers (72.5±5.4 years) were included in this study as control group volunteers (CG). The following measurements were conducted: (1) dynamic balance tests: functional reach (FR), and 3m Timed-Up and Go (TUG), and (2) static balance tests: open eye sitting balance (OESB), close eye sitting balance (CESB), open eye standing balance (OESTB), and close eye standing balance (CESTB).

**RESULTS:** The results demonstrated that PVDD group subjects had significant poor dynamic balance performance than the CG subjects, lower FR (20.8±6.9cm vs. 28.9±4.5cm, p<0.001) and slower TUG (14.99±8.79s vs. 10.20±2.06s, p<0.05). PVDD subjects demonstrated significant lower center of pressure (COP) velocity of postural control than control group during four static balance tests, (38.9±13.6 vs. 62.3±13.3 cm/10sec, 35.3±12.4 vs. 59.2±14.9 cm/10sec, 44.0±17.1 vs. 61.2±10.0 cm/10sec, 48.1±22.0 vs. 64.6±10.7 cm/10sec, for OESB, CESB, OESTB and CESTB, respectively).

**CONCLUSIONS:** PVDD subjects had poor dynamic and static balance. COP velocities (cm/10sec) during four static balance tests are reliable variables for elderly balance function. Compare to dynamic balance tests, static balance tests are more tolerable, which can be conducted before and after the surgery, to evaluate the treatment effect for PVDD subjects.

Being able to drive is an important issue for subjects with spinal cord injury (SCI); the driving performance and seated posture control ability influence the ability of independent driving. However, only few studies concerned these two factors together. Furthermore, although being trained and getting license were important demands for SCI, and virtual reality driving simulator (VRDS) was suggested to be useful in training, the protocol and effects of training with VRDS for SCI have not been established.

**PURPOSE:** To develop a proper VRDS and training program and to evaluate the effects of VRDS training for SCI.

**METHODS:** Twelve SCI subjects were randomly assigned to either VRDS with moving base group (MB) or VRDS with stationary base group (SB). All subjects received ten 30 minutes VRDS training sessions, as well as driving performance in VRDS (total driving time, speed and speed variation, steering control, collisions, and traffic signal violation), balance control ability, cybersickness, enjoyment, workload and realism were measures as outcome variables. The variables between pre- and post- intervention were analysis by Friedman 2-way analysis of variances by ranks. And Wilcoxon Signed-Ranks test. Mann-Whitely U tests were then used to compare the difference between two groups. The a level of .05 was set for the statistical significance.

**RESULTS:** The VRDS training program was realistic and enjoyable without adverse effects of cybersickness. All subjects reported the VRDS training program decreases the fear of driving. Taking 5 sessions of VRDS training resulted in significant improvement on speed control (average speed: 34.08±2.99 vs. 37.15±2.18km/hr); the steering control is harder and takes more training times to improve. After 5 training sessions, MB had better driving performance training effects than SB (average speed: 38.62±1.27 vs. 35.67±1.91 km/hr). MB also had lower physical demands (1 vs. 7, p<.05) and lower frustration (1 vs. 6, p<.05) than SB in the 7-point scale. However, no significant improvement was found in balance control ability of both groups after VRSD training program.

**CONCLUSIONS:** This is the very first study as we know to investigate the effects of the VRDS training with multiple sessions. The VRDS program is effective tool and moving base has better training effects than stationary base.

**Neuromuscular Capacity In Relation To Maximal Exercise Capacity During Incremental Bicycle Test In Healthy Sedentary Male Subjects**  
Asa Segerstrom<sup>1</sup>, Anna-Maria Holmback<sup>1</sup>, Targ Elzyri<sup>2</sup>, Karl-Fredrik Eriksson<sup>2</sup>, Karin Ringsberg<sup>2</sup>, Leif Groop<sup>2</sup>, Ola Thorsson<sup>2</sup>, Per Wollmer<sup>2</sup>. <sup>1</sup>Lunds University, Institute of Health science, Lund, Sweden. <sup>2</sup>Lunds University, Institute of Clinical Sciences, Malmoe, Sweden.  
Email: asa.segerstrom@med.lu.se  
(No relationships reported)

In exercise testing work capacity (maximal oxygen uptake ( $VO_{2peak}$ ) and work rate ( $WR_{leg}$ )) is assessed using large muscles groups, generally by performing primary leg exercise. However the relationship between work capacity and neuromuscular capacity are seldom described when evaluating exercise response.

**PURPOSE:** To investigate the relation between work capacity during an incremental bicycle exercise test and neuromuscular capacities in sedentary healthy male subjects before and after six months of supervised group training.

**METHODS:** Thirty-two male sedentary healthy subjects (37.3+ 4.6 yrs) participated in a training period 3 times per week during 6 month, 1 session of spinning and 2 sessions of mixed exercise. Work capacity was assessed using an incremental bicycle test. Neuromuscular capacities of the knee extensors and flexors were assessed at 60°/s and 120°/s using isokinetic dynamometry. Trunk extensor and flexor strength was assessed using isometric dynamometry, and arm muscle endurance ( $WR_{arm}$ ) was evaluated with a bench press.

**RESULTS:** Maximal oxygen consumption ( $VO_{2peak}$ ) and work rate leg ( $WR_{leg}$ ) increased (0.34+ 0.28 l/min, 35+ 23 W, p<0.05). Work economy,  $VO_{2peak}/WR_{peak}$ , decreased (-0.35+1.0 l/min/W, p<0.05).  $WR_{arm}$  increased (13+5 number, p<0.05). Maximal voluntary contraction (MVC) trunk extension (TE) increased (47+20 N, p<0.05). MVC trunk flexion (TF) did not change. Peak torque (PT) 60°/s knee flexion (F) and 60°/s knee extension (E) did not change. Deceleration (D) 60°/s E decreased (-47.7+ 73.7 msec, p<0.05) and time to PT 60°/s F decreased (-103.8+ 176 msec, p<0.05).  $WR_{arm}$  correlated to  $WR_{leg}$  ( $r_p=0.46$ , p<0.005) at baseline and at 6 month. MVCTE correlated to  $WR_{leg}$  ( $r_p=0.53$ , p<0.005) at baseline and at 6 month. MVCT F correlated and to  $WR_{leg}$  (0.40, p<0.05) at 6 month. PT 60°/s E correlated to  $WR_{leg}$  ( $r_p=0.54$ , p<0.005) at baseline and at 6 month. PT 60°/s F correlated and to  $WR_{leg}$  (0.49, p<0.005) at 6 month.

**CONCLUSIONS:** Six months of combined exercise may relate to an increase in work economy due to improved co-ordination of the knee extensors and flexors as well as modification of the neuromuscular capacity via upper body position.

## Should Arm Exercise Test Follow The Traditional 8-12 Minutes Ramp Protocol?

Sabrina Pedrosa<sup>1</sup>, Eduardo B. Sousa<sup>1</sup>, Fernanda Chabalgoity<sup>1</sup>, Antonio Claudio L. Nobrega, FACSM<sup>2</sup>, Renata RT Castro<sup>1</sup>. <sup>1</sup>Exercise Physiology Laboratory - Instituto Nacional de Traumatologia e Ortopedia, Rio de Janeiro, Brazil. <sup>2</sup>Exercise Sciences Laboratory - Universidade Federal Fluminense, Niterói, Brazil.

Email: sabrinapedrosa@bol.com.br

(No relationships reported)

Ramp protocol is the most used exercise test protocol, since the continuous increase in intensity allows for the achievement of maximal aerobic power in 10±2 minutes without precocious interruption due to muscle fatigue. When small muscle groups are exercised, as in arm ergometry (AE), local fatigue may be a limiting factor that interrupts test before the achievement of maximal aerobic effort. There is no consensus about the optimal duration of a ramp exercise test when AE is performed.

**PURPOSE:** To evaluate if AE exercise test should be programmed to achieve maximal effort at 10±2 minutes.

**METHODS:** Healthy individuals (n=16; 8 men; age=27±4 years; BMI=23.2±2.8 kg/m<sup>2</sup>) were submitted to two maximal cardiopulmonary (Ultima CardIO<sub>2</sub>, MedGraphics, USA) AE tests (Angio, LODE, Netherlands) following different ramp exercise protocols with different load increases each 6 sec: Fast (FP)=2W; Slow (SP)=1W. Tests were performed in two different days following a latin square randomized order. Eight individuals also performed a maximal cardiopulmonary exercise test in a cycle ergometer (CE) (Excalibur, LODE, Netherlands). Cardiopulmonary variables in both protocols were compared using paired Student t test.

**RESULTS:** FS was longer than FP (mean±SD): 10'08''±3'53'' vs FP: 07'26''±2'; p<0.01). During FP a higher load was achieved (FP: 120±40 vs. SP:103±39W; p<0.01), with the same peak oxygen consumption (FP:24.3±6.1 vs. SP:23.5±7.8 ml/kg/min; p=0.88). Exercise economy was higher at CE peak exercise (CE:98.8±9.1<FP:72.6±10.7<SP:64.5±8.9 W/L/min; p<0.01). There was no difference between other exercise variables in both protocols.

**CONCLUSION:** During AE, subjects achieved the same peak oxygen consumption with higher economy when the fast protocol was used, suggesting that there is no need for an AE exercise test to be as long as the usual bike and treadmill tests. The optimal duration of arm exercise test remains to be defined.

#### Cardiorespiratory Fitness In Women With Fibromyalgia: Hemodynamic Correlates

Thomas S. Nabity, Barry Franklin, FACSM, Martin Tamler, Adam DeJong. *William Beaumont Hospital, Royal Oak, MI.*

Email: tnabity@beaumont.edu

(No relationships reported)

Fibromyalgia (FM) is a chronic painful disorder characterized by muscle tenderness as well as other systemic complaints including fatigue, sleep disturbance, and bowel irregularity. Recently, cardiopulmonary exercise testing has been suggested to determine if aerobic capacity (VO<sub>2</sub>max) is uniformly reduced in this patient population.

**PURPOSE:** To evaluate hemodynamic responses to symptom-limited exercise testing in patients with FM, with specific reference to those with normal and reduced levels of cardiorespiratory fitness.

**METHODS:** Female patients (n=20) with diagnosed FM were referred from a single physiatrists office on a voluntary basis. Patients exercised to volitional fatigue or adverse signs/symptoms on a treadmill using the standard Bruce protocol with simultaneous measurements of gas exchange. Heart rate (HR) and blood pressure (BP) values were obtained at rest, during submaximal and peak exercise, and 6 minutes after test termination.

**RESULTS:** Exercise tests on 20 of the 20 patients were terminated due to volitional fatigue. For the entire group (n=20), mean ± SD age and body mass index were 49.0 ± 11.3 years and 27.5 ± 7.1 kg/m<sup>2</sup>. Measured VO<sub>2</sub>max for the cohort was 24.1 ± 6.7 mL/kg/min, and the corresponding respiratory exchange ratio generally exceeded unity (mean, 1.06). Subjects were categorized into 2 groups: Group 1 (n=12), had normal fitness, that is, a functional aerobic impairment <20%; and, Group 2 (n=8), demonstrated a reduced level of cardiorespiratory fitness. Although the groups were comparable in age, mean VO<sub>2</sub>max values were 27.3 and 19.3 mL/kg/min for Groups 1 and 2, respectively. A comparison of hemodynamic responses also revealed that Group 2 had higher values for resting HR and systolic BP, lower peak systolic BP, and a steeper HR slope with progressive exercise. In contrast, there were no differences between the groups in the peak HR, recovery HR, and systolic BP.

**CONCLUSION:** Female patients with FM have varied levels of cardiorespiratory fitness, similar to those observed in the general population. Those with reduced VO<sub>2</sub>max values, however, demonstrate altered hemodynamics at rest and during exercise, responses that may be attributed to hormonal anomalies.

#### Fire Fighters Under Report Rpe During Maximal Treadmill Testing

Matthew J. Comeau, Marla Graves, Meg Williamson. *Arkansas State University, State University, AR.* (Sponsor: Lee Brown, FACSM)

Email: mcomeau@astate.edu

(No relationships reported)

**PURPOSE:** To determine if fire fighters under report their rating of perceived exertion (RPE) during VO<sub>2</sub> max testing.

**METHODS:** Maximal VO<sub>2</sub> values were determined for fire fighters (FF) (N=92) using the Bruce protocol as part of their annual health and fitness assessment. Criteria to determine if a maximal test was performed were: heart rate (HR) equal to or greater than 85% of age predicted maximum as monitored by EKG, RPE above 17, and RER values above 1.15. Completion of the test was volitional, but all FF were told that certain criteria needed to be met prior to termination in an effort to validate the test. However, they could stop at any time. HR and RER were monitored every 20 seconds throughout the test with RPE being assessed at minute two of each stage and a final RPE was assessed at the completion of the test. When criteria for HR and RER had been met, FF were told of this fact.

**RESULTS:** Forty-six FF met two criteria (HR and RER) with twenty-two additional FF meeting all 3 criteria for a total of sixty-eight. Of the remaining twenty-four FF, twenty-three met only the HR criteria and one FF didn't meet any of the criteria before terminating the test. Therefore, 67.6% of firefighters meeting physiological determinants of a VO<sub>2</sub> max test (HR and RER) under reported their RPE.

**CONCLUSIONS:** When utilizing RPE as a determinant of a valid VO<sub>2</sub> max test, caution should be used when subjects have been exposed to dangerous or high stress situations when performing job related duties. While only FF were used, similar results may be seen in police, military personnel or those working in high stress situations.

#### Estimation Error When Using The %HRR Method Compared To The Lactate Turn Point

Peter Hofmann<sup>1</sup>, Gerhard Tschakert<sup>1</sup>, Markus Stark<sup>1</sup>, Günther Schwaberg<sup>2</sup>, Rochus Pokan, FACSM<sup>3</sup>, Manfred Wonisch, FACSM<sup>4</sup>, Gerhard Smekal<sup>3</sup>, Franz-Josef Seibert<sup>2</sup>, Serge P. von Duvillard, FACSM<sup>5</sup>. <sup>1</sup>Karl-Franzens-University and Medical University of Graz, Graz, Austria. <sup>2</sup>Medical University of Graz, Graz, Austria. <sup>3</sup>University of Vienna, Vienna, Austria. <sup>4</sup>Cardiac Rehabilitation Center St. Radegund, St. Radegund, Austria. <sup>5</sup>University of Salzburg, Salzburg, Austria. (Sponsor: S. P. von Duvillard, FACSM)

Email: peter.hofmann@uni-graz.at

(No relationships reported)

Percent heart rate reserve (%HRR) is widely used for exercise training prescription. However, this method relies on a linear relationship between HR and exercise workload. Recently it has been shown that the HR Performance Curve (HRPC) is neither linear nor uniform in different groups of healthy subjects and patients.

**PURPOSE:** The aim of this study was to compare the target training HR of 70 and 80% HRR, and HR at the second lactate turn point (LTP<sub>2</sub>) an objective individual measure of submaximal aerobic performance.

**METHODS:** A set of data (N=186) from several groups of subjects was analyzed retrospectively. The groups consisted of young healthy males (N=60) and females (N=30) sports students, older healthy subjects (N=11), patients after myocardial infarction (N=44) and young obese male and female subjects (N=41). All subjects underwent incremental exercise tests and the first and the second lactate turn point were obtained in all subjects applying the same linear regression break point model. The degree and the direction of the HRPC were calculated by means of a second degree polynomial model ( $k_{HR}$ ). 70% and 80% HRR were calculated according to established standards. The error of estimate was calculated as  $[(HRR - HR \text{ at LTP}_2)/HR \text{ at LTP}_2] \times 100$ .

**RESULTS:** The range of error was found between -14.9% and +29.2% for 70%HRR and between -7.5% and +37.3% for 80%HRR. The error of estimate for the 70% and 80% HRR model was significantly related to the degree and the direction of the deflection of the HRPC ( $k_{HR}$ ) (70%HRR:  $r=-0.71$ ,  $p<0.001$ ; 80%HRR:  $r=-0.70$ ;  $p<0.001$ ) and %HRmax at the LTP<sub>2</sub> (70%HRR:  $r=-0.92$ ,  $p<0.001$ ; 80%HRR:  $r=-0.96$ ,  $p<0.001$ ).

**CONCLUSION:** The %HRR values underestimate most young healthy male and female subjects, however, they overestimate target training HR in patients and older subjects. The error of estimate is strongly dependent on the time course of the HRPC. The error of estimate may increase to an unacceptable level of up to 35% in subjects who generated a non regular inverted HRPC.

**1506 Board #108 May 27 11:00 AM - 12:30 PM**  
**Does Negative Heel Shoes Alter A Person's Exercising Metabolism As Advertised**

AJ Kinsella, Kristin Soupa, Amy Kappel, Ambareen Khan, Nida Malik, Nicholas DeRienzo, Laura Gruss, Craig E. Broeder, FACSM. *Benedictine University, Lisle, IL*

Email: aj.kinsella@gmail.com

(No relationships reported)

**PURPOSE:** This study determined the effects negative heel (NH) shoes (3.7% negative heel design) had on walking metabolic efficiency, EMG, and gait in 17 subjects (13 male; 4 female). This abstract focuses on only the metabolic efficiency data.

**METHODS:** Each subject completed 2 trials in both the NH and standard running shoes (SR), respectively. Maximal and submaximal metabolic responses were measured comparing VO<sub>2</sub>, VCO<sub>2</sub>, RER, heart rate, substrate utilization and total steady-state energy expenditure after a 7-10 day accommodation period.

**RESULTS:** VO<sub>2</sub> max test-retest results showed exceptional reliability for each shoe (NH  $r$ -value= .97, SEE=1.1 ml,  $P$ = .0001; SR  $r$ -value= .98, SEE= 1.1ml,  $P$ = .0001). The VO<sub>2</sub> max correlation between NH and SR shoes showed a  $r$ -value=.89, SEE= 1.42ml, and  $P$ = >.0001. The VO<sub>2</sub> max results showed there were no significant differences observed, indicating equal max performances for each shoe and all trials. Steady-state VO<sub>2</sub> results indicated no significant differences between NH and SR shoes' oxygen uptake at 0% grade and 3.7% grade at 3.0 mph. These results repudiate the manufacturer's claim that NH shoes, due to 3.7% negative heel design, will increase a person's metabolic demand during walking exercise. Fat and carbohydrate (CHO) substrate utilization responses at steady state were also not significantly different between shoes when walking at 3.0 mph & either 0% or 3.7% grade. However, as expected, there were a greater total amount of kcals expended and CHO utilized when walking at 3.7 % compared to 0% grade in both shoes. Steady state heart rate results showed near significant increases while wearing NH compared to SR shoes when walking at both 0% and 3.7 % grades ( $p$  = .06) However, this may only be due to using untrained muscles not in use when walking in normal running shoes. As expected, total kcal expenditure between shoe types showed no significant differences after 20 minutes of walking at a 0% grade (NH = 258kcal; SR= 253kcal).

**CONCLUSIONS:** These results indicate negative heel shoe design did not alter a person's oxygen consumption, kcal expenditure, or substrate utilization usage (fat versus CHO) compared to standard exercise shoes as advertised by the NH shoe company.

**1507 Board #109 May 27 11:00 AM - 12:30 PM**  
**Low Reproducibility Of Lactate Markers During Incremental Cycle Exercise**

R. Hugh Morton<sup>1</sup>, Stephen R. Stannard<sup>1</sup>, Bartholomew Kay<sup>2</sup>. <sup>1</sup>Massey University, Palmerston North, New Zealand. <sup>2</sup>Auckland University, Auckland, New Zealand. (Sponsor: Francois Peronnet, FACSM)

Email: H.Morton@massey.ac.nz

(No relationships reported)

**PURPOSE:** Previous reports on reproducibility of lactate markers during incremental exercise have usually considered only two trials, and these predominantly in running. This study was undertaken to determine the reproducibility of power output at four different markers in a group of subjects over at least six repeated incremental cycling trials held under tightly controlled conditions.

**METHODS:** Ten subjects undertook six, and an eleventh undertook seven, repeated incremental exercises (50W start, +50W every 3-min to volitional exhaustion) on a cycle ergometer. At each trial blood lactate concentration was determined at rest and within the final 30s of each 3-min workload. The Rest+1 and 4.0 mMol.L<sup>-1</sup> markers were determined by interpolation, and the blood lactate vs. power output relationship was modelled using a quadratic function, from which the nadir (lactate minimum) and D-max markers were determined. Analyses of variance were utilised to partition inter- and intra-subject variation in power output at these markers. Intraclass correlation coefficients were evaluated to assess reproducibility. Standard calculations were performed for assessment of statistical power.

**RESULTS:** Power output at all markers differed significantly between subjects, but not between trials. Intraclass correlation coefficients were 0.799 for the Rest+1 point, 0.903 for D-max, 0.677 for the nadir, and 0.807 for the 4.0 mMol.L<sup>-1</sup> point. Standard errors of measurement were 11.9, 2.5, 9.2 and 9.1 W respectively. Corresponding pooled within-subject standard deviation estimates were 26.1, 7.9, 16.2 and 20.8 W, yielding 95% confidence intervals of width 105.2, 31.8, 65.3 and 83.8 W respectively. At a significance level of 0.05 the calculated powers of detecting a 30 W increment in these markers are 0.31, 0.98, 0.58 and 0.42 respectively.

**CONCLUSIONS:** These results suggest that during incremental cycling exercise the reproducibility of power output at lactate markers other than D-max are not as good as those previously reported for running. In addition, apart from D-max, their error margins are of such magnitude that in trained subjects only gross changes in training status can be identified with significant power.

**1508 Board #110 May 27 11:00 AM - 12:30 PM**  
**Aerobic Capacity Testing With Sedentary Adults: Rates And Predictors Of Meeting Criteria For Valid VO<sub>2</sub>Max**

Renea Nilsson<sup>1</sup>, Bethany Kwan<sup>1</sup>, Renee Magnan<sup>2</sup>, Laura Carpenter<sup>1</sup>, Angela Bryan<sup>2</sup>. <sup>1</sup>University of Colorado at Boulder, Boulder, CO. <sup>2</sup>University of New Mexico, Albuquerque, NM.

Email: renea.nilsson@gmail.com

(No relationships reported)

Maximal aerobic capacity (VO<sub>2</sub>max) testing is used in exercise interventions to establish baseline rates of cardiovascular function and as an objective measure of intervention effects. However, participants in exercise interventions are likely sedentary, and unaccustomed to pushing themselves to their maximum capacity, potentially leading to inaccurate assessments of VO<sub>2</sub>max.

**PURPOSE:** To determine rates and predictors of meeting a valid VO<sub>2</sub>max in sedentary individuals.

**METHODS:** 285 sedentary men and women participating in the Colorado STRIDE exercise intervention RCT completed a VO<sub>2</sub>max test. We tested three of the four criteria for

a valid  $\text{VO}_2\text{max}$  test: 1. Respiratory exchange ratio (RER)  $\geq 1.1$ ; 2. Achievement of age predicted maximum heart rate (HR); 3. Rating of perceived exertion (RPE)  $\geq 18$ . BMI, age, self-reported exercise frequency over the previous three months (EF3), and total minutes of at least moderate physical activity over the past week (MINWK) were examined as predictors of a valid  $\text{VO}_2\text{max}$ .

**RESULTS:** Preliminary results indicated that 50.2% of participants achieved all three criteria and 13.0% achieved one or none of the criteria tested. Age ( $OR = -1.06, p < 0.01$ ), EF3 ( $OR = -1.02, p < 0.01$ ), and MINWK ( $OR = -1.00, p = 0.03$ ) significantly predicted whether or not participants reached an RER  $\geq 1.1$ . BMI ( $OR = 0.91, p = 0.03$ ) predicted whether or not a participant reached an RPE  $\geq 18$ . There were no significant predictors of whether or not a participant came within 10bpm of age-predicted maximum HR. BMI ( $Adj. OR = -0.92, p = 0.05$ ), EF3 ( $Adj. OR = -0.34, p < 0.01$ ) and age ( $Adj. OR = 1.05, p = 0.07$ ) predicted whether or not a participant met all three criteria.

**CONCLUSIONS:** Most participants provided a valid  $\text{VO}_2\text{max}$  test. Older, less active individuals were more likely to achieve the RER threshold and to meet all three criteria. Individuals with higher BMI were more likely to achieve the RPE threshold but less likely to meet all three criteria.  $\text{VO}_2\text{max}$  testing may be particularly difficult for individuals with higher BMI, even for those that are more active. RPE may not be a good criterion for achieving a valid  $\text{VO}_2\text{max}$  in these individuals because subjectively they are experiencing greater exertion while, based on more objective physiological measures, they are not working as hard as those who have a lower BMI.

**1509 Board #111 May 27 11:00 AM - 12:30 PM**  
**Accuracy Of The American College Of Sports Medicine Metabolic Equation For Predicting Oxygen Cost During Leg Ergometry.**

L.C. Eschbach<sup>1</sup>, M. Magal<sup>2</sup>, A. Street<sup>1</sup>, M. Woessner<sup>1</sup>. <sup>1</sup>Meredith College, Raleigh, NC. <sup>2</sup>North Carolina Wesleyan College, Rocky Mount, NC.

Email: eschbach@meredith.edu

(No relationships reported)

Measurement of submaximal oxygen consumption ( $\text{VO}_2$ ) is a pivotal part of any aerobic exercise prescription. Often,  $\text{VO}_2$  is not measured but rather estimated using different equations due to cost, required equipment and time constraints.

**PURPOSE:** To investigate the accuracy of the American College of Sports Medicine (ACSM) metabolic equation for leg cycling when compared to actual  $\text{VO}_2$  measures obtained during graded exercise testing (GXT) on a isokinetic cycle simulator with the participants own bike.

**METHODS:** Oxygen cost of cycling was obtained for 195 trained, healthy subjects (152 men; 47 women; age  $40.6 \pm 9.65$  yrs; body mass  $74.5 \pm 15.0$  kg; percent body fat  $16.7\% \pm 10.4$ ; mean  $\pm$ SD) during a GXT to exhaustion. Each GXT began with a 10-min warm-up at 100 watts (W) and utilized a continuous protocol that increased workload linearly by between 20 and 50 watts every 3-min until exhaustion (maximal workloads ranged between 200 and 450 W). During the GXT,  $\text{VO}_2$  was averaged during the last 30-sec of each stage utilizing a calibrated metabolic cart. Using the ACSM's leg cycling equation,  $\text{VO}_2$  ( $\text{ml/kg/min}$ ) =  $10.8 \times (\text{work rate in watts})/(\text{body mass}) + 7$ , an estimation for the oxygen cost of each workload was also determined. The predicted  $\text{VO}_2$  values from the equation were statistically correlated to the actual measured  $\text{VO}_2$ .

**RESULTS:** Examination of  $\text{VO}_2$  at each workload revealed a significant correlation; average measured  $\text{VO}_2$  of  $32.06 \pm 8.93$  vs. average estimated  $\text{VO}_2$  of  $32.14 \pm 8.68$ ;  $R = .932$ . The standard error of estimate for the prediction of  $\text{VO}_2$  was  $3.15 \text{ ml/kg/min}$ .

**CONCLUSION:** Based upon these findings the ACSM equation for leg ergometry is accurate for predicting  $\text{VO}_2$  over a wide range of workloads when using a isokinetic cycle ergometer.

**Cold-induced Vasodilation At Various Water Temperature And Its Reproducibility During Cold Water Finger Immersion**

Byeong Jo Kim, Dae Taek Lee, Myung Chun Lee, Kyong Tae Kim. *Kookmin Univ., Seoul, Republic of Korea.*

Email: kbc3926@naver.com

(No relationships reported)

**PURPOSE:** Cold-induced vasodilation (CIVD) at various water temperatures was evaluated, and test-retest repeatability of the response was examined.

**METHODS:** Ten healthy collegiate men ( $21 \pm 3$  yrs,  $175 \pm 4$  cm,  $70 \pm 8$  kg,  $11 \pm 4\%$  fat) underwent two tests. At the first test (1ST), subjects repeated five cycles of a same procedure at ambient condition; 1) middle finger immersion at  $43^\circ\text{C}$  water for 5 min followed by 2) resting at ambient air for 25 min, then 3) cold water finger immersion at one of the five temperatures (5, 8, 11, 14, and  $17^\circ\text{C}$ ) at random order for 20 min. Once a cycle was completed, they immediately started the next cycle. The second test (2ND) was performed within a week after the first test with having an identical procedure except the order of water temperature. During the test, rectal temperature ( $T_{re}$ ), finger temperature from middle finger nail bed, and heart rate (HR) were measured every six second. CIVD was evaluated by the lowest ( $T_{fmin}$ ) and the highest ( $T_{fmax}$ ) temperatures recorded, the time period between min 0 and time at  $T_{fmin}$  ( $D_{tonset}$ ), time between at  $T_{fmin}$  and at  $T_{fmax}$  ( $D_{tpeak}$ ), and  $D_{tonset}$  plus  $D_{tpeak}$  ( $D_{tmax}$ ).

**RESULTS:** The urine specific gravity, HR, and  $T_{re}$  in 1ST and 2ND was  $1.021 \pm 0.004$  and  $1.022 \pm 0.004$  unit,  $70 \pm 8$  and  $71 \pm 8$  bpm, and  $37.0 \pm 0.2$  and  $37.0 \pm 0.2^\circ\text{C}$ , respectively ( $P > 0.05$ ).  $T_{fmax}$  at 1ST was  $10.2 \pm 1.0$ ,  $11.9 \pm 1.0$ ,  $13.7 \pm 1.0$ ,  $16.6 \pm 1.0$ , and  $19.3 \pm 0.8$  and at 2ND was  $9.9 \pm 1.3$ ,  $11.3 \pm 1.3$ ,  $13.7 \pm 1.2$ ,  $16.6 \pm 1.2$ , and  $18.9 \pm 0.9^\circ\text{C}$ , at 5, 8, 11, 14, and  $17^\circ\text{C}$  water, respectively. No differences were noticed in  $T_{fmax}$  in each water between 1ST and 2ND. The  $T_{fmax}$  minus water temperature was 5.2, 3.9, 2.7, 2.6, and 2.3 in 1ST and 4.9, 3.3, 2.7, 2.6, and  $1.9^\circ\text{C}$  in 2ND at 5, 8, 11, 14, and  $17^\circ\text{C}$  water, respectively. No differences were noticed in  $T_{fmin}$ ,  $D_{tonset}$ ,  $D_{tpeak}$ , and  $D_{tmax}$  at each water temperature between trials.

**CONCLUSIONS:** CIVD was highly reproducible in terms of variables tested in this study. A gradual reduction of value in  $T_{fmax}$  minus water temperature was apparent as water temperature increased.

**1511 Board #113 May 27 11:00 AM - 12:30 PM**  
**The Effects Of Localized Cold Exposure On Proprioception**

Tyler Whitcomb, Shanlyn Souza, Shawn O. Henry. *Pacific University, Forest Grove, OR.*

(No relationships reported)

Exposure to cold may lower intramuscular temperature and affect neuromuscular sensory receptors and neural pathways, possibly altering proprioception - awareness of body and limb position in space and time.

**PURPOSE:** The current study investigated effects of localized cold exposure (COLD) on three selected measures of proprioception.

**METHODS:** Using digital inclinometers, force transducers, and data acquisition system, proprioception was assessed by participant's ( $n = 8$ ) ability to actively replicate a target (actively-determined reference) angle and velocity of knee flexion and extension. Force gradation, the ability to produce a target sub-maximal isometric force (25%, 50%, or 75% maximal voluntary isometric contraction), was assessed via force transducer. All testing trials were conducted in random and repeated design and without immediate

visual or auditory feedback of performance. After establishing baseline, one leg was randomly chosen for cold exposure treatment (whole leg submersion at 5°C for 10 min) using contralateral leg as control. Posttesting followed. For each set of proprioceptive tests, constant error, absolute error, and percent error (from reference value) were calculated; percent error was used for analysis.

**RESULTS:** Two-way repeated measures ANOVA for repeated measures ( $\alpha=0.05$ ) revealed no difference for joint angle replication ( $F_{1,7} = 0.68$ ,  $p = 0.44$ ), joint velocity replication ( $F_{1,6} = 0.038$ ,  $p = 0.851$ ), or isometric grip force gradation ( $F_{1,6} = 1.31$ ,  $p = 0.295$ ).

	Control (CONT)	Cold-Exposure (COLD)
	Pre-test, Post-test	Pre-test, Post-test
Angle Replication (% error)	2.43 $\pm$ 2.15, 2.03 $\pm$ 0.88	2.27 $\pm$ 0.92, 2.01 $\pm$ 0.95
Velocity Replication (% error)	20.41 $\pm$ 15.52, 16.93 $\pm$ 10.74	18.26 $\pm$ 13.19, 22.23 $\pm$ 18.44
Grip Force Gradation (% error)	32.98 $\pm$ 5.66, 36.47 $\pm$ 14.11	31.12 $\pm$ 10.95, 38.12 $\pm$ 12.23

**CONCLUSION:** Localized lower-extremity cold exposure had no effect on ability to replicate a target joint angle, joint velocity (passively-presented reference target), or ability to scale submaximal force, as indicated by increased error.

## 1512 Board #114 May 27 11:00 AM - 12:30 PM

### Aging Augments Pressor Responses To Mild Skin Surface Cooling In Humans

Kari L. Hess<sup>1</sup>, Thad E. Wilson<sup>2</sup>, Chester A. Ray, FACSM<sup>1</sup>, Kevin D. Monahan<sup>1</sup>. <sup>1</sup>Penn State College of Medicine, Hershey, PA. <sup>2</sup>Ohio University College of Osteopathic Medicine, Athens, OH.

(No relationships reported)

Cardiovascular mortality increases during the cold winter months, particularly in older adults. Acute physiological responses to cold exposure, such as increases in blood pressure may contribute to these effects.

**PURPOSE:** To determine if the acute blood pressure-raising effect (pressor response) of acute non-hypothermic cold stress is augmented with age in humans.

**METHODS:** We measured acute physiological responses to skin surface cooling, induced by a water-perfused suit, in 12 young (25 $\pm$ 1 years old, mean $\pm$ SE) and 12 older (65 $\pm$ 2) adults. During cooling the temperature of the water perfusing the suit was reduced from 35 to 15-18° C for 20 min (cooling trial). During this time brachial blood pressure was measured at 2 min intervals and skin surface and sublingual temperature at 5 min intervals. Responses to a control trial in which water perfusion temperature was maintained at 35° C were also determined.

**RESULTS:** During the cooling trial skin surface temperature decreased similarly in young and older adults ( $\sim$ D-4° C) and sublingual temperature did not change in either group. Systolic, diastolic, and mean blood pressure increased during skin surface cooling (all  $P<0.05$ ) in young and older subjects although the magnitude of this response was at least 2-fold larger in older adults for systolic (D10 $\pm$ 1 vs. D26 $\pm$ 3 mmHg for young and older, respectively) and mean blood pressure (D7 $\pm$ 1 vs. D14 $\pm$ 2; both  $P<0.05$  young compared to older). Augmented pressor responses to skin surface cooling in older adults were associated with greater ( $P<0.05$ ) increases in indices of myocardial oxygen demand, such as rate-pressure product in older than in young adults. None of the measured variables changed during the control trial.

**CONCLUSIONS:** These data indicate that there is a greater pressor response to acute non-hypothermic cold stress with age in humans. This greater pressor response to cold stress results in significant increases in markers of myocardial oxygen demand in older, but not young adults. These responses may help to explain in part why cardiovascular mortality increases during the cold winter months in older adults.

## 1513 Board #115 May 27 11:00 AM - 12:30 PM

### Local Tetrahydrobiopterin Administration Augments Reflex And Tyramine-induced Cutaneous Vasoconstriction In Aged Human Skin

James A. Lang, Lacy A. Holowatz, W. Larry Kenney, FACSM. The Pennsylvania State University, University Park, PA.

Email: jal493@psu.edu

(No relationships reported)

Reflex vasoconstriction (VC) is attenuated in aged skin resulting in greater heat loss during cold exposure. Reflex VC in young skin is comprised of both adrenergic ( $\sim$ 60%) and nonadrenergic (i.e. coreleased sympathetic neurotransmitters) components ( $\sim$ 40%); however, cotransmitter-mediated VC is functionally lost and responsiveness of adrenergic receptors are diminished in older subjects. Adrenergic function may be further compromised in aged skin due to depletion of an oxidant-sensitive essential cofactor for tyrosine hydroxylase, tetrahydrobiopterin (BH<sub>4</sub>), which is required for catecholamine synthesis.

**PURPOSE:** We hypothesized that local BH<sub>4</sub> supplementation would functionally augment reflex-induced and pharmacologically-induced VC elicited by gradual whole-body cooling ( $T_{sk}=30.5^{\circ}\text{C}$ ) and tyramine infusion (which displaces norepinephrine (NE) in storage vesicles), respectively.

**METHODS:** Three microdialysis (MD) fibers were placed in the forearm skin of 11 young (Y) and 11 older (O) human subjects for infusion of 1) Ringers solution (control), 2) 5 mM BH<sub>4</sub>, and 3) 5mM BH<sub>4</sub> + adrenoceptor blockade (5mM yohimbine + 1mM propranolol). Red blood cell flux (LDF) was measured by laser Doppler flowmetry over each MD site. Cutaneous vascular conductance was calculated ( $\text{CVC} = \text{LDF}/\text{MAP}$ ) and expressed as percent change from baseline ( $\text{DCVC}_{\text{base}}$ ).

**RESULTS:** VC was lower at the control site in O during cooling (Y:  $-34 \pm 2$ , O:  $-17 \pm 2\%$ ;  $\text{DCVC}_{\text{base}}$ ;  $P<0.001$ ) and tyramine infusion (Y:  $-33 \pm 4$ , O:  $-15 \pm 3\%$ ;  $\text{DCVC}_{\text{base}}$ ;  $P<0.001$ ). BH<sub>4</sub> infusion normalized VC to Y values in O during cooling (Y:  $-34 \pm 4$ , O:  $-34 \pm 2\%$ ;  $\text{DCVC}_{\text{base}}$ ;  $P<0.001$ ) and tyramine (Y:  $-38 \pm 4$ , O:  $-35 \pm 3\%$ ;  $\text{DCVC}_{\text{base}}$ ;  $P<0.001$ ), both of which were abolished with adrenoceptor blockade in aged skin ( $P<0.001$  versus control).

**CONCLUSION:** Local BH<sub>4</sub> supplementation augments reflex and tyramine-induced VC in aged skin, suggesting that reduced BH<sub>4</sub> bioavailability significantly contributes to the attenuated VC response.

### Does Hypoxia Affect Post-junctional Vasoconstrictor Responsiveness In Human Skin?

Grant H. Simmons, Christopher T. Minson, FACSM, John R. Halliwill, FACSM. University of Oregon, Eugene, OR.

Email: gsimmon1@uoregon.edu

(No relationships reported)

We have previously shown that cutaneous vasoconstriction during 30 minutes of cold exposure is potentiated by hypoxia. The contributions to this response of changes in central integration and peripheral vascular responsiveness are unclear.

**PURPOSE:** To test whether post-junctional vasoconstrictor responsiveness is altered in the skin during hypoxia. We tested the hypothesis that cutaneous vascular responses to intradermal tyramine are increased during hypoxia, and this effect is at least partly explained by increased cotransmitter-mediated vasoconstriction.

**METHODS:** 6 men and 6 women had 3 microdialysis fibers placed in the ventral forearm. One fiber received lactated ringers, a second fiber received 5mM yohimbine ( $\alpha$ -adrenergic blockade), and a third received 10.5 $\mu$ M BIBP-3226 (to antagonize neuropeptide Y-Y<sub>1</sub> receptors). Skin blood flow was assessed at each site (laser-Doppler flowmetry) and cutaneous vascular conductance (CVC) was calculated (red blood cell flux/mean arterial pressure) and scaled to baseline. Vasoconstrictor responses to tyramine were tested during normoxia and steady state isocapnic hypoxia (SaO<sub>2</sub> = 80%) in random order, and trials were separated by > 90 minutes. For each infusion, 30  $\mu$ g/ml tyramine was delivered through each fiber at 4  $\mu$ l/min for 210 seconds.

**RESULTS:** During normoxia, tyramine reduced CVC by  $56.0 \pm 5.6$  and  $50.3 \pm 8.0$  % baseline in control and BIBP-3226 sites (both  $P < 0.05$  vs. pre-tyramine;  $P = 0.45$  vs. between sites) while CVC in the yohimbine site did not change ( $P = 0.40$  vs. pre-tyramine). During hypoxia, tyramine reduced CVC by  $55.9 \pm 5.1$  and  $54.2 \pm 5.4$  % baseline in control and BIBP-3226 sites (both  $P < 0.05$  vs. pre-tyramine;  $P = 0.81$  between sites) while CVC was unchanged in the yohimbine site ( $P = 0.73$  vs. pre-tyramine). Hypoxia did not affect vasoconstrictor responses at any site (all  $P > 0.05$  vs. normoxia).

**CONCLUSIONS:** Thus, tyramine does not stimulate cotransmitter-mediated vasoconstriction in human skin (at doses which match vasoconstriction observed during whole body cooling). We conclude that post-junctional  $\alpha$ -adrenergic vasoconstrictor responsiveness is not affected by hypoxia in non-acral skin, while the effect of hypoxia on cotransmitter-mediated vasoconstrictor responsiveness remains unknown.

(No relationships reported)

**PURPOSE:** To determine the effect of sensory integration exercise program on motor ability and cognitive competence of children with moderate mental retardation.

**METHODS:** Subjects were 24 children with mental retardation. The 24 children were randomly divided into two groups. One group (N=12) was an experimental group and the other group (N=12) was a control group. The experimental group performed a sensory integration exercise program 3 times a week, 40 minutes a day for 20 weeks. Before and after intervention, gross motor ability and cognitive competence for each group was measured by using the TGMD-2 (Test of Gross Motor Development) and K-WISC-III (Korean - Wechsler Intelligence Scale for Children-III), respectively. Paired t-test and independent t-test were used to examine within and between group effects using SPSS 10.0 program. The statistical significant level was at  $p < .05$ .

**RESULTS:** After 20 weeks of intervention, the experimental group significantly ( $p < .05$ ) improved scales of gross motor abilities, including locomotor skill ( $2.75 \pm 0.97$  vs.  $4.42 \pm 1.00$ ), object control skill ( $1.33 \pm 0.49$  vs.  $3.00 \pm 0.74$ ), and functional fitness ( $4.08 \pm 1.08$  vs.  $7.42 \pm 1.08$ ). The experimental group also significantly ( $p < .05$ ) improved cognitive competence, including picture completion ( $2.17 \pm 0.72$  vs.  $3.67 \pm 0.98$ ), coding ( $2.50 \pm 0.90$  vs.  $3.75 \pm 1.06$ ), picture arrangement ( $1.92 \pm 0.67$  vs.  $3.25 \pm 0.87$ ), block design ( $2.00 \pm 0.74$  vs.  $3.08 \pm 0.67$ ), object assembly ( $4.67 \pm 0.89$  vs.  $5.67 \pm 1.07$ ), symbol search ( $4.75 \pm 0.75$  vs.  $5.33 \pm 0.78$ ), and mazes search ( $1.17 \pm 0.39$  vs.  $1.67 \pm 0.65$ ). However, the control group did not change in these variables.

**CONCLUSIONS:** We found that the sensory integration exercise program improves gross motor ability and cognitive competence in children with moderate mental retardation. It suggests that the sensory integration exercise program can be very useful treatment for children with moderate mental retardation.

#### **Effect Of Move Grow Learn Program On Improvements In Maladjustment Behavior In Mentally Disabled Individuals**

Young-Sung Hwang<sup>1</sup>, Jae-Sung Park<sup>2</sup>, Il-Hong Jeang<sup>1</sup>, Sang-Chul Lee<sup>1</sup>, Hyun-Woo Park<sup>3</sup>, Myung-Soo Kim<sup>4</sup>. <sup>1</sup>Pusan National University, Busan, Republic of Korea. <sup>2</sup>Yongsan University, Busan, Republic of Korea. <sup>3</sup>Chonnam National University, Gang-Ju, Republic of Korea. <sup>4</sup>Pohang University of Science and Technology, Pohang, Republic of Korea.

Email: yshwang117@yahoo.co.kr

(No relationships reported)

**PURPOSE:** This study was initiated to evaluate the effect of "Move Grow Learn" program on mentally disabled individuals.

**METHODS:** Thirty two mentally disabled individuals participated in this study. They were randomly divided into an experimental group (N=16) and a control group (N=16). The experimental group performed MGL (Move Grow Learn) program 60 min a day, 3 times per week for 8 weeks. The MGL program consisted of spatial movement exercise, non-spatial movement exercise, and coordination exercise. Before and after conducting MGL program, the K-WAIS (Korean Wechsler Adult Intelligence Scale) test was used to measure recognition ability and intelligence. Social adaptation was measured by Doll's Vineland Social Maturity Scale. Exercise adaptation was measured by using the Helmas automatic machine (Se woo System, Korea). Emotional adaptation was measured by EBC (Emotional Behavioral Checklist). A paired t-test and ANCOVA was carried out to analyze data and a statistical significant level was at  $p < 0.05$ .

**RESULTS:** With MGL program, the experimental group significantly ( $p < 0.05$ ) increased physical fitness, including muscular strength and endurance, flexibility, power, agility, and balance. The experimental group also significantly increased all items of recognition ability, intelligence, and social maturity. In emotional behavior, the experimental group significantly improved instigation, depression, attack, actuality, but not anxiety, socialization, and self-consciousness. The control group did not change any of these measurements.

**CONCLUSIONS:** This data indicates that "Move Grow Learn" program improves the maladjustment behavior of mentally disabled individuals, suggesting that a movement education program is very useful for them.

#### **Associations Between Physical Activity And Depression By Weight Status Among U.S. Men And Women**

David R. Brown, FACSM, Susan A. Carlson, Dianna Densmore, Megan Wall, Lauren Workman. *Centers for Disease Control and Prevention, Atlanta,*

GA.  
Email: DBrown@cdc.gov  
(No relationships reported)

**PURPOSE:** Recently the 2008 Physical Activity Guidelines for Americans concluded that physically active adults have lower risk of depression compared to inactive adults. The purpose of this study is to evaluate whether the associations between physical activity [PA] and depression are modified by body mass index [BMI] category.

**METHODS:** Depression is defined as self reported depression during the past 12 months (Yes or No). Using the 2008 Guidelines, respondents PA level was classified as: Active [A] ( $\geq 150$  minutes a week of moderate-intensity PA,  $\geq 75$  minutes a week of vigorous-intensity PA, or an equivalent combination of moderate- and vigorous-intensity PA), Insufficiently active [INSA] (some PA, but not enough to meet the active definition), and Inactive [INA] (no PA for at least 10 min/wk). BMI was classified as: Normal Weight =  $< 25$  kg/m<sup>2</sup>, Overweight =  $> 25$  -  $< 30$  kg/m<sup>2</sup>, and Obese =  $> 30$  kg/m<sup>2</sup>. Data of 21189 adults aged  $> 18$  years from the National Health Interview Survey, 2007, were analyzed. Multivariable logistic regression was used to estimate the gender-specific odds of depression by PA level stratified by BMI category.

**RESULTS:** The association between depression and PA was not significantly modified by BMI category (p-value for interaction: men,  $p = 0.30$ ; women,  $p = 0.97$ , Table 1). Overall, A and INSA women are at lower odds of depression compared to INA women (respectively, Adjusted Odds Ratio [AOR] = 0.54; 95% Confidence Interval [CI] = 0.45, 0.64 and AOR = 0.67; 95% CI = 0.56, 0.80). A and INSA men are at lower odds of depression compared to INA men [respectively, AOR = 0.48; 95% CI = 0.39, 0.59; AOR = 0.65, 95% CI = 0.50, 0.84].

**CONCLUSIONS:** Physical activity is associated with lower odds of depression among adults regardless of weight status.

Table 1. Prevalence and odds of depression with PA level by BMI category.				
PA	MEN Normal Weight		WOMEN Normal Weight	
	%	AOR* (95% CI)	%	AOR* (95% CI)
Inactive	12.8	1.00	12.9	1.00
Insufficiently Active	9.8	0.93 (0.60, 1.44)	9.2	0.76 (0.55, 1.06)
Active	6.3	0.58 (0.40, 0.84)	6.6	0.61 (0.46, 0.81)
	MEN Overweight		WOMEN Overweight	
	%	AOR* (95% CI)	%	AOR* (95% CI)
Inactive	10.1	1.00	16.0	1.00
Insufficiently Active	4.5	0.49 (0.31, 0.78)	10.1	0.70 (0.48, 1.01)
Active	4.2	0.51 (0.36, 0.73)	9.2	0.66 (0.48, 0.91)
	MEN Obese		WOMEN Obese	
	%	AOR* (95% CI)	%	AOR* (95% CI)
Inactive	14.8	1.00	27.2	1.00
Insufficiently Active	9.4	0.63 (0.41, 0.97)	18.7	0.62 (0.48, 0.80)
Active	5.5	0.38 (0.26, 0.57)	16.3	0.50 (0.37, 0.66)

**Short-term Modified Tai Chi Exercise Improves Quality Of Life In Hemodialysis Patients**

Chwan-Li Shen<sup>1</sup>, Ming-Chien Chyu<sup>2</sup>, Sorot Phisitkul<sup>1</sup>, Jean-Michel Brismee<sup>1</sup>, Ke T. Xu<sup>1</sup>, Daphne Di-Fan Lo<sup>1</sup>, Sharma Prabhakar<sup>1</sup>. <sup>1</sup>Texas Tech University Health Sciences Center, Lubbock, TX. <sup>2</sup>Texas Tech University, Lubbock, TX.

Email: Leslie.Shen@ttuhsc.edu

(No relationships reported)

**INTRODUCTION:** Benefits of intradialytic exercise performed during outpatient hemodialysis (HD) therapy sessions have been demonstrated in End-Stage Renal Disease patients in previous studies. However, there is little evidence on the benefits of quality of life (QOL) as maintenance HD patients often show substantial reductions in QOL. Most studies used stationary cycling, strength and resistance training as modes of exercise. This is the first study that implemented an intradialytic mind-body exercise which has the advantages of requiring no equipment and little training or supervision.

**PURPOSE:** To test the feasibility and to determine the impact of an 8-week intradialytic modified Tai Chi (MTC) exercise intervention on QOL in HD patients.

**METHODS:** Maintenance HD patients ( $n=21$ , 9 females,  $52.2 \pm 12.1$  yr) were recruited from a local dialysis center and screened based on clinical criteria. All participants were encouraged to perform MTC for 1 hr within the first 2 hours of each 4-hr HD session, 3x/wk. The MTC was designed based on traditional Tai Chi for a patient to perform while sitting in a recliner with one arm connected to the dialysis machine. QOL was assessed at baseline, 4 wk, and 8 wk using the SF-36® scale. Time effects were assessed with repeated measures ANOVA.

**RESULTS:** Intradialytic MTC never caused any interference or inconvenience to hemodialysis treatment, and no adverse effect was observed or reported. Participants needed less than 3 hr to learn the exercise, and were then able to perform the exercise with complete independence following a written instruction. Three participants dropped out due to loss of interest or change of health condition unrelated to the current exercise intervention. MTC significantly improved mental health ( $P < 0.001$ ) after 4 wk and sustained to 8 wk. After 8 wk, significant improvements were observed in physical function ( $P = 0.023$ ), role-physical ( $P < 0.001$ ), vitality ( $P = 0.013$ ), and role-emotional ( $P < 0.001$ ), but no effect on bodily pain, general health, or social functioning.

**CONCLUSION:** MTC may be a feasible, low-cost, and effective exercise to improve QOL in maintenance HD patients. Our preliminary observations underscore the need for further long-term studies using larger sample size to establish the benefits of MTC in HD patients.

**Effect Of A Defined In-hospital Sports Program On The Physical, Psychological And Sociological Aspects Of Patients Suffering From Cancer And Patients Suffering From Obesity**

Jens A. Leifert, Roland Mertelsmann, Martina Kleber, Hartmut Bertz, Fiona Streckmann. University Medical Center, Freiburg, Germany.

Email: jensleifert@uniklinik-freiburg.de

(No relationships reported)

**PURPOSE:** Regular physical exercise has positive effects on body composition and function as well as on mental aspects such as concentration, depression or self-esteem. The clinical course of many illnesses can also be improved by regular sports activity.

In obese patients sports activity is a crucial compound of an effective treatment. Many obese patients see their health problem as self-inflicted and consequent treatment requires

a high amount of an often lacking self-discipline.

In malignant disease, physical exercise is also an integrative part of cancer treatment. Cancer patients usually see their illness not as self-inflicted and their motivation to “fight the disease” is often very high. Because of the different motivational starting points we were interested in evaluating the effects of a defined sports program on each of the groups.

**METHODS:** In a retrospective study we asked 20 patients that completed the program to evaluate their physical, emotional, social and functional status by a quality of life questionnaire (QLQ-C30) after a course of 6 months of participation in a defined sports program. Training units consisted of 60-90 minutes 2-3 times per week.

**RESULTS:** Physical parameters throughout the course showed a constant and comparable improvement of physical performance in both groups.

However, significant differences in terms of changes in emotional, social and functional status could be detected. In obese patients the drop-out rate (64,2 %) was significantly higher than in cancer patients (14,6 %).

Patients that completed the program showed a significant improvement in the assessed global health status/quality of life, fatigue and physical function parameters in both groups. However, subgroup analysis showed highly significant improvements ( $p < 0,001$ ) only for cancer patients in role function and emotional function and significant changes in cognitive function and perception of pain or dyspnea.

In contrast, obese patients showed improvements in social function and the perception of financial problems.

**CONCLUSIONS:** Moderate physical activity as part of the therapy has an intrinsic effect on performance and quality of life for cancer and obesity patients. However, results especially concerning the psychological and sociological effects of the physical exercise differ between the two groups.

---

**1520 Board #122 May 27 9:30 AM - 11:00 AM**  
**Mood Enhancement Persists For Up To 12 Hours Following Aerobic Exercise**

Jeremy S. Sibold, Kathy Berg MS, CSCS. *University of Vermont, Burlington, VT.*

(No relationships reported)

Although there is general agreement in the literature that mood is enhanced following aerobic exercise, studies have limited post exercise mood assessment to only a short period, with a majority evaluating mood for only 40-60 minutes following the exercise bout. Recommendations have been made for longer post exercise assessment periods as a way to determine optimal exercise frequency prescription for mood improvement.

**PURPOSE:** To determine the impact of aerobic exercise on mood at 1,2,4,8, 12, and 24 hours after exercise.

**METHODS:** Forty eight healthy adult men ( $n=13$ ) and women ( $n=35$ ) aged 18-25 ( $M=20.2$  yr;  $SD=3.4$ ) were randomly assigned to either control or exercise groups. Subjects completed the Profile of Mood States (POMS) before and after exercise at 60% of aerobic capacity on a cycle ergometer, or quiet rest. Additionally, all subjects completed the POMS at one, two, four, eight, twelve, and twenty four hours following either the exercise or control session. Repeated measures analysis of covariance was performed to determine the duration of mood change with  $VO_2$  Max entered as a covariate.

**RESULTS:** The exercise group showed significantly lower total mood disturbance acutely ( $F=15.408$ ,  $p=.000$ ,  $d=1.12$ ), as well as at four ( $F=6.939$ ,  $p=.011$ ,  $d=0.79$ ), eight ( $F=4.972$ ,  $p=.031$ ,  $d=0.658$ ), and twelve hours ( $F=4.481$ ,  $p=.040$ ,  $d=0.613$ ) following exercise. There were no observed differences due to gender or fitness level.

**CONCLUSIONS:** Based on this research, it is prudent to conclude that aerobic exercise improves mood acutely, and these improvements can be sustained for up to twelve hours following exercise. These results improve the ability of the practitioners in the field to prescribe exercise as a treatment modality for mood enhancement in healthy populations.

**Health Behavior And Psychological Well-being Of Young Adults**

Yahya Al-Nakeeb<sup>1</sup>, Lorna Dodd<sup>1</sup>, Alan M. Nevill<sup>2</sup>. <sup>1</sup>Newman University College, Birmingham, B32 3NT, United Kingdom. <sup>2</sup>University of Wolverhampton, Birmingham, United Kingdom.

Email: y.al-nakeeb@newman.ac.uk

(No relationships reported)

**PURPOSE:** Healthy lifestyle and habitual physical activity (PA) are strongly and inversely related to all-cause mortality and in particular to coronary artery disease. While the impact of lifestyle on the physiological aspects is well documented in the literature, there appears to be limited attention given to the psychological health and well-being of young adults. Although stress amongst young adults has been associated with unhealthy behaviors, the nature of these relationships has yet to be clarified.

**PURPOSE:** To examine the relationship between behavioral aspects such as active lifestyle and health habits on psychological well-being amongst young adults; to explore possible differences in patterns of behavior and health habits between specific groups within the targeted population (e.g., gender, age, and ethnicity).

**METHODS:** 306 female and 104 male University students (mean =  $22.8 \pm 5.7$  yrs) from Central England completed a questionnaire that included self-report measures on health status, psychological well-being, PA, drinking and smoking habits, dietary intake and the barriers to healthy lifestyle.

**RESULTS:** Pearson's correlations revealed a significant negative relationship between PA and psychological stress ( $r = -.218$ ,  $p < .001$ ), PA and fat intake ( $r = -.138$ ,  $p = .005$ ) and PA and alcohol consumption ( $r = -.132$ ,  $p = .008$ ). Additionally, high alcohol consumption appeared to be positively associated with fat intake ( $r = .132$ ,  $p = .008$ ) and smoking behavior ( $r = .202$ ,  $p < .001$ ). Furthermore, ANCOVA revealed significant differences due to ethnicity on high intensity PA for males and females when controlling for perceived stress ( $F_{3,401} = 2.862$ ,  $p = .037$ ).

**CONCLUSIONS:** Regular PA was associated with better perceived psychological health. Those who exercised regularly reported less psychological stress, lower alcohol consumption and less fat intake. Generally, males reported significantly higher levels of PA than females across all ethnic groups with these differences being particularly marked in the South East Asian group. Improving our understanding of the factors that affect young adults' health behaviour provides much needed information for developing interventions. Hence, further studies are warranted to evaluate factors that may influence the uptake of unhealthy behaviors within this population.

**Comparison Of The Cross-stressor Adaptation Between Exercisers, Athletes, And College Students To Mental Stress**

Daniel B. Hollander, Ashish C. Patel, Tammara Jefferson, Sruthi Mareedu, Anil K. Kanakadandi, Tyler Paopao. *Southeastern Louisiana University, Hammond, LA.*

Email: dhollander@selu.edu

(No relationships reported)

Sothmann and colleagues (1996) proposed that training aids the fit individual by affording a blunted cardiovascular response to stress when compared to their less fit counterparts. This phenomenon is known as the cross-stressor adaptation hypothesis.

**PURPOSE:** To examine physiological responses (i.e., cardiac and blood pressure response) to mental stressors during a 10-minute mental arithmetic challenge with noxious auditory feedback testing the cross stressor adaptation hypothesis.

**METHODS:** Cardiovascular responses were measured in a group of exercisers ( $N=35$ ), college athletes ( $N=14$ ), and non-exercising, college students ( $N=20$ ). Measures were taken at baseline, then in 2 minute intervals for the duration of the stressor. Perception of mental effort, stress, and attention were also assessed. Four subjects presented with

hypertension and were eliminated from the data analysis. Family history of cardiovascular disease, gender, perceptual measures were analyzed and were not statistically significant. Next, repeated measures ANOVAs were performed to examine the change of baseline Heart Rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP), and mean arterial pressure (MAP) from each recording (taken every 2 minutes during the stressor).

**RESULTS:** HR, SBP, and DBP failed to significantly vary based on physical activity classification. Moreover, only the time variable was significant ( $P < 0.001$ ) for all measures except MAP.

**CONCLUSIONS:** Thus, no support was demonstrated for the cross-stressor adaptation hypothesis even though trends toward support were evident. Future studies should employ more sophisticated measures of cardiovascular function to detect changes to physiological stress response.

Means and Standard Errors Between Groups			
	Students	Athletes	Exercisers
HR	78.18±2.34	70.59±2.90	74.91±1.74
SBP	120.81±2.37	117.31±2.94	118.76±1.79
DBP	77.18±1.57	77.06±1.94	77.60±1.18
MAP	43.63±1.86	40.25±2.31	41.16±1.41

**Television Viewing, Computer Use, And Sleeping Time In Relation To Depressive Symptoms Among Taiwanese Freshman**

Yu-Chien Wei, LEE-HWA CHEN. *NATIONAL TAIWAN SPORT UNIVERSITY, Taoyuan county, Taiwan.*

Email: bow\_0321@yahoo.com.tw

(No relationships reported)

**PURPOSE:** To exam the effect of time spent in television watching (TV), computer use (CU) and sleeping (SL) on depressive symptoms (DS) in a college freshmen sample.

**METHODS:** Six hundred college freshmen were consented and surveyed by questionnaire and 408 valid cases (male=212, female=187, missing=9,  $20.0 \pm 3.5$  yo) were included in the study. DS was measured by the Beck Depression Inventory-II (BDI-II), and time spent in TV (min/wk), CU (min/wk) and SL (min/day) were collected by the self-administered questionnaire. Descriptive statistics and Pearson's Correlation Coefficient were used in this analysis.

**RESULTS:** Mean DS score as measured by BDI-II of the subjects was 10.3 with all subjects within normal range. The average time for TV was  $288.7 \pm 366.3$  min/wk, for CU was  $1399.3 \pm 1112.2$  min/wk and for SL was  $411.8 \pm 77.6$  min/day. There were no significant difference between sex in DS, TV, CU and SL. Also there were no significant relationships between DS and TV, and DS and CU respectively. There was, however, a significantly negative correlation between DS and SL for all subjects ( $r = -0.195, p < .05$ ).

**CONCLUSIONS:** In this study, TV and CU, as normally classified as sedentary behavior, were not related to depressive symptoms as measured by the BDI-II among the Taiwanese freshmen students. However, a significantly negative correlation was found between DS and SL indicating less sleeping time among freshmen in Taiwan may compromise their mental health. Recommendation of a more suitable sleeping time management should be encouraged to ensure psychological well-being for this young population.

**Validity Of Triaxial Accelerometer For Estimating Energy Expenditure In Non-athletes And Athletes**

Yukako Hashii<sup>1</sup>, Yosuke Yamada<sup>2</sup>, Soichi Ando, PhD<sup>1</sup>, Misaka Kimura, PhD<sup>1</sup>. <sup>1</sup>Kyoto Prefectural University of Medicine, Kyoto, Japan. <sup>2</sup>Kyoto University, Kyoto, Japan.

Email: km02104@stu.kpu-m.ac.jp

(No relationships reported)

**PURPOSE:** Energy requirements of athletes are dependent on daily activities as well as the practice quantity. Thus, the accurate estimation of 24-h total energy expenditure (TEE) of athletes is essential for sports nutritionists to assess energy balance. We examined the validity of a uniaxial accelerometer (ACCuni) and a newly developed triaxial accelerometer (ACCtri) for estimating 24-h TEE in non-athletes and long distance runners in comparison with doubly labeled water (DLW).

**METHODS:** A total of 15 young adults (18-34 years old) participated in this study. The TEE was measured using the DLW method over 7 and 14-day periods. The <sup>18</sup>O and <sup>2</sup>H dilution spaces and TBW were determined by dividing the dose of the tracer administered. The rate of CO<sub>2</sub> production (rCO<sub>2</sub>) was determined and TEE (kcal day<sup>-1</sup>) was calculated using a modified Weir's formula based on rCO<sub>2</sub> and the food quotient (FQ), which was calculated from the daily record of the food intake. ACCuni and ACCtri were worn were attached to an elastic belt and worn at the back of the waist for entire two weeks.

**RESULTS:** TEE estimated by ACCuni was significantly lower than TEE measure by DLW ( $2520 \pm 681$  kcal day<sup>-1</sup>) and showed wider limits of agreement. TEE estimated by ACCtri ( $2561 \pm 543$  kcal day<sup>-1</sup>) did not differ from TEE measured by DLW and showed narrower limits of agreement. No significant difference was observed between TEE estimated by ACCtri and TEE measured by DLW both in the long distance runners and non-athletes.

**CONCLUSIONS:** This study suggest the ACCtri could be applied to estimate the group mean of TEE in the long distance runners and to predict their energy requirements.

**Validation Of The ReeVue™ And CardioCoachCo2™ Metabolic Systems For Measuring Resting Energy Expenditure**

Stephanie Sun, Jennifer Reynolds, David N. Erceg, Christina M. Dieli-Conwright, Hyun Ho Song, Varshini Chakravarthy, E. Todd Schroeder. *University of Southern California, Los Angeles, CA.*

(No relationships reported)

**PURPOSE:** To examine the validity of the ReeVue™ (RV) and CardioCoachCO2™ (CC) metabolic systems to measure oxygen consumption by comparison to a reference

criterion, the MedicalGraphics CardiO2/CP™ (MG).

**METHODS:** Thirty subjects (10 men, 20 women;  $26.0 \pm 3.9$  years of age,  $168.5 \pm 9.6$  cm,  $66.0 \pm 11.9$  kg) completed two resting energy expenditure tests. The order of the RV and CC tests were randomly assigned. The MG system was simultaneously recorded during the RV or CC test to standardize the testing procedures. The MG mouthpiece and pneumotach were connected to the RV or CC one-way valve with disposable tubing using a rubber washer. Ten to twenty minutes of data were collected on each subject lying in a comfortable supine position before the metabolic systems (RV and CC) determined stabilization and subsequently terminated the test. One-way ANOVA ( $\alpha=0.05$ ) was utilized to compare absolute VO<sub>2</sub> values between the 3 devices and a paired t test was used to compare the two MG tests.

**RESULTS:** There were no statistical differences between the two MG tests. Therefore, MG VO<sub>2</sub> values were averaged and compared to the RV and CC. No significant differences were found between the RV ( $202 \pm 45$  mL O<sub>2</sub>/min), CC ( $209 \pm 51$  mL O<sub>2</sub>/min), and MG ( $226 \pm 57$  mL O<sub>2</sub>/min) systems.

**CONCLUSIONS:** These findings indicate that the ReeVue™ and CardioCoachCO<sub>2</sub>™ metabolic systems are comparable devices to the selected reference criterion for measuring oxygen consumption to assess resting energy expenditure.

**Energy Expenditure Differences Between Running And Walking In College Aged Students**

Matthew C. Jackson, Antoinette P. Cheryl, Sarah R. Jarvis, Bryan L. Haddock, Linda D. Wilkin. *California State University, San Bernardino, San Bernardino, CA.*

Email: lwilkin@csusb.edu

(No relationships reported)

According to the CDC, obesity continues to be a problem for adults and adolescents. It is important to find accessible activities that provide an opportunity for caloric expenditure. Running and walking are activities that most people can perform without great expense.

**PURPOSE:** To examine the differences between males and females on energy expenditure during a one mile walk and a one mile run.

**METHODS:** 15 males and 15 females between the ages of 18 - 30 years ( $21.90 \pm 2.52$  years) were recruited from college classes. The average height of the participants was  $168.89 \pm 11.20$  cm, the average weight was  $71.01 \pm 17.30$  kg, the average BMI was  $24.57 \pm 3.89$  kg/m<sup>2</sup>, and the average VO<sub>2max</sub> was  $41.51 \pm 6.31$  mL/kg/min. After signing an informed consent, each participant completed a VO<sub>2max</sub> test. Participants were randomly assigned to run one mile at 6 miles per hour (mph) and walk one mile at 3 mph on two separate days. Data collected included VO<sub>2max</sub>, energy expenditure (EE), and respiratory exchange ratio (RER). EE was collected for 15 minutes prior to exercise and during exercise.

**RESULTS:** There was no difference in age between males and females. Males were taller, weighed more, and had a higher maximal VO<sub>2</sub> than females. The average walk and run EE was higher for males than females (5.04, 12.86 kcal/min and 3.86, 9.66 kcal/min respectively). Total EE for running one mile was 128.6 kcal and 96.6 kcal and walking was 100.8 kcal and 77.2 kcal for males and females, respectively. Overall, the average (RER) was different for walk and run (0.89 and 0.98, respectively).

**CONCLUSION:** Fitness professionals are always attempting to identify the most effective modality to maximize energy expenditure. Running yields a greater number of kcal expended covering the same distance compared with walking in less time. At the level of EE in the current study, running at 6 mph would cause a total EE of 1,930 kcal for males and 1,458 kcal for females running 5 days a week for 30 minutes each day. Walking at 3 mph would cause a total EE of 755 kcal for males and 580 kcal for females walking 5 days a week for 30 minutes each day. Running will yield a higher caloric expenditure. During running, more of the calories expended are carbohydrates.

**Effect Of A Seven-week Weight Training Course On Resting Energy Expenditure In Women**

Steve Burns, Kevin Smith. *University of Central Missouri, Warrensburg, MO.*

Email: sburns@ucmo.edu

(No relationships reported)

Resistance training can potentially increase lean body mass which should lead to an increased resting energy expenditure (REE) and decrease the percentage of body fat.

**PURPOSE:** Our hypothesis was that students who attend an undergraduate weight training classes would have an increased REE over the period of the semester.

**METHODS:** Participants (n=12 females) college students with no previous weight training experience. Subjects participated in a seven-week resistance training program consisting of general conditioning exercises two times per week. Data collected included pre and post measures of REE, 1 rep max (1 RM) on bench press, total body weight, and percent body fat (%BF).

**RESULTS:** No significant differences were observed pre- and post-REE, 1RM, and %BF ( $1667.9 \pm 463$ ,  $1638.08 \pm 334$  kCal/day; 35.1 kg, 37.69 kg; and 27.06%, 26.55%  $\pm$  4.25 respectively).

**CONCLUSION:** The seven-week resistance training program was not of sufficient intensity or duration to observe a significant change in REE or %BF, however there was a significant difference in strength. Though researchers observed positive trends in the data, perhaps a longer training program, more subjects, or a higher intensity program would have led to a significant result REE and %BF.

**Substrate Oxidation And Energy Expenditure During And After Isocaloric Exercise Bouts Of Different Intensity**

Raul Y. Zubia<sup>1</sup>, Stephen F. Burns<sup>2</sup>, George A. King<sup>1</sup>, Joseph Tomaka<sup>1</sup>, Chantal A. Vella<sup>1</sup>. <sup>1</sup>The University of Texas at El Paso, El Paso, TX. <sup>2</sup>Children's Hospital of Pittsburgh, Pittsburgh, PA.

Email: rzubia@utep.edu

(No relationships reported)

Physical activity contributes to reductions in body weight and body fat. Determining the optimal exercise intensity for fat reduction is important in order to design effective physical activity programs that are attractive to overweight individuals.

**PURPOSE:** To compare the effects of two different exercise intensities on fat and carbohydrate (CHO) contribution and total energy expenditure during and one hour after isocaloric exercise bouts in sedentary, healthy, overweight (BMI  $25-29.9$  kg/m<sup>2</sup>) males.

**METHODS:** In a random order, fifteen males (mean  $\pm$  SE; age:  $24.9 \pm 1.2$  y; mass:  $83.5 \pm 2.4$  kg; BMI:  $27.2 \pm 0.5$  kg/m<sup>2</sup>; VO<sub>2max</sub>:  $39.5 \pm 1.3$  mL/kg/min) volunteered to perform treadmill walking at 45% (moderate intensity) and 65% (high intensity) VO<sub>2max</sub> until they expended 300 kcal. On each occasion, exercise was followed by one hour of recovery in a seated, recumbent position. Expired gases were measured continuously during exercise and recovery, and substrate utilization was determined from the respiratory exchange ratio (RER). A two-way ANOVA with repeated measures was used to assess differences between trials and over time for both the exercise and recovery periods.

**RESULTS:** Exercise RER was significantly lower (main effect of trial,  $P < 0.05$ ) during the moderate ( $0.86 \pm 0.01$ ) than high intensity trial ( $0.92 \pm 0.01$ ). Recovery RER was similar between moderate and high intensity trials ( $0.85 \pm 0.01$  vs.  $0.84 \pm 0.01$ , respectively,  $P > 0.05$ ). Total energy expenditure during exercise was similar between trials. However, fat provided a greater energy contribution toward exercise on the moderate than high intensity trial (main effect of trial,  $P < 0.05$ ) while the reverse was true for CHO (main effect of trial,  $P < 0.05$ ). The energy contribution of fat and carbohydrate was similar during recovery, although the total energy expenditure was significantly higher

during recovery from the high than moderate intensity exercise ( $391.2 \pm 2.6$  vs.  $382.0 \pm 2.5$  kcal, respectively).

**CONCLUSION:** Sedentary, overweight males expended more calories from fat during moderate than high intensity exercise. However, total energy expenditure was greater during recovery from high intensity exercise. Training studies are needed to determine if these findings translate into differences in body composition and weight loss with long term exercise.

**The Effect Of Consecutive Bouts Of Resistance Training On Resting Energy Expenditure**

Kyle J. Hackney<sup>1</sup>, Andrew R. Kelleher<sup>1</sup>, Lori L. Ploutz-Snyder, FACSM<sup>2</sup>. <sup>1</sup>Syracuse University, Syracuse, NY. <sup>2</sup>Universities Space Research Association, NASA Lyndon B Johnson Space Center, Houston, TX.

Email: kjhackne@syr.edu

(No relationships reported)

**PURPOSE:** To investigate the influence of consecutive bouts (alternating upper and lower body) of resistance training (RT) on resting energy expenditure (REE) and the respiratory exchange ratio (RER).

**METHODS:** Eight men had REE and RER measured on 7 consecutive mornings. The mean of morning 1 and morning 2 for REE and RER represented baseline. Immediately following measurements on mornings 2 and 4, participants performed lower body RT. On mornings 3 and 5 they performed upper body RT. All workouts were performed using 6 exercises, 3 sets, at 70% of 1-repetition maximum until volitional fatigue. Finally, on days 6 and 7 REE and RER were evaluated to determine if there were any delayed responses as a result of the RT.

**RESULTS:** The coefficient of variation for baseline measures for REE (kcal/day, kcal/kg/day) and RER ( $\text{VCO}_2 / \text{VO}_2$ ) were 1.8%, 2.2%, and 2.8%, respectively. The results of a repeated measures ANOVA with a planned Bonferroni corrected t-tests are summarized in the table below (mean  $\pm$  SE).

Measure	Day 1	Day 2	Day 3	Day 4	Day 5	Day 6	Day 7
kcal/day	1771 $\pm$ 77	1766 $\pm$ 69	1931 $\pm$ 72*	1859 $\pm$ 57	1899 $\pm$ 67*	1877 $\pm$ 77	1825 $\pm$ 61
kcal/kg/day	22.5 $\pm$ 9	22.4 $\pm$ 9	24.7 $\pm$ 1.3*	23.8 $\pm$ 1.2	24.2 $\pm$ 1.1*	23.9 $\pm$ 1.1	23.3 $\pm$ 1.1
RER	0.81 $\pm$ 0.02	0.81 $\pm$ 0.02	0.78 $\pm$ 0.02	0.77 $\pm$ 0.02	0.79 $\pm$ 0.03	0.80 $\pm$ 0.02	0.80 $\pm$ 0.01

\*p <0.01

**CONCLUSION:** Our findings suggest that significant elevations (~8%) in REE primarily occur the day after lower body RT. Consistent increases in REE can lead to elevated total daily energy expenditure and potentially facilitate a negative energy balance.

Supported by NSCA-GNC Nutritional Research Grant.

**Comparison Of The Body Gem And The Harris Benedict Equation For Determining Resting Energy Expenditure**

Ronald K. Hetzler, FACSM, Kurt C.L. Go, Christopher D. Stickley, C. Alan Titchenal, Iris F. Kimura, Michelle A. Cleary. *University of Hawaii, Honolulu, HI.*

(No relationships reported)

The ability to accurately measure resting energy expenditure (REE) is essential in both the study of exercise science and human nutrition. The Harris Benedict equation (HBEq) is commonly used by nutritionists to estimate REE when developing weight loss programs. Relatively inexpensive portable indirect calorimeters for estimating REE have been developed which measure oxygen consumption but when estimating caloric expenditure rely on the Weir equation which assumes a respiratory exchange ratio of 0.85.

**PURPOSE:** to compare measurements of REE using the Body Gem (MicroLife, Dunedin, FL) and the Harris Benedict equation with measurements obtained via indirect calorimetry.

**METHODS:** Twenty-five adults (12 females: age  $26 \pm 5$  years, wt  $54.7 \pm 8.0$  kg, ht  $157.3 \pm 7.4$  cm, BMI  $22.1 \pm 3.3$ , body fat  $23.5 \pm 6.4$  %; 13 males: age  $26 \pm 4$  years, wt  $79.7 \pm 15.7$  kg, ht  $172.4 \pm 6.2$  cm, BMI  $26.7 \pm 4.4$ , body fat  $15.5 \pm 6.0$  %) were tested following a 12 hour fast. Anthropometric data were collected to estimate REE using the HBEq. Following a 30-minute rest in a semi-recumbent position, REE data were obtained via indirect calorimetry during the last 5 minutes of a 30 minute collection period. REE was then estimated for all subjects using the Body Gem portable indirect calorimeter by breathing through the device for 5-12 minutes until steady state was detected. The Body Gem was held in place by a rolled-up towel so that subjects were not required to hold the device during data collection.

**RESULTS:** Mean REE (kcal/day) for all subjects were: HBEq =  $1609.7 \pm 312.7$ , Body Gem =  $1280.5 \pm 255.9$ , Indirect calorimetry =  $1321.7 \pm 317.8$ . Mean REE (kcal/day) for males and females were: HBEq =  $1853.4 \pm 233.4$  and  $1345.7 \pm 88.1$ , Body Gem =  $1468.3 \pm 195.7$  and  $1077.1 \pm 119.2$ , Indirect calorimetry =  $1543.9 \pm 267.3$  and  $1081.0 \pm 144.4$ , respectively. REE estimated from HBEq was significantly higher compared to indirect calorimetry ( $p < 0.05$ ). No significant differences in REE were found between the Body Gem and indirect calorimetry.

**CONCLUSIONS:** The HBEq significantly overestimated REE in healthy young adults by 288 kcal/day (21.8%). The Body Gem provided valid estimates of REE and may be used as a substitute for indirect calorimetry to estimate REE in the development of weight loss programs. The HBEq should only be used when other, more accurate methods for estimating REE are not available.

---

**1531 Board #133 May 27 9:30 AM - 11:00 AM**  
**Effect Of Moderate Altitude On Excess-Post Oxygen Consumption Following Maximal Exercise**

Alex Montoye, Nathan Garvin, Bruno Gervasi, Corey McCue, John Davis. *Alma College, Alma, MI.*

Email: 10ahmont@alma.edu

(No relationships reported)

It has been well documented that oxygen consumption and thus energy expenditure is elevated following maximal exercise. However, no studies have examined the effect of altitude exposure on excess post-oxygen consumption (EPOC) following maximal exercise.

**PURPOSE:** To determine the effect of moderate altitude exposure on the excess post-oxygen consumption following maximal exercise.

**METHODS:** Twelve healthy, active subjects (age =  $23.7 \pm 10.1$  yrs., weight  $170.6 \pm 38.4$  lbs.) were asked to complete a graded-exercise test to exhaustion on a cycle ergometer at sea level (SL1), upon acute exposure to 3400m (ALT1), two weeks following acclimatization at 3400m (ALT2), and upon return to sea level (SL2). Workloads began at 420 kg.m/min and were increased by 420 kg.m/min for the men and 210 kg.m/min for the women and were increased every two minutes until volitional fatigue.  $\text{VO}_2$  measurements were determined via a Parvo TrueOne 2400 Metabolic Measurement System every 30 seconds during exercise and every minute after exercise until recovery to within 5% of resting  $\text{VO}_2$ . Lines of best fit were

determined for the data for each subject, and total O<sub>2</sub> consumption was calculated by integrating the equation for the line of best fit to find the total area under the curve for 10 (T10) and 20 (T20) minutes after exercise.

**RESULTS:** As expected, VO<sub>2max</sub> decreased from SL1 (3.7±0.8 L/min) to ALT1 (3.2±0.8 L/min) and remained lower at ALT2 (3.3±0.6 L/min). Also, VO<sub>2max</sub> was significantly higher at SL2 (3.8±0.8 L/min). Only T10 increased significantly ( $p<0.05$ ) during SL2 (10.3±3.1 L) relative to SL1 (8.0±1.8 L). T10 tended to increase during SL2 (10.3±3.1) relative to ALT2 (8.7±1.2), but was not statistically significant ( $p=0.09$ ). T20 did not show any significant differences.

**CONCLUSION:** The greater EPOC observed at SL2 relative to SL1 may be due to the higher VO<sub>2max</sub> values causing higher starting EPOC values. Furthermore, these data indicate that the lack of significant differences in total oxygen consumption observed at ALT1 and ALT2 could be due to the lower max VO<sub>2</sub> levels being compensated by higher resting VO<sub>2</sub> levels resulting from an altitude-induced increase in sympathetic stimulation.

---

**1532 Board #134 May 27 9:30 AM - 11:00 AM**  
**Resting Energy Expenditure Of Overweight/obese And Non-obese Individuals Determined Using The Body Gem® And Oxycon Mobile®**

Lynn A. Darby, FACSM, Jessica E. Mospan, Richard P. Heitkamp, Robert A. Carels, Bonnie G. Berger. *Bowling Green State University, Bowling Green, OH.*

Email: ldarby@bgsu.edu

(No relationships reported)

Assessment of resting energy expenditure (REE) may be useful for educating clients in weight management programs. In addition, regression equations commonly used to predict REE may not be accurate (Frankenfield et al., 2005). The BodyGem® and OxyCon Mobile® have been suggested as reliable devices to measure REE.

**PURPOSE:** To determine the repeatability of measurements of REE in individuals of various body weights and compositions, as well as to determine the reproducibility of REE using two pieces of equipment: 1) OxyCon® Mobile, a portable metabolic cart; 2) the portable handheld BodyGem®, an at-home use device.

**METHODS:** Pilot data were collected for 20 subjects; data from three subjects were excluded. Subjects were divided into Overweight/Obese ( $n=8$ ; BMI > 25 kg/m<sup>2</sup>) and Non-obese ( $n=9$ ; BMI < 25 kg/m<sup>2</sup>) groups. REE was collected for two trials for all subjects using the BodyGem® and for 10 subjects using the OxyCon®. One-way between subjects ANOVA's were calculated for demographic variables and REE. A two-way (Trial × Type of Equipment) repeated measures ANOVA was calculated for REE. Intraclass correlation coefficients (R) were used to determine reliability of REE for each type of equipment.

**RESULTS:** The Overweight/Obese group was significantly different from the Non-obese group for body weight, BMI, % body fat, hip circumference, and abdominal diameter. Group means for REE determined using the BodyGem® were not different. No significant differences were found between the REE determined by BodyGem® (Trials 1, 2: 1459 ± 276, 1469 ± 222 kcal/day;  $n=8$ ) and OxyCon® (Trials 1, 2: 1390 ± 307, 1386 ± 273 kcal/day;  $n=8$ ) [ $F(1,7) = .81, p = .398$ ]. There were no significant differences between Trials for either the BodyGem® [ $F(1,16) = 3.93, p = .06$ ] (Trials 1, 2: 1585 ± 292, 1535 ± 267 kcal/day;  $n=17$ ) or OxyCon® [ $F(1,7) = .005, p = .94$ ]. Comparison of the mean REE's for power, effect size, and R by Trial for BodyGem® and for OxyCon® were: 1- $b = 0.99, 0.95$ ;  $f = 0.48, 0.03$ ;  $R = 0.96, 0.92$ , respectively. Body weight, lean body weight, fat weight, and abdominal diameter were significantly correlated to REE from BodyGem® for each Trial ( $p < .05$ ).

**CONCLUSIONS:** REE was reproducible in individuals of varied BMI's. The "convenient to use" BodyGem® device produced comparable results to the OxyCon Mobile®.

**Comparison Of Net Energy Expenditure And Steps Among Lean And Overweight Women During Walking And Jogging**

James D. LeCheminant<sup>1</sup>, Tim D. Heden<sup>2</sup>, Kay Covington<sup>2</sup>, John D. Smith<sup>3</sup>. <sup>1</sup>Brigham Young University, Provo, UT. <sup>2</sup>Southern Illinois University Edwardsville, Edwardsville, IL. <sup>3</sup>Texas A&M University Kingsville, San Antonio, TX.

Email: lecheminant@byu.edu

(No relationships reported)

**PURPOSE:** To compare net energy expenditure (EE) and pedometer steps during walking and jogging in overweight and lean women.

**METHODS:** Twenty-three healthy women (20.7±1.6 y, 66.2±9.4 kg, 35.9±5.4 ml/kg/min, 24.4±3.3 kg/m<sup>2</sup>) participated in this study. Thirteen were normal weight (BMI < 25 kg/m<sup>2</sup>), ten were overweight (BMI ≥ 25 kg/m<sup>2</sup>), and all were non-smokers, not on medications affecting metabolism, and able to run 1 mile continuously at 5 mph. Each participant reported to the laboratory on 3 separate days, within a 1-week period, at the same time, under the same conditions, and with at least 1 day separating each visit. During the first visit, tests for resting metabolic rate (RMR) via indirect calorimetry, anthropometric measures, and VO<sub>2max</sub> via indirect calorimetry were determined. On the second visit, EE was assessed using indirect calorimetry during a 1-mile walk at 3 mph. On the third visit, EE was again assessed using indirect calorimetry during a 1-mile jog at 5 mph. Net EE was determined by subtracting RMR from the total EE during the 1-mile walk and 1-mile jog. During both the walk and the jog participants wore a pedometer to account for steps taken.

**RESULTS:** For the lean women, RMR was 1461±162 kcal/d and was significantly lower than the overweight women (1643±108 kcal/d). Net EE was 30% lower than total EE for the walk and 13% lower for the jog in lean women and 28% lower during the walk and 12% lower for the jog in overweight women. The net EE during the 1-mile walk was 47±5 kcal for the lean women and 59±7 kcal for the overweight women and during the 1-mile jog was 82±11 kcal for the lean women and 100±14 kcal for the overweight women. The overweight women burned more energy for both the walk and the jog compared to the lean women ( $P<0.05$ ). For both groups, pedometer steps were lower during the jog than the walk ( $P<0.05$ ); however, there were no differences in steps between groups for the walk or jog ( $P>0.05$ ).

**CONCLUSIONS:** These data indicate that there is a significant difference in EE during walking and jogging between lean and overweight women. These data may be used as a practical measure in teaching lean and overweight individuals the reality of EE during walking and jogging activities.

**Energy Expenditure Of Mechanical Horse Riding And Its Measurement Reliability Among Young Adults**

Jackson Pui Man Wai, Kuo-Yuan Chen, Dirk Tso-Yen Mao, Yu-Chang Huang, Huan-Yang Peng. *National Taiwan Sport University (Taoyuen), Taoyuen, 33333, Taiwan.* (Sponsor: Priscilla Clarkson, FACSM)

Email: jpmwai@ms43.hinet.net

(No relationships reported)

Mechanical horse riding has been shown to improve insulin resistance in elder diabetic patients, and physical functions and body dimensions in healthy adults. Nevertheless, its energy demand appears to be relatively low and may not produce beneficial effects for cardiorespiratory fitness and weight control among younger adults.

**PURPOSE:** To study the energy expenditure (EE) and exercise intensity of mechanical horse riding and its measurement reliability.

**METHODS:** A Joba® mechanical horse (EU-6441, Panasonic, Japan), which provided forward tilt (FT), backward tilt (BT) and level (L) modes, was used at the highest operating speed (1.76 cycle·s<sup>-1</sup>). In experiment 1, first time riders exercised for 10 min either using FT (6 men and 6 women) or BT (4 men and 3 women) mode across 4 different days. Expired gas was collected every 2-min stage in Douglas bags and the last 3 stages were used to obtain intraclass reliability. In experiment 2, 15 men and 15 women ( $M \pm SD$ : age = 21.6 ± 3.8 and 21.9 ± 3.5 yr; height = 173.6 ± 8.1 and 160.1 ± 7.1 cm; weight = 69.0 ± 11.5 and 53.6 ± 5.0 kg, respectively) exercised for 10 min using all 3 modes, with 15-min rest in between and counter-balanced order. The last 6-min expired gas was collected to obtain EE. Heart rate was measured at the end of each minute. A practice session identical to the actual experiment was given to each subject at least 48 h prior to actual measurements. Maximum oxygen uptake was measured using

maximum progressive treadmill protocol. Repeated measures 2-way ANOVA was used to study gender and mode effects.

**RESULTS:** Intraclass coefficients ranged 0.82 - 0.95 with between-subject variance accounted for most of the total variance. EE of FT, BT and L were  $2.468 \pm 0.655$ ,  $2.136 \pm 0.471$ , and  $2.178 \pm 0.447$  kcal·h<sup>-1</sup>·kg<sup>-1</sup> (MET) for men; and  $2.004 \pm 0.419$ ,  $1.917 \pm 0.352$ , and  $1.863 \pm 0.375$  kcal·h<sup>-1</sup>·kg<sup>-1</sup> for women respectively. Among men, FT's EE was higher ( $P < 0.05$ ) than that of BT and L, and the later two modes had similar values. Among women, no EE differences were found among exercise modes. Gender difference occurred (men > women,  $P < 0.05$ ) in FT. Exercise intensities were 16 - 20% maximum oxygen uptake or heart rate reserve.

**CONCLUSIONS:** Energy expenditures or exercise intensities (1.9 - 2.5 MET) produced by the mechanical horse studied are in general lower than the recommended level ( $\geq 3$  MET) of physical activity.

**1535 Board #137 May 27 9:30 AM - 11:00 AM**

**Energy Expenditure In Severe Obesity**

Kazanna C. Hames, Jolene A. Brown, Amy D. Otto, John M. Jakicic, FACSM, James P. DeLany, Bret H. Goodpaster, The RENEW Study Research Group, *University of Pittsburgh, Pittsburgh, PA.*

*(No relationships reported)*

Obesity can be caused by an energy imbalance created by a high energy intake and/or low energy expenditure (EE). However, both resting EE (REE) and total daily EE (TDEE) have been shown to be higher in obesity. It is not clear to what extent the higher TDEE is due to resting and activity-related components, particularly in severe (Class II and III) obesity.

**PURPOSE:** The primary purpose of this study was to characterize TDEE, REE and active EE (AEE) in severe obesity. A second objective was to determine whether a wearable activity monitor (SenseWear Pro 3, BodyMedia, Pittsburgh, PA) can provide reasonably accurate estimates of EE compared to the criterion method of doubly labeled water (DLW) in severely obese.

**METHODS:** 62 Class II and Class III obese (BMI =  $42.7 \pm 5.2$  kg/m<sup>2</sup>, total body fat =  $58.5 \pm 10.4\%$ ), adult (45  $\pm$  7 yr) males (n=6) and females (n=57) completed assessments for body composition by dual x-ray absorptiometry or air-displacement plethysmography, REE by indirect calorimetry, TDEE by DLW (TDEE-D), and TDEE and AEE by activity monitor (TDEE-M and AEE-M, respectively).

**RESULTS:** TDEE-D was on average high ( $3235 \pm 520$  kcal/day) in accord with these subjects' high fat free mass, and was highly correlated ( $R^2 = 0.47$ ,  $P < 0.01$ ) with TDEE-M ( $3130 \pm 587$  kcal/day). In addition to the high REE ( $1823 \pm 315$  kcal/day), these severely obese subjects also had, on average, high AEE-M ( $813 \pm 586$  kcal/day).

**CONCLUSIONS:** Severe obesity is characterized by both high REE and, somewhat paradoxically, high AEE. In addition, innovative wearable activity monitors provided reasonably good estimates of TDEE and AEE compared to DLW methodology in this population. Further studies are needed to address the effects of structured physical activity and weight loss on energy expenditure in severe obesity.

**Energy Availability And Menstrual Regularity In African Black Female Runners**

Hattie Wright, Judy Prinsloo, Hans de Ridder, Szabolcs Peter. *North-West University, Potchefstroom, South Africa.* (Sponsor: South African Sugar Association, FACSM)

*(No relationships reported)*

**PURPOSE:** Endurance female athletes are at risk of having low energy availability which can have detrimental effects on their health and performance. It is also linked with exercise-induced menstrual dysfunction and disordered eating, collectively referred to as the female athlete Triad. Research regarding the prevalence of these components amongst black South African female athletes is limited. Method: Thirty two (n=32) recreational competitive black South African female distance runners, between the ages of 15 and 40 years (mean age:  $21.44 \pm 6.69$ ), were selected on the basis of availability. Two 24-hour dietary recalls were completed for each athlete to assess mean daily energy intakes, Actical® physical activity monitors measured daily and exercise energy expenditure, the Bod Pod® measured body composition, and menstrual irregularity was assessed with a questionnaire compiled from reviewed literature. Risk for disordered eating was assessed via the EAT-26 questionnaire.

**RESULTS:** Mean energy availability for the group was  $124.16 \pm 94.93$  kJ/kg LBM/day, even though 11 of the athletes were below the recommended daily energy availability to ensure menstrual health. Four of the thirty two athletes (12.5%) reported menstrual irregularities. 40.6% reported risk for disordered eating via the EAT-26 questionnaire. In the total group two athletes presented with low energy availability and irregular menstrual function while five presented with low energy availability and a high risk for disordered eating.

**CONCLUSION:** This group of black female athletes are at risk to develop the Triad since some already present with early stages of one or more components. .

**Balance: Bioengineering Approaches For Lifestyle Activity And Nutrition Continuous Engagement**

Deonna C. Hughes, Adrienne Andrew, Rohit Chaudhri, Tamara Denning, Carl Hartung, Philip Hurvitz, Jonathan Lester, Shirley Beresford, Gaetano Borriello, Barbara Bruemmer, Anne Vernez Moudon, Glen E. Duncan. *University of Washington, Seattle, WA.*

*(No relationships reported)*

New and innovative approaches are required to address the global obesity epidemic. Methods to accurately measure energy intake, expenditure, and balance to facilitate weight loss or maintenance goals represent important scientific needs.

**PURPOSE:** To create a practical, pervasive platform that provides users with a visualization of daily energy balance in "real-time".

**METHODS:** Using a list of design goals developed and refined over several months, we built a prototype food diary with energy balance visualization on a cell phone and integrated it with our multi-sensor board (MSB) via wireless connection. The MSB uses a decision stumps classifier and Hidden Markov Models to infer activities, and the ACSM prediction equation and user's body weight to estimate energy expenditure based on the classified activity.

**RESULTS:** The software is comprised of 3 major components: a food diary to enter amounts and types of foods and beverages consumed using the USDA database; an activity diary to manually enter intentional activity not classified by the MSB (e.g., water-based activities); and, the BALANCE visualization, which computes and displays the difference between energy intake from electronic food entry and expenditure from the MSB (accuracy for estimated energy expenditure is about 90%) and activity diary. Basal energy expenditure is "credited" to the user every hour using the Harris-Benedict formula.

**CONCLUSION:** We developed a cutting-edge tool to help people achieve weight-related goals that users will find both attractive and harmonious with their daily lives. In addition, using GIS we assembled an up-to-date dataset of the greater Seattle area to describe locations associated with physical activity and eating episodes. The data is being integrated with Google Maps to provide users with a visual display of food sources and their classification, and locations associated with physical activity, within the user's proximal environment. Thus, our tool will capture peoples' movement through space and time under free-living conditions and conveniently assist in the monitoring of food intake. This work could lead to numerous applications, for example, use as a personal assistive device to monitor energy balance and facilitate behavior changes favorable to weight loss.

**Nutrition And Exercise Lifestyle Intervention Program (NELIP) Prevents Excessive Pregnancy Weight Gain In Overweight Women.**

Michelle F. Mottola, FACSM<sup>1</sup>, Maggie M. Sopper<sup>1</sup>, Margie H. Davenport<sup>1</sup>, Kristen Brandao<sup>1</sup>, Isabelle Giroux<sup>2</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>Brescia University College, London, ON, Canada.

Email: mmottola@uwo.ca

(No relationships reported)

Excessive pregnancy weight gain and weight retention in the postpartum period have been linked to obesity and chronic disease risk.

**PURPOSE:** To determine the effect of a Nutrition and Exercise Lifestyle Intervention Program (NELIP) for overweight and obese women on pregnancy weight gain, offspring birth weight and maternal weight retention at 2 months postpartum.

**METHODS:** Case-control matched design by pre-pregnant body mass index (BMI), age, and parity; 4 controls per case. Cases had a pre-pregnancy BMI of  $\geq 25.0$  kg/m<sup>2</sup> (N=65) and participated in a NELIP starting at 16-20 weeks of pregnancy, continuing until delivery. NELIP consisted of an individualized nutrition plan with total energy intake of approximately 2000 kcal/day (8360 kJ/day), and 40 - 55% of total energy intake from carbohydrate. Exercise consisted of a walking program (30% heart rate reserve), 3 - 4 times per week, using a pedometer to count steps. The Matched Cohort (MC; N=260) was from a large local perinatal database.

**RESULTS:** Weight gained by women on the NELIP was  $6.8 \pm 4.1$  kg ( $0.38 \pm 0.2$  kg/week), with a total pregnancy weight gain of  $12.0 \pm 5.7$  kg. Excessive weight gain occurred before NELIP began at 16 weeks gestation. Eighty percent of the women did not exceed recommended pregnancy weight gain on NELIP. Weight retention at 2 months postpartum was less compared to weight retention between pregnancies in the MC ( $2.2 \pm 5.6$  kg vs  $4.2 \pm 7.9$  kg; respectively,  $p < 0.05$ ). Mean birth weight was not different between groups ( $3.59 \pm 0.5$  kg vs  $3.56 \pm 0.6$  kg, respectively).

**CONCLUSIONS:** NELIP prevented excessive pregnancy weight gain with minimal weight retention at 2 months postpartum in overweight and obese women. This intervention may assist overweight and obese women in successful weight control after childbirth.

**The Association Between Soft Drink Consumption And Adiposity In Young Females**

Megan Costello, Kate A. Heelan, Deborah Mowry. *University of Nebraska - Kearney, Kearney, NE.*

Email: costellomm@unk.edu

(No relationships reported)

Soft drink consumption (SDC) has increased since the 1960's surpassing all other kinds of beverage consumption. The increasing amount of SDC has been linked to the rising epidemic of obesity in children and postmenopausal women, however, it is unclear the quantity of SDC in college females and the impact it has on adiposity.

**PURPOSE:** The purpose of this study was to determine the quantity of SDC and the association between SDC and adiposity in young women, ages 16-24 years.

**METHODS:** Sixty-six female participants (age:  $19.86 \pm 2.13$  yrs, BMI:  $23.5 \pm 4.29$  kg·m<sup>-2</sup>) were asked to complete a 3-day food record and an assessment of body composition by dual-energy x-ray absorptiometry (DXA). Participants were compared based on SDC greater or less than 32 fl oz/day.

**RESULTS:** On average, participants consumed  $29.44 \pm 44.68$  fl oz/day of soft drinks and body fat (BF%) was  $33.2 \pm 8.53\%$ . Although modest, a significant association between SDC and adiposity ( $r=0.244$ ,  $p < 0.05$ ) was apparent. Comparisons between groups are seen in Table 1 (\*  $p < 0.05$ ).

**CONCLUSION:** It appears that SDC is associated with adiposity in college-aged females and high levels of SDC may significantly impact BF%. The increase in simple sugar consumption may be a significant contributor to the obesity epidemic due to its low satiety levels, and low caloric value. 38% of our population's soft drink consumption was > 32 fl oz per day suggesting moderation of SDC is a necessary public health promotion in this age group.

Table 1.			
Group	N	Soda Consumption (fl. oz.)	BF%
SDC <32 fl oz/d	41	$6.05 \pm 9.19$	$31.35 \pm 7.81$
SDC >32 fl oz/d	25	$67.8 \pm 52.91^*$	$36.24 \pm 8.94^*$

**Relationship Between Sleep Time And Markers Of Obesity In Young Women**

Joshua Eberhard, Kathleen Woolf, Brandy-Joe Milliron, Shauna Salvesen, Mark Johnson, Mallory Adams. *Arizona State University, Mesa, AZ.*

Email: joshua.eberhard@asu.edu

(No relationships reported)

Sleep may play an important role in human metabolism. Previous research has suggested an association between sleep time and obesity, with both sleep loss and sleep excess associated with increased risk of obesity.

**PURPOSE:** The purpose of this study was to examine the relationship between sleep time and markers of adiposity.

**METHODS:** Young (25-40 y) normal weight (BMI  $22.2 \pm 1.8$  kg/m<sup>2</sup>; n=28), overweight (BMI  $27.2 \pm 1.4$  kg/m<sup>2</sup>; n=22), and obese (BMI  $34.4 \pm 2.7$  kg/m<sup>2</sup>; n=27) women were recruited for the study. Height, weight, waist circumference, and body composition (dual energy x-ray absorptiometry) were determined for each participant. Participants kept a 7-day log reporting time to bed and time awake. Sleep (minutes/day) and awake (minutes/day) times were calculated for each day and a 7-day average was computed. One-way analysis of variance compared descriptive variables for each BMI category. Partial correlations (controlling for age) examined the relationship between sleep time (minutes/day) and markers of adiposity.

**RESULTS:** Markers of adiposity increased significantly in a stepwise fashion for each BMI category (waist circumference [cm]: normal weight  $77 \pm 7$ , overweight  $92 \pm 6$ , obese  $105 \pm 9$  [ $p < 0.01$ ]; body fat [%]: normal weight  $32 \pm 6$ , overweight  $41 \pm 6$ , obese  $48 \pm 4$  [ $p < 0.01$ ]; trunk fat [%]: normal weight  $31 \pm 7$ , overweight  $41 \pm 5$ , obese  $48 \pm 3$  [ $p < 0.01$ ]). The normal weight, overweight, and obese women reported sleeping for  $474 \pm 44$ ,  $498 \pm 52$ , and  $498 \pm 70$  minutes, respectively [ $p = 0.22$ ]. Using partial correlations (controlling for age), time (minutes/day) spent sleeping was positively associated with waist circumference ( $r = 0.21$ ;  $p = 0.04$ ) and trunk fat ( $r = 0.20$ ;  $p = 0.04$ ). No relationship was seen between sleep time and body weight, total body fat, or leg fat.

**CONCLUSIONS:** In this study, more time spent sleeping was associated with unfavorable markers of adiposity in young women.

## Effect Of Physical Exercise On Risk Factors For Chronic Diseases In Obese Women.

Silvia -V. S. Rocca, Sandra M. L. Ribeiro, Camila M. Melo, Julio Tiraepgui. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

Obesity is associated with an increased risk for developing chronic diseases. The weight loss and body fat reduction, decrease the mortality and control these diseases. Exercise is one of the strategies used for the treatment of obesity by oxidize fat, increasing energy expenditure and mitigating the loss of lean body mass.

**PURPOSE:** Evaluate the effects of physical exercise on body weight reduction.

**METHODS:** For 12 weeks, 22 obese women (BMI>30 kg/m<sup>2</sup>) were submitted to a physical exercise program. At the beginning and at the end of the program were evaluated: BMI, waist (WC) and hip circumferences (HC), and waist-hip ratio (WHR); body composition by DEXA; total cholesterol, HDL-c, LDL-c, triacylglycerol and blood glucose; aerobic power.

**RESULTS:** At the end of the program, aerobic power values were significantly increased (VO<sub>2</sub>max. 19.8 ± 3.5 to 23.0 ± 4.3 ml/kg/min, p<0.05), confirming the physical training effects. Related to anthropometric values, only the visceral fat was reduced (WC 103.17 ± 9.89 to 99.38 ± 9.68cm and WHR 0.84±0.08 to 0.82 ± 0.07, p<0.05). Concerning to biochemical variables a meaningful increase in HDL-c (39.47 ± 9.56 to 43.40 ± 10.05 mg/dl, p<0.05) and significant decrease in blood glucose (100.15 ± 18.02 to 93.73 ± 14.54 mg/dl, p<0.05).

**CONCLUSIONS:** Exercise proves to be an important support in the body weight loss program, not necessarily promoting body weight loss, but lowering risk factors to develop chronic diseases.

Thanks FAPESP- Brazil- for the financial support.

#### Relationships Of Physical Activity Level With Obesity And Fitness In Children

Misaka Kimura<sup>1</sup>, Aya Itoi<sup>2</sup>, Yosuke Yamada<sup>3</sup>, Yukako Hashii<sup>1</sup>. <sup>1</sup>Kyoto Prefectural University of Medicine, Kyoto, Japan. <sup>2</sup>Kobe Women's Junior College, Hyogo, Japan. <sup>3</sup>Kyoto University, Kyoto, Japan.

Email: misaka@cmt.kpu-m.ac.jp

(No relationships reported)

It has long been indicated in Japan that improvements in physique of children are not associated with improvements in exercise abilities or fitness, and increases in obesity and metabolic syndrome in children have recently been reported. Physical changes in children are considered to be markedly affected by lifestyle, particularly diet and exercise.

**PURPOSE:** The effects of the physical activity level on obesity and exercise abilities were evaluated in elementary schoolchildren.

**METHODS:** The subjects were 334 3rd-5th graders (162 males and 172 females) at an elementary school that covers a wide district. In the survey, 1) the height, body weight, and BMI were determined; 2) the physical activity level was evaluated by measuring the daily number of walking steps, total energy expenditure, and energy expenditure by exercise using an accelerometer (Select2, Kenz) on 3 weekdays; 3) the state of exercising in extracurricular sports activities and time spent in going to and coming from school were investigated using a self-administered questionnaire; and 4) exercise abilities were evaluated using new sports tests by the Ministry of Education, Culture, Sports, Science and Technology.

**RESULTS:** 1) The BMI of the subjects was lower than the national average, and the percentage of obese children was low. 2) The number of walking steps was 16,000-20,000 in boys and 15,000-18,000 in girls, being considerably higher than the average in elementary schoolchildren in Kyoto City (about 14,000 in boys, about 11,000 in girls). 3) A significant correlation (r= about 0.6) was observed between the number of walking steps and time spent in going to and coming from school. 4) No significant correlation was noted between the activity level and exercise abilities. 5) Exercise abilities were significantly higher in those who participated in extracurricular sports activities than in those who did not, and the difference widened as the grade advanced.

**CONCLUSIONS:** The low percentage of obese children at this elementary school is considered to be related to the high number of walking steps. However, as fitness and exercise abilities were more closely related to sports activities than the number of walking steps, stimulation by sports is considered necessary for improving exercise abilities in elementary schoolchildren.

#### A Multidisciplinary School Intervention To Improve Nutritional Knowledge, Increase Physical Activity, And Reduce Body Mass

Wendy M. Miller, Silvia Veri, Peter A. McCullough, Barry A. Franklin, FACSM. *William Beaumont Hospital, Royal Oak, MI.*

Email: wmillers@beaumont.edu

(No relationships reported)

Assessment of community interventions aimed at preventing and treating childhood obesity are greatly needed given the escalating prevalence of obesity. Successful interventions can, over time, be widely disseminated to halt or reverse current obesity trends.

**PURPOSE:** Evaluate the impact of a multidisciplinary 12-week school intervention that included two interactive educational sessions with a registered dietitian and bi-weekly physical activity sessions lead by creative movement dancers. Physical activity sessions included instruction and reinforcement of healthy lifestyle habits.

**METHODS:** Body mass index (BMI) was measured and questionnaires were administered at baseline to 77 intervention participants at a suburban public school. Follow-up surveys were completed after the 12-week intervention and follow-up BMI was measured 1 year after the baseline evaluation.

**RESULTS:** Mean age was 9.6 ± 1.0 years and 52% were male. Baseline BMI was 19.5 ± 4.3 kg/m<sup>2</sup>, with a BMI z-score of 0.8 ± 1.0 and a BMI percentile of 70.0 ± 26.3%. Over one-third of the children (38%) were either overweight or obese with a BMI percentile at or above 85%, and 19% were obese with a BMI percentile at or above 95%. There was significant improvement in post-program nutritional knowledge compared with baseline, with correct responses to food group questions of 100% vs. 78%, p<0.001, for the fruit group, 89% vs. 66%, p=0.006, for the vegetable group, and 94% vs. 75%, p=0.008, for the milk group, respectively. The majority of parents, 74%, reported an increase in their child's physical activity level during the program. There was a significant reduction in BMI at 1-year among overweight/obese children with a decrease in mean BMI z-score from 1.7 to 1.4, p=0.03, and a decrease in BMI percentile from 94.0% to 83.5%, p=0.02.

**CONCLUSIONS:** A 12-week multidisciplinary school intervention was associated with improved nutritional knowledge and reported physical activity levels, as well as a reduction in BMI among overweight children at 1 year follow-up. Further evaluation of this type of intervention, including a randomized-controlled trial and long-term studies, is warranted.

Affect has been investigated as a determinant of attendance and adherence in exercise programs. Exercise at intensities below the ventilatory threshold (VT) is typically

associated with a more pleasurable experience than exercise above the VT. Previously, normal and overweight adults have been shown to have similar affective responses (AR) when exercising at intensities above the VT. However, this relation between affective responses and the VT has not been examined in obese subjects.

**PURPOSE:** To compare acute affective responses during treadmill exercise intensities based on the VT between normal-weight (BMI: 18.5 - 24.9 kg·m<sup>-2</sup>), overweight (BMI: 25.0 - 29.9 kg·m<sup>-2</sup>) and obese (BMI: ≥30.0 kg·m<sup>-2</sup>) women.

**METHODS:** Each BMI group had 22 subjects. Participants performed an incremental treadmill test until the point of volitional exhaustion to determine VO<sub>2max</sub>. Oxygen uptake (VO<sub>2</sub>) was measured continuously, and affective responses (Feeling Scale, Hardy & Rejeski, 1989) were recorded every minute. The VT was determined using the ventilatory equivalent method. Three intensities based on the VT were determined: 10% below (-)VO<sub>2VT</sub>, VO<sub>2VT</sub>, and 10% above (+)VO<sub>2VT</sub>. One-way ANOVA was used to compare AR obtained at each intensity ((-)VO<sub>2VT</sub>, VO<sub>2VT</sub>, (+)VO<sub>2VT</sub>) between BMI groups.

**RESULTS:** Relative (-)VO<sub>2VT</sub>, VO<sub>2VT</sub>, or (+)VO<sub>2VT</sub> did not differ between BMI groups. The obese group had a lower (p<0.05) AR associated with VO<sub>2VT</sub> and (+)VO<sub>2VT</sub> (0.5±0.85 and -1.95±2.36) than the normal-weight (2.50±1.79 and 1.18±2.50) and overweight groups (1.77±1.27 and 0.91±1.13). No other differences in AR were noted between BMI groups.

**CONCLUSION:** The relative exercise intensities (%VO<sub>2max</sub>) examined presently were similar between groups. However, the obese group had a lower AR, compared to the other two groups at VO<sub>2VT</sub> and (+)VO<sub>2VT</sub>. This corresponds to an unpleasurable experience during moderate to intense exercise. There may be underlying physiological and psychological mechanisms in obese, previously sedentary women that mediate this affective response.

(No relationships reported)

**PURPOSE:** An increasing prevalence of overweight and obesity in young people has been widely reported in the literature. However, there is little information regarding obesity and its risk factors available for medical students, individuals whose habits and BMIs may affect the whole population through role modeling, and effects on counseling. The purpose of the study was to evaluate the prevalence of overweight and obesity, mean PA levels and related nutrition habits of freshman and senior Colombian medical students (MS)

**METHODS:** A cross-sectional survey of a representative sample of Colombian MS from 24 schools from first (n=1322) and fifth (n=844) year was conducted during 2007. The survey used an electronic, web-based, culturally-adapted Spanish version of the "Healthy doc=healthy patient" survey (response rate= 74.6%).

**RESULTS:** Obesity and overweight were significantly higher in fifth than in first year for men (4.3% vs 0.7%, p=0.01; and 25.1% vs 13.8%; p<0.01) and was significantly higher for obesity but not for overweight in women (2.0% vs 0.9%, p=0.1; and 9.1% vs 9.4%; p=0.9). Daily number of standardized servings of fast food (2.2 vs 2.0, p=0.2), carbohydrates (6.3 vs 5.8, p=0.06), soft drinks servings (0.8 vs 1.0, p=0.01) and fruit and vegetables (2.4 vs 2.4, p=0.8) was not meaningfully different between first and fifth year for men or women (1.7 vs 1.6, p=0.2; 4.1 vs 4.7, p<0.01; 0.5 vs 0.5, p=0.3; 2.7 vs 2.8, p=0.4). Number of portions was higher in men than in women, both in first (11.9 vs 9.1; p<0.01) and fifth year (11.4 vs 9.7; p<0.01). On the other hand, mean reported minutes of moderate or vigorous PA was significantly lower in fifth than in first year, both for men (183 vs 212, p<0.05; 108 vs 180, p<0.01) and women (144 vs 181, p=0.01; 59 vs 97, p<0.01).

**CONCLUSIONS:** The study shows a significant higher prevalence of obesity in fifth year compared to first year MS. Although estimation of caloric intake did not show important differences, we found a significantly lower prevalence of moderate and vigorous PA for fifth year. To what extent these PA findings contribute to the higher obesity prevalence in last year MS need to be further evaluated with longitudinal studies.

(No relationships reported)

The purpose of this study is to examine the changes in body fat mass of previously sedentary, de-conditioned subjects who began following the US Surgeon General's recommendation in frequency of exercise.

**METHODS:** Ninety subjects of both genders were recruited; ages ranged from 22 to 74, (mean = 37.5±13). Subjects were prescribed exercise of four times a week, 30 minutes of continuous exercise, for eight weeks. Eighty subjects completed the eight week study and were categorized based on voluntary compliance: Control (no exercise); Exercise < 2 times/week; Exercise 3-4 times/week; Exercise ≥ 4 times/week. Body Fat mass was the dependent variable in this study, as measured by air displacement plethysmography, and data analysis was accomplished with a repeated measures analysis of variance.

**RESULTS:** There was a significant change in body fat mass in this study, but the only significant difference between groups was for the group that exercised ≥ 4 times/week, (P = 0.004).

**CONCLUSION:** Voluntary compliance was used instead of randomization to reflect actual compliance in prescribed clinical exercise. Adherence to the US Surgeon General's Guidelines for frequency of exercising four times per week for 30 minutes was effective in reducing subjects' body fat mass in this study.

Results By Category of Compliance								
8 week tests	Initial	Final	Initial	Final	Initial	Final	Initial	Final
GROUP	Control (zero exercise)	Control (zero exercise)	Trains < 2 times/week	Trains < 2 times/week	Trains 2-3 times/week	Trains 2-3 times/week	Trains ≥ 4/wk	Trains ≥ 4/wk
Mean Pounds of FAT	64.4lbs	65.6lbs	49.4lbs	44.4lbs	59.3lbs	55.3lbs	58.4lbs	45.1lbs
SD	27.3	27.9	20.1	19.6	27.8	27.2	15.5	12.2
SEM	6.1	6.0	4.5	4.3	6.2	6.1	3.4	2.7

### 1547 Board #149 May 27 11:00 AM - 12:30 PM The Effect Of Exercise Volume On The Performance Of Student Military Aviators

Martin R. Wright. *University of West Florida, Pensacola, FL* (Sponsor: Dr. Ludmila Cosio-Lima, FACSM)  
Email: mrw24@students.uwf.edu

(No relationships reported)

The future helicopter pilots of the Navy and Marine Corps undertake an extremely rigorous six months of advanced helicopter training prior to earning their wings and the designation of Naval Aviator. With varying personal exercise regimens among the students, it is unclear whether the volume of exercise influences the overall performance of a student military aviator (SMA).

**PURPOSE:** To determine whether exercise volume is related to academic and aviation performance during advanced flight school.

**METHODS:** 69 healthy SMAs (62 male, 7 female) from four different classes (1, 2, 3, and 4) voluntarily completed exercise questionnaires at the conclusion of their flight school syllabus. The data was matched with the SMAs' Naval Standard Score (NSS) which measures their performance against the peers within their class. The data was analyzed using SPSS.

**RESULTS:** 47.8 % of the SMAs reported working out 2-3 times/ wk, and 42 % of the SMAs reported working out 3-5 hrs/wk. 55.1 % of the SMAs did resistance training once or less per wk. The same percentage of SMAs also reported doing 2-3 cardio workouts per wk. A Pearson correlation coefficient was calculated for each class examining the relationship between NSS and actual hours of workout per wk. For class 1 and 3, a negative non significant correlation was found: class 1,  $r(18) = -.062$ ,  $p > .05$  and (class 3,  $r(12) = -.180$ ,  $p > .05$ ). For class 2, a non significant relationship was found ( $r(17) = .007$ ,  $p > .05$ ). Finally, a significant negative relationship was found for class 4 ( $r(14) = -.683$ ,  $p < .01$ ).

**CONCLUSION:** Exercise volume is not related to performance as measured by NSS of SMAs in advanced rotary flight school. A future study which examines a larger sample size and utilizes a measurement of performance that can be standardized over the entire population of flight school graduates is recommended (not NSS). Additionally, the daily recording of an SMA's workout time and study time throughout the syllabus is recommended instead of a questionnaire at the completion of training.

---

### 1548 Board #150 May 27 11:00 AM - 12:30 PM Gender Differences In Preparatory Exercise Training Among Marine Recruits

Emily Schmied, Mitchell Rauh, FACSM, Carol Macera, FACSM, Peggy Han, Daniel Trone, Richard Shaffer. *Naval Health Research Center, San Diego, CA*

Email: emily.schmied@med.navy.mil

(No relationships reported)

Stress fractures are a problem in military and athletic populations, particularly among women. While poor aerobic fitness levels have been associated with increased stress fracture risk in military populations, recent research suggests that lower extremity weight training may be protective. Understanding physical preparations performed by incoming Marine Corps recruits may help explain the gender difference in stress fracture occurrence during basic training.

**PURPOSE:** The objectives of this study were to (1) assess the frequency of aerobic and weight training Marine Corps recruits participated in prior to entering basic training, and (2) identify differences in aerobic and weight regimens between male and female recruits.

**METHODS:** A total of 911 male and 693 female Marine Corps recruits from San Diego, CA, and Parris Island, SC, voluntarily participated. Participants completed the Physical Training Footwear & Musculoskeletal Injuries Trainee Survey, highlighting their aerobic and weight regimens in the year preceding basic training.

**RESULTS:** Significantly more female than male participants (49.9% and 18.6%, respectively;  $P < 0.001$ ) reported engaging in running or jogging training 4 or more months prior to basic training. However, there was no significant difference in frequency of running or jogging in the 2 months prior to basic training ( $P = 0.15$ ). Men reported weight training more often than women in the 2 months preceding basic training (women, 18.4%; men, 24.2%;  $P < 0.001$ ). Additionally, nearly half of the female subjects (46.5%) reported no history of weight training in the year preceding basic training compared with 31.4% of the male subjects ( $P < 0.001$ ).

**CONCLUSIONS:** Although female recruits reported performing cardiovascular training more months prior to the start of basic training than did the males, significantly more female than male recruits reported no history of weight training. The findings suggest that women and men prepare differently for basic training. Future studies should explore how this difference in training might affect the risk of injury in basic training.

### 1549 Board #151 May 27 11:00 AM - 12:30 PM Lower Body Fat Improves Physical And Physiological Performance In Army Soldiers

Kim Crawford<sup>1</sup>, John Abt<sup>1</sup>, Timothy Sell<sup>1</sup>, Takashi Nagai<sup>1</sup>, Jennifer Deluzio<sup>1</sup>, Rusty Rowe<sup>2</sup>, Mark McGrail<sup>3</sup>, Scott Lephart, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>Department of the Army, Stuttgart, Germany. <sup>3</sup>Department of the Army, Fort Campbell, KY.

(No relationships reported)

The Department of the Army's maximal allowable percent body fat varies depending on gender and age, ranging between 30-36% for females and 20-26% for males. However, the Army Weight Control Program policy stipulates all soldiers are encouraged to achieve the more stringent Department of Defense goal, which is 18% body fat for males and 26% for females.

**PURPOSE:** To determine if active duty soldiers who meet the Department of Defense percent body fat goals perform better on physiological and musculoskeletal tests and the Army Physical Fitness Test compared to soldiers who exceed the standards.

**METHODS:** A total of 99 male 101st Airborne Division (Air Assault) soldiers (age=28±7.0 years, height= 1.77±7.4 cm, mass= 82.9±12.4 kg) participated. Percent body fat (%BF) was assessed using air-displacement plethysmography. Based on the %BF, subjects were assigned to group 1 (body fat < 18%) or group 2 (body fat > 18%). Subjects completed a series of physical performance tests consisting of anaerobic power, anaerobic capacity, maximal oxygen consumption (VO2max), push-ups, sit-ups, two mile timed run test, shoulder internal and external rotation strength, and knee flexion and extension strength.

**RESULTS:** The mean %BF was  $13.3 \pm 3.7\%$  (group 1) and  $25.8 \pm 5.2\%$  (group 2). Subjects who met the Department of Defense body fat goals (group 1) performed significantly better on seven of the 10 tests including anaerobic capacity ( $8.3 \pm 0.6$  w/kg;  $7.2 \pm 1.0$  w/kg;  $p \leq 0.001$ ), VO<sub>2</sub>max ( $52.2 \pm 5.4$  ml/kg/min;  $44.1 \pm 6.8$  ml/kg/min;  $p \leq 0.001$ ), push-ups ( $78.2 \pm 18.5$  reps;  $65.7 \pm 13.9$  reps;  $p = 0.002$ ), shoulder internal rotation ( $66.1 \pm 16.2$  N/kg;  $50.4 \pm 14.5$  N/kg;  $p \leq 0.001$ ) and external rotation strength ( $45.4 \pm 7.7$  N/kg vs.  $36.6 \pm 7.4$  N/kg;  $p \leq 0.001$ ), and knee flexion ( $127.9 \pm 23.9$  N/kg;  $103.6 \pm 26.6$  N/kg;  $p \leq 0.001$ ) and extension strength ( $263.5 \pm 49.0$  N/kg;  $219.0 \pm 41.7$  N/kg;  $p \leq 0.001$ ).

**CONCLUSIONS:** Soldiers who met the Department of Defense %BF goals performed better on the physiological and musculoskeletal tests and Army Physical Fitness Test than soldiers who exceeded the standards. The higher performance on military physical readiness tests by soldiers with a lower percent body fat substantiates the need to continue to enforce stringent body fat standards for Army personnel in order to optimize military readiness.

**1550 Board #152 May 27 11:00 AM - 12:30 PM**  
**Body Mass Bias And Allometric Scaling In The Army Physical Fitness Test Among Infantry Soldiers**

Nathan R. Hendrickson<sup>1</sup>, Marilyn A. Sharp<sup>1</sup>, Joseph J. Knapik, FACSM<sup>2</sup>, Roberto Marin<sup>3</sup>. <sup>1</sup>*U.S. Army Research Institute of Environmental Medicine, Natick, MA.* <sup>2</sup>*U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen, MD.* <sup>3</sup>*Womack Army Medical Center, Fort Bragg, NC.*  
(No relationships reported)

Previous research has reported that body mass is negatively correlated with performance in the APFT which includes push up (PU), sit-up (SU) and 2-mile run (RUN) events. Vanderburgh et al., (Med Sci Sports Exerc 40:1538, 2008) reports that these relationships result in a significant bias against larger individuals. By reducing the correlation between body mass and scaled scores, allometric scaling has been suggested as a means to reduce body mass bias in these tests.

**PURPOSE:** To determine the relationship between body mass and lean body mass and APFT performance, and to evaluate the effectiveness of allometric scaling in a sample of active duty soldiers.

**METHODS:** 187 Infantry soldiers ( $23 \pm 5$  yrs) were measured for body composition using dual energy x-ray absorptiometry. They performed the APFT consisting of completing the maximum number of PU in two minutes, maximum number of SU in two minutes and running two-miles as fast as possible. Allometric scaling was achieved by multiplying APFT raw scores for PU and SU by body mass<sup>1/3</sup> and multiplying RUN time by body mass<sup>-1/3</sup> (kg).

**RESULTS:** SU were not significantly correlated to total body mass ( $r = -0.11$ ) or lean body mass ( $r = -0.02$ ). There was a slight negative correlation between PU and body mass ( $r = -0.23$ ,  $p = 0.01$ ) but none between PU and lean body mass ( $r = -0.10$ ). There were significant correlations between RUN and total body mass ( $r = 0.37$ ,  $p < 0.01$ ) as well as lean body mass ( $r = 0.17$ ,  $p < 0.01$ ). Allometric scaling resulted in greater correlations between body mass and lean body mass with SU ( $r = 0.26$  and  $r = 0.31$ , respectively  $p < 0.01$ ) and RUN ( $r = 0.34$  and  $r = -0.48$ , respectively  $p < 0.01$ ), increasing body mass bias in these measures. After allometric scaling, PU was no longer correlated with body mass or lean body mass ( $r = 0.03$ ,  $r = 0.13$ ).

**CONCLUSION:** The Army does not correct for body size in scoring APFT events. In trained Infantrymen, allometric scaling did not reduce the correlation between body size measures and either SU or RUN. However, a body mass<sup>1/3</sup> correction for push-ups appears warranted since allometric scaling eliminated body mass bias from PU performance.

---

**1551 Board #153 May 27 11:00 AM - 12:30 PM**  
**Temperature Effect On Military Endurance And Strength Performances**

Ren-Chang Chang, Lu Ling Cheng, Hsien Chin Yu, Li Yen Tsao, Chia Hua Kuo. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L. Ivy, FACSM)  
Email: niche99@seed.net.tw  
(No relationships reported)

**PURPOSE:** In the study, we determined the temperature effect on military physical fitness test for young soldiers.

**METHODS:** 31 male soldiers from military special force performed standardized 3000-meter running and chin-up strength test under 27 degree Celsius and 32 degree Celsius.

**RESULTS:** Increasing ambient temperature significantly impaired performance on 3000-meter running (from  $619 \pm 6.4$  seconds to  $724 \pm 5.4$  seconds,  $P < 0.001$ ), whereas slight enhanced chin-up strength (from  $18.1 \pm 0.5$  times to  $21.8 \pm 0.7$  times,  $P < 0.05$ ). Interestingly, the temperature effect on running performance was more affected on the individual had better performance at 27 degree Celsius ( $R = -0.55$ ,  $P < 0.001$ ).

**CONCLUSIONS:** Only 5 degree difference can cause a significant effect on endurance but not strength fitness. Bias-free endurance performance tests can be achieved by using temperature-adjusted scoring tables.

**Relationship Between Aerobic Capacity And Sleep Quality In Military Men**

Amanda E. Markham<sup>1</sup>, Benjamin S. McKenna<sup>2</sup>, Sean P.A. Drummond<sup>3</sup>, Walter Carr<sup>4</sup>, Nausheen Momen<sup>1</sup>, Genieleah A. Padilla<sup>1</sup>, Katherine E. Evans<sup>1</sup>, Jennifer C. Kanady<sup>3</sup>, Marcus K. Taylor<sup>5</sup>. <sup>1</sup>*Naval Health Research Center, San Diego, CA.* <sup>2</sup>*SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA.* <sup>3</sup>*Veterans Affairs San Diego Healthcare System, San Diego, CA.* <sup>4</sup>*Naval Medical Research Center, Silver Spring, MD.* <sup>5</sup>*Naval Aerospace Medical Research Laboratory, Pensacola, FL.*  
Email: amanda.markham@med.navy.mil  
(No relationships reported)

Previous research has shown that exercise influences sleep in a variety of populations. In addition, aerobic fitness has been shown to affect sleep quality in specific population samples, including older adults and young females. Little research has studied the effect of aerobic capacity on sleep quality in healthy military populations.

**PURPOSE:** The purpose of this study was to explore the relationship between aerobic capacity and sleep quality in healthy military men.

**METHODS:** A sample of 28 military men (mean age =  $31.4 \pm 7.4$  y) participated in this study. Subjects self-reported their most current Physical Readiness Test (PRT) run time (time to complete a 1.5-mile run) and completed a self-report sleep diary over 7 consecutive days. Sleep quality was assessed through sleep onset latency (SL), number of minutes of wake time after sleep onset (WASO), total sleep time (TST), and how refreshed the participant felt upon waking (REFRESH). Each sleep variable was averaged over the 7-day period. Correlational analyses were used to explore the relationship between aerobic capacity and SL, WASO, TST, and REFRESH.

**RESULTS:** WASO was positively correlated with PRT run time ( $r = .565$ ,  $p = .028$ ). SL, TST, and REFRESH did not significantly correlate with run time ( $r = .122$ ,  $p = .642$ ;  $r = -.356$ ,  $p = .161$ ;  $r = -.037$ ,  $p = .889$ , respectively).

**CONCLUSIONS:** Number of minutes of wake time after sleep onset appears to be influenced by aerobic capacity, such that lower aerobic capacity (measured as slower run times) was associated with more disturbed sleep (a greater amount of time spent awake after the onset of sleep). However, sleep onset latency, total sleep time, and how refreshed one felt upon waking do not appear to be influenced by aerobic capacity. Larger study samples are needed to confirm these findings. Additionally, future research should prospectively evaluate the effect of exercise training on aerobic fitness and sleep quality using gold-standard measures of fitness and sleep.

*This study was Supported by the Office of Naval Research Core Capabilities Research Program, Grant #N0001407WX20658.*

**1553 Board #155 May 27 11:00 AM - 12:30 PM**  
**Relationship Between The Army Physical Fitness Test And Laboratory-based Physiological And Musculoskeletal**

## Assessments

John Abt<sup>1</sup>, Timothy Sell<sup>1</sup>, Takashi Nagai<sup>1</sup>, Jennifer Deluzio<sup>1</sup>, Karen Keenan<sup>1</sup>, Rusty Rowe<sup>2</sup>, Mark McGrail<sup>3</sup>, Sylvain Cardin<sup>4</sup>, Scott Lephart, FACSM<sup>1</sup>.

<sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>Department of the Army, Stuttgart, Germany. <sup>3</sup>Department of the Army, Fort Campbell, KY. <sup>4</sup>Telemedicine and Advanced Technology Research Center, Fort Detrick, MD.

(No relationships reported)

The Army Physical Fitness Test (APFT) is administered twice a year and is designed to evaluate cardiorespiratory fitness, strength, and endurance. The APFT is scored according to gender and age for the number of completed sit-ups and push-ups per two minutes and a two mile run. Despite the goal of the testing protocol, the APFT may not provide a complete picture of individual military readiness or potential for injury.

**PURPOSE:** To determine the relationship between the APFT and laboratory testing for physiological and musculoskeletal variables.

**METHODS:** A total of 90 male Army 101<sup>st</sup> Airborne (Air Assault) soldiers participated (Age:  $28.4 \pm 7.1$  years; Height:  $1.77 \pm 0.08$  m; Mass:  $83.1 \pm 12.2$  kg). Subjects performed the standard APFT and a battery of laboratory assessments consisting of VO<sub>2</sub> max, anaerobic power and capacity, torso rotation strength, shoulder internal and external rotation strength, quadriceps and hamstring strength, and body composition. The laboratory testing battery was based on variables that would most contribute to optimizing overall military readiness and those most likely related to injury in the Army. Subjects were ranked according to performance for each APFT and laboratory test, with a separate cumulative ranking score calculated for the APFT and laboratory tests. A Spearman Rho correlation was calculated to determine the relationship between the cumulative ranking scores for the APFT and laboratory tests. Secondary Spearman Rho correlations were run between the APFT cumulative ranking score and the individual laboratory tests.

**RESULTS:** A moderate relationship was identified between the cumulative APFT and laboratory testing ( $\rho = 0.653$ ,  $p < 0.001$ ). A moderate relationship was identified between the APFT and the VO<sub>2</sub> max ( $\rho = 0.709$ ,  $p < 0.001$ ), anaerobic capacity ( $\rho = 0.654$ ,  $p < 0.001$ ), and body composition ( $\rho = 0.632$ ,  $p < 0.001$ ).

**CONCLUSIONS:** The cumulative ranking relationship between the APFT and laboratory testing was mostly related to the VO<sub>2</sub> max, anaerobic capacity, and body composition test. The lack of relationship between the APFT and the other laboratory tests suggests that despite the potential to score high on the APFT, additional or modified training is necessary to optimize military readiness and prevent musculoskeletal injury.

## A-32 Free Communication/Poster - Musculoskeletal Mechanics I

MAY 27, 2009 7:30 AM - 12:30 PM

ROOM: Hall 4F

---

### 1554 Board #156 May 27 11:00 AM - 12:30 PM

#### A Gender Comparison of Lower Extremity Landing Biomechanics Utilizing Different Tasks

Erik E. Swartz<sup>1</sup>, Adam Hernandez<sup>2</sup>, Dain LaRoche<sup>1</sup>, Laura C. Decoster<sup>3</sup>. <sup>1</sup>University of New Hampshire, Durham, NH. <sup>2</sup>Indiana State University, Terre Haute, IN. <sup>3</sup>New Hampshire Musculoskeletal Institute, Manchester, NH.

Email: eswartz@unh.edu

(No relationships reported)

Jump landings are routinely used to study gender differences in landing. Standardizing the jump height to a fixed vertical distance may bias results as women are forced to land from heights that are a greater percentage of their own maximum vertical jump (MVJ).

**PURPOSE:** To compare lower extremity mechanics between genders from a fixed height and from a self initiated jump.

**METHODS:** Nine male ( $21.50 \pm 1.20$  years,  $173.25 \pm 2.82$  cm,  $75.58 \pm 7.92$  kg,  $60.97 \pm 5.81$  cm MVJ) and 8 female ( $20.56 \pm 1.24$  years,  $161.11 \pm 6.01$  cm,  $57.58 \pm 11.65$  kg,  $33.13 \pm 9.76$  cm MVJ) subjects participated in this study. Subjects were given standard footwear. Maximum vertical jump heights were obtained. Subjects performed 6 successful trials of a drop landing (DL) from a 61 cm height and a self initiated vertical jump landing (VJ) at their 80% MVJ height in random order. A 6-camera, EVa 3-D motion capture system (Motion Analysis, Santa Rosa, CA) captured (120 Hz) and analyzed (EVa version 5.11 and KinTrak 6.0 software) dominant lower extremity joint kinematics based on an 11 marker, 3 segment (thigh, shank, foot) model. Joint centers for the hip, knee and ankle were created according to Euler angle calculations. A synchronized force plate (AMTI, Watertown, MA) recorded time of initial contact and maximal vertical force. Dependent variables included: knee flexion angles at initial contact (KFIC), at maximal vertical ground reaction force (KFMZ) and maximum knee flexion angle (MaxKF). Data were exported into spreadsheet and means for all trials in both conditions were created and imported to SPSS 13.0. Two 1-way ANOVAs tested for differences ( $P = 0.05$ ) between groups in each condition.

**RESULTS:** No significant differences were found between males and females for KFIC or KFMZ in either the VJ or DL. No significant difference was found in MaxKF between males ( $75.55 \pm 8.46$ ) and females ( $67.52 \pm 6.31$ ) in the DL. However, males had greater MaxKF angles ( $83.38 \pm 18.90$ ) than females in the VJ ( $66.22 \pm 15.01$ ) ( $P = .001$ ).

**CONCLUSIONS:** Contrary to other published reports, our results showed no difference in knee flexion angles between genders in a DL task. Males exhibited greater absolute knee flexion in the VJ, which is not surprising given their MVJ heights. Future research investigating lower extremity motion during landing should incorporate appropriately comparable tasks.

---

#### Effect Of Pre-Load On Muscle Activation And Joint Mechanics During A Maximal Vertical Jump

Darren Dutto, Emily Bottjen, Danielle Tams, Jeremy Templeton, Zach Heath. Eastern Oregon University, La Grande, OR.

Email: ddutto@eou.edu

(No relationships reported)

Maximal vertical displacement during jumping is obtained by use of a pre-load of the lower limb musculature, where the muscle-tendon unit is rapidly stretched followed immediately by a concentric muscle action. A plyometric jump from a box involves such a pre-load. It has been established that maximum vertical jump height is greater with a plyometric jump, however the sites of enhanced energy generation have not been reported.

**PURPOSE:** To compare the push-off phase of plyometric (PJ) and static (no pre-load; SJ) maximum vertical jumps in terms of muscle activation and joint dynamics.

**METHODS:** Twelve experienced jumpers performed plyometric (off of a 60 cm box) and static (start from an initial squat position) maximum vertical jumps off of a force platform. Kinematic analysis of the lower limb was performed for the ankle, knee, and hip from sagittal plane video recordings. Electromyographic recordings of the gluteus maximus (GM), semitendinosus (S), rectus femoris (RF), vastus lateralis (V), and gastrocnemius (G) were also taken. Kinematic and force data were combined using inverse dynamic analysis to determine joint torque, power, and work. Condition comparisons were made using a two-way ANOVA with repeated measures.

**RESULTS:** Plyometric pre-load increased maximal vertical jumping by  $5.0 \pm 2.3$  cm. Average peak joint extensor torques at the ankle ( $4.3$  vs  $3.3$  Nm/kg,  $p = 0.06$ ), knee ( $5.1$  vs  $3.9$  Nm/kg,  $p = 0.07$ ) and hip ( $6.5$  vs  $5.0$  Nm/kg,  $p = 0.06$ ) tended to be greater for the PJ, due to the greater peak vertical force ( $28.3$  vs  $22.8$  N/kg,  $p = 0.03$ ). There were no significant differences in work and power output (Net Work:  $14.1$  vs  $12.2$  J/kg for PJ and SJ, respectively;  $p = 0.30$ ). Greater muscle activation was observed during the first half of the push-off for the PJ (GM:  $107$  vs  $34$  mV, RF:  $131$  vs  $54$  mV, V:  $240$  vs  $136$  mV, G:  $121$  vs  $46$  mV,  $p < 0.05$ ), while muscle activity was similar for the two conditions during the second half of the take-off.

**CONCLUSIONS:** Pre-loading had a small effect on vertical jump performance. Muscle activation was higher earlier during PJ due to the eccentric requirements of landing

prior to the jump, however this greater activation did not appear to translate into greater net work at any of the joints.

**1556 Board #158 May 27 11:00 AM - 12:30 PM**  
**Reliability And Validity Of A Hand-held Myotonometer For Assessing Skeletal Muscle Stiffness**

Steven M. Zinder, Darin A. Padua. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*  
(No relationships reported)

Active stiffness of the muscles surrounding a joint has been shown to be an essential component for maintaining joint stability. To date, methods for measuring active muscle stiffness have utilized complicated computer algorithms and sophisticated laboratory hardware, making accurate assessment of muscle stiffness for the clinician nearly impossible.

**PURPOSE:** To examine the reliability and validity of a hand-held device for assessing skeletal muscle stiffness.

**METHODS:** Active muscle stiffness of the rectus femoris muscle was collected on 20 subjects ( $21.88 \pm 2.86$  yrs,  $169.96 \pm 9.29$  cm,  $71.17 \pm 11.82$  kg) over loads of 10, 20, 30, 40, and 50% of their maximum voluntary isometric contraction. Subjects were seated in an isokinetic dynamometer with their knee flexed to 60 degrees. Measurements were collected from the mid-bellies of the rectus femoris with a myotonometer that exerted a local impact on the tissue by means of a brief mechanical impulse. Five trials were measured in each condition. Intraclass correlations (ICC(2,1)) were performed across the five trials in each load condition to assess trial reliability.

**RESULTS:** Mean stiffness values for each of the load conditions (10% =  $314.52 \pm 69.11$ , 20% =  $344.74 \pm 85.96$ , 30% =  $362.26 \pm 99.28$ , 40% =  $371.76 \pm 99.11$ , 50% =  $386.79 \pm 120.40$  N/rad) were consistent with previous literature. Post-hoc analysis revealed that stiffness values at 10% load were significantly different than those at 30, 40, and 50% loads, and that 20% was significantly different than stiffness levels at 50% MVIC. Trial reliability was excellent for each load condition with ICCs ranging from 0.86-0.96 with SEMs ranging from 19.38-46.78 N/rad.

**CONCLUSION:** The results suggest that a hand-held myotonometer is a reliable tool for measuring muscle stiffness over a range of contraction levels. Stiffness levels increased with the proportional increase in force output, which agrees with previous literature showing an increase in active muscle stiffness values with an increase in contraction level. While we did not find a direct linear relationship between level of contraction and measured stiffness values, the data trend suggests the myotonometer measurements are also valid.

**Strategies Used By Professional Movers To Reduce The Impact Of Carrying Loads And Ways To Assist Them**

Joan M. Stevenson, Ian A. Kudryk, Susan A. Reid. *Queen's University, Kingston, ON, Canada.*  
Email: joan.stevenson@queensu.ca  
(No relationships reported)

Professional movers often carry loads against their backs rather than against their abdomen. When asked about this strategy, they believed it is easier on their backs. However, there is little research on hand-held load carriage.

**PURPOSE:** The purpose of this study was two-fold: (1) to assess the biomechanical differences between hand-held anterior load carriage (ALC) and posterior load carriage (PLC); and, (2) to determine if an assistive load carriage device (ALCD) could reduce muscle effort while carrying loads either anterior or posterior to the pelvis.

**METHODS:** The ALC and PLC were compared using an electromyographic (EMG) analysis while participants carried a load on a treadmill. Isometric maximum voluntary exertions (iMVE) were measured for right side of erector spinae (T9 and L3), trapezius, and anterior and posterior deltoid, rectus abdominis, external oblique and forearm flexors. Ten male subjects then conducted three trials of 10 strides for the ALC and PLC techniques while carrying 20% body weight in a specialized box. In a second study with an additional 10 male subjects, four conditions were used: ALC, PLC, anterior ALCD and posterior ALCD. Amplitude probability distribution functions (APDF) were used to compare EMG amplitudes at the 10<sup>th</sup>, 50<sup>th</sup>, and 90<sup>th</sup> percentiles.

**RESULTS:** Results indicated that PLC significantly reduced EMG activity of the erector spinae (>50%), trapezius, and anterior deltoid ( $p < 0.05$ ) as well as increasing EMG activity in the posterior deltoid ( $p < 0.05$ ). Results of the second study confirmed that PC significantly reduced erector spinae activity ( $p < 0.05$ ) and moved the shoulder load from the trapezius and anterior deltoid and focused it on the posterior deltoid. The assistive device reduced flexor digitorum activity (>40% reduction,  $p < 0.03$ ) and anterior deltoid activity (>75% reduction,  $p = 0.5$ ) in both ALC and PLC.

**CONCLUSIONS:** There were large reductions (>50%) in erector spinae muscle activity during PLC which explains why professional movers found it easier. When an assistive device was used, back muscle and forearm flexors (>40%) were the main beneficiaries. These results provide evidence that the ALCD used in this study can be an effective ergonomic tool to alleviate grip effort and shoulder activity in both ALC and PLC conditions.

**Effect Of Artificial Center Of Mass Height Changes On Landing Forces And Emg**

Philip Schot, Chantelle Bruyn, Kristina Stevens. *Pacific University, Forest Grove, OR.*  
Email: philipschot@pacificu.edu  
(No relationships reported)

Anterior cruciate ligament (ACL) rupture is a topic of great interest because it is a particularly devastating injury, occurs mainly in non-contact, large deceleration situations and has a disproportionate incidence among women. Through various means, greater hamstrings involvement is thought to stabilize and protect the knee. Various gender-related factors have been suggested as contributors to ACL injury, but one that has not apparently been explored is weight distribution. Men typically have more upper body mass and thus a higher center of mass (CM). This may demand greater hamstring activation to control the forward trunk rotational inertia encountered in landing which could serve to protect the ACL. The potentially greater hip contribution to overall leg stiffness might also elicit different reaction force features.

**PURPOSE:** To explore whether manipulating the CM height elicited changes in reaction forces and EMG levels among men and women during landings.

**METHODS:** EMG and force platform records from 12 height-matched pairings of men ( $173 \pm 7$  cm,  $73 \pm 9$  kg) and women ( $173 \pm 8$  cm,  $64 \pm 10$  kg) performing bipedal landings from 60 cm were gathered. CM height was manipulated by adding 6.8 kg at the ankles, waist, or shoulders and directly measured using a reaction board. Ten landings in each condition were used for analysis. RMS EMG values for the initial 120 ms of contact were calculated for the vastus medialis, rectus femoris, biceps femoris and semitendinosus. Peak force (PF), loading rate (LR), leg stiffness (KL), and time to stability (TS) were derived from the force records. A 2 x 3 ANOVA was used to assess CM height and gender effects.

**RESULTS:** Among the force variables, no gender effects were identified. No differences were noted between the high and middle CM placements, but the low CM condition did result in greater PF (4%), greater KL (52%) and shorter TS (11%). For EMG activity there were no gender or CM height effects.

**CONCLUSION:** The added mass locations resulted in shifting the CM 2x lower than it was raised. The hastened TS may be attributable to the enhanced physical stability of the system. The KL response was unexpected since the mass was added below the hip and knee joints. The response is compatible with the TS outcome, however, and may suggest that riskier responses were provoked by this manipulation.

**1559 Board #161 May 27 11:00 AM - 12:30 PM**  
**Lower Extremity Kinematics Of A Double Leg Jump Landing Task And Overhead Squat Are Correlated**

Benjamin M. Goerger, Marc F. Norcross, J. Troy Blackburn, Darin A. Padua. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*  
(No relationships reported)

Movement screenings involving a squat task are used clinically to assess lower extremity movement patterns and identify individuals at risk for injury. However, there is little evidence supporting a link between movement patterns observed during movement screenings and dynamic tasks.

**PURPOSE:** To determine if lower extremity movement patterns during an overhead squat (OS) were correlated with those during a double leg jump landing (DLJL).

**METHODS:** Lower extremity kinematics were collected for 25 physically active subjects (8 Males, 17 Females) as they performed 3 trials of a DLJL, consisting of jumping from a 31 cm platform located a distance equal to 50% body height, landing on a force plate, and then immediately jumping for maximum vertical height. The OS consisted of a standard double leg squat with the arms raised above the head and the elbows extended. Three-dimensional knee and hip joint angles were analyzed for the descent phase of each task, defined as the start of the trial to peak knee flexion for the OS and from initial contact with the force plate to peak knee flexion for the DLJL. Pearson correlations were performed for each kinematic variable to assess the correlation within subject and between tasks.

**RESULTS:** Correlation coefficients are provided in Table 1. Frontal plane motion of the hip and knee, and transverse plane motion of the knee were significantly correlated between tasks ( $p < 0.05$ ).

**CONCLUSION:** The OS is an adequate predictor of the amount of frontal plane and transverse plane lower extremity motion an individual will exhibit during more dynamic tasks experienced in sport participation. This suggests that the OS may represent a clinical tool for identifying individuals who are at heightened risk for lower extremity injury.

Table 1. Correlation Coefficients for Lower Extremity Kinematics of DLJL and OS									
Hip Flexion	Hip Abduction	Hip Adduction	Hip External Rotation	Hip Internal Rotation	Knee Flexion	Knee Valgus	Knee Varus	Knee External Rotation	Knee Internal Rotation
$r = 0.028$ $p = 0.895$	$r = 0.633$ $p = 0.001$	$r = 0.742$ $p < 0.001$	$r = 0.053$ $p = 0.800$	$r = 0.000$ $p = 0.773$	$r = 0.145$ $p = 0.488$	$r = 0.892$ $p < 0.001$	$r = 0.944$ $p < 0.001$	$r = 0.822$ $p < 0.001$	$r = 0.860$ $p < 0.001$

**Assessing The Reliability Of Asymmetrical Strength And Power Deficit Evaluation In Functionally-Limited Elders**

Robert J. Carabello, Edward Phillips, Kieran Reid, Roger Fielding. *Tufts University - HNRCA, Boston, MA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to assess the reliability of evaluating asymmetrical strength and power deficits in the lower-limbs of functionally-limited elders.

**METHODS:** A cross-sectional evaluation was performed on 57 older ( $74.2 \pm 0.9$ y, 26 male,  $SPPB \leq 9$ ) adults. Testing was performed twice, at the same time of day, separated by one week. Bilateral knee extensor strength and power was evaluated on Keiser pneumatic resistance training equipment. Asymmetrical strength deficit was defined as the 1 Repetition Maximum (1RM) difference between the right and left legs (Right Leg 1RM - Left Leg 1RM). Asymmetrical power deficit was defined as the difference in Peak Power (PP) between the right and left legs (Right Leg PP - Left Leg PP) at resistances equal to 40% and 70% of the 1RM. The results from the two individual testing days were evaluated for test-retest reliability. In addition, the relationship between asymmetrical strength and power and various measures of functional performance was explored.

**RESULTS:** Asymmetrical strength (Intra Class Correlation (ICC) = 0.799) and power @ 40 (ICC = 0.698) and 70% (ICC = 0.708) of 1RM all showed fair reliability between the two testing days. Correlations showed a moderate association between asymmetrical strength and power and chairstand time: strength ( $r = 0.497$ ,  $p < 0.003$ ) and power @ 40 ( $r = 0.315$ ,  $p < 0.042$ ) and 70% ( $r = 0.330$ ,  $p < 0.021$ ) of 1RM.

**CONCLUSIONS:** These findings support the reliability of evaluating asymmetrical strength and power deficits in the lower limbs of functionally-limited elders as well as the existence of a relationship between strength and power asymmetry and functional performance.

**Decrease In Bowstring Lateral Deflection In Olympic Archery: A Case Report**

Hayri Ertan<sup>1</sup>, Axel J. Knicker<sup>2</sup>, A. Ruhi Soylu<sup>3</sup>, Heiko Strueder<sup>2</sup>. <sup>1</sup>Anadolu University, School of Physical Education and Sports, Eskisehir, Turkey.  
<sup>2</sup>German Sports University, Cologne, Germany. <sup>3</sup>Hacettepe University, Ankara, Turkey.  
Email: hayriertan@gmail.com  
(No relationships reported)

Archery can be defined as a static sport requiring strength and endurance of the upper body, in particular the forearm and shoulder girdle. A predominant forearm and pull finger muscle contraction strategy in archery is defined as the response to the audible impetus or "snap" of a so called "clicker" by active contraction of the m. extensor digitorum (MED) and gradual relaxation of the m. flexor digitorum superficialis (MFDS) at all performance levels. However, one particular archer with a long history at elite performance level showed a different strategy, which is thought to have considerable positive effects on her performance.

**PURPOSE:** To carry out a detailed analysis of the contraction strategy performed by this particular top-level archer and to consider the advantages of her strategy on bowstring release.

**METHODS:** Electromyographic (EMG) activity of the MFDS and MED of elite archer were recorded together with a pulse synchronized with the clicker snap. Raw EMG records as 1 s before and after the clicker pulse were rectified, integrated, and normalized. The data was then averaged for successive shots. Mean scores were calculated for the subject's 12 shots and averaged. Paired samples t-tests were used for assessing differences between scores of MED and MFDS during each time interval. A probability of  $p < 0.05$  was selected to indicate statistical significance.

**RESULTS:** The current archer presented a sharp relaxation of MFDS about 100 ms later than the fall of the clicker. Besides, she showed a gradual relaxation of MED after the fall of the clicker. On the other words, there was no active contraction of MED. However, an active contraction of MFDS was observed at about 200 msec after the snap of the clicker and just after the sharp relaxation. During the whole shot, the normalized value of the MED and MFDS was significantly ( $p < 0.05$ ) different at the time intervals of -1000, -900, 100, 200 ms.

**CONCLUSION:** She responds to the fall of the clicker by relaxing MFDS and without active involvement of MED. The contraction-relaxation strategy that she performs is different than the earlier findings. In her strategy, release of the bowstring is accomplished by only relaxing the MFDS. So, the force of the string on the fingers is sufficient to produce the extension of the three-finger hook, which may decrease the lateral deflection of bowstring.

**1562 Board #164 May 27 11:00 AM - 12:30 PM**  
**Influence Of Time Forecast On Electromechanical Delay In Older Women**

Koichi Takase<sup>1</sup>, MASAHIRO TAGUCHI<sup>2</sup>, MAYUMI KAKIMOTO<sup>2</sup>. <sup>1</sup>MEIO UNIVERSITY, Nago okinawa, Japan. <sup>2</sup>FUKUOKA UNIVERSITY, Fukuoka, Japan.

Email: k\_takase@meio-u.ac.jp

(No relationships reported)

The presence of a time forecast has influences on muscle reaction times.

**PURPOSE:** The purpose of this study is, by measuring electromechanical delay(EMD) and muscle reaction times in the condition that the sense of seeing is intercepted and the forecast of time is interrupted for older women, to investigate how the restricted condition affects the electromechanical delay(EMD) and various reaction time.

**METHODS:** 25 healthy older women subjects gave informed consent for participating in this experiment. Their age, height, and weight are 74.1±5.3 years, 149.8±5.3 cm, 48.3± 7.4kg(mean±SD), respectively. The measurement is performed for extension movement of knee joint. And we investigated the trial both in normal condition(NOR-C) and the restricted condition(RES-C).

**RESULTS:** The main results are as follows: EMD of RES-C(CON: 96.7±12.3ms, ECC: 98.0±8.7ms) is significantly longer( $p<0.001$ ) than NOR-C(CON: 89.6±10.3ms, ECC: 88.4±7.0ms). Similarly, in total reaction time and pre-motor reaction time, there are significant difference( $p<0.001$ ) between NOR-C and RES-C. Moreover, in movement time to the peak torque, there is no significant difference between NOR-C and RES-C.

**CONCLUSION:** These results suggested that the EMD has an effect on time forecast; this older is considered to cause falls during a walk and occurrence of injuries.

**1563 Board #165 May 27 11:00 AM - 12:30 PM**

**Latent Effect Of Passive Static Stretching On Driver Clubhead Speed, Distance, Accuracy, And Solid Contact In Male Competitive Golfers.**

Jeffrey C. Gergley, Stephen F. Austin, Nacogdoches, TX.

Email: jgergley@sfasu.edu

(No relationships reported)

**PURPOSE:** This investigation was conducted to determine the effect of two different warm-up treatments over time on driver clubhead speed, distance, accuracy, and consistent ball contact in male competitive golfers.

**METHODS:** Two supervised warm-up treatments, an active dynamic warm-up with golf clubs (AD) and a 20 minute total body passive static stretching routine plus an identical AD warm-up (PSS), were applied prior to each performance testing session using a counterbalanced design on non-consecutive days. Immediately following the AD treatment, subjects were instructed to hit three full swing golf shots with their driver with one minute rest in between swing trials. Immediately following the PSS treatment, subjects were instructed to hit three full swing golf shots and thereafter at 15, 30, 45, and 60 minutes post PSS with their driver with one minute rest between swing trials.

**RESULTS:** Significant decreases ( $p < 0.05$ ) in clubhead speed, distance, accuracy, and solid contact were observed between AD and PSS. At 15, 30, 45, and 60 minutes post PSS, significant performance decrements continued but with less magnitude. Theoretical explanations for this acute decrease in performance is a more compliant muscle tendon unit, decrease neuromuscular reflex sensitivity, and neural inhibition due to the PSS treatment. Of interest, however, the clubhead speed measurements highly correlated with skeletal muscle force production recovered at faster rates than measures dependent upon neuromuscular coordination.

**CONCLUSIONS:** The results of this inquiry confirm previous findings from this laboratory strongly suggesting that passive static stretching should be avoided prior to practice or competition in favor of a gradual active dynamic warm-up with golf clubs. From this applied sport data, it appears that the muscle tendon unit recovers from passive static stretching at faster rates than coordinating / neurological mechanisms contained in the muscle spindle.

**Landing Patterns In Subjects With Recurrent Lateral Ankle Sprains**

Hon-Wen Cheng, Fu-Hsiu Hsieh, Yu-Lin Ning, Ching-Ya Huang, Chia-Lo Ho, Ming-Chia Lin. Taipei Physical Education College, Taipei, Taiwan.

Email: knhpt@yahoo.com.tw

(No relationships reported)

The most common symptoms after ankle sprains were chronic ankle instability, proprioception defect and probable neuromuscular adaptation.

**PURPOSE:** The purpose of this study was to identify the normal landing pattern using detailed biomechanical analysis including analysis of the kinematics and ground reaction force, and to compare the landing pattern in the subjects with recurrent ankle sprain and normal subjects.

**METHODS:** Ten male adults were recruited in this study (5 subjects with recurrent lateral ankle sprains group, 5 subjects with normal control group). All subjects would be asked to perform maximal standing jumps and drop landing from 3 platforms with different heights (0.37 m, 0.67 m, & 0.97 m, respectively). Those movements were collected by VICON 512 (Oxford Metrics, UK) motion analysis system and the kinematics was analyzed using self making software with MATLAB. The ground reaction force of both lower limbs was recorded by two AMTI force platforms, and the kinetic data were calculated with inverse dynamics.

**RESULTS:** In the different landing height, the main differences of kinematics were the maximum flexion angles of hip and knee joints in normal landing patterns and the flexion angles increased with the landing height, as well as the flexion of pelvis, hip abduction, and knee external rotation in the subjects with recurrent ankle sprains. When compare those two groups, the landing pattern in the subjects with recurrent ankle sprain was significant smaller than normal subjects in knee flexion ( $65.71^\circ \pm 6.43^\circ$  vs.  $70.19^\circ \pm 13.76^\circ$ ) and hip flexion ( $34.15^\circ \pm 5.42^\circ$  vs.  $42.54^\circ \pm 10.07^\circ$ ). The time to maximum angles in ankle dorsiflexion and foot pronation were also quite different between these two groups. The maximum vertical ground reaction force in sprain group was significant smaller than normal group.

**CONCLUSIONS:** In this study, we have revealed the adaptation of performing drop landing in the individuals with recurrent ankle sprains. It could be considered as a recommendation of the rehabilitation.

**1565 Board #167 May 27 11:00 AM - 12:30 PM**

**Single Leg Cycling; An Evaluation Of Pedal Powers**

L Nathan Thomas. University of Utah, Salt Lake City, UT.

Email: nate.thomas@utah.edu

(No relationships reported)

Single and double-leg cycling have been used in therapeutic and training settings. The benefits of single-leg training may be compromised because single and double-leg cycling are biomechanically different. Specifically, during normal double-leg cycling the gravitational forces acting on each leg are essentially balanced by the contralateral limb and thus do not require active leg flexion. Conversely, single-leg cycling requires active leg flexion to lift the leg. Recently, we devised a counterweighted cycling crank that may facilitate single-leg cycling with similar biomechanics to normal double leg cycling.

**PURPOSE:** The purpose of this study was to determine the optimal counterweight to facilitate single-leg cycling with biomechanics similar to normal bilateral cycling.

**METHODS:** Following warm up (5 min), three trained cyclists (age: 33 +/- 4 years) performed 105 second trials (single leg and double leg) on a cycle ergometer equipped with a force and position sensing pedal. Single-leg protocol was repeated four times (with counterweights of 10, 20, 25 and 30 lbs). Trials were performed at 60rpm with increased power every 15 seconds (50, 100, 150, 200, 250, and 300 watts for double-leg and half of those powers for single-leg). Pedal forces were recorded for each power condition and averaged every 6 degrees of crank rotation. Differences between single and double-leg cycling for each 6 degree interval were determined. Sum of squared differences for each condition were used to evaluate optimal counterweight.

**RESULTS:** Sum of squared difference varied among the counterweights evaluated and reached a minimum at 20 lbs. For our current sample population, 20lb counterweight produced the closest approximation to double leg cycling.

**CONCLUSIONS:** Single-leg cycling may be a beneficial training and rehabilitation modality and determining the optimal counterweight is an important first step towards that end.

**1566 Board #168 May 27 11:00 AM - 12:30 PM**  
**Effect Of Variable Numbers Of Repetitions On Peak Torque In Isokinetic Testing Of The Knee Extensors**

Deanna Malikie, Sarah Moody, Barbara Warren, FACSM. *Univeristy of Puget Sound, Tacoma, WA.*

Email: dmalikie@ups.edu

(No relationships reported)

Isokinetic testing devices have allowed for the evaluation of strength across a wide spectrum of populations and muscle groups; however a specific protocol for isokinetic testing of the knee extensors with an emphasis on the specificity of repetitions has not been established.

**PURPOSE:** The purpose of the study was to examine the effect(s) of variable repetitions of maximal isokinetic knee extensions on peak torque production in males. Secondly, the purpose was to assess if differences existed between athletes and non-athletes. **METHOD:** Thirty, healthy college aged males (15 athletes and 15 non-athletes) with no history of knee injury were recruited from the University of Puget Sound to attend two familiarization and four test sessions to perform maximal knee extensions on a Cybex NORM at 60, 120, 180, 240, and 300°·sec<sup>-1</sup>. Rest periods were held constant at 60 seconds and knee flexions were held constant at 300°·sec<sup>-1</sup>. Four, six, eight and ten repetitions were randomly assigned at each test session. Peak torque was recorded for each trial. Data were analyzed using a 2 x 4 x 5 repeated measures ANOVA design with group, repetitions, and velocity as the independent variables, and peak torque as the dependent variable, alpha <0.05.

**RESULTS:** There were no significant differences in peak torque for variable repetitions. Male varsity athletes produced significantly greater peak torque than non-athletes at all velocity sets (F= 25.385, p<0.05). Finally, there was a significant difference in peak torque by velocity (F=757.503, p<0.05).

**CONCLUSION:** Peak torque production in males was not affected by the number of repetitions. Athletes were able to generate more peak torque at all velocities than their non-athletic peers. Research was funded by a summer grant from the University of Puget Sound.

**1567 Board #169 May 27 11:00 AM - 12:30 PM**  
**Acute Effects Of Static Stretching On Peak Torque And The Rate Of Velocity Development**

Pablo B. Costa, Eric D. Ryan, Trent J. Herda, Jason M. DeFreitas, Travis W. Beck, Joel T. Cramer, FACSM. *University of Oklahoma, Norman, OK.*

Email: pcosta@ou.edu

(No relationships reported)

**PURPOSE:** To examine the acute effects of hamstring and calf static stretching on peak torque (PT) and the rate of velocity development (RVD) during leg flexion muscle actions at 60, 180, and 300°·s<sup>-1</sup> in men and women.

**METHODS:** Thirteen women (mean ± SD age = 20.8 ± 1.8 yrs; body mass = 64.0 ± 8.3 kg; height = 163.1 ± 5.7 cm) and fifteen men (22.0 ± 4.4 yrs; 82.7 ± 16.1 kg; 173.1 ± 6.8 cm) performed three maximal voluntary isokinetic leg flexion muscle actions at three randomly-ordered velocities (60, 180, and 300°·s<sup>-1</sup>) before and after a bout of hamstring and calf static stretching. The stretching consisted of 1 unassisted and 3 assisted static stretching exercises designed for the posterior muscles of the thigh and leg. Four repetitions of each stretch were held for 30 s with 20-s rest between repetitions. Torque, position, and velocity signals were sampled from the dynamometer at 1 KHz. PT (Nm) was the highest 20-point average value during each repetition, while RVD was the latency time (s) from the initiation of lever arm movement to attainment of the pre-set velocity.

**RESULTS:** PT decreased ( $p \leq 0.05$ ; collapsed across velocity) as a result of the stretching, but only for the women. There were no other stretching-related changes for PT or RVD ( $p > 0.05$ ). PT and RVD decreased from 60 to 300°·s<sup>-1</sup> ( $p \leq 0.05$ ; collapsed across time and gender).

**CONCLUSION:** The stretching caused a 7.5% decrease in leg flexion PT for the women, but there were no changes for the men. RVD was unaltered from pre- to post-stretching for both genders. These findings suggested that the stretching-induced torque deficits experienced by the women were unrelated to the mechanisms that influence the RVD.

Table 1. Mean (± SE) values of Peak Torque and Rate of Velocity Development during leg flexions at 60, 180, and 300-s-1 for the pre- and post-stretching isokinetic assessments.						
	Pre-stretching			Post-stretching		
Women	60-s-1	180-s-1	300-s-1	60-s-1	180-s-1	300-s-1
PT (N·m)	47.430 ± 3.865	32.325 ± 3.248	25.102 ± 3.375	42.967 ± 3.124*	31.195 ± 3.216*	22.853 ± 3.207*
RVD (s)	0.043 ± 0.003	0.111 ± 0.009	0.185 ± 0.018	0.048 ± 0.003	0.112 ± 0.009	0.178 ± 0.017
Men	60-s-1	180-s-1	300-s-1	60-s-1	180-s-1	300-s-1
PT (N·m)	78.389 ± 3.274	64.352 ± 3.543	56.705 ± 2.578	79.266 ± 4.215	63.979 ± 4.116	55.277 ± 3.205
RVD (s)	0.035 ± 0.003	0.081 ± 0.005	0.114 ± 0.005	0.036 ± 0.004	0.077 ± 0.005	0.115 ± 0.007
PT = Peak Torque; RVD = Rate of Velocity Development						
* Indicates significant decrease from pre- to post-stretching

**The Effect Of Reproductive Hormones On Muscle Properties Across The Menstrual Cycle**

David R. Bell, Jonathan T. Blackburn, Marc F. Norcross, Kristin S. Ondrak, Anthony C. Hackney, FACSM, Darin A. Padua. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Kevin Guskiewicz, FACSM)

(No relationships reported)

Reproductive hormones influence mechanical properties of ligamentous tissues such as the anterior cruciate ligament (ACL), potentially increasing their susceptibility to injury. However, little research has focused on the influence of reproductive hormones on muscle properties. As the hamstrings are capable of limiting ACL loading, changes in their mechanical properties may influence ACL injury risk.

**PURPOSE:** To determine if hamstring properties including stiffness (K), electromechanical delay (EMD), rate of force production (RFP), and time to 50% peak force (TT50) change across the menstrual cycle and differ across sex.

**METHODS:** Muscle properties were assessed at two time points in each subject: 7 days apart in males (n=15) and at points in the menstrual cycle corresponding with low (3-5 days post menses) and high (2-4 days post ovulation) estrogen concentrations in females (n=15). K was assessed by quantifying the damping effect imposed by the hamstrings on oscillatory knee flexion/extension induced by perturbation. EMD, TT50, and RFP were assessed during maximal isometric knee flexion. EMD was defined as the time interval between the onsets of EMG and force. TT50 was calculated as the time between the onset of force and the instant at which 50% peak force was attained. This force was expressed relative to body mass (N/kg), and RFP was calculated as the ratio of this normalized force to TT50. Blood hormone levels (estrogen [E], progesterone [P], and free testosterone [FT]) were assessed with radioimmunoassay procedures. 2 (sex) x 2 (time) repeated measures ANOVAs were used for analysis.

**RESULTS:** Females had greater [E] ( $68.0 \pm 23.2$  vs  $99.0 \pm 28.5$  pg/mL,  $p < 0.01$ ) and [P] ( $0.79 \pm 0.5$  vs  $6.6 \pm 6.7$  ng/mL,  $p < 0.01$ ) at ovulation than menses and equal [FT] ( $1.5 \pm 0.6$  vs  $2.1 \pm 0.6$  ng/mL,  $p = 0.63$ ). No interaction effects were observed for K ( $p = 0.43$ ), EMD ( $p = 0.65$ ), or TT50 ( $p = 0.62$ ), or RFP ( $p = 0.93$ ). Males had greater K ( $13.9 \pm 2.6$  vs  $11.5 \pm 1.7$  N/cm,  $p < 0.01$ ), RFP ( $1042 \pm 619$  vs  $501 \pm 223$  N/kg·sec<sup>-1</sup>,  $p < 0.01$ ), and faster TT50 ( $103 \pm 46$  vs  $129 \pm 32$  ms,  $p < 0.05$ ).

**CONCLUSION:** Muscle properties did not change during low and high estrogen periods of the menstrual cycle but sex differences were present. Results may be driven primarily by muscle mass than hormonal fluctuations. Future research needs to test at more time points during the menstrual cycle.

1569 Board #171 May 27 11:00 AM - 12:30 PM

### The Effects Of Fatigue And Decision Making On Lower Limb Kinematics After Neuromuscular Training Program.

Tyler N. Brown, Riann Palmieri-Smith, Scott McLean. *University of Michigan, Ann Arbor, MI.*

(No relationships reported)

Despite the efficacy of neuromuscular training programs in countering risk factors associated with ACL injury, injury rates have not diminished. Fatigue and decision-making, factors synonymous with sports participation and known to promote high-risk mechanics, are not currently accounted for within the prevention modality. By failing to do so, we propose prevention efforts may remain substantially compromised.

**PURPOSE:** To determine whether the kinematic adaptations achieved through neuromuscular training are maintained over time in an unanticipated fatigued movement scenario.

**METHODS:** Thirty four (22 trained, 12 control) females had initial contact (IC) and peak stance (PS) lower limb kinematics initially quantified during non-fatigued anticipated (NAN) and then during fatigued unanticipated (FUN) single-leg land-and-cut tasks. Fatigue was induced cumulatively with subjects performing sets of 8 repetitive squats between unanticipated trials until squats could no longer be performed. All subjects were tested before (Base), immediately after (Post0) and six weeks (Post6) following a six week neuromuscular training program. Subject-based mean NAN IC and PS knee and hip flexion angles and corresponding angles from the final FUN trial were subsequently quantified and submitted to repeated measures three-way ANOVAs to test for the main and interaction effects of movement condition, time and group.

**RESULTS:** While a trend of a more extended landing posture was evident for FUN compared to NAN landings, statistically significant differences were not observed between these two conditions for IC or PS hip and knee flexion postures. Further, training did not counter this trend, with a consistently more extended posture evident for FUN tasks in both the control and training groups, both immediately and six weeks post.

**CONCLUSION:** Sports relevant movement tasks, incorporating fatigue and decision making, induce a more extended lower limb landing posture, which may increase the potential for ACL injury. Exposure to a standard, lab-based neuromuscular training protocol, however, does not reverse this trend, suggesting trained adaptations in the control strategy may not hold up under the rigors of realistic sports participation. Consideration of this fact within ongoing prevention efforts is warranted.

1570 Board #172 May 27 9:30 AM - 11:00 AM

### 53 Hrs Of Sleep Deprivation On Thermoregulation During Multiple Stages Of Acute Cold Exposure

Katherine E. Pierce<sup>1</sup>, Tiffany A. Collinsworth<sup>2</sup>, Edward J. Ryan<sup>3</sup>, Chul-Ho Kim<sup>3</sup>, Keisuke Ida<sup>3</sup>, Jacob E. Barkley<sup>3</sup>, Gary H. Kamimori, FACSM<sup>4</sup>, Ellen L. Glickman, FACSM<sup>3</sup>. <sup>1</sup>Mount Union College, Alliance, OH. <sup>2</sup>Kennesaw State University, Kennesaw, GA. <sup>3</sup>Kent State University, Kent, OH. <sup>4</sup>Walter Reed Army Institute of Research, Silver Springs, MD.

(No relationships reported)

**BACKGROUND:** While the effects of sleep deprivation have proven to be psychologically detrimental, the physiological responses remain unclear. Sleep deprivation may alter a number of physiological processes; thereby suggesting that in combination with cold exposure, the ability of the body to maintain thermoregulatory homeostasis may be impaired. The relationship between sleep deprivation and thermoregulation has not been extensively evaluated.

**PURPOSE:** To evaluate the effect of 53-hrs of sleep deprivation on the thermoregulatory responses of young adult Caucasian males during multiple bouts of acute cold exposure.

**METHODS:** Eight males ( $22.8 \pm 1.7$  y) underwent two conditions [control (CON) or sleep deprivation (SDEP)] during which they were exposed to cold air (10°C) for 120-min, once per day, for 3 consecutive days (i.e., stage 1, 2, 3) beginning at 6:00am. Rectal temperature ( $T_{re}$ ), mean skin temperature ( $T_{sk}$ ) and oxygen consumption ( $\dot{V}O_2$ ) was collected at baseline (BASE) and 5-min, 15-min and every 15-min thereafter for the duration of the trial. Additionally, physical activity (PA) was continuously monitored with the use of an accelerometer.

**RESULTS:** Condition (SDEP, CON) by time (BASE, 5, 15min and every 15min until 120min), repeated measures ANOVAs revealed a significant interaction for  $T_{re}$  ( $p = 0.02$ ) during stage 2. The interaction was due to a significantly greater  $T_{re}$  ( $p < 0.05$ ) in the SDEP vs. the CON condition during BASE and minute 5 and 15 of ACE and no difference thereafter during Stage 2 of ACE. As expected, during SDEP volunteers expended  $400 \pm SD$  more kcal than CON as a result of increased ( $p = 0.001$ ) PA (SEDP  $679,470.00 \pm 135,598.89$  counts, CON  $389,024.13 \pm 114,933.04$  counts). Multilevel model regression analyses then demonstrated that daily PA across both conditions was positively associated ( $p \leq 0.01$ ) with BASE  $T_{re}$  across the final 2 stages.

**CONCLUSION:** SDEP appears to affect an individual's thermoregulatory response in a cold environment as the sleep deprived volunteers exhibited a greater  $T_{re}$  in SDEP than CON.

**The Effects Of 53 Hours Of Sleep Deprivation On Thermal Sensation During Acute Cold Exposure.**

Ellen L. Glickman, FACSM<sup>1</sup>, Katie Pierce<sup>1</sup>, Tiffany Collinsworth<sup>1</sup>, Jacob E. Barkley<sup>1</sup>, Gary Kamimori, FACSM<sup>2</sup>, Keisuke Ida<sup>1</sup>, Chul-Ho Kim<sup>1</sup>. <sup>1</sup>Kent State University, Kent, OH. <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD.

Email: eglickma@kent.edu

(No relationships reported)

The relation between cold perception (i.e., an individual's ability to sense and scale thermal discomfort) and acute cold exposure (ACE) is an area that has considerable practical application to those individuals who may work in environmental extremes. Furthermore, it is well known that sleep deprivation (SDEP) decreases cognitive function which may influence individuals' perception of cold or thermal sensation (TS).

**PURPOSE:** To determine the effects of 53-h of SDEP on thermal sensation using the Gagge scale [TS: Gagge Scale (1967)] and Modified Gagge Scale [(TSM: Glickman-Weiss et al. 1994)] in apparently healthy Caucasian males during 3 separate stages of ACE.

**METHODS:** Eight males (22.8 ± 1.7 y) underwent 2 conditions [control (CON) or SDEP] during which they were exposed to cold air (10°C) for 120 min, once per day, for 3 consecutive days (or 3 stages). TS, TSM and rectal temperature ( $T_{re}$ ) was collected at baseline and 5 min, 15 min and every 15 min thereafter for the duration of the trial.

**RESULTS:** Two-way, repeated measures ANOVAs revealed significant condition by time interactions for  $T_{re}$  ( $p = 0.02$ ), TS ( $p = 0.05$ ) and TSM ( $p = 0.03$ ).  $T_{re}$  was greater ( $p < 0.05$ ) in the SDEP vs. the CON condition during min 0, 5, 15 then not different thereafter during Stage 2 of ACE. TS and TSM were greater (individuals sensed and scaled that they were colder) in the SDEP vs. the CON condition at 75 and 90 min for TS and 45 and 75 min for TSM (then not different thereafter) during Stage 2 of ACE.

**CONCLUSION:** From these data it appears that SDEP alters the perception of one's environment as participants, when sleep deprived, exhibited a greater  $T_{re}$  but sensed and scaled that they were colder.

**Effects Of Sleep Deprivation On The Thermoregulatory Responses During Recovery From Acute Cold Exposure**

Tiffany A. Collinsworth<sup>1</sup>, Katherine E. Pierce<sup>2</sup>, Judith A. Juvancic-Heltzel<sup>3</sup>, Jacob E. Barkley<sup>3</sup>, Gary H. Kamimori, FACSM<sup>4</sup>, Ellen L. Glickman, FACSM<sup>3</sup>. <sup>1</sup>Kennesaw State University, Kennesaw, GA. <sup>2</sup>Mount Union College, Alliance, OH. <sup>3</sup>Kent State University, Kent, OH. <sup>4</sup>Walter Reed Army Institute of Research, Silver Springs, MD.

(No relationships reported)

While the physiological responses to acute cold exposure (ACE) have been examined, little research has been conducted examining the recovery (ACE-REC) aspect of ACE specifically during the presence of additional physiological stressors such as sleep deprivation (SDEP). Therefore, further examination of ACE-REC during SDEP warrants investigation to examine the afterdrop associated with cold exposure as this is the critical period when core temperature typically decreases and hypothermia may ensue.

**PURPOSE:** To examine the effects of 53 hours of SDEP on the thermoregulatory responses of males during recovery (ACE-REC) from three consecutive bouts of acute cold exposure (ACE).

**METHODS:** Eight healthy, Caucasian males (22.8 ± 1.7 y) completed a control (CON) trial during a normal night's sleep and an experimental trial during 53 hours of SDEP in which they were exposed to cold air (10°C) for 120-min, once per day beginning at 6:00am, for 3 consecutive days (ACE REC stage 1, 2, 3) followed by 120-min of ACE-REC beginning at 8:00am in 25°C. During ACE-REC, rectal temperature ( $T_{re}$ ) and mean skin temperature ( $T_{sk}$ ) were examined at baseline (BASE), 5-min, 15-min and every 15-min thereafter for the duration of the ACE-REC. Aerobic metabolic rate ( $\dot{V}O_2$ ) was measured at BASE, 15-min, 25-min and every 30-min thereafter for the duration of the ACE-REC.

**RESULTS:** Condition by time repeated measures ANOVAs demonstrated a main effect for time ( $p \leq 0.001$ ) for  $T_{re}$  for all stages of ACE-REC whereby  $T_{re}$  decreased across time. ACE-REC Stage 3 demonstrated a condition by time interaction ( $p \leq 0.001$ ) whereby  $T_{re}$  was greater for SDEP relative to CON. Condition by time ANOVAs for all three ACE-REC stages also demonstrated a main effect for time ( $p \leq 0.001$ ) for  $T_{sk}$  and  $\dot{V}O_2$ . as  $T_{sk}$  and  $\dot{V}O_2$  decreased across time.

**CONCLUSION:** Based on these data, during ACE-REC,  $T_{re}$  was increased during SDEP conditions as compared to CON conditions after 53-hours of sleep deprivation. Alterations of the sleep-wake cycle through SDEP may have altered core temperature.

(No relationships reported)

It is well documented that circadian desynchronization caused by long haul travel can have a negative effect on athletic performance. However, the majority of available research using elite athletes has simply focused on subjective parameters of sleep.

**PURPOSE:** To quantify the effect of circadian desynchronization on objective parameters of sleep following long haul travel crossing 8 time zones.

**METHODS:** 6 male (mean age 23.3 ± 5.8 yrs) and 9 female (mean age 22.1 ± 3.8 yrs) GB Olympic Squad divers were monitored using wristwatch actigraphy over 16 nights which included 10 nights in their home environment in Great Britain (baseline) and 6 nights post travel from Great Britain to China (nights 1-6). Key measures included: time in bed (TIB), actual sleep time (AST), sleep latency (SL), mean wake bout time (MWBT) and sleep efficiency (SE).

**RESULTS:** The largest disruption in sleep parameters occurred on nights 1 and 4. Athletes had more TIB (09:54 ± 01:09 vs. 08:42 ± 00:35 hrs,  $p < 0.05$ ) and experienced higher AST (08:12 ± 01:07 vs. 06:59 ± 00:34 hrs,  $p < 0.01$ ) on night 1 post travel compared to baseline. During nights 2 and 3, parameters of sleep closely resembled baseline. During night 4 post travel, athletes experienced lower AST (05:56 ± 01:20 vs. 06:59 ± 00:34 hrs,  $p < 0.05$ ) and higher MWBT (02:58 ± 02:16 vs. 02:07 ± 00:24 mins,  $p < 0.05$ ) compared to baseline. SL was longer on night 4 than night 1 (00:33 ± 00:51 vs. 00:20 ± 00:15 hrs,  $p < 0.05$ ). SL and MWBT were negatively correlated with SE ( $r = -0.57$ ,  $p < 0.01$  and  $r = -0.62$ ,  $p < 0.01$ , respectively).

**CONCLUSION:** The apparent reduction in parameters of sleep on night 4 are likely due to a combination of 1) delayed effect of extra sleep acquired relative to baseline on night 1, and 2) negative effect of circadian desynchronization, in particular on SL and MWBT. Objectively monitoring the effects of circadian desynchronization by wristwatch actigraphy proved an indispensable tool for planning future travel strategies in this group of athletes.

Email: i.lahart@ucb.ac.uk  
(No relationships reported)

The Race Across America (RAAM) is a continuous cycle race in which having adequate sleep and recovery represents an important aspect of performance.

**PURPOSE:** To investigate sleep quantity and quality among riders in a 4-man team participating in the RAAM.

**METHODS:** Riders followed a daily work-rest strategy consisting of two episodes of 3 hours riding and 3 hours recovery, and one episode of 6 hours riding and 6 hours recovery. The sleep pattern measurements of 3 endurance-trained cyclists were obtained from an actigraph activity monitor secured to the right ankle of each cyclist. The monitors recorded activity counts per minute for 3 days pre-race and throughout the 3,014 mile race duration. Derived measures include sleep duration, wake time after sleep onset, and sleep efficiency ((sleep duration – wake time)/sleep duration) × 100).

**RESULTS:** Baseline measures showed the participants to be highly efficient sleepers (sleep efficiency mean + SD: 83.8 + 3.4 %). Cyclists mean sleep efficiency decreased to 17.9 + 10.6 % during the RAAM. The mean sleep duration per episode of sleep of cyclist 1, 2, and 3 was 51 + 46.3, 40.6 + 43, and 51.6 + 36.3, respectively. After the onset of sleep, the three cyclists mean wake time per sleep episode was 54.7 + 57.3, 47.7 + 62.5, and 47.9 + 57.6, respectively. The cyclists mean sleep efficiency per episode of sleep was 18.4 + 15.3, 14.4 + 12.8, and 20.7 + 12.6, respectively. Although the amount of sleep recorded declined significantly as the event progressed, there was considerable intra-individual variation. In the first six sleep attempts cyclists 1, 2 and 3 slept for total durations of 385, 347, and 352 min, respectively. However, in the last 6 sleep attempts one cyclist recorded just 9 min sleep in contrast to 129 and 173 min for the other two cyclists, a finding that is illustrative of large intra-individual variation.

**CONCLUSIONS:** Riding in the RAAM was associated with significant disruption to measures of sleep quantity and quality. Although the sleep patterns exhibited were related to a successful 3<sup>rd</sup> place finish, improved sleep may have resulted in enhanced performance. Due to the wide variation between the cyclists in the amount of sleep disruption experienced, interventions to improve sleep quantity and quality during multi-day ultra-endurance events such as the RAAM should be individually based.

**1575 Board #177 May 27 9:30 AM - 11:00 AM**  
**Effect Of Sleep Deprivation On Running Time To Exhaustion In Untrained Males**

Christine A. Craig, Tracey D. Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*  
(No relationships reported)

Sleep deprivation (SD) has consistently been shown to negatively impact thought processes and mood. Elite and amateur athletes, as well as military personnel, regularly experience SD, yet the impact on exercise performance has yet to be fully elucidated.

**PURPOSE:** To compare the running time to exhaustion (RTE) of untrained males under normal sleep (NS) and SD conditions. Rate of perceived exertion (RPE), heart rate (HR), oxygen consumption (VO<sub>2</sub>), respiratory exchange ratio (RER), and lactate (LCT) were also considered.

**METHODS:** Two endurance runs to volitional exhaustion at 75% VO<sub>2peak</sub>, one after NS and one after SD (22.3 ± 0.68 hr), were completed by 6 untrained males (29 ± 6.5 yrs, 35 ± 3.7 ml/kg/min) following an 8 hr fast. VO<sub>2</sub>, VCO<sub>2</sub>, and RER were measured by a PhysioDyne Max II Metabolic Cart, HR was measured by a Polar HR Monitor, LCT was analyzed with an AccuTrend lactate analyzer, RPE was self reported from the Borg Scale, and RTE was recorded with a Timex Stopwatch. Repeated measures t-tests were computed for RTE, VO<sub>2</sub>, and RPE. Repeated measures ANOVAs were computed to compared differences in RER, LCT, and HR.

**RESULTS:** No significant interactions (p > 0.05) existed between sleep and time for RER, LCT, and HR. No significant differences (p > 0.05) existed for RTE, VO<sub>2</sub>, and RPE. A significant main effect (p < 0.05) for time existed for LCT and HR. Mean LCT (mmol/l) increased during NS and SD exercise (1.87 ± 0.06 at baseline, 4.44 ± 0.60 at the completion of exercise, and 2.85 ± 0.36 at 10 min post exercise, p < 0.05). Mean HR (bpm) increased during NS and SD exercise (63.25 ± 2.48 at baseline, 175 ± 6.43 at the completion of exercise, and 96.00 ± 4.35 at 10 min post exercise, p < 0.05). A significant main effect (p < 0.05) for condition existed for HR. HR during the NS trial was significantly higher than mean HR during the SD trial (112.8 ± 3.36 v. 109.9 ± 2.87, p < 0.05).

**CONCLUSION:** Sleep deprivation appears to impact HR, and SD may influence exercise performance.

Soller<sup>1</sup>. <sup>1</sup>University of Massachusetts Medical School, Worcester, MA. <sup>2</sup>Wyle Integrated Science and Engineering, Houston, TX. <sup>3</sup>NASA Johnson Space Center, Houston, TX.  
Email: gwenn.ellerby@umassmed.edu  
(No relationships reported)

Lunar and planetary exploration space suit design can be enhanced by considering the physiologic responses of individual muscles during locomotion in reduced gravity. Near-infrared spectroscopy (NIRS) provides a non-invasive method to study metabolic responses of individual muscles in ambulatory subjects during reduced gravity simulations.

**PURPOSE:** To investigate calf muscle oxygen saturation (SmO<sub>2</sub>) and pH during reduced gravity walking at varying treadmill inclines and added mass conditions using NIRS.

**METHODS:** Four male subjects aged 42.3 ± 1.7 years (mean ± SE) and weighing 77.9 ± 2.4 kg walked at a moderate speed (3.2 ± 0.2 km•h<sup>-1</sup>) on a treadmill at inclines of 0, 10, 20, and 30%. Unsuit subjects were attached to a partial gravity simulator which unloaded the subject to simulate body weight plus the additional weight of a space suit (121 kg) in lunar gravity (0.17G). Masses of 0, 11, 23, and 34 kg were added to the subject and then unloaded to maintain constant weight. Spectra were collected from the lateral gastrocnemius (LG), and SmO<sub>2</sub> and pH were calculated using previously published methods (Yang et al. 2007 Optics Express ; Soller et al. 2008 J Appl Physiol). The effects of incline and added mass on SmO<sub>2</sub> and pH were analyzed through repeated measures ANOVA.

**RESULTS:** SmO<sub>2</sub> and pH were both unchanged by added mass (p > 0.05), so data from trials at the same incline were averaged. LG SmO<sub>2</sub> decreased significantly with increasing incline (p = 0.003) from 61.1 ± 2.0% at 0% incline to 48.7 ± 2.6% at 30% incline, while pH was unchanged by incline (p = 0.12).

**CONCLUSIONS:** Increasing the incline (and thus work performed) during walking causes the LG to extract more oxygen from the blood supply, presumably to support the increased metabolic cost of uphill walking. The lack of an effect of incline on pH may indicate that, while the intensity of exercise has increased, the LG has not reached a level of work above the anaerobic threshold. In these preliminary studies, 30% incline walking at reduced gravity may not require anaerobic LG activity due to the low exercise intensity (42.8 ± 1.6% of VO<sub>2max</sub>). It is also possible that at reduced gravity additional work required for increased inclines may be performed by other muscles.

Supported by the National Space Biomedical Research Institute through NASA NCC 9-58

**Low Load Resistance Training With Blood Flow Restriction As A Countermeasure To Disuse Atrophy**

Lori Ploutz-Snyder, FACSM. *Universities Space Research Association, NASA Lyndon B Johnson Space Center, Houston, TX.*  
Email: lori.ploutz-snyder-1@nasa.gov  
(No relationships reported)

Decreases in strength and neuromuscular function are observed following prolonged disuse. Exercise countermeasures to prevent muscle dysfunction during disuse typically involve high intensity resistance training.

**PURPOSE:** To evaluate the effectiveness of low-load resistance training with a blood flow restriction to mitigate muscle loss and dysfunction during 30 days of unilateral lower limb suspension (ULLS).

**METHODS:** Sixteen subjects (9M, 7F; 18-49 yr) underwent 30 days of ULLS. Measurements of voluntary and evoked forces and muscle cross-sectional area (CSA) of the knee extensors were collected before and after ULLS. During ULLS, 8 subjects (5M, 3F) participated in a low-load (20% of an isometric maximum voluntary contraction (MVC)) resistance training program with a blood flow restriction (1.3 times systolic blood pressure) on the knee extensors three times per week.

**RESULTS:** After 30 days of ULLS, the subjects who performed the blood flow restricted resistance training experienced a 1.3% loss of quadriceps femoris CSA and a 1.5% decrease in one repetition maximum (1-RM) strength while the subjects who did not exercise lost 8% CSA and 21% strength. The loss of CSA and 1-RM strength was significantly different between the groups ( $p=0.04$  and  $p=0.02$ , respectively). The number of repetitions completed during a dynamic knee extension muscular endurance task at a workload of 40% MVC improved 31% in the subjects who performed blood flow restricted exercise, but decreased 24% in those who did not exercise ( $p=0.01$ ). No changes during ULLS, or between the groups were found for twitch and doublet force, central activation, rates of force development and rates of relaxation ( $p>0.05$ ).

**CONCLUSIONS:** Low-load blood flow restricted resistance training of the knee extensors can maintain muscle strength and size during 30 days of ULLS and results in improved muscular endurance.

**1578 Board #180 May 27 9:30 AM - 11:00 AM**  
**Baroreflex Sensitivity Decreases During 90-day Bed Rest**

Michael B. Stenger<sup>1</sup>, Natalia M. Arzeno<sup>1</sup>, Steven H. Platts<sup>2</sup>. <sup>1</sup>Wyle Integrated Science and Engineering Group, Houston, TX. <sup>2</sup>NASA Johnson Space Center, Houston, TX.  
Email: michael.b.stenger@nasa.gov  
(No relationships reported)

**PURPOSE:** Baroreflex sensitivity (BRS) decreases during spaceflight and simulated spaceflight (head down bed rest [BR]). However, previous studies have only examined BRS in response to a limited blood pressure (BP) range or to a single sudden change in BP. The purpose of this study was to examine BRS during 90 days of 6° head-down tilt BR over a broad range of BP perturbations.

**METHODS:** Nineteen normal volunteers (12M, 7F) were tested one day before BR, and then near BR days 30, 60 and 90. BP was pharmacologically altered by continuous infusions of phenylephrine (PE) and sodium nitroprusside (SNP). Electrocardiogram and continuous BP were collected during 10 min of normal saline (NS), followed by increasing concentrations of PE (10 min each of 0.4, 0.8 and 1.6 µg/kg/min). After a 20 min break, NS was infused again for 10 min, followed by increasing concentrations of SNP (10 min each of 0.4, 0.8, 1.2 µg/kg/min). Baroreceptor sensitivity was measured as the slope of a sequence of 3 or more beats in which the systolic BP and following R-R interval (RR) both increased or decreased. Spectral heart rate variability (HRV) and mean RR were analyzed using data from only the NS infusions. Two-way repeated-measures analysis of variance was performed to examine the effects of BR and gender.

**RESULTS:** RR decreased ( $p<0.001$ ) from pre-BR across BR days. High frequency in normalized units, a measure of parasympathetic activity, decreased with BR ( $p=0.027$ ) and was lower ( $p=0.046$ ) in men ( $0.39\pm0.02$ , mean  $\pm$ SEM) than women ( $0.48\pm0.02$ ). The spontaneous baroreflex slope, our measure of BRS, increased with PE and decreased with SNP across BR ( $p<0.001$ ). The percentage decrease in BRS from pre- to post-BR appeared to be larger in women ( $43.6\pm7.0\%$ ) than in men ( $31.3\pm3.9\%$ ,  $p=0.06$ ).

**CONCLUSIONS:** Parasympathetic activity and baroreflex sensitivity decrease during 90 days of BR, and BRS tends to diminish more in women than in men.

**Graded Compression Stockings Prevent Post-spaceflight Orthostatic Hypotension**

Steven H. Platts<sup>1</sup>, Angela K. Brown<sup>2</sup>, James P. Locke<sup>1</sup>, Michael B. Stenger<sup>3</sup>. <sup>1</sup>NASA Johnson Space Center, Houston, TX. <sup>2</sup>MEI Technologies, Houston, TX. <sup>3</sup>Wyle Integrated Science and Engineering Group, Houston, TX.  
Email: steven.platts-1@nasa.gov  
(No relationships reported)

**PURPOSE:** Post-spaceflight orthostatic intolerance is observed in 20-30% of astronauts. Previous data from our laboratory suggests that this is largely a result of decreased venous return. Currently, NASA astronauts wear an anti-gravity suit (AGS) which consists of inflatable air bladders over the calves, thighs and abdomen, which are typically pressurized from 0.5 to 1.5 PSI (~27 to 78 mmHg). ISS crew members sometimes wear Russian Kentavrs which consist of laced compression shorts and gaiters, providing ~30 mmHg nominally. While these garments are effective during reentry, there are a number of drawbacks that make them impractical for postflight use. We studied the ability of commercially available, custom fit, graded compression stockings (Jobst, 55 mmHg at ankle to 6 mmHg at top of thigh, 25 mmHg mean compression) to prevent postflight orthostatic intolerance, hypothesizing that these garments would prevent orthostatic intolerance following short duration space flight.

**METHODS:** Five crew members from a single Space Shuttle flight were tilted to 80° for 10 min while wearing the stockings upon arrival at the clinic (~2 hrs after landing). Hemodynamic data were compared to data from all crewmembers tested (without countermeasures) since return to flight ( $n=9$ ).

**RESULTS:** Two-way, repeated measures ANOVA, using the entire tilt time curve (0-10 min) show that systolic blood pressure (SBP,  $p=0.008$ ), stroke volume (SV,  $p=0.003$ ), and cardiac output (CO,  $p=0.004$ ) were higher in crewmembers who wore the Jobst stockings. A one-way ANOVA comparing the last minute standing also showed that SV ( $p=0.001$ ) and CO ( $p<0.001$ ) were higher and SBP tended to be higher ( $p=0.06$ ) in Jobst subjects compared to controls. Control subjects had a higher rate of presyncope than Jobst subjects (3/9 vs 0/5) during the tilt on landing day.

**CONCLUSIONS:** Orthostatic hypotension continues to present following spaceflight, despite fluid loading and other countermeasures. This preliminary study shows that compression stockings may ameliorate this problem. These stockings are readily available, inexpensive, and can be worn for days following landing. We have observed similar protection against orthostatic intolerance in ground-based studies of hypovolemic test subjects. Further refinements to the design of these stockings are in progress.

**Effect Of Ankle Bracing On Vertical Jump: Performance And Muscle Activation Patterns In Lower Limb.**

Eric Snyder, Julie Duling, Casey Luttfing, Lucinda Bouillon. *University of Findlay, Findlay, OH.*  
(No relationships reported)

A powerful vertical jump is an important aspect of being a successful volleyball player. Often times, athletes may use ankle bracing to reduce injuries. Currently, it is unclear whether bracing may alter muscle activation patterns in the lower limb secondary to increased stabilization.

**PURPOSE:** To determine if ankle bracing has an effect on muscle activation patterns and performance during vertical jump (VJ) in braced (B) and unbraced (NB) conditions.

**METHODS:** Eight healthy volleyball collegiate females (18.7 + 1.03yr; 172.9+ 6.52cm; 76.0+ 20.99kg) were recruited. Bi-polar surface electromyography (SEMG), sampling at 1000Hz, was utilized to record muscle activity of 8 muscles on the dominant limb, the rectus femoris (RF), vastus medialis oblique (VMO), biceps femoris (BF), gluteus maximus (GMax), gluteus medius (GMed), tibialis anterior (TA), peroneus longus (PL), and lateral gastrocnemius (LG), during the VJ after random assignment to either B or NB conditions. Muscle activity was analyzed for 3 seconds, and SEMG amplitude values (root mean square) were rectified and normalized to each respective maximal voluntary isometric muscle contraction (MVC). The rectified and normalized SEMG amplitude values were then averaged for all subjects across the three trials of the VJ and expressed as %MVC. The Vertec was used to measure VJ height starting with both feet planted on the ground and then jumping to reach the highest point on the Vertec. Three trials were performed and the mean value of VJ and SEMG for each muscle were recorded for each subject and compared between conditions (B and NB) using paired t-tests ( $\alpha=0.05$ ).

**RESULTS:** The intrareliability ICCs ranged from 0.90-0.99, with the CVs ranging .58% to 2.1%. Paired t-tests found that jump height for B group (258.8+ 9.32 cm) and NB group (259.6+ 8.16 cm) were not significantly different. Differences in muscle activity with the LG demonstrated higher mean activity when braced, (B: 73.5+ 22.23%; NB:66.2+ 25.74%,  $p=0.05$ ) and the PL exhibited lower mean activity when braced, (B: 53.1+ 29.57%; NB: 67.22+ 21.49%,  $p<0.05$ ).

**CONCLUSION:** Ankle bracing does not have an effect on an individual's performance with vertical jump, but there is greater activation of the lateral gastrocnemius and decreased activity of the peroneus longus with the ankle brace during a vertical jump.

**1581 Board #183 May 27 9:30 AM - 11:00 AM**  
**Test-retest Reliability And Validity Of Ultrasonic 3d-motion Analysis System**

Ting-Chia Chang<sup>1</sup>, Chi-Huang Huang<sup>1</sup>, Heng-Ju Lee<sup>2</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan County, Taiwan. <sup>2</sup>National Taiwan Normal University, Taipei, Taiwan.  
(No relationships reported)

There are many motion capture systems which can measure three-dimensional human motion. However, most of motion capture system required large space and not cost friendly. Zebris 3D-motion analysis system adopted ultrasound as the measurement tool instead of using video resource. The strength of ultrasonic 3D-motion analysis is easy to maneuver, less space requirement and cost friendly. So far, there were few studies using ultrasonic 3D-motion analysis system as the research tool since the system was relative new on the market. Therefore, the reliability and validity of ultrasound motion analysis system has not been really examined.

**PURPOSE:** To exam reliability and validity of ultrasonic 3D-motion analysis system when compared to Biodex system.

**METHODS:** The Zebris ultrasonic 3D-motion analysis system CMS-HS v10 (Medical GmbH, Tübingen, Germany) was used to measure validity of rigid body angular motions when compared to Biodex system (Biodex medical system, Shirley, NY). Two sets of ultrasound cluster (each has three markers) were separately placed on the Biodex rotational axis and its attachment arm. The calibration of Biodex was defined when Biodex attachment arm placed parallel to the floor and set it as 0°. Positive angle direction was defined when the attachment arm went upward. Ultrasonic 3D kinematic data were measured every 10° of Biodex attachment arm motion from -70° and end at 110° at 50 Hz sampling rate. Repeated experiments were performed again next week to exam intra-session test-retest reliability of ultrasonic 3D-motion analysis system.

**RESULTS:** The validity test between ultrasonic 3D-motion analysis system and Biodex system showed strong correlation ( $r=1.0$ ). The test-retest reliability coefficient of ultrasonic 3D-motion analysis system in flexion-extension direction was approached to 1(0.998-1); in valgus-vargus direction was about 0.855(0.529-0.93); in rotational direction was 0.997(0.983-0.997).

**CONCLUSIONS:** Ultrasonic 3D-motion analysis system demonstrated high validity when compared to Biodex system. It also demonstrated good consistency and repeatability in test-retest reliability examinations. The findings presented in this study suggest that ultrasonic 3D-motion analysis system is a trustable and equally efficient tool to measure 3D kinematics data.

**Knee Wraps Change The Angle Of Peak Torque During Leg Extension Among Collegiate Powerlifters**

Glen E. Fincher II, Joshua Rohr. *Ashland University, Ashland, OH.*  
Email: gfincher@ashland.edu  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effect of knee wraps on the angle of peak torque during continuous passive movement isokinetic leg extension in collegiate powerlifters.

**METHODS:** Nine (6 male, 3 female) healthy, competitive collegiate powerlifters, ranging in age from 19-23, were utilized in this study. A CSMI Humac Norm isokinetic extremity testing system was used to evaluate the angle of peak torque during continuous passive movement isokinetic leg extension with knees (a) unwrapped and (b) wrapped. Paired samples t-tests were used to determine if there were statistically significant differences in the angle of peak torque during the two testing conditions. Alpha levels were set a priori at 0.05 to determine statistical significance.

**RESULTS:** (reported by mean change + SD): The change in the angle of peak torque during continuous passive movement isokinetic leg extension (67.00 + 40.46 degrees) was significant ( $p<0.001$ ).

**CONCLUSIONS:** The data from this study indicate that the use of knee wraps significantly changes the angle of peak torque during continuous passive movement isokinetic leg extension in collegiate powerlifters.

**Validity Of New Chronopic V.3 Open Hardware To Measure Time On Jump Related Tests**

Xavier de Blas<sup>1</sup>, Juan González-Gómez<sup>2</sup>, Ricardo Gómez<sup>3</sup>. <sup>1</sup>FPCEE Blanquerna. Universitat Ramon Llull, Barcelona, Spain. <sup>2</sup>Escuela Politécnica Superior. Universidad Autónoma de Madrid, Madrid, Spain. <sup>3</sup>Ilfara tecnologías, Madrid, Spain.  
Email: xaviblas@gmail.com  
(No relationships reported)

Chronojump project involves the creation of an electronic short time tracking device focused on measuring the time of jumps. Chronojump uses a measurement PIC device called Chronopic. Early versions of Chronopic were adapted from a microcontroller used in robotics area. The new Chronopic v.3 has been developed from scratch, with only

the components needed for sports time evaluation (eg. Bosco tests). It's licensed as open hardware in order to be accessible, to allow derivative development and to be fully peer-reviewable.

**PURPOSE:** validate Chronopic v.3 for jump time tests.

**METHODS:** Square waves generators Hameg HM 8035 and HM 8030-4 (for lower frequencies unavailable on 8035) create waves with 50% of duty cycle which are detected by an Agilent 54621A Oscilloscope. Agilent and Chronopic v.3 recorded waves from 9 to 1.5 Hz at intervals of 0.5 Hz and the data was compared.

**RESULTS:** On full studied spectrum; at low signal (corresponding to TC -Contact Time on a jump) AVG error is 0.04% and 0.18 SD, while at high signal (TF -Flight Time) AVG error is 0.05% and 0.19 SD. Sampling normal jump data (200-700 ms): at low signal AVG error is 0.04% and 0.16 SD, while at high signal AVG error is 0.13% and 0.21 SD. These results were satisfactory. On the other hand, the intentional limitation of Chronopic v.3 on filtering signals corresponding to a TC or TF lower than 50 ms in order to prevent electronic rebounds doesn't work in all situations: two ranges of instability were found: 9.390-9.950 Hz (53.248-50.251 ms of TC or TF) and 20-20.200 Hz (25-24.752 ms of TC or TF). This filtering problem is not significant in jump tests because the instability occurs at intervals below the lowest contact times of a drop jump: 150 ms approx. Also the conflictive full range time is shorter than 4 ms.

**CONCLUSIONS:** Chronopic v.3 measurements are optimal for jump tests time tracking. Two little signal ranges can produce rebound problems at really low times. This withdrawal is far related to the Chronopic v.3 intended range of frequencies (jump time tests) but it will be studied further and fixed in firmware if necessary.

**Effects Of Football Equipment On Average Momentum: Implications For High School Players.**

Matt Lopez, Brian Campbell, Andrew Hatchett, Torie Guidry, Bradley Burkhalter, Shawn Hodge. *University of Louisiana at Lafayette, Lafayette, LA.*  
Email: mjl6322@louisiana.edu

(No relationships reported)

The concept of momentum is continuously demonstrated through collisions on the football field. A player's momentum is an essential component of routine responsibilities, such as tackling or blocking an opposing player during a game. Momentum is related to a player's mass and velocity. A traditional measure of assessing a player's velocity is done through administering the 40-yd dash without protective equipment. Previous research has shown the addition of protective equipment will cause an increase in a player's mass and a decrease in the player's velocity; however, this variable trade-off's effect on momentum has yet to be determined.

**PURPOSE:** : To determine effects of football equipment on players' average momentum in the 40-yd dash.

**METHODS:** Sixty-six high school football players (weight  $78.28 \pm 15.45$  kg) were timed in the 40-yd dash, wearing either standard football equipment (EP) or nylon shorts and a T-shirt (NEP), on a natural grass field. An automatic timing system with high speed video camera (30 frames/sec), starter pistol, receiver, and timing software was utilized to collect 40-yd dash times. Participants performed two trials under each condition and the faster of the two trials for each condition were used for analysis. A calibrated balance scale was used to record participant weight, both with and without pads. A dependent samples T-test was utilized to assess significance between momentum with and without equipment at an alpha level of 0.05.

**RESULTS:** A significant difference was found between NEP ( $499.51 \pm 79.97$  kg-m/s) and EP ( $512.43 \pm 77.81$  kg-m/s) conditions ( $p < 0.05$ ).

**CONCLUSIONS:** Momentum of high school football players increased significantly with the addition of standard football equipment. Though there is a decrease in velocity with the added weight of equipment, the product of the reduced velocity and the increased weight is greater than the product of the increased velocity and reduced weight. . Examining differences in momentum (with and without equipment) can aid in the identification of players that fall below the norm. The players that carry extra weight inefficiently may require specific training to accommodate the increase in mass caused by protective equipment.

---

**1585 Board #187 May 27 9:30 AM - 11:00 AM**  
**Physical And Mechanical Properties Of Commercialized Mouthguard Materials Across A Range Of Temperatures**

Trenton E. Gould, Scott G. Piland, Charles E. Hoyle, Sergei Nazarenko. *The University of Southern Mississippi, Hattiesburg, MS.* (Sponsor: Michael J. Webster, FACSM)

Email: Trent.Gould@usm.edu

(No relationships reported)

Mouthguards (MG) should be tested and function well at their theoretical end-use intra-oral temperature (approx 37°C). However, the influences of breathing and ambient environment make it unlikely that MGs could maintain this constant temperature. Therefore, a MG materials need to perform consistently over a wide range of possible temperatures (-20 to 40°C).

**PURPOSE:** To characterize commercialized MG materials' properties and investigate the effect of temperature on these properties.

**METHODS:** Five commercial thermoplastic MG materials (ER, EF, PR, PL, PS) were tested. The durometer hardness, water absorption, tear strength, and impact attenuation of the MG materials were measured according to ASTM D2240-05, D570-98 (2005), D624-00, and ASTM D6110-06f (modified) guidelines. Tests were conducted on 5 separate specimens at both room 23  $\pm$  2°C and intra-oral 37  $\pm$  2°C temperatures. Data was entered into the Statistical Package for Social Sciences (SPSS v. 15.0, SPSS Inc., Chicago, Ill.). Independent t-tests (Type I error = 0.05) were implemented to test for differences between room and intra-oral temperatures.

**RESULTS:** Material hardness between room and intra-oral temperatures was significantly different for the ER ( $t(8) = 20.87, p < .05$ ), EF ( $t(8) = 19.61, p < .05$ ), PR ( $t(8) = 15.18, p < .05$ ), PL ( $t(8) = 16.44, p < .05$ ), and PS ( $t(8) = 17.71, p < .05$ ) materials. Water absorption between room and intra-oral temperatures was significantly different for the ER ( $t(4) = -7.23, p < .05$ ), EF ( $t(4) = -25.325, p < .05$ ), PR ( $t(4) = -3.11, p < .05$ ), PL ( $t(4) = -5.95, p < .05$ ), and PS ( $t(4) = -88.22, p < .05$ ) materials. Tear strength between room and intra-oral temperatures was significantly different for the ER ( $t(6) = 14.14, p < .05$ ), EF ( $t(6) = 18.91, p < .05$ ), PR ( $t(6) = 5.34, p < .05$ ), PL ( $t(6) = 6.15, p < .05$ ), and PS ( $t(6) = 14.26, p < .05$ ) materials. Impact attenuation between room and intra-oral temperatures was significantly different for the EF ( $t(4) = 7.92, p < .05$ ), PL ( $t(4) = 3.62, p < .05$ ), and PS ( $t(4) = -11.15, p < .05$ ). However, there was no difference between temperatures for the ER ( $p = .058$ ) or PR ( $p = .275$ ) materials.

**CONCLUSIONS:** Temperature negatively affects the physical and mechanical properties of MG materials. It is particularly noteworthy that none of the commercialized products met current ANSI and SAI standards for impact attenuation.

---

**1586 Board #188 May 27 9:30 AM - 11:00 AM**  
**An Electromyographic Investigation Of The Biceps Brachii Using Adjustable Variable Resistance**

Daniel G. Drury, FACSM, Glenn Cain, Joe Kember, Kristy Rubino, Kristin Stuempfle, FACSM. *Gettysburg College, Gettysburg, PA.*

Email: ddrury@gettysburg.edu

( D.G. Drury, STRIVE Enterprises, Inc, Consulting Fee.)

Although variable resistance has been used extensively in the production of strength training equipment for many years, the physiological and biomechanical data analyzing this type of training remains scant. Furthermore, very few investigations have quantified how the use of different cams can alter muscle fiber recruitment.

**PURPOSE:** To investigate differences in the electromyographic (EMG) muscle fiber recruitment of the Biceps Brachii (BB) at various joint angles during the Concentric (Con) and Eccentric (Ecc) phases of exercise on an Adjustable Variable Resistance (AVR) machine.

**METHODS:** Eighteen healthy college aged ( $20.61 \pm 1.42$ ) males performed 2 sets of BB flexion and extension exercise using divergent cam settings (A & B) of a STRIVE AVR machine. EMG and Electrogoniometer (EG) measurements were taken simultaneously to determine the electrical activity of the BB at joint angles corresponding to 40°,

85° and 120° during both the Con and Ecc phases of the movement. The pace of the exercise was controlled using a metronome and the resistance was a weight corresponding to 50% of a predetermined 6 repetition maximum. The Root Mean Square (RMS) EMG scores were rectified and normalized by dividing each score into a maximal isometric reference contraction performed prior to testing. The order in which the cam positions were introduced was randomized and sets were separated by 3:00 minutes of rest. EMG scores were analyzed using a standard T-test with an a-priori value of significance set at  $p < 0.05$ .

**RESULTS:** RMS EMG scores are reported below for cam positions A & B.

Cam	40° Con	85° Con	120° Con	40° Ecc	85° Ecc	120° Ecc
A	32.63±12.10	40.67±14.01	62.33±23.16	18.70±9.88	18.77±8.95	24.15±13.20
B	26.86±11.17	37.36±10.32	63.54±22.18	13.73±7.34	17.58±8.83	25.22±11.07
P-value	0.0005**	0.2131	0.6164	0.0002**	0.3146	0.6875

**CONCLUSIONS:** Based upon the limitations of this study, we conclude that muscle activation can indeed be altered within a given range of motion by altering the orientation of the Cam.

**1587 Board #189 May 27 9:30 AM - 11:00 AM**  
**Makiwara Punching Board Performance Evaluation**

Paul K. Smith<sup>1</sup>, Timothy Nüller<sup>2</sup>, Peter W. McCullough<sup>1</sup>. <sup>1</sup>West Chester University of PA, West Chester, PA. <sup>2</sup>Penn State Brandywine, Media, PA.  
 (Sponsor: W. Craig Stevens, FACSM)  
 Email: psmith@wcupa.edu  
 (No relationships reported)

**PURPOSE:** Makiwara, punching board, training is an integral part of the development of proper karate punching technique. Karate practitioners use a board design and wood type based on their skill level and physical characteristics. This study compared the force-deflection, or stiffness of two makiwara board designs (tapered and stacked) made with four species of wood commonly used for punching boards (oak, cherry, ash, and fir).

**METHODS:** Five replications each of Northern White Ash, Pennsylvania Cherry, Red Oak, and Douglas Fir makiwara boards of the tapered board and stacked board designs were constructed for testing in a base/loading mechanism specifically designed for this purpose (N = 20). Boards were tested by static loading each with weights and recording deflection values at 111.2 N (25 lbs) increments of weight ranging from 111.2 N to 1000.8 N (25-225 lbs) in counterbalanced order. Force-deflection data were plotted for each board specie and design. ANOVA (2 x 4) with repeated measures as used to determine if differences exist among the designs and species.

**RESULTS:** Mean deflections were significantly different for all conditions ( $p < 0.05$ ) of board type and load for stacked and tapered makiwara board types. Tapered boards showed less flexure upon loading than did stacked boards ( $p < 0.05$ ). For both tapered and stacked board types, oak had the least average deflection followed by fir, cherry, and ash ( $p < 0.05$ ). Load/deflection curves show approximate linearity of all board types over all wood species. Stiffnesses calculated from the best fit load/deflection lines show the same trends as with average deflections with oak being the stiffest wood and ash being the most compliant. Stacked boards were more prone to breakage. Specifically, four of the stacked fir boards broke (80%), all five of the stacked ash boards broke (100%), and two of the stacked cherry boards broke (40%). None of the oak boards broke.

**CONCLUSION:** The results of this study suggest compliance with recommendations of progressive overload in sports training. The lower stiffness (by a factor of two) of stacked boards implies a greater suitability for novice practitioner as these will offer less resistance to the punch. For truly progressive training one could start with the most compliant wood type (ash) and move up towards the stiffest (oak).

**1588 Board #190 May 27 9:30 AM - 11:00 AM**  
**Comparison Of Forefoot And Heel Pressures Across Fast Walking And Four Elliptical Trainer Conditions**

Adam P. Taylor, Thad W. Buster, Bethany R. Barber, Judith M. Burnfield. *Madonna Rehabilitation Hospital, Lincoln, NE.*  
 Email: ataylor@madonna.org  
 (No relationships reported)

Elliptical training is growing in popularity in many medically-based fitness facilities and rehabilitation centers as a method of building cardiovascular fitness. However, some exercisers with underlying medical conditions may be at risk for stress-related foot injuries.

**PURPOSE:** To enhance understanding of how plantar pressures (heel, forefoot) vary across elliptical trainers and in comparison to walking in order to guide clinical decision-making related to elliptical training exercise prescriptions.

**METHODS:** 20 healthy adults participated (10 male, 10 female; age 46±23yrs). After a familiarization session, each subject performed comfortable and fast walking (FW) trials followed by a randomized order of elliptical training on the following devices: LifeFitness (L), Octane (O), SportsArt (S) and True (T). To simulate FW, subjects were instructed to use the longest stride length available on each device while maintaining an elliptical training speed that matched their comfortable walking speed. Pressure data were recorded during fast walking and the final 30 seconds of the third minute of each elliptical trial. For each subject, Peak Pressure (PP, in KPa) and Pressure-Time Integral Dosage (DOS, defined as the cumulative pressure during one minute of activity) values were calculated using data recorded from 10 cycles for each activity. Separate 5x1 ANOVAs with repeated measures identified significant differences for the heel and forefoot.

**RESULTS:** Forefoot: PP (Mean±SD): FW>L,O,T (272+80>166+48, 165+57, 154+53;  $p < .001$ ). DOS: T,L,O,S>FW (7621+2152, 7541+1773, 7270+2022, 7216+2132>5764+1055;  $p < .002$ ). Heel: PP: FW>S,O,L,T (256+62>137+39, 118+35, 115+39, 109+32;  $p < .001$ ). DOS: FW>T,L (5731+2735>3319+1972, 3302+1878;  $p < .001$ ) & S>T (4810+2600>3319+1972;  $p < .001$ ).

**CONCLUSION:** While forefoot peak pressures were consistently lower during elliptical training, the finding that cumulative pressures (DOS) were higher suggests care should be used during extended periods of exercise at longer stride lengths if forefoot protection is warranted (e.g., diabetes). Pressure patterns under the heel indicate that elliptical training may provide a protective benefit compared to FW when injury to the heel is of concern (e.g., heel spurs).

**Cardiovascular Reactivity To Psychological Stress And Carotid Intima-media Thickness In Children**

Maya J. Lambiase, James N. Roemmich, FACSM, Christina L. Lobarinas, Parveen N. Joseph, Fred D. Archer III, Joan Dorn. *University at Buffalo, Buffalo, NY.*

Email: ml62@buffalo.edu

(No relationships reported)

The antecedents of atherosclerosis and CVD occur during childhood. Reactivity to psychological stress may be pathogenic for CVD in that it is associated with the precursors of essential hypertension and left ventricular mass in children. Carotid artery intima-media thickness (IMT) is a valid index of diffuse subclinical atherosclerosis. The relationship between cardiovascular stress reactivity and carotid artery IMT has been established in adults, but not yet studied in children.

**PURPOSE:** To determine whether a child's cardiovascular reactivity to an interpersonal stressor is associated with greater carotid artery IMT.

**METHODS:** Cardiovascular reactivity to an interpersonal stress (ad lib speech) was measured in 20 boys and 20 girls age 11.0 + 1.4 years. Each child was tested on three days; a stress day, non-stress control day, and an IMT measurement day. The order of the stress and non-stress days was counterbalanced across subjects. Measures included heart rate (HR), systolic (SBP) and diastolic (DBP) blood pressure reactivity by an automated monitor, and mean common carotid artery IMT measured by ultrasound imaging.

**RESULTS:** Univariate correlation showed that SBP reactivity was correlated ( $r=0.40$ ,  $p<0.05$ ) with carotid artery IMT. DBP and HR reactivity were not significantly ( $p>0.22$ ) correlated with carotid artery IMT. Sequential regression analyses were used to establish the incremental increase in  $R^2$  ( $R^2_{inc}$ ) for the prediction of IMT due to cardiovascular reactivity independent of age, SES, race, percentage body fat, and baseline BP or HR. SBP reactivity ( $\beta=0.002$ ,  $R^2_{inc}=0.10$ ,  $p<0.05$ ) independently predicted carotid artery IMT. DBP reactivity ( $p>0.12$ ) and HR reactivity ( $p>0.82$ ) were not predictive of carotid artery IMT.

**CONCLUSIONS:** Youth's cardiovascular reactivity to laboratory-based psychological stressors predicts BP responses to daily stress and is stable over time. Thus, youth who have the greatest BP reactivity to laboratory stressors may be most at risk for developing CVD later in life. SBP reactivity to psychological stress is associated with IMT and perhaps the early pathogenesis of CVD in childhood.

Email: heathermhayes@gmail.com

(No relationships reported)

Although the independent associations between fatness and physical activity on blood pressure (BP) have been observed in children, it is also known that fatness mediates the relationship between physical activity and cardiovascular disease risk factors in youth.

**PURPOSE:** The purpose of this study was to determine the combined influence of fatness and moderate-to-vigorous physical activity (MVPA) on resting BP in children.

**METHODS:** Participants were 157 (78 males, 79 females) children ages 5 to 9 yrs who participated in the UNKids Study. Minutes of MVPA were assessed using accelerometry. Body fatness was determined by dual energy absorptiometry and resting BP was measured according to standard procedures. Four categories were formed by cross tabulation of high/low levels of MVPA and high/normal levels of fatness. Group differences were determined by ANCOVA, controlling for age, sex, and height.

**RESULTS:** Overall, the high fat group as a whole had significantly higher BP than the normal fat group ( $p<0.05$ ). While the high MVPA group as a whole had lower systolic BP (SBP), diastolic BP (DBP), and mean arterial pressure (MAP) than the low MVPA group, significance was not reached. There were significant differences in SBP and MAP across the four groups ( $p<0.05$ ). Overall, the normal fat/high MVPA had the lowest BPs (e.g., SBP = 101.3+0.9 mmHg) and the high fat/low MVPA group had the highest BPs (e.g., SBP = 106.0+1.3 mmHg). When comparing the fat/MVPA groups, SBP was significantly lower in the normal fat/high MVPA group (101.3+0.9 mmHg) compared to both low and high MVPA groups within the high fat group (105.3+1.6 mmHg in high MVPA group and 106.0+1.3 mmHg in low MVPA group). MAP was also significantly different between the normal fat/high MVPA (79.7+0.7 mmHg) and the high fat/low MVPA group (83.4+1.0 mmHg) and between the normal fat/low MVPA group (80.8+0.8 mmHg) and the high fat/low MVPA group (83.4+1.0 mmHg). Although BP was slightly lower between the high and low MVPA groups within a fat group, this did not reach statistical significance.

**CONCLUSIONS:** The results indicate a clear pattern across fat/MVPA groups. Regardless of participating in a level of MVPA that meets the current guidelines ( $>60$  minutes/d), overfat children had higher resting SBP than normal fat children.

(No relationships reported)

Brachial artery flow mediated dilation (FMD) has become a commonly applied technique for the assessment of vascular health in humans. Although shear stress and artery size are acknowledged determinants of the FMD response, recent studies suggest that FMD is also governed by other factors.

**PURPOSE:** To investigate the relationships between vascular function and body composition variables in children.

**METHODS:** FMD (FMD%) was recorded and then normalised for the stimulus shear rate (FMD/SR<sub>AUC</sub>) in 129 healthy children (75 female; 10.3±0.3 yrs; 54 male; 10.4±0.3 yrs). Body composition variables (mass, lean mass and fat mass in the whole body, arm and forearm) were assessed by DEXA. Bivariate correlations explored the association between FMD%, FMD/SR<sub>AUC</sub> and body composition variables. A stepwise multiple linear regression investigated the relative contribution of baseline diameter, SR<sub>AUC</sub> and body composition variables to FMD%.

**RESULTS:** FMD% significantly ( $p<0.05$ ) correlated with arm fat mass ( $r=-0.18$ ) and forearm fat mass ( $r=-0.201$ ). FMD/SR<sub>AUC</sub> significantly correlated with whole body mass ( $r=-0.26$ ), whole body fat mass ( $r=-0.24$ ), arm mass ( $r=-0.25$ ), arm fat mass ( $r=-0.28$ ), forearm mass ( $r=0.194$ ) and forearm fat mass ( $r=0.211$ ). Baseline artery diameter accounted for 13.5 % of the variation in FMD%, while shear rate stimulus and body composition variables did not significantly contribute to FMD% prediction. Significant correlations were observed between baseline artery diameter and whole body mass ( $r=0.21$ ), whole body lean mass ( $r=0.28$ ), arm mass ( $r=0.23$ ), arm lean mass ( $r=0.32$ ), forearm mass ( $r=0.24$ ) and forearm lean mass ( $r=0.31$ ).

**CONCLUSIONS:** Significant correlations were observed between FMD%, FMD/SR<sub>AUC</sub> and measures of total and fat mass suggestive that fat mass has a negative association with vascular health. Although whole body and segmental body composition variables exert a relatively weak influence with regard to the determination of vascular function in children, further research might focus on the utility of ratio and allometric scaling procedures to explain the magnitude of the FMD response.

(No relationships reported)

In youth, remedial benefits of exercise training on conduit vessel endothelium-dependent vasodilator function have recently been documented, however it remains to be established whether exercise training also impacts on endothelium-dependent vasodilator function at the microvascular level in youth who are free from chronic disease.

**PURPOSE:** To determine whether a group of trained youth have superior skin microvascular endothelium-dependent vasodilator function compared to untrained healthy controls.

**METHODS:** Forearm skin blood flow (SkBF) was assessed in 17 trained ( $14.6 \pm 0.2$  yrs,  $VO_{2peak}$ :  $54.9 \pm 1.5$  mL.kg<sup>-1</sup>.min<sup>-1</sup>, Self-assessed Tanner stage 2 - 4) and 9 untrained ( $15.6 \pm 0.2$  yrs,  $VO_{2peak}$ :  $43.1 \pm 1.7$  mL.kg<sup>-1</sup>.min<sup>-1</sup>, Tanner stage 2 - 4) male adolescents using laser Doppler flowmetry at baseline (basal SkBF) and following physiological provocation. Endothelium-dependent vasodilator function of the skin microcirculation was assessed physiologically through local heating to 44°C for 30 minutes (maximal SkBF) and post-occlusive reactive hyperaemia (PORH), which involved SkBF assessment following 3 minutes of arterial occlusion. Cutaneous vascular conductance (CVC) (SkBF/MAP) was calculated at baseline and at maximal thermal flux.

**RESULTS:** Maximal SkBF was significantly higher in trained versus untrained youth (Trained:  $281.7 \pm 29.2$  vs Untrained:  $204.2 \pm 22.6$  PU,  $p=0.04$ ). Maximal flux during PORH was also significantly higher in trained compared to untrained youth (Trained:  $50.4 \pm 5.2$  vs Untrained:  $35.2 \pm 5.0$  PU,  $p=0.04$ ). Trained youth also demonstrated significantly greater basal SkBF and basal CVC (basal SkBF Trained:  $11.2 \pm 0.9$  vs Untrained:  $8.6 \pm 1.0$  PU,  $p=0.03$ ; basal CVC Trained:  $0.12 \pm 0.01$  vs Untrained  $0.08 \pm 0.01$  PU/mmHg,  $p=0.04$ ) and possessed superior maximal CVC (Trained:  $3.00 \pm 0.34$  vs  $2.02 \pm 0.23$  PU/mmHg,  $p=0.03$ ) compared to their untrained counterparts.

**CONCLUSION:** Skin microvascular endothelium-dependent vasodilator function is significantly enhanced in healthy, trained male adolescents. This may have implications for the prevention of endothelial dysfunction with aging and chronic diseases such as diabetes.

(No relationships reported)

A decline in endothelial function as measured by flow mediated dilatation (FMD) is an early independent predictor of cardiovascular disease (CVD) and has been seen in diabetes and following the menopause in women. The influence of exercise training upon FMD in postmenopausal women with type 2 diabetes is however, unclear.

**PURPOSE:** to determine the effect of a 6 month exercise training regime at 75%  $VO_{2peak}$  upon FMD and CVD risk factors in postmenopausal women with type 2 diabetes.

**METHODS:** Peak oxygen uptake ( $VO_{2peak}$ ) was assessed via a Bruce treadmill test in 15 women. Eight participants then trained under supervision twice per week (+one home session) at 55, rising to 75%  $VO_{2peak}$  for six months. Seven participants acted as controls. CVD risk factors were assessed pre and post intervention. Body composition was assessed via skinfold analysis and measurement of waist and hip circumferences, BMI and body mass. A fasting venous blood sample was analyzed for total cholesterol, high (HDL-C) and low density lipoproteins, triglycerides, glucose, insulin, glycosylated haemoglobin (HbA1c) and high sensitivity C-reactive protein (hsCRP). Flow mediated dilatation (FMD) during reactive hyperaemia was recorded as an index of endothelial function. The impact of the intervention upon FMD and any confounding effect of key risk factors were analyzed using two way ANCOVA.

**RESULTS:** Exercise training significantly improved  $VO_{2peak}$  (trained baseline:  $22.12 \pm 5.8$ ; post:  $24.50 \pm 6.7$ , control baseline:  $19.11 \pm 4.2$ ; post:  $19.22 \pm 2.5$  mL.kg.min<sup>-1</sup>), waist circumference (trained baseline:  $99.5 \pm 15$ ; post:  $93.5 \pm 13.2$ , control baseline:  $102.5 \pm 11.5$ ; post  $102 \pm 11.9$  cm) and FMD (trained baseline  $4.2 \pm 2.7$ ; post  $7.1 \pm 2.8$ , control baseline  $4.5 \pm 2.8$ , post:  $2.9 \pm 1.4$  %) compared to controls ( $P < 0.05$ ). There was no significant impact of training upon any of the remaining CVD risk factors ( $P > 0.05$ ). The 69% improvement in FMD was not influenced by adding covariates to the analysis.

**CONCLUSION:** Aerobic exercise training can significantly improve endothelial function in postmenopausal women with type 2 diabetes and importantly, this improvement is independent of changes in any other key CVD risk factor.

**Change In Plasma Nitrite Following An Acute Bout Of Exercise In Older Women**

Devon A. Dobrosielski, Anthony P. Marsh, Tennille D. Presley, Andreas S. Perlegas, Daniel B. Kim-Shapiro, Walter J. Rejeski. Wake Forest University, Winston-Salem, NC. (Sponsor: Peter H. Brubaker, FACSM)

Email: dobrosda@wfu.edu

(No relationships reported)

Nitric oxide (NO) has many anti-atherogenic properties and is a key mediator of arterial vasodilation. Thus, it may play a critical role in facilitating the delivery of blood to active skeletal muscle in older adults, ultimately impacting functional health. Plasma nitrite may be an effective marker of vascular NO bioavailability.

**PURPOSE:** To determine whether a change in plasma nitrite following an acute bout of physical activity differs in older adults with different physical function.

**METHODS:** Physical function was evaluated using the Short Physical Performance Battery (SPPB, range 0-12). On a separate visit, venous blood was drawn before and 10 minutes following the completion of a 400 m walk test. Blood samples were added to heparin and frozen for subsequent analysis using chemiluminescence.

**RESULTS:** Twenty six women ( $79 \pm 4$  years, SPPB range: 3-12) participated in the study. Plasma nitrite levels decreased approximately 22% following the 400 meter walk (Baseline:  $129 \pm 82$  nM vs. Post:  $100 \pm 62$  nM,  $p=0.005$ ), although no change or an increase in nitrite levels was observed in some subjects. Percent change in plasma nitrite

was related to walking speed ( $r=-.550$ ,  $p=0.004$ ) (Figure 1). Walking speed was significantly related to SPPB ( $r=.723$ ,  $p=0.001$ ), but there was no association between SPPB score and change in plasma nitrite.

**CONCLUSIONS:** These findings suggest a role for plasma nitrite in the adaptation to physical exertion in older adults. Interestingly, the magnitude and direction of change in plasma nitrite levels appears to be influenced by walking speed. Whether this response is involved in blood flow regulation is not known and warrants further study.

**Increased Fitness Attenuates Endothelial Dysfunction Following A High Fat Meal In Postmenopausal Women**

Damon L. Swift, Siddhartha S. Angadi, Judith Y. Weltman, Eugene J. Barret, James Patrie, Glenn A. Gaesser, FACSM, Arthur Weltman, FACSM.  
University of Virginia, Charlottesville, VA. (Sponsor: Dr. Arthur Weltman, FACSM)

Email: dls3s@virginia.edu

(No relationships reported)

Endothelial dysfunction is a known predictor of coronary artery disease (CAD) and may be worsened in the postprandial state, particularly after ingestion of a high-fat meal. Post-menopausal status also confers a greater risk for the development of endothelial dysfunction and CAD, whereas cardiorespiratory fitness is positively associated with endothelial function.

**PURPOSE:** To examine if increased fitness ( $VO_{2max}$ ) attenuates postprandial endothelial dysfunction that follows the ingestion of a high-fat meal challenge in sedentary post-menopausal women.

**METHODS:** Fifteen sedentary post-menopausal women (Age=56.6 ± 4.2 yr; BMI=27.0 ± 4.9 kg/m<sup>2</sup>; % body fat=40.9 ± 7.1%;  $VO_{2max}$ =22.6 ± 4.3 ml.kg<sup>-1</sup>.min<sup>-1</sup>; range =16.4-31.5) were admitted to the General Clinical Research Center on two occasions for  $VO_{2max}$  and brachial artery flow mediated dilation testing. Subjects underwent an incremental  $VO_{2max}$  protocol and on a separate day underwent serial brachial artery flow mediated dilation measurements at baseline (after an overnight fast) and 2 and 4-hours after ingestion of a high-fat breakfast meal challenge (57% fat, 25% protein, and 18% carbohydrate). Percent flow-mediated dilation (% FMD) was quantified by comparing B-mode ultrasound images of the brachial artery at rest and during reactive hyperemia following 5-min of forearm occlusion with a blood pressure cuff at 50mmHg above systolic blood pressure. Measurements of brachial artery diameter were made by using computerized edge detection software.

**RESULTS:** A significant relationship was observed between  $VO_{2max}$  and %FMD at 2 hours ( $r=-.52$ ,  $p=0.047$ ) and 4 hours ( $r=0.63$ ,  $p=0.012$ ) postprandially.

**CONCLUSION:** Fitness is associated with increased %FMD in post-menopausal women following a high fat meal challenge, with elevated fitness associated with an improved endothelial response in the postprandial period. This may be yet another mechanism by which increased cardio-respiratory fitness lowers cardiovascular risk.

**Aging Slows Muscle Oxygenation Responses During Reactive Hyperemia In Women**

Masahiro Horiuchi<sup>1</sup>, Koichi Okita<sup>2</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>Hokusho University, Ebetsu, Japan.

Email: horiuchim@health.missouri.edu

(No relationships reported)

Aging is associated with impaired arterial compliance and endothelial function, furthermore, menopause may accentuate endothelial dysfunction. These alterations might also affect not only vasodilatation of large arteries but also microvasculature function. Near infrared spectroscopy (NIRS) can allow to determine the relative changes of oxygenated hemoglobin (HbO<sub>2</sub>) in the microvasculature with high temporal resolution. However, little is known about microvasculature function of aged women.

**PURPOSE:** To determine the influence of aging on microvascular reactivity in women.

**METHODS:** Ten younger (22±0.4yrs, mean± S.E.M.) and ten older healthy women (62±0.6yrs) were studied. Resting cardiovascular measurements and post occlusive reactive hyperemia were performed in supine position. NIRS signals were measured during 5 min of arterial cuff occlusion (cuff pressure > 50mmHg above systolic blood pressure), and during 3 min of post occlusive reactive hyperemia at their forearm muscle. Skinfold thickness was measured by B-mode ultrasound. Beta-stiffness was also calculated from pulse wave velocity as an index of arterial compliance. The recovery time of HbO<sub>2</sub> is half the time required for the HbO<sub>2</sub> to reach maximal value in response to cuff release from the time of cuff occlusion. The recovery rate of HbO<sub>2</sub> was assessed by determining the slope of HbO<sub>2</sub> and time relationship during first 20 sec.

**RESULTS:** Although there were no significant differences in body mass index (21.3±0.8 vs 22.5±0.6 kg/m<sup>2</sup>, young vs old), skinfold thickness (3.9±0.3 vs 4.1±0.3 mm, young vs old), and mean blood pressure (88±1.4 vs 90±1.3 mmHg, young vs old) in two groups, beta-stiffness in old (8.14±0.24) was significantly impaired compared to the young subjects (5.55±0.25,  $p<0.05$ ). Recovery time of HbO<sub>2</sub> in old (12.0±0.7sec) was significantly slower than that in young subjects (8.4±0.4 sec,  $p<0.05$ ). Slope of HbO<sub>2</sub> in young (1.53±0.09  $\mu\text{mol/l}\cdot\text{sec}^{-1}$ ) was significantly steeper than that in old subjects (1.17±0.13,  $\mu\text{mol/l}\cdot\text{sec}^{-1}$ ,  $p<0.05$ ).

**CONCLUSIONS:** These results indicate that post menopausal women exhibit a delayed HbO<sub>2</sub> response during reactive hyperemia. We suggest that these alterations in HbO<sub>2</sub> kinetics are indicative of microvasculature dysfunction in these subjects.

**Changes In Vascular And Physical Function With Exercise Training In The Aged**

Ryan D. Russell<sup>1</sup>, Daniel P. Credeur<sup>1</sup>, Devon A. Dobrosielski<sup>2</sup>, Tracie R. Parish<sup>3</sup>, Michael A. Welsch, FACSM<sup>1</sup>. <sup>1</sup>LSU, Baton rouge, LA. <sup>2</sup>Wake Forest, Winston-Salem, NC. <sup>3</sup>SLU, Hammond, LA.

Email: rrusse3@lsu.edu

(No relationships reported)

Previous work from our laboratory indicates the ability of the vasculature to respond favorably to a regional-specific exercise stimulus, even in individuals in their 9<sup>th</sup> and 10<sup>th</sup> decade of life. Interestingly, few studies have examined whether changes in vascular function can be induced through whole-body training and contribute to preserving functional ability in the aged.

**PURPOSE:** This study aimed to determine the effects of eight weeks of structured exercise, followed by a 4 week retention period, on measures of vascular and physical function in individuals in their 8<sup>th</sup>-10<sup>th</sup> decade of life.

**METHODS:** Twenty-one participants (age: 83±5.yrs) engaged in both resistance and aerobic training, performed for 60-minutes, two times per week. Brachial artery dimensions and reactivity were measured before and after training, using ultra-high resolution ultrasonography. A previously validated physical functional performance test (CSFP10) was used to assess basic and instrumental activities of daily living.

**RESULTS:** Training volume, defined as amount of weight lifted and aerobic work performed, increased significantly from the first to the last week of training (Weight Lifted: 3181±1481 to 5819±1877lbs,  $p=0.001$ ; Aerobic Load: 1.91±1.85 to 2.54±2.45AU,  $p=0.005$ ). Baseline brachial artery cross-sectional area (CSA) increased significantly after training (Pre: 12.42±6.42 to Post: 13.28±6.80 mm<sup>2</sup>,  $p=0.001$ ), whereas brachial artery reactivity remained unchanged (Pre: 4.92±2.29 to Post: 4.19±1.65%,  $p=0.31$ ). Physical function improved in all individual domains, except for upper body flexibility, collectively contributing to a 15% increase in the total CS-PFP10 score (Pre: 50.55±14.76 to Post: 57.94±14.43U,  $p=0.001$ ). The change in CSA was related to the change in the total amount of weight lifted over the course of the training ( $r^2=0.19$ ). No vascular or functional changes were noted in age-matched controls. Individuals who maintained a training volume of at least 70% of their 8<sup>th</sup>-week workload showed no reversal of the training-induced changes in vascular or physical function.

**CONCLUSIONS:** This study suggests exercise training induces conduit artery expansion and enhanced physical function in individuals, in their 8<sup>th</sup> through 10<sup>th</sup> decade of life. Removal of the training stimulus reverses these changes.

1598 Board #200 May 27 11:00 AM - 12:30 PM

**Effects Of 6-week Kaatsu Walking Training On Limb Venous Compliance In Elderly Subjects**

Toshiaki Nakajima, Miwa Kurano, Haruko Iida, Haruhito Takano, Tomohiro Yasuda, Satoshi Fujita, Toshihiro Morita, Yoshiaki Sato, Tatsuya Yamasoba, Takashi Abe. *University of Tokyo, Tokyo, Japan.*

Email: masamasa@pb4.so-net.ne.jp

(No relationships reported)

Venous compliance declines with age and improves with chronic endurance exercise. KAATSU-walking is a unique training method for promoting muscle hypertrophy and strength gains under the conditions with restricted venous blood flow, and inducing venous pooling of blood, which may affect limb venous compliance. However, the effects of KAATSU training on venous properties have not been investigated.

**PURPOSE:** This study investigated the influence of a 6-week-walk training combined with KAATSU on venous properties in older men and women.

**METHODS:** Twenty-two elderly men and women, aged 60-78 years, were randomized into either a KAATSU-walk training group (n=11, KAATSU-walk) or a non-exercising control group (n=11, Control). The KAATSU-walk group performed 20 min treadmill walking (67 m/min), five days/wk for 6 wk. A non-exercising group was advised to perform daily slow walk for 20 min five days/wk during the study. Before (pre) and after (post) 6 wk, strain gauge venous occlusion pletysmography was used to assess limb venous vascular properties. Venous volume variation (VVV) was defined as the maximal relative volume increase in the limb at a certain cuff pressure, and VVV at different occlusion pressures represents the pressure-volume curve. Compliance was derived from the slope of the pressure-volume curve. Venous emptying rate was calculated as the slope of the tangent at the curve 0.5 s after cuff release. The time 0.5 s after cuff deflation was chosen to avoid any cuff artifact, and the effective pressure of the cuff on the venous system at 0.5 s was calculated by using the pressure-volume curve.

**RESULTS:** Leg venous compliance was significantly increased in KAATSU-walk group (pre  $0.066 \pm 0.004$  ml·100ml<sup>-1</sup>·mmHg<sup>-1</sup>, post  $0.078 \pm 0.007$ ,  $P < 0.05$ ), compared with control group (pre  $0.069 \pm 0.008$ ; post  $0.068 \pm 0.04$ ). Leg venous flow resistance decreased (pre  $1.31 \pm 0.1$  mmHg·ml<sup>-1</sup>·100 ml·min; post  $1.08 \pm 0.08$ ) in KAATSU-walk group, compared with control group (pre  $1.23 \pm 0.12$ ; post  $1.38 \pm 0.07$ ). In contrast, arm compliance did not change significantly in KAATSU-walk and control group.

**CONCLUSIONS:** The present study provides the first evidence that daily KAATSU-walk may be a unique and novel training for improving limb venous compliance in untrained older subjects.

**Effects Of 12 Weeks Of Group Training On Arterial Stiffness In Elderly Hypertensives**

Hajime Miura, Yoshinori Takahashi. *University of Tokushima, Tokushima, Japan.*

Email: hajime-m@ias.tokushima-u.ac.jp

(No relationships reported)

The decline in arterial function with aging is considered to be part of a physiological process reflected in elevated blood pressure. For elderly men, regular physical exercise is recommended for the prevention and treatment of cardiovascular diseases. However, few attempts have so far been made to identify the role of exercise training in arterial function in elderly hypertensives.

**PURPOSE:** The aim of this study was to evaluate the effects of group training on arterial stiffness and blood pressure in elderly hypertensives and to compare these effects to those on healthy elderly.

**METHODS:** 36 elderly women with systolic blood pressure (SBP) 140 to 159 mmHg or diastolic blood pressure (DBP) 90 to 99 were assigned to the hypertensive group (HTT), and 34 elderly women with normal blood pressure were assigned to the normal blood pressure group (NP). All subjects participated in 90-min group training twice a week for 12 weeks. Before and after training, SBP, DBP and brachial to ankle pulse wave velocity (baPWV) were obtained in the supine position using an automatic pulse wave form analyzer.

**RESULTS:** After training duration, baPWV reduced  $-3.8 \pm 9.5\%$  in HTT ( $1960.4 \pm 275.6$  to  $1884.8 \pm 280.4$  cm/sec) and  $-7.5 \pm 7.2\%$  in NT ( $1598.5 \pm 205.3$  to  $1490.1 \pm 221.2$  cm/sec), respectively. Compared with HTT, a greater reduction in delta baPWV was observed in NP ( $p < 0.05$ ). However, no significant differences were found in SBP ( $-3.1 \pm 9.2\%$  in HTT vs.  $-3.6 \pm 9.9\%$  in NP) and DBP ( $-3.1 \pm 9.8\%$  in HTT vs.  $-3.8 \pm 8.2\%$  in NP).

**CONCLUSIONS:** Even though elderly hypertensives show a reduction of baPWV, larger reduction was found in NP compared with HTT. These results indicate that short term group training produces less improvement of arterial stiffness in elderly hypertensives than in healthy elderly.

**Effects Of "Life-long" Exercise Training On Arterial Stiffness In The Elderly**

Shigeki Shibata, Paul S. Bhella, Nicole Minniefield, Melyn Galbreath, Jeff L. Hastings, Eric Pacini, Felix Krainski, Dean Palmer, James McLoughlin, Tiffany VanGundy, Daniel Creson, Qi Fu, Rong Zhang, Benjamin D. Levine, FACSM. *Institute for Exercise and Environmental Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

Email: ShigekiShibata@texashealth.org

(No relationships reported)

**BACKGROUND:** It is well known that human arteries become stiffer with sedentary aging. Conversely, studies by us and others have revealed that Masters athletes (Age > 65) who have been training 6-7 sessions/wk throughout their adult lives maintain youthful aortic compliance. Although previous findings support the beneficial effects of exercise training on arterial compliance in the elderly, it is still unknown how lower doses of "life-long" exercise training ameliorate arterial compliance.

**METHODS:** We recruited senior adults (Age > 65) with different life-long exercise doses from the Aerobic Center Longitudinal Study, in which patterns of physical activity have been measured for > 25 yrs; 1) sedentary seniors (Q1: no regular exercise, N=7), 2) mild-active seniors (Q2: Exercise; 2-3 times/wk, N=3), 3) moderate-active seniors (Q3: Exercise; 4-5 times/wk, N=7), and 4) Masters athletes (Q4: Exercise; 6-7 times/wk, N=13). Central aortic and peripheral arterial compliance were estimated by central (carotid-femoral) and peripheral (carotid-radial) pulse wave velocity (PWV), respectively. Common carotid arterial compliance was estimated by cross-sectional area changes of systolic and diastolic phases (Sono-CT), and corresponding systolic and diastolic blood pressures with beta-stiffness index.

**RESULTS:** Central PWV was significantly slower in seniors who trained 2-3, 4-5 or 6-7 times per week (Q2, Q3, and Q4) than in sedentary seniors (Q1), indicating that even 2-3 times per week exercise training has beneficial effects on aortic compliance. Interestingly, central PWV was not significantly different among Q2, Q3 and Q4, suggesting that this beneficial effect could plateau at small doses of exercise training. Similarly, the beta stiffness index of the common carotid artery was lower (more compliant) in Q2, Q3, and Q4 than in Q1, and was not different among Q2, Q3 and Q4. Peripheral PWV was not significantly different among all groups, suggesting limited effects of exercise training on upper limb peripheral arterial compliance.

**CONCLUSIONS:** It appears that 2-3 times per week of "life-long" regular exercise training provides similar beneficial effects on arterial compliance as more vigorous exercise regimens.

## Relationship Between Vasoreactivity And Structure In An Elderly Cohort Of The Louisiana Healthy Aging Study

Michael A. Welsch, FACSM<sup>1</sup>, Daniel P. Credeur<sup>1</sup>, Darcy Johannsen<sup>2</sup>, Eric Ravussin<sup>2</sup>, S. Michal Jazwinski<sup>3</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>3</sup>Tulane University, New Orleans, LA.  
Email: mwelsch@lsu.edu

(No relationships reported)

Brachial flow mediated dilation (BAFMD), and carotid intima media thickness (CIMT), physiologic and structural measures of subclinical atherosclerosis are typically not related in population-based studies. This results in the interpretation that the controlling mechanisms for these measures are distinct and independent.

**PURPOSE:** (1) To examine the association between BAFMD and carotid artery dimensions and (2) to determine the link between measures of physical activity, vasoreactivity and structure, and physical function, in the elderly.

**METHODS:** Participants (n=69; Age: 83±12, Range: 61 to 98yrs) from the LHAS were used for these analyses. Brachial (Diameter and BAFMD) and carotid artery dimensions (Diameter, CIMT, and arterial mass (CMASS)) were determined using high-resolution ultrasonography. Physical activity status (Total Daily Energy Expenditure (TDEE) and amount of daily physical activity (PAL=TDEE/RMR) were assessed using doubly-labeled water. Physical function (CSPFP-10) was determined from a previously validated instrument used to assess basic and instrumental activities of daily living.

**RESULTS:** The association between CIMT and BAFMD was not quite significant ( $r=-0.28$ ,  $p=0.06$ ). However, linear regression for BAFMD and CMASS was highly significant ( $\text{CMASS} = -0.314 * (\text{BAFMD}) + 14.14$ ,  $r=-0.48$ ,  $p=0.01$ ). In addition, PAL ( $r=0.45$ ,  $p=0.001$ ) was significantly related to BAFMD, and TDEE ( $r=-0.33$ ,  $p=0.03$ ) and PAL ( $r=-0.41$ ,  $p=0.006$ ) were significantly related to CMASS. Both BAFMD ( $r=0.37$ ,  $p=0.002$ ) and CMASS ( $r=-0.38$ ,  $p=0.01$ ) were significantly associated with the CSPFP-10 total score. Interestingly, a MANCOVA for nonagenarians (n=28, Age: 92±2yrs) revealed those in the higher functional tertiles had greater BAFMD ( $p=0.05$ ), compared to those in the lowest tertile, yet similar CMASS.

**CONCLUSION:** These data indicate a significant inverse relationship between BAFMD and CMASS, in an elderly cohort of the LHAS. Moreover, it appears these measures (BAFMD and CMASS) are sensitive to a person's daily energy expenditure, which may subsequently contribute to one's physical functionality. However, the finding that nonagenarians with higher function have greater BAFMD yet similar CMASS, suggests the underlying mechanisms for these measures can still change in a distinct and independent manner.

### Attenuated Age-related Increase In Carotid Intima-media Thickness In Cardiorespiratory Fit Men And Women

Motohiko Miyachi<sup>1</sup>, Kiyoshi Sanada<sup>2</sup>, Yuko Gando<sup>2</sup>, Kenta Yamamoto<sup>2</sup>, Haruka Murakami<sup>1</sup>, Michiya Tanimoto<sup>1</sup>, Yumi Ohmori<sup>1</sup>, Izumi Tabata, FACSM<sup>1</sup>. <sup>1</sup>National Institute of Health and Nutrition, Tokyo, Japan. <sup>2</sup>Waseda University, Tokyo, Japan.

Email: miyachi@nih.go.jp

(No relationships reported)

**PURPOSE:** Age-related increase in carotid intima-media thickness (IMT) has been identified as an independent risk factor of cardiovascular disease (CVD). Cardiorespiratory fitness is generally associated with a lower incidence of CVD. Although the mechanisms underlying this protective effect are not fully understood, it is possible that fitness attenuates the age-related increase in carotid IMT. Accordingly, the present investigation was performed to determine the possible influence of fitness on the age-related increase in carotid IMT using a cross-sectional study design.

**METHODS:** A total of 926 healthy men and women (age 18-76 yr) participated in this study. All subjects underwent fitness assessment (maximal oxygen uptake) by a graded incremental cycle exercise test and were divided into either the fit or unfit group. Carotid IMT was measured from the images obtained using an ultrasound machine equipped with a high-resolution linear array transducer.

**RESULTS:** In both groups, carotid IMT increased progressively with age ( $P<0.001$ ). In middle-aged and older men and women, the carotid IMT in the fit group ( $0.68\pm0.11$  mm) was significantly thinner than that in the unfit group ( $0.70\pm0.11$ ,  $P<0.01$ ). The carotid systolic blood pressure (SBP) in the fit group ( $121\pm22$  mmHg) was also lower than that in the unfit group ( $127\pm25$ ,  $P<0.001$ ). There were no significant differences in carotid IMT or SBP in young men and women ( $P<0.001$ ). When ANCOVA was performed with carotid SBP as a covariate, differences in carotid IMT between fit and unfit groups were abolished.

**CONCLUSIONS:** In conclusion, the results of this study support the hypothesis that maintenance of cardiorespiratory fitness exerts a protective effect against CVD in part by attenuating the age-related increase in carotid IMT. This modulatory effect on carotid IMT may be due to the high fitness to prevent or reduce the age-associated elevation of carotid distending pressure.

### Mechanisms Of Enhanced Endothelium-dependent Vasodilation In Skeletal Muscle Resistance Vasculature Following Acute Exercise

Scott A. Spier, Jay Gallegly, Lindsay Deal, Eric Buess, Marcus P. Patrick. *University of Texas at Tyler, Tyler, TX.*

Email: sspier@uttyler.edu

(No relationships reported)

Skeletal muscle blood flow remains elevated following acute exercise. Enhanced endothelium-dependent vasodilation of the skeletal muscle resistance vasculature may contribute to the enhanced blood flow following acute exercise. However, the mechanism mediating this enhanced vascular responsiveness following acute exercise is not known.

**PURPOSE:** To determine the mechanism responsible for the enhanced endothelium-dependent vasodilation observed in skeletal muscle arterioles and feed arteries following an acute bout of exercise.

**METHODS:** Male Sprague-Dawley rats were divided into exercise (EX) and sedentary control groups (SED). The EX group ran on a treadmill at 30 m/min (15° incline) for 45 minutes. First-order (1A) arterioles and feed arteries (FA) were isolated from the soleus muscle, cannulated, and pressurized. Luminal diameter changes were determined in response to the endothelium-dependent vasodilator acetylcholine (ACh,  $10^{-9}$  -  $10^{-4}$  M), alone and in the presence of the nitric oxide synthase (NOS) inhibitor L-NAME ( $10^{-5}$  M) or the combination of L-NAME and the cyclooxygenase (COX) inhibitor indomethacin ( $10^{-5}$  M). Luminal diameter changes were also determined in response to the nitric oxide donor, sodium nitroprusside (SNP,  $10^{-10}$  -  $10^{-4}$  M).

**RESULTS:** Responsiveness to ACh was enhanced in soleus muscle FA and 1A arterioles from EX rats compared to SED rats. NOS inhibition reduced vasodilation in and eliminated differences between SED and EX 1A arterioles. In contrast, NOS inhibition significantly reduced vasodilation to ACh in both SED and EX FA, but did not eliminate differences between them. NOS + COX inhibition abolished the enhanced vasodilation to ACh in both soleus FA and 1A arterioles and eliminated the differences between SED and EX in both soleus muscle 1A arterioles and FA. Responsiveness to SNP was not different between either 1A arterioles or FA from soleus muscle.

**CONCLUSIONS:** These data demonstrate that the enhanced endothelium-dependent vasodilation in soleus muscle 1A arterioles following acute exercise is mediated through the NO signaling pathway, whereas the enhanced endothelium-dependent vasodilation in soleus muscle FA following acute exercise is mediated through the COX signaling pathway.

### Initial Orthostatic Hypotension Upon Rising From Squat Is Explained By Rapid Vasodilation In Leg Muscles

Kristine Matusiak, Lisa McVicar, Catherine Vipond, Michael E. Tschakovsky. *Queen's University, Kingston, ON, Canada.*

Email: matusiakk@gmail.com

(No relationships reported)

Standing up is a frequent (3-10 %) trigger of loss of consciousness both in young and old subjects. This is due to an exaggerated transient BP (blood pressure) fall within 15 s upon standing, referred to as initial orthostatic hypotension (IOH). It is unclear what causes the marked increase in systemic vascular conductance that leads to IOH. Two possibilities have been proposed: 1) rapid vasodilation in the contracting leg muscles, and 2) systemic sympathetic withdrawal evoked by a sudden increase in right atrial pressure.

**PURPOSE:** This study tested the hypothesis that IOH is due to rapid vasodilation in contracting leg muscles with the effort of standing.

**METHODS:** 17 young healthy University undergraduates performed three different experimental conditions; standing up after a 10 s squat, a 1 min squat, or a 5 min squat. Beat by beat mean arterial blood pressure (MAP), cardiac output (CO), heart rate (HR) and stroke volume (finger photoplethysmography, Finometer) and right femoral artery blood flow (FABF; Doppler and Echo ultrasound) were recorded.

**RESULTS:** data mean  $\pm$ SE. Quiet standing represented baseline for all hemodynamic responses. Within 10 s of standing from squat, MAP (mmHg) fell to a nadir significantly below baseline in all conditions (baseline vs. standing from squat: 10 s squat  $89.1 \pm 3.8$  vs.  $72.0 \pm 3.9$ , 1 min squat  $91.2 \pm 3.6$  vs.  $69.2 \pm 3.1$ , 5 min squat  $91.1 \pm 3.1$  vs.  $62.8 \pm 4.4$ , all  $P < 0.001$ ). This occurred despite elevations in CO (L/min) (baseline vs. standing from squat: 10 s squat  $4.2 \pm 0.3$  vs.  $6.7 \pm 0.5$ , 1 min squat  $4.3 \pm 0.3$  vs.  $7.0 \pm 0.5$ , 5 min squat  $4.1 \pm 0.3$  vs.  $7.6 \pm 0.5$ , all  $P < 0.01$ ) and was explained by large increases in total vascular conductance (TVC; ml/min/100mmHg). The increase in TVC could be attributed primarily too increased 2-legged vascular conductance (LVC; ml/min/100mmHg) (TVC vs. LVC increase from standing baseline: 10 s squat  $43.0 \pm 5.3$  vs.  $36.7 \pm 6.3$ , 1 min squat  $47.8 \pm 4.5$  vs.  $44.6 \pm 6.8$ , 5 min squat  $54.9 \pm 4.2$  vs.  $55.7 \pm 12.2$ ) which co-occurred with the MAP nadir.

**CONCLUSIONS:** Rapid vasodilation in leg muscles with the effort of standing outstrips compensatory CO responses and is the cause of IOH.

**Arterial Structure And Function In Women And Men Following Long Duration Bed Rest**

Stuart M. C. Lee<sup>1</sup>, Michael B. Stenger<sup>1</sup>, David S. Martin<sup>1</sup>, Steven H. Platts<sup>2</sup>. <sup>1</sup>Wyle Integrated Science and Engineering, Houston, TX. <sup>2</sup>National Aeronautics and Space Administration, Houston, TX.

Email: stuart.lee-1@nasa.gov

(No relationships reported)

Orthostatic intolerance is a well-recognized consequence of space flight and bed rest (BR), with a greater incidence reported in women.

**PURPOSE:** We hypothesized that leg, but not arm, arterial structure and function would be altered following prolonged BR, as a model of space flight, and that women would be more susceptible to BR-induced deconditioning than men.

**METHODS:** Ten volunteers (5 males, 5 females) completed 90 d of 6° head-down BR. Subjects participated in tests of brachial (BA) and anterior tibial (AT) artery endothelium-dependent (flow mediated dilation [FMD] following 5-7 min of arterial occlusion) and endothelium-independent (0.4 mg sublingual nitroglycerin [SN]) vasodilation before BR (PRE) and on days 7 (BR7), 21 (BR21), and 90 (BR90) of BR. Vessel diameter and intimal medial thickness (IMT) were measured by ultrasound. IMT, baseline diameter, and percent change in diameter from baseline during FMD and SN tests were compared across BR and between genders using repeated measures two-way ANOVA with Bonferroni *post-hoc* tests in which PRE and women were control conditions.

**RESULTS:** Baseline vessel diameter was lower in women than in men in both the BA ( $p=0.005$ ) and AT ( $p=0.01$ ) across all days. Baseline AT diameter decreased during BR ( $p=0.01$ ) and tended to be more profound in women (interaction,  $p=0.06$ ). AT diameter was reduced in women at BR21 and BR90 ( $p<0.01$ ) but not in men. In contrast, there was no BR effect on baseline BA diameter. IMT also decreased in the AT ( $p<0.001$ ) but not in the BA during BR; AT IMT was reduced by BR21 ( $p<0.05$ ). As a group, there was no effect of BR on AT FMD, BA FMD, and AT SN-dilation, although BA SN-dilation was significantly reduced on BR21 ( $p=0.01$ ). Across all BR days, women exhibited higher AT FMD ( $p=0.03$ ), BA FMD ( $p=0.02$ ), and BA SN-dilation ( $p=0.01$ ) and tended to demonstrate greater AT SN-dilation ( $p=0.11$ ).

**CONCLUSIONS:** These preliminary results suggest that arterial remodeling occurs during BR in the leg (decreased diameter and IMT), but not in the arm, and that women appear to be more responsive to BR than men. These changes in the leg, coupled with larger responses to direct and indirect stimulation of the arterial smooth muscle, may be related to the greater incidence of orthostatic intolerance in women after BR and space flight.

**Eccentric Muscle Damage And Macrovascular Function: Stiff Muscles And Stiff Arteries?**

Jill N. Barnes, Justin R. Trombold, Hirofumi Tanaka, FACSM. University of Texas at Austin, Austin, TX.

Email: jillcook@mail.utexas.edu

(No relationships reported)

In animal models, muscle damage caused by eccentric contractions instigates an inflammatory response, and reduces local microcirculatory blood flow and vasodilator function. Local alterations in the microcirculation may translate to unfavorable changes in the larger, central blood vessels. Currently, it is unknown if local muscle damage is potent enough to alter macrovascular function in humans.

**PURPOSE:** To determine whether muscle damage caused by eccentric contractions reduce macrovascular function.

**METHODS:** Recreationally-active males ( $n=16$ , age  $24 \pm 6$  years) participated in a randomized crossover experiment consisting of 2 trials, separated by at least 14 days. Prior to the start of each trial, subjects were familiarized with isometric force and vascular measurements. In each trial, muscle damage was induced using 2x20 unilateral eccentric contractions of the elbow flexors and randomized between dominant and non-dominant arm. Measurements were taken at baseline, and at 1, 24, 48, and 72 hours following the eccentric exercise.

**RESULTS:** Isometric muscle force was lower ( $p<0.01$ ), and muscle soreness ratings were higher ( $p<0.01$ ) than baseline for all time points in both trials. In addition, serum creatine kinase was elevated at 24h and 72h post ( $p<0.05$ ). Aortic pulse wave velocity, a measure of central arterial stiffness, and aortic augmentation index, a measure of arterial wave reflection, did not change throughout the experimental period despite significant muscle damage to the elbow flexors. In addition, there was no difference in pulse wave velocity or augmentation index between the dominant and non-dominant trials at any time point.

**CONCLUSION:** Muscle damage to the elbow flexors does not translate to unfavorable changes in central macrovascular function.

**Peripheral Arterial Compliance Is Compromised In Young Multiple Sclerosis Patients**

Cecilie Fjeldstad<sup>1</sup>, Christine Frederiksen<sup>2</sup>, Anette S. Fjeldstad<sup>3</sup>, Michael Bembem, FACSM<sup>2</sup>, Gabriel Pardo<sup>1</sup>. <sup>1</sup>NeuroScience Institute, Oklahoma City, OK. <sup>2</sup>University of Oklahoma, Norman, OK. <sup>3</sup>University of Utah, Salt Lake City, UT.

Email: Cecilie.Fjeldstad@Mercy.Net

(No relationships reported)

A reduction of arterial elasticity in patients with autoimmune and inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus has been previously reported and believed to be secondary to systemic inflammation. Similar involvement of peripheral arteries is not expected in a disease that affects exclusively the central nervous system, such as Multiple Sclerosis (MS).

**PURPOSE:** The primary purpose of this study was to examine large arterial compliance and small arterial compliance (C1 and C2 respectively) in patients with MS and

compare them to healthy age-matched controls. Our hypothesis is that healthy controls will have more compliant arteries compared to individuals with MS.

**METHODS:** Men and women between the ages of 20 to 39 years, 9 with Relapsing Remitting MS ( $\mu = 34.4 \pm 6.3$  yrs), and 9 healthy, age matched controls ( $\mu = 30.2 \pm 4.4$  yrs) volunteered for this study. Arterial compliance was measured by using Pulse Contour Analysis (PCA), which records and analyzes the blood pressure waveform data from the Arterial PulseWave Sensors.

**RESULTS:** There were no significant differences between the two groups for age, height or weight ( $p > 0.05$ ); however, there were significant differences in C1 and C2 between the groups ( $p < 0.05$ ). The MS group had less arterial compliance of both large (C1) ( $14.8$  vs  $19.9$  ml/mmHg), and small (C2) ( $6.1$  vs  $10.5$  ml/mmHg) arteries compared to healthy controls. Absolute C2 recordings for the young MS group corresponded to values seen in people in the sixth decade of life.

**CONCLUSION:** Arterial compliance is significantly compromised in young individuals with MS, compared to age matched controls, suggesting a systemic effect of an inflammatory process that is believed to be confined to the CNS.

**Wasted Left Ventricular Pressure Energy is Increased In Patients With Refractory Angina**

Alvaro N. Gurovich, Wilmer W. Nichols, Randy W. Braith, FACS. *University of Florida, Gainesville, FL*

Email: algurov@hhp.ufl.edu

(No relationships reported)

Increased myocardial oxygen demand contributes to refractory angina. Afterload plays a key role on myocardial stress and it is directly related to the Tension Time Index (TTI), a marker of myocardial oxygen consumption. TTI depends on cardiac output and reflected pressure waves from the vascular tree. Conduit arterial stiffness, length and diameter, and muscular arterial vasodilation are major factors that determine pressure wave reflection. Left ventricular (LV) wasted pressure energy (Ew) is the portion of TTI curve attributed to amplitude (RWA) and duration (RWD) of wave reflection, and can be interpreted as the excess of energy expended by the LV.

**PURPOSE:** The aim of this study was to determine differences in central hemodynamics, wave reflection characteristics, and Ew between patients with chronic stable angina resistant to anti-anginal therapy and patients with controlled hypertension.

**METHODS:** High-fidelity radial artery pressure waveforms were recorded non-invasively by applanation tonometry and ascending aortic pressure waveforms generated using a mathematical transfer function in 36 patients (age  $65 \pm 9$  yrs) with refractory angina taking two or more anti-anginal drugs (RAP) and 36 treated hypertensive patients (CON) matched for age, sex, height, weight, blood pressure and heart rate. Pulse wave analysis was used to determine arterial properties and wave reflection characteristics and calculation of  $Ew = [(p/4) * (RWA \times RWD) * 1.333]$ .

**RESULTS:** Augmentation index ( $AI_a$ ) ( $27 \pm 9$  vs.  $19 \pm 7\%$ ,  $P < 0.001$ ), reflected wave amplitude ( $15 \pm 8$  vs.  $8 \pm 4$  mmHg,  $P < 0.001$ ) and duration ( $189 \pm 29$  vs.  $165 \pm 22$  ms,  $P < 0.001$ ) were higher in RAP compared to CON. Aortic systolic ( $123 \pm 19$  vs.  $115 \pm 10$  mmHg,  $P < 0.03$ ) and pulse ( $51 \pm 15$  vs.  $40 \pm 10$  mmHg,  $P < 0.01$ ) pressures, and Ew ( $3053 \pm 1878$  vs.  $1457 \pm 896$  dyne\*cm<sup>-2</sup>\*s,  $P < 0.001$ ) were also higher in RAP than CON.

**CONCLUSIONS:** Patients with refractory angina have increased  $AI_a$ , and wave reflection amplitude and duration compared to treated hypertensive patients. This phenomenon causes the LV to expend wasted energy in late systole resulting in an imbalance between myocardial oxygen supply and demand, despite anti-anginal therapy. These results suggest that improved peripheral arterial function could decrease myocardial oxygen demand and refractory angina.

**1609 Board #211 May 27 11:00 AM - 12:30 PM**  
**Validation Of A Novel Wristband Micromanometer Used For Applanation Tonometry**

Darren T. Beck, Alvaro N. Gurovich, Jeffrey S. Martin, Wilmer W. Nichols, Randy W. Braith, FACS. *University of Florida, Gainesville, FL*

Email: dbeck@hhp.ufl.edu

(No relationships reported)

**PURPOSE:** To validate the clinical use of a newly designed wristband micromanometer. Augmentation Index ( $AI_x$ ),  $AI_x$  normalized at 75bpm ( $AI_x@75$ ), and round trip travel time of the reflective waveform ( $Dtp$ ) were compared to measurements produced using the traditional pencil-type micromanometer (Millar Instruments, Houston, Texas).

**METHODS:** Resting pulse wave analysis was measured non-invasively in triplicate using radial artery applanation tonometry in 32 apparently healthy subjects (males  $n = 21$ ; females  $n = 11$ ). Each subject was randomized to testing first with either the novel wristband micromanometer or pencil-type micromanometer.  $AI_x$ ,  $AI_x@75$ , and  $Dtp$  were calculated from aortic pressure waveforms which were synthesized using a generalized transfer function from high fidelity radial pressure waveforms calibrated from standard brachial artery sphygmomanometry. Paired t-tests and Wilcoxon's signed rank test, for non-normally distributed variables, was performed between means and coefficients of variation; at  $\alpha = 0.05$ . Bland-Altman analyses were performed to test for agreement between micromanometers.

Table 1. Means, Coefficients of Variations, and Standard Deviations for all Variables Measured

	Wristband		Pencil Type

Note: \* =  $p < 0.05$ , \*\* =  $p < 0.01$ , paired t-test, † =  $p < 0.01$  Wilcoxon's signed rank test

**RESULTS:** The Bland-Altman analyses show full agreement between micromanometers. The observed minor but statistically significant differences, for only 5 variables, in coefficients of variation and means will have no impact in a clinical or research interpretation model.

**CONCLUSIONS:** Our results show that the novel wristband micromanometer is highly correlated with the traditionally accepted pencil-type micromanometer used to determine  $AI_x$ ,  $AI_x@75$ , and  $Dtp$  in males and females. These data suggest that the wristband micromanometer is a valid and reliable alternative to the pencil type

**The Acute Effects Of Smokeless Tobacco On Central Hemodynamics**

Jeffrey S. Martin, Darren T. Beck, Alvaro N. Gurovich, Randy W. Braith, FACSM. *University of Florida, Gainesville, FL*  
 Email: martin.jef@gmail.com

(No relationships reported)

It has been shown that one time use of smokeless tobacco (ST) in habitual and recreational users increases heart rate, peripheral blood pressures, and circulating plasma levels of epinephrine. These changes suggest there may also be alteration in central hemodynamics and cardiovascular workload.

**PURPOSE:** This study sought to examine the acute effect of a single bout of ST on central hemodynamics.

**METHODS:** Eight apparently healthy male subjects (age =  $31.5 \pm 6.4$  yrs), who were recreational and/or habitual ST users were given a 2.5-gram oral dose of ST after baseline measurements were recorded. ST was held in the lower lip for 30 min while measurements were taken at 10 min intervals. After removal of the ST, measurements continued at 10 min intervals for an additional 30 min. All measurements were obtained in triplicate, non-invasively using radial artery applanation tonometry. Aortic pressure waveforms were synthesized using a generalized transfer function from high fidelity radial pressure waveforms calibrated from standard brachial artery sphygmomanometry.

**RESULTS:**

Values reported as Mean (SE); \* significant difference from baseline ( $p < 0.05$ ); †  $p = 0.071$

B=Brachial, A=Aortic, SP=Systolic Pressure (mmHg), DP=Diastolic Pressure (mmHg), MP=Mean Pressure (mmHg), PP=Pulse Pressure (mmHg), HR=Heart Rate (beats/min), Tr=Travel time of reflected pressure wave (msec), Aix@75=Augmentation Index normalized to 75 beats/min (%), Buckberg=Sub Endocardial Viability Ratio (%), ESP=End Systolic Pressure (mmHg), WLVE=Wasted Left Ventricular Energy (Dynes/cm<sup>2</sup>·min x 10<sup>3</sup>)

**CONCLUSIONS:** One time use of ST results in a transient significant increase in central pressures, HR, Aix@75, and WLVE. Travel time of reflected pressure waves is significantly decreased following ST administration which contributes to elevated central pressures and is reflected by the significant elevations in augmentation index, ESP, and WLVE. The changes in central hemodynamics associated with one time ST use in recreational and habitual users appears to contribute to an increase in cardiac stress.

**Correlates Of Endothelial Function And The Peak Systolic Blood Pressure Response To A Graded Maximal Exercise Test**

Kayla M. Olson<sup>1</sup>, Amanda L. Augeri<sup>1</sup>, Matthew A. Kostek<sup>1</sup>, Gregory J. Tsongalis<sup>2</sup>, Richard L. Seip<sup>3</sup>, Carl M. Maresch, FACSM<sup>1</sup>, Paul D. Thompson, FACSM<sup>3</sup>, Linda S. Pescatello, FACSM<sup>1</sup>. <sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>Dartmouth Hitchcock Medical Center, Lebanon, NH. <sup>3</sup>Hartford Hospital, Hartford, CT.

(No relationships reported)

**PURPOSE:** An elevated systolic blood pressure (SBP) response during maximal exercise may be a predictor of endothelial dysfunction and future hypertension. We examined associations among the peak SBP response to a graded exercise stress test (GEST) and correlates of endothelial function among men ( $n=48$ ,  $43.7 \pm 1.4$  yr) with high BP ( $145.6 \pm 1.5/85.9 \pm 1.1$  mmHg).

**METHODS:** For 20 min prior to the GEST, BP was measured every 2 min in the seated position via auscultation and averaged as baseline BP. Volunteers completed a maximal cardiopulmonary GEST to determine peak oxygen consumption ( $\text{VO}_{2\text{peak}}$ ). Brachial artery reactivity (BAR) was measured 3 and 5 min post-occlusion and expressed as a % change from baseline. Nitric Oxide (NO) was measured via chemiluminescence assay. Plasma glucose concentrations were determined in duplicate by an automated glucose oxidase method. Endothelial nitric oxide synthase genotype (ENOS -786 T>C; rs2070744) (ENOS TT,  $n=24$ ; ENOS TC/CC,  $n=24$ ) was determined by polymerase chain reaction and restriction enzyme digestion. Simple linear and multiple variable regression analyses examined relationships among the change in peak SBP achieved on the GEST and correlates of endothelial function.

**RESULTS:** Linear regression analyses revealed the peak SBP change was positively correlated to blood glucose ( $r^2=0.063$ ,  $p=0.015$ ), age ( $r^2=0.016$ ,  $p=0.024$ ),  $\text{VO}_{2\text{peak}}$  ( $r^2=0.014$ ,  $p=0.037$ ), ENOS -786 T>C ( $r^2=0.051$ ,  $p=0.026$ ), baseline SBP ( $r^2=0.005$ ,  $p=0.084$ ), and baseline NO ( $r^2=0.013$ ,  $p=0.053$ ); and negatively correlated to % BAR change at 3 min post-occlusion ( $r^2=0.104$ ,  $p=0.029$ ). Multiple variable regression analyses indicated that this model explained 26.7% of the peak SBP response to a GEST. Lastly, among carriers of the ENOS C<sup>786</sup> risk allele, the peak SBP change was  $11.1 \pm 5.0$  mmHg higher ENOS TT homozygotes, 92.4 versus 81.3 mmHg, respectively ( $p=0.03$ ).

**CONCLUSIONS:** Surrogate measures of endothelial function appear to explain a clinically significant portion of the peak SBP response to a GEST. Further work is needed to investigate how interactions among clinical and genetic correlates of endothelial function explain the variability in the peak SBP response to a GEST.

**Effects Of A Novel Whey-derived Peptide On Vascular Responses In Healthy Individuals**

Kevin D. Ballard, Richard S. Bruno, Richard L. Seip, Erin E. Quann, Brittanie M. Volk, Daniel J. Freidenreich, Diana M. Kawiecki, William J. Kraemer, FACSM, Jeff S. Volek. *University of Connecticut, Storrs, CT*. (Sponsor: William J. Kraemer, FACSM)  
 Email: kevin.ballard@uconn.edu

(No relationships reported)

**PURPOSE:** Whey protein is a potential source of bioactive peptides. Based on findings from *in vitro* experiments showing a whey derived peptide increased endothelial nitric oxide synthesis, we tested the *in vivo* bioactivity of the peptide on vascular function in healthy humans.

**METHODS:** A randomized, double blind, placebo-controlled, crossover study design was used. Twenty healthy men and women (age  $25 \pm 5$  yr, body mass  $69.8 \pm 9.1$  kg, BMI  $24.3 \pm 2.3$  kg/m<sup>2</sup>) participated in two vascular testing days each preceded by 2 wk of supplementation with 5 g/day of a novel whey-derived peptide (WP) or placebo. There was a 1-2 wk washout period between trials. After two weeks of supplementation, vascular function and circulating biomarkers were assessed in response to a single dose of either WP or

placebo. Macrovascular and microvascular function were assessed using brachial artery flow mediated dilation (FMD) via high-resolution ultrasound and venous occlusion strain gauge plethysmography, respectively.

**RESULTS:** Baseline peak FMD was not different for placebo (7.7%) and WP (7.8%). Placebo intake had no effect on FMD at 30, 60, and 90 min post-ingestion (7.5%, 7.2%, and 7.6%, respectively) whereas WP resulted in a significant increase compared to baseline (8.9%, 9.9%, and 9.0%, respectively) ( $P = 0.000$  for time x trial interaction). Baseline reactive hyperemia forearm blood flow was not different for Placebo ( $27.2 \pm 7.2$  %/min) and WP ( $27.3 \pm 7.6$  %/min). Placebo intake had no effect on reactive hyperemia forearm blood flow measured 120 min post-ingestion ( $27.2 \pm 7.8$  %/min) whereas WP resulted in a significant increase compared to baseline ( $29.9 \pm 7.8$  %/min) ( $P = 0.008$  for time x trial interaction). The insulin response was significantly higher during WP than placebo at 15, 30, and 45 min, but there were no significant differences in glucose, myeloperoxidase, total nitrites/nitrates, and inflammatory responses.

**CONCLUSIONS:** Consistent with cellular work showing components of whey protein have nitric oxide enhancing effects, these findings indicate that supplementation with a novel whey derived peptide in healthy individuals improves vascular function, perhaps by increasing basal NO bioavailability.

**Regular Swimming Exercise And Central Artery Compliance**

Nantinee Nualnim, Jill N. Barnes, Hirofumi Tanaka, FACSM. *University of Texas at Austin, Austin, TX.*

Email: nantinee\_pt@mail.utexas.edu

(No relationships reported)

Swimming is an exercise modality that is highly suitable for health promotion and disease prevention, and is one of the most popular, most practiced, and most recommended forms of physical activity. Yet little information is available concerning the influence of regular swimming on coronary heart disease (CHD).

**PURPOSE:** To determine whether central artery compliance in middle-aged and older swimmers is higher than sedentary controls, but lower than runners.

**METHODS:** Eighty apparently healthy adults (57 men and 23 women) aged 35 to 80 yrs were studied: 20 swimmers (age  $57 \pm 11$  yr), 20 runners ( $58 \pm 10$  yr), and 40 sedentary controls ( $57 \pm 8$  yrs).

**RESULTS:** Groups were not different in age, height, plasma cholesterol, LDL cholesterol, and glucose concentrations. Maximal oxygen consumption (on the treadmill) was higher and body fat percentage (via DEXA) was lower in runners than in sedentary controls (both  $p < 0.05$ ); there were no differences between swimmers and sedentary controls. Central artery compliance (via simultaneous B-mode ultrasound and arterial applanation tonometry on the common carotid artery) was 67% greater ( $p < 0.05$ ) in runners than sedentary controls. There were no significant differences in central artery compliance between swimmers and sedentary controls ( $0.11 \pm 0.05$  vs.  $0.10 \pm 0.03$  mm<sup>2</sup>/mmHg). Systolic blood pressure was higher ( $p < 0.05$ ) in swimmers than in runners and sedentary controls. In the pooled population, central artery compliance was modestly associated with maximal oxygen consumption ( $r = 0.38$ ) and body fat percentage ( $r = -0.26$ ).

**CONCLUSIONS:** We concluded that middle-aged and older swimmers do not exhibit typical central arterial stiffness phenotypes that are often displayed in their running peers.

(No relationships reported)

Cardiovascular disease remains the number one cause of morbidity and mortality in the United States. American football players engage in unique training regimens that may have unfavorable effects on vascular health and subsequently increase risk for future cardiac events. Interior lineman may be especially vulnerable due to high levels of body fat.

**PURPOSE:** To evaluate vascular structure and function in collegiate football players and to determine whether they are associated with traditional cardiovascular risk factors.

**METHODS:** Members of the Wake Forest University football team were recruited to participate in this study. Resting blood pressure and anthropometrics were assessed according to established guidelines. Brachial artery reactivity and carotid artery distensibility were evaluated using high resolution ultrasonography.

**RESULTS:** Thirteen "skill position players" (SP) ( $20 \pm 1.6$  yrs) and thirteen interior lineman (IL) ( $20 \pm 1.0$  yrs) completed all facets of the study. Significant group differences were observed for body weight (SP:  $86.7 \pm 3.1$  kg vs. IL:  $131.2 \pm 13.2$  kg), body fat (SP:  $11.7 \pm 1.8$  % vs. IL:  $24.9 \pm 4.3$  %), BMI (SP:  $26.4 \pm 1.6$  m·kg<sup>-2</sup> vs. IL:  $36.1 \pm 3.6$  m·kg<sup>-2</sup>) and resting systolic blood pressure (SP:  $121 \pm 5$  vs. IL:  $134 \pm 12$ ), (All  $p$ 's  $< 0.01$ ). In addition, carotid distensibility was significantly greater in SP compared to IL ( $p = 0.026$ ). There was no significant difference in brachial artery reactivity between the two groups. Interestingly, resting systolic blood pressure correlated with distensibility ( $r = -0.409$ ,  $p = 0.034$ ) and body fat percentage ( $r = 0.728$ ,  $p = 0.000$ ).

**CONCLUSIONS:** These findings suggest that collegiate interior linemen are at an elevated risk for cardiovascular disease compared to the skill position players based on measures of body fat and resting systolic blood pressure. The significant association between systolic blood pressure and carotid distensibility suggest that alterations in the mechanical properties of the vasculature may be involved in the development of hypertension in this cohort.

**The Impact Of Exercise On Derived Central Measures Obtained From The Sphygmocor Device**

Ellen A. Dawson, Mark A. Black, Jennifer Pybis, N. Timothy Cable, Keith P. George, FACSM, Daniel J. Green. *Liverpool John Moores University, Liverpool, United Kingdom.*

Email: e.dawson@ljmu.ac.uk

(No relationships reported)

**PURPOSE:** To investigate whether measures derived from the SphygmoCor device and its associated transfer function are influenced by exercise-induced alterations in vascular tone. To do this, measurements were taken from either the exercised or the contra-lateral non-exercised limb, during repeated and identical incremental hand-grip protocols.

**METHODS:** Eight male subjects performed 3, 3-minute bouts of handgrip exercise, on two occasions. The exercise intensities were set at 3kg and 5kg, with a final 1.5kg bout performed during cuff ischaemia (1.5Isch). Blood pressure waveforms were recorded from the radial artery of either the exercised or non-exercised limb using applanation tonometry (SphygmoCor) during a 90 s rest period immediately after each exercise bout. Central blood pressures and augmentation indices, an index of arterial stiffness, were derived using the peripheral waveform and the inbuilt SphygmoCor transfer function (TF).

**RESULTS:** Augmentation index (AIx) was consistently ~10% higher in the exercised arm during all trials compared to the non-exercised limb. Similarly, there was a consistent and significant difference (~3 mmHg;  $P < 0.05$ ) between exercised and non-exercised arms for the derived central systolic and mean arterial blood pressures.

**CONCLUSIONS:** Despite similar central haemodynamic responses to the identical bouts of exercise, AI and well as central systolic and mean arterial blood pressures derived from applanation tonometry at the peripheral radial artery were statistically different when assessed at the exercising arm versus the non-exercising arm. Changes in vascular tone with exercise may modify the intrinsic characteristics of the vessel wall and could compromise the assumptions underlying transfer functions used to derive central measures using applanation tonometry.

**Vasodilation Of Vascular Smooth Muscle At Different Temperatures**

Kirk W. Evanson, Audrey J. Stone, Heidi A. Kluess. *University of Arkansas, Fayetteville, AR.* (Sponsor: Charles Riggs, FACS)M)  
(No relationships reported)

**PURPOSE:** To examine the influence of vascular smooth muscle (VSM) on vasodilation during periods of increased temperature.

**METHODS:** Femoral arteries were excised from female, F-344 rats, and cut into two millimeter segments. These segments were mounted in a tissue bath containing modified Krebs-Henseleit buffer at a pH of 7.4. All vessels were stimulated for vasoconstriction using phenylephrine ( $10^{-5}$  M) or potassium chloride (40 mM). This precontraction phase was followed by the endothelium-independent vasodilator, sodium nitroprusside (SNP), which was administered in a series of increasing concentrations ( $10^{-9}$ - $10^{-5}$  M). Following the 37°C condition, the tissue bath temperature was increased to 41°C and allowed to equilibrate for 30 minutes before commencing with the SNP curve.

**RESULTS:** In experiments using phenylephrine as the precontractive stimulus, there were no differences in EC50 or slope between 37°C (EC50:  $-7.71 \pm .44$  log M SNP, slope:  $-1.38 \pm .42$  tension(g)/log M SNP) and 41°C (EC50:  $-7.59 \pm .30$  log M SNP, slope:  $-1.28 \pm .19$  tension(g)/log M SNP). Similarly, there were no EC50 or slope differences in the potassium chloride experiments between 37°C (EC50:  $-7.25 \pm .07$  log M SNP, slope:  $-.80 \pm .00$  tension(g)/log M) and 41°C (EC50:  $-6.90 \pm .14$  log M SNP, slope:  $-.75 \pm .07$  tension(g)/log M SNP).

**CONCLUSION:** These data suggest that VSM-mediated vasodilation is unaffected by increases in temperature.

**Comparison Of Brachial Artery Blood Flow To Total [hemoglobin+myoglobin] Response During Post-occlusive Reactive Hyperemia.**

Christopher M. Bopp, Dana K. Townsend, Thomas J. Barstow, FACS. *Kansas State University, Manhattan, KS.*

Email: cbopp@ksu.edu

(No relationships reported)

The measurement of brachial artery blood flow (BABF) during post-occlusive reactive hyperemia (PORH) demands expertise and requires specialized equipment. Near-infrared spectroscopy (NIRS) is a non-invasive technology that allows for the measurement of total [hemoglobin + myoglobin] (as t[Hb+Mb]) in tissues of interest. Changes in t[Hb+Mb] of the forearm during PORH most likely reflect changes in total tissue hemoglobin, which would arise from changes in skeletal muscle microvascular hematocrit and/or microvascular blood flow. If true, t[Hb+Mb] could be a useful window into skeletal muscle microvascular function in health and disease.

**PURPOSE:** The purpose of this investigation was to explore the temporal relationship between t[Hb+Mb] and BABF during PORH. We hypothesized that the transient changes in brachial artery blood flow during PORH would be detectable in the downstream microvasculature as temporally similar changes in t[Hb+Mb].

**METHODS:** Fourteen healthy subjects of both sexes had concurrent assessment of brachial artery blood flow by Doppler ultrasound, and t[Hb+Mb] responses by NIRS, during post-occlusive reactive hyperemia.

**RESULTS:** The average correlation between these measurements was 0.90 (range 0.697-0.999). Because many of the subjects demonstrated a significant time lag between the peak BABF and the peak t[Hb+Mb] signal, a cross correlation analysis was also run to see if altering the time displacement improved the degree of correlation between these measurements. Cross correlation analysis showed that for 3 subjects there was no lag between the peak amplitudes for both measures. For 9 subjects the BABF values peaked prior to the t[Hb+Mb] signal; average lag time was 4 seconds (range 0.7-9.7 seconds). Two subjects showed BABF peaking after the t[Hb+Mb] signal with an average lag time of -2.4 seconds between the peaks.

**CONCLUSIONS:** These data demonstrate that, in healthy subjects, there is a close temporal association between changes in t[Hb+Mb] and changes in BABF, which suggests that changes in t[Hb+Mb] during PORH may reflect changes in microvascular flow.

**Does Laughter Improve Endothelium-dependent Vasodilatation?**

Takashi Tarumi, Jun Sugawara, Hirofumi Tanaka, FACS. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACS)M)

Email: takatr@gmail.com

(No relationships reported)

The concept that humor or laughter can relieve stress and improve health has been around for more than centuries, and abundant anecdotal evidence supports such concept. However, the scientific evidence supporting the benefits of humor or laughter on various health aspects, particularly vascular function, is lacking.

**PURPOSE:** To determine whether laughter acutely increases endothelium-dependent vasodilatation.

**METHODS:** Using an interventional study design, 10 apparently healthy adults (9 males and 1 female, 23-42 years old) were randomly assigned to watch either 30 minutes of a comedy or a serious documentary to induce emotional stress (e.g., Nazi concentration camp) over 2 consecutive days. Brachial artery flow-mediated dilatation (FMD), an index of endothelium-dependent vasodilatation, was measured via B-mode ultrasound before (baseline), 30 minutes and 24 hours after each viewing session. Laughter was quantified by the analysis of subjects' breathing pattern (via Pneumotrace).

**RESULTS:** Baseline FMD values were not different before comedy and documentary viewing conditions. FMD at 30 minutes after viewing the comedy was 21% greater than the baseline values ( $p < 0.05$ ), and the elevated FMD remained significant ( $p < 0.05$ ) 24 hours after viewing the comedy. In contrast, FMD measured 30 minutes after documentary watching was 18% lower than the baseline values ( $p < 0.05$ ).

**CONCLUSION:** Laughter elicited by viewing a comedy has acute and sustaining favorable influence on endothelium-dependent vasodilatation.

(No relationships reported)

**PURPOSE:** Microparticles (MP) are cell fragments shed from formed elements such as circulating platelets, leukocytes, and vascular endothelial cells. Microparticles of different origin have been shown to play an important role in health and disease. For example, endothelial microparticles (EMP) are associated with endothelial dysfunction. Exercise is commonly used as a non-pharmacologic intervention in the primary and secondary prevention of cardiovascular disease. This study examined the effect of acute exercise on circulating EMPs.

**METHODS:** 10 healthy men ( $21 \pm 3.1$  yrs;  $VO_{2max}$ :  $58.8 \pm 6.6$  ml/kg/min; BMI:  $23.2 \pm 2.1$ ) exercised on a treadmill at 60%  $VO_2$  until they expended 400 kcal. Blood samples were taken before and immediately after the exercise and at 2 h, 4 h and 6 h after the end of the exercise bout. Subjects received a drink containing 400 kcal after the 2 hour blood sample to ensure consistent caloric intake during the 6 h post exercise recovery period. Circulating EMP were analyzed using flow cytometry.

**RESULTS:** Circulating EMPs as measured by flow cytometry using endothelial specific markers were elevated at 6 h post exercise. EMPs were 1.4 fold higher than baseline values, 1.6 fold higher than values immediately post exercise and 1.5 fold higher than values 2 h post exercise at the 6 h time point ( $p < 0.05$ ).

**CONCLUSIONS:** Acute exercise transiently increases EMPs 6 h post exercise in young healthy men. Understanding the cellular/molecular mechanisms by which interaction of exercise and EMP effect endothelial function is important if exercise is to be used in the prevention and treatment of cardiovascular disease.

(No relationships reported)

A tonic increase in muscle sympathetic nerve activity (MSNA) has been associated with advancing age. Whether this tonic increase in efferent sympathetic nerve activity alters non-adrenergic protein expression and the responsiveness of non-adrenergic receptors in resting and contracting skeletal muscles has not been clearly established. Therefore, the purpose of the present study was to investigate the effect of aging on the density and responsiveness of neuropeptide Y - Y<sub>1</sub> (NPY) and purinergic (P2X) receptors in skeletal muscle. Young ( $n = 6$ ;  $22 \pm 3$ ) and old ( $n = 7$ ;  $119 \pm 22$  months) beagles were instrumented chronically with transit-time flow probes on the external iliac arteries and an indwelling catheter in a branch of the femoral artery. On separate days, flow-adjusted doses of selective NPY (Leu<sup>31</sup>-Pro<sup>34</sup> NPY; 1  $\mu\text{g}/\text{ml}/\text{min}$ ) and P2X (a-b-methylene ATP; 1  $\mu\text{g}/\text{ml}/\text{min}$ ) agonists were infused at rest and during treadmill running at 2.5 miles/h and 4 miles/h with 2.5% grade. Hindlimb blood flow (HBF) and mean arterial pressure (MAP) were recorded continuously and vascular conductance (VC) was calculated as HBF/MAP. After dissecting feed arteries from gracilis muscles, NPY and P2X receptor protein content was determined by Western Blot and adjusted for b-actin content. Infusion of NPY resulted in similar ( $p > 0.05$ ) declines in VC in young and old beagles at rest (Young:  $-40 \pm 18\%$ ; Old:  $-39 \pm 23\%$ ) and during exercise at 2.5 miles/h (Young:  $-47 \pm 14\%$ ; Old:  $-40 \pm 15\%$ ) and 4 miles/h with 2.5% grade (Young:  $-40 \pm 8\%$ ; Old:  $-38 \pm 5\%$ ). a-b-methylene ATP infusion also produced similar ( $p > 0.05$ ) decreases in VC in young and old beagles at rest (Young:  $-36 \pm 20\%$ ; Old:  $-40 \pm 10\%$ ) and during exercise at 2.5 miles/h (Young:  $-42 \pm 21\%$ ; Old:  $-40 \pm 23\%$ ) and 4 miles/h with 2.5% grade (Young:  $-47 \pm 12\%$ ; Old:  $-42 \pm 20\%$ ). NPY and P2X receptor protein expression were similar ( $p > 0.05$ ) in young and old beagles. These results demonstrate that the vascular response to selective NPY and P2X receptor agonists does not decline with advancing age. Moreover, the similar receptor protein expression suggests that the tonic increase in efferent MSNA with aging does not alter the density of post-synaptic receptors in canine feed arteries.

**The Impact Of Lower Limb Blood Flow Restriction On Hemodynamics During Low Intensity Aerobic Exercise**

Christopher Renzi, Jun Sugawara, Hirofumi Tanaka, FACSM. The University of Texas at Austin, Austin, TX.

(No relationships reported)

"Kaatsu" (ie, blood flow restricted exercise) is a popular exercise modality in Japan and is spreading widely to the rest of the world. The underlying principle of this training is that under the conditions of restricted muscle blood flow, even low-intensity exercise can induce muscle strength and hypertrophy. One concern, however, is that blood flow restriction (BFR) would increase vascular resistance and could induce increase blood pressure as well as myocardial oxygen demand, which may be harmful for those with compromised cardiac function.

**PURPOSE:** To determine the effects of leg BFR on hemodynamic factors during low intensity aerobic exercise.

**METHODS:** Eight young ( $27 \pm 4$  years) healthy volunteers were studied under parallel conditions on 2 separate days. For each exercise session, the volunteer stood 3 minutes for baseline, followed by five 2 minute walking intervals, with one minute rest between intervals. During the BFR condition, two pneumatic cuffs (inflated to 160mmHg) were placed around the upper thighs. The order of experiments was randomized between the BFR condition and the control (without BFR cuff) condition.

**RESULTS:** Increases in systolic, mean, and diastolic blood pressure were 2- to 3-fold greater in the BFR session compared with the control session. The elevated blood pressure was associated with higher total peripheral resistance in the BFR session. Cardiac output was similar during both exercise sessions, but stroke volume increased less and heart rate increased more during exercise with the BFR cuffs. As a result, double product, an index of myocardial oxygen demand, was more than 2-fold higher during the BFR condition.

**CONCLUSION:** Blood flow restriction induces excessive blood pressure responses during low intensity aerobic exercise through increases in total peripheral resistance and cardiac afterload. These results suggest that "Kaatsu" may need to be more cautiously prescribed to those with compromised cardiac conditions.

**Comparison Of 8 Months Aerobic Versus Resistance Training On Endothelial Function In Apparently Healthy Adults**

Katherine E. LaCoste, Aarti A. Kenjale, Cris A. Slentz, FACSM, Lori A. Bateman, William E. Kraus, FACSM, Jason D. Allen. Duke University Medical Center, Durham, NC. (Sponsor: Michael Welsch, FACSM)

Email: katherine.lacoste@duke.edu

(No relationships reported)

Selye's theory of stress-response-adaptation suggests an exercise stress, when applied to the vascular system, results in an increased delivery of blood flow to active skeletal muscle, and if the stress is repeated over time contributes to a series of vascular adaptations. There is a consensus of studies demonstrating improvements in endothelial function with short term ( $< 12$  weeks) aerobic exercise (AE) training but relatively little data on longer term training effects ( $> 6$  months) and/or resistance training (RT).

**PURPOSE:** To examine the effects of 8 months AE versus RT on brachial artery flow-mediated dilation (BAFMD-a non-invasive measure of endothelial function).

**METHODS:** Thirty-five subjects (26-66yr) were randomly assigned to AE (1200kcal/week, 60-80%  $\text{VO}_{2\text{peak}}$ ,  $n=17$ ) or RT (3 sets/day, 8-12 reps/set of 8 exercises; 3 sessions/wk with progressive wt increase). BAFMD was performed at baseline, post training and following 2 weeks of detraining.

**RESULTS:**

		Base Diam (mm)	Peak Diam (mm)	Dilation (%chg)
AE Group (n=17)	Pre Tx	3.36 $\pm$ 0.12	3.60 $\pm$ 0.12	7.21 $\pm$ 0.73
	Post 8m Tx	3.67 $\pm$ 0.11*	3.91 $\pm$ 0.11*	6.67 $\pm$ 0.74
	Post 2wk DeTx (n=8)	3.78 $\pm$ 0.15**	4.01 $\pm$ 0.15**	6.08 $\pm$ 0.98
RT Group (n=18)	Pre Tx	3.34 $\pm$ 0.17	3.52 $\pm$ 0.17	5.72 $\pm$ 0.52
	Post 8m Tx	3.26 $\pm$ 0.17	3.51 $\pm$ 0.16	7.95 $\pm$ 0.82*
	Post 2wk DeTx (n=10)	3.36 $\pm$ 0.20	3.60 $\pm$ 0.20	7.56 $\pm$ 0.98

Mean $\pm$ SE, \* =  $p < 0.05$  compared to pre Tx, \*\* =  $p < 0.01$  compared to pre Tx.

AE showed increases in immediate hyperemic blood volumes ( $341.93 \pm 27.20$  v  $480.99 \pm 39.17$  ml,  $p < 0.05$ ) but no changes in calculated shear stress.

**CONCLUSION:** AE demonstrated an increase in vessel caliber (structural adaptation) and hyperemic flow possibly commensurate with the ability to meet increased muscle demands during exercise. AE had no changes in endothelial responsiveness (stress response). Alternately RT showed no changes in vessel caliber (structural adaptation), but had increased reactivity (stress response). This may be reflective of the more intermittent nature of the exercise stimulus and relatively lower blood flow demands.

**P2y Receptors Play An Important Role In Skeletal Muscle Blood Flow Regulation In Exercising Swine**

Stefan P. Mortensen<sup>1</sup>, Ylva Hellsten<sup>1</sup>, Steve H. Yang<sup>2</sup>, Harold M. Laughlin, FACSM<sup>2</sup>, Richard M. McAllister<sup>2</sup>. <sup>1</sup>*Copenhagen Muscle Research Centre, Copenhagen, Denmark.* <sup>2</sup>*University of Missouri, Columbia, MO.*

Email: stefan@sport.dk

(No relationships reported)

Skeletal muscle blood flow is closely regulated to match O<sub>2</sub> delivery to the metabolic demand, but the precise mechanisms involved in this regulation remain unclear. Plasma nucleotides (ATP, UTP, ADP and UDP) could play an important role in skeletal muscle blood flow regulation by activating endothelial P2Y receptors.

**PURPOSE:** To investigate the role of P2Y receptors in skeletal muscle blood flow regulation.

**METHODS:** Regional blood flow and systemic hemodynamics were measured before and after arterial infusion of Reactive Blue 2 (RB2; P2Y antagonist; 1.0 and 3.0 mg/kg) in exercising (5.2km/h) female Yucatan miniature swine (~30kg).

**RESULTS:** Mean blood flow during exercise from the 16 sampled skeletal muscle tissues was 137±39 ml/min/100g (mean±SE), and it was reduced by 17 and 28% when RB2 was infused at the low and high dose, respectively ( $P<0.05$ ). The reduced skeletal muscle blood flow with RB2 infusion was paralleled by an increase in arterial lactate concentration from 1.6±0.5 to 3.4±0.6 (low dose) and 3.9±1 (high dose) mmol/L ( $P<0.05$ ). Infusion of RB2 did not alter arterial blood pressure or visceral blood flow.

**CONCLUSIONS:** These results indicate that P2Y receptors play an important role in regulating skeletal muscle blood flow during exercise.

**Relationship Between Endothelial Function And Oxidative Damage In Hypercholesterolemic Pigs**

Arturo A. Arce-Esquivel<sup>1</sup>, Sean C. Newcomer<sup>2</sup>, James R. Turk<sup>1</sup>, M. Harold Laughlin, FACSM<sup>1</sup>. <sup>1</sup>*University of Missouri, Columbia, MO.* <sup>2</sup>*Purdue University, West Lafayette, IN.*

(No relationships reported)

Increased levels of oxidative stress are known to impair endothelium-dependent dilation, promoting endothelial dysfunction and leading to the development of cardiovascular disease.

**PURPOSE:** To characterize the relationship between endothelial function and oxidative stress status in a hereditary hypercholesterolemic (HH) swine model.

**METHODS:** Sixteen adult pigs were randomly assigned into either exercise trained (EX) or sedentary groups (SED). Exercise training consisted of 16 weeks of treadmill running. Upon sacrifice brachial (BR) and femoral (FEM) arteries were harvested. In vitro assessment of endothelium-dependent dilation (EDD) was determined by administering increasing doses of acetylcholine to BR and FEM rings. Oxidative damage was quantified by immunohistochemistry using macrophage scavenger receptor A (SRA), adipophilin, and nitrotyrosine antibodies.

**RESULTS:** Endurance exercise training increased EDD in both the BR and FEM. The average percentage for SRA, Adipophilin, and Nitrotyrosine were not significantly different between EX and SED swine in the BR and FEM arteries. Interestingly, significant relationships were found between the BR and FEM-EDD and two of the antibodies, SRA and Adipophilin.

**CONCLUSIONS:** These findings demonstrate that EX increases EDD in the BR and FEM arteries, but did not alter markers of inflammation (SRA) or oxidant stress in arteries of HH swine.

Supported by NIH HL36088 and HL52940.

**Physical Training Attenuates Ischemic Pressor Response In Swine With Bilateral Femoral Artery Occlusion**

Hsiao Tung Yang, Douglas K. Bowles, FACSM, Harold M. Laughlin, FACSM, Ronald L. Terjung, FACSM. *University of Missouri, Columbia, MO.*

Email: yangh@missouri.edu

(No relationships reported)

Patients with intermittent claudication exhibit elevated systemic blood pressure (BP) during increased physical activity. The increased BP is likely due to the perception of pain and the ischemic pressor response that trigger greater sympathetic nerve activation that exacerbates an increase in peripheral resistance.

**PURPOSE:** To determine whether physical training could alleviate this pressor response in a swine model of peripheral arterial insufficiency. **METHOD:** Yucatan male pigs received bilateral femoral artery occlusion and placement of flow probes on both iliac arteries and the left distal femoral arteries. BP was monitored through a catheter in the thoracic aorta. Pigs were either limited to cage activity (Sed) or walked about 30 min/d (3 mph) on treadmill for 8wks (Tr). Blood flows (BFs) and BP response to a progressive treadmill stress test (1,2,3,4, & 5 mph) were performed twice/wk.

**RESULTS:** Treadmill exercise for 8 wks greatly reduced peak BP responses during the stress test (Sed/Tr group: @ wk1:159±3/ 142±1, @wk8:148±11/101±13 mmHg). BFs through the iliac arteries of the Tr pigs increased just as much as measured in the arteries of the Sed pigs, even though systemic perfusion pressure was ~25% lower. Angiograph showed similar collateral vessel growth over this relatively short period of training.

**CONCLUSION:** Our data demonstrate that exercise training helps mitigate the pressor response observed in animals with peripheral arterial insufficiency during increased activity. If our results are applicable to humans, then chronic exercise programs provide yet another benefit to patients with peripheral arterial insufficiency that should help reduce their risk of cardiovascular accidents.

**Differential Effects Of Exercise Training On Endothelial Phenotype In Porcine Conduit Arteries and Veins.**

M. Harold Laughlin, FACSM, Sean Newcomer, Shawn B. Bender, Arturo Arce, Richard M. McAllister. *Univ. of Missouri Health Activity Ctr., Columbia, MO.*

Email: LaughlinM@missouri.edu

(No relationships reported)

**PURPOSE:** We previously reported (*J Appl Physiol* 90:501, 2001) that exercise training (EX) produced differential effects on expression of endothelial nitric oxide synthase (eNOS) and superoxide dismutase (SOD) protein in different sized coronary arteries. This study tested the hypothesis that EX produces similar increases eNOS and SOD expression in endothelial

cells (EC) of conduit arteries and veins of the porcine systemic vascular tree.

**METHODS:** Aorta and vena cava (thoracic and abdominal portions), brachial, femoral, and renal arteries & veins, carotid artery and jugular vein were isolated from 3 EX and 3 sedentary (SED) pigs and EC were scraped from each artery & vein providing 12 EC samples/pig. Samples were processed for immunoblot analysis with gels loaded with equal numbers of SED and EX samples of each artery & vein for analysis of expression levels of eNOS, and SOD-1-3.

**RESULTS:** Results reveal that eNOS expression was increased by EX only in the aorta, but decreased in the carotid artery and renal vein. Aortic ECs contained the greatest amount of eNOS of any artery or vein studied. EX decreased SOD-1 content in the aorta but did not alter SOD-1 expression in any other artery or vein. SOD-3 (ecSOD) content was not changed in any vessel except for a decrease in brachial vein and in renal artery and vein.

**CONCLUSIONS:** These results indicate that EX-induced changes in EC phenotype are different among conduit arteries & veins of the systemic circulation. Combined with previous results the results indicate that EX induces differential effects on arteries and vein's throughout the vascular tree.

**The Effect Of Resistance Training On Vascular Function And Central Blood Pressure In African American Men**

Kevin S. Heffernan, Christopher A. Fahs, Gary A. Iwamoto, Sae Young Jae, Kenneth R. Wilund, Jeffrey A. Woods, FACSM, Bo Femhall, FACSM.

*University of Illinois at Urbana Champaign, Champaign, IL.*

Email: kheffer2@uiuc.edu

(No relationships reported)

**PURPOSE:** Young African American men have stiffer large central arteries, impaired dilation of smaller peripheral arteries and greater central blood pressure (BP) when compared to their white peers. The purpose of this study was to examine the effect of resistance exercise training (RT) on vascular function and central BP in young (age 22 yrs) African American and white men.

**METHODS:** Vascular and hemodynamic measures were made in 19 African American and 18 white men at baseline and following 6-weeks of RT. Carotid BP and carotid artery beta-stiffness were measured by tonometry and ultrasonography respectively. Aortic BP and augmentation index (AIx) were measured by radial artery tonometry and a generalized transfer function. Aortic and brachial stiffness were measured by pulse wave velocity (PWV). Brachial blood flow was assessed by Doppler ultrasonography. Forearm blood flow was measured by strain-gauge plethysmography at rest and during reactive hyperemia (RH) induced by 5-min of upper arm occlusion.

**RESULTS:** There were similar reductions in aortic systolic BP, carotid systolic BP, forearm vascular resistance and brachial vascular resistance in both African American and white men following training ( $p < 0.05$ ). There were similar increases in peak forearm blood flow and forearm blood flow area under the curve measured during RH in both African American and white men following training ( $p < 0.05$ ). There were no changes in brachial systolic BP, carotid stiffness, aortic AIx, aortic PWV, and brachial PWV in either group ( $p > 0.05$ ).

**CONCLUSIONS:** RT reduced central BP while having no effect on brachial BP in young African American and white men. Resistance exercise training appears to be a useful lifestyle intervention for improving peripheral vascular function while not detrimentally affecting central vascular function in young African American men.

**Long-term Effects of Lifestyle Modification on Cardiovascular Function and Subsequent Drug Treatment in High-risk Individuals**

Kunihiko Aizawa, J Kevin Shoemaker, FACSM, Tom J. Overend, Robert J. Petrella, FACSM. *The University of Western Ontario, London, ON, Canada.*

Email: kuninosuke@gmail.com

(No relationships reported)

**PURPOSE:** To assess 1) the long-term effects of lifestyle modification, and 2) the effects of an angiotensin receptor blocker (telmisartan) on central artery stiffness and endothelial function in people at increased risk for cardiovascular disease (CVD).

**METHODS:** This is a follow-up study of the SNAC (Staged Nutrition and Activity Counseling) study that originally examined the effects of lifestyle modification prescribed by family physicians on cardiovascular structures and function in people at increased risk for CVD. Twenty-four subjects ( $58.5 \pm 8.4$  yrs, 12F) were assessed following (mean of 26.3 months) discontinuation of the 1-year SNAC study. Carotid artery stiffness and flow-mediated dilation (FMD) of the brachial artery were assessed by Doppler ultrasound. Components of the metabolic syndrome (MS) [triglycerides (TG), high-density lipoprotein cholesterol, blood pressure (BP), fasting glucose (FG), and waist circumference] and exercise capacity ( $\text{VO}_2\text{max}$  by treadmill test) were also assessed. Subsequently, 17 subjects ( $58.0 \pm 7.9$  yrs, 7F) were reassessed following the 24-week telmisartan treatment.

**RESULTS:** The reduction in carotid artery stiffness observed at 1-year was still maintained at the time of follow-up, whereas the improved FMD at 1-year returned to the pre-intervention level ( $p < 0.05$ ). Similarly, the reductions in TG and FG seen at 1-year were maintained at the time of follow-up ( $p < 0.05$ ). Following the 24-week telmisartan treatment, carotid artery stiffness and FMD significantly improved even after adjusting for confounders. While BP was significantly reduced (DSBP  $13.6 \pm 16.3$  mmHg, DDBP  $7.9 \pm 5.6$  mmHg,  $p < 0.05$ ), other MS components and  $\text{VO}_2\text{max}$  remained unchanged throughout the drug treatment.

**CONCLUSIONS:** These results show that 1) our lifestyle modification strategy can maintain a reduction in carotid artery stiffness as well as TG and FG even after the active intervention, and 2) the telmisartan treatment may be another option to reduce carotid artery stiffness and improve endothelial function in this population. Future study will answer whether the reduction in central artery stiffness would lead to a reduction in the occurrence of CVD.

Supported by a grant from Lawson Health Research Institute.

**Effects Of Combined Exercise With Ace-i On Blood Pressor Responsivity And Plasma Volume In Shr**

Masato Suzuki, Daisuke Shindo, Yuka Nagashima. *The jikeikai Univ., Tokyo, Japan.*

(No relationships reported)

**PURPOSE:** The present study investigated the effects of a single treatment with exercise and combination treatment with exercise and an antihypertensive drug, angiotensin converting enzyme inhibitor captopril (ACE-I, Capt), on blood pressor responsivity and circulating plasma volume (CPV) in SHR as a model of human essential hypertension.

**METHODS:** Sixty-two male SHR and twelve normotensive WKY rats were used in this study. SHR rats were assigned to exercise, Capt, or combined exercise with Capt, and sedentary control groups. WKY rats were also assigned to an exercise group or a sedentary control group. Voluntary exercise was performed daily using a rotatory wheel from 7 to 23 weeks of age. Approximately 20 mg/kg/day of Capt was given dissolved in tap water. Both exercise and the administration of Capt were conducted daily in the combination treatment group. Body weight and blood pressure (BP) were measured during treatment. Blood pressor responsivity and CPV were examined before and after treatment. In anesthetized animals, blood pressor responsivity (BPR) test was performed by monitoring the responses of arterial pressure via a transducer inserted into the left carotid, while pressor agents, phenylephrine and angiotensin II, were infused into the left jugular vein. CPV was determined by dilution of  $^{131}\text{I}$ -RISA, according to the method described by Trippodo et al.

**RESULTS:** While the increase in BP with aging in SHR was inhibited by combination treatment, it was not inhibited by exercise alone. Further, even in WKY rats, exercise alone did not inhibit the increase in BP with aging. The present BPR test showed that responsiveness to pressor agents accelerated with aging, and voluntary exercise had no

effects on blood pressor responsivity in either SHR or WKY rats. Furthermore, Capt attenuated responsiveness to pressor agents in SHR with and without exercise. Further, neither age, nor voluntary exercise produced any effects on CPV in either SHR or WKY rats.

**CONCLUSION:** The single treatment with exercise could not lower increased BP, and did not produce any effects on blood pressor responsivity and CPV with aging in both SHR and WKY rats. On the contrary, the combination treatment inhibited increases in BP and pressor responsivity, without any effects on CPV.

**Influences Of Dehydration On The Sympathetic Nervous System In Humans: Role Of Angiotensin**

Jennifer Rabbitts, Emma Hart, Niki Dietz, Timothy Curry, Nisha Charkoudian. *Mayo Clinic, Rochester, MN.*

Email: rabbitts.jennifer@mayo.edu

(No relationships reported)

Exercise induced dehydration increases incidence of blood pressure (BP) dysfunction, particularly orthostatic hypotension and syncope, impairing performance. Dehydration (DEH) affects the sympathetic nervous system (SNS) and volume regulating hormones, e.g. angiotensin II (ang II). Animal data suggests these hormones have a mechanistic role in the effects of DEH on the SNS. Since the SNS is key to baroreflex control of BP, mechanisms underlying the changes in the SNS during DEH in humans are key to understanding this dysfunction.

**PURPOSE:** To determine the effects of DEH on the SNS and to determine whether ang II has a mechanistic role in these changes.

Hypothesis: (1) Muscle sympathetic nerve activity (MSNA) and baroreflex control of MSNA are increased during DEH (vs euhydration[EUH]); (2) Blockade of ang II receptors with Losartan reverses these changes.

**METHODS:** 15 subjects were studied on 2 separate study days, during EUH and DEH by 24 hour fluid restriction. MSNA was recorded by microneurography at the peroneal nerve. Blood samples were obtained and MSNA, BP, electrocardiogram, and central venous pressure (CVP) were recorded continuously. Pharmacologic tests of the baroreflex were performed. Losartan was then administered and measurements were repeated. MSNA and baroreflex sensitivity were compared between DEH and EUH as well as between pre-Losartan and post-Losartan measurements.

**RESULTS:** Blood tests were consistent with mild to moderate dehydration (increased Hct, osmolality, renin activity and arginine vasopressin). CVP was lower during DEH ( $2.8 \pm 3.0$  vs  $5.3 \pm 3.1$  mmHg,  $p=0.05$  vs EUH). MSNA showed a strong trend to be higher during DEH (burst incidence and burst frequency of  $43.1 \pm 19.4$  and  $25.5 \pm 11.0$  respectively during DEH vs  $34.6 \pm 15.9$  and  $20.2 \pm 8.4$  during EUH) ( $p=0.07$  for BI and BF). The baroreflex was not consistently more responsive in the dehydrated state. Losartan did not influence any of these variables.

**CONCLUSIONS:** Sympathetic neural mechanisms appear to contribute to maintenance of BP in the dehydrated condition by increasing tonic firing rate of sympathetic vasoconstrictor nerves. Potential interactions between neural mechanisms and hormones other than ang II during dehydration in humans require further study.

**Obesity Is Associated With Increased Blood Pressure And Decreased Vascular Function In Firefighters**

Lindy Rossow<sup>1</sup>, Sushant Ranadive<sup>1</sup>, Christopher Fahs<sup>1</sup>, Stamatis Agiovlasis<sup>1</sup>, George Echols<sup>1</sup>, Gavin Horn<sup>1</sup>, Denise Smith<sup>2</sup>, Kevin Heffernan<sup>1</sup>, Bo Fernhall, FACSM<sup>1</sup>. <sup>1</sup>University of Illinois at Urbana-Champaign, Champaign, IL. <sup>2</sup>Skidmore College, Saratoga Springs, NY.

Email: lrossow@illinois.edu

(No relationships reported)

Acute myocardial infarction is the most common cause of death in firefighters (FFs) during firefighting. Obesity is associated with cardiovascular health problems including vascular dysfunction. This association is of particular concern in FFs as cardiovascular stress intensifies during firefighting due to smoke exposure, physical exertion, and heat stress.

**PURPOSE:** To determine the impact of obesity on BP and vascular function in FFs.

**METHODS:** 110 young (mean age=29.7 yrs), current FFs were classified for obesity and overweight according to WHO BMI criteria (lean 18.5-24.9; overweight 25.0-29.9; obese >30.0), and underwent assessments of aortic pulse wave velocity (aPWV), carotid beta stiffness (cb), carotid intima media thickness (cIMT), brachial blood pressure (BP), aortic blood pressure (aBP), carotid blood pressure (cBP), conduit artery (brachial) flow mediated dilation (bFMD) and microvascular function (peak forearm blood flow following reactive hyperemia (RH)).

**RESULTS:** Obese FFs had increased BP, aBP and cBP, increased arterial stiffness of both the aorta and carotid artery and increased carotid IMT compared to lean FFs ( $p<0.05$ ). Indices of conduit artery and microvascular endothelial function were not different between groups.

Table 1. Mean (SD)

Variable	Lean (n= 28)	Overweight (n=50)	Obese (n=32)
BMI (kg/m <sup>2</sup> )	23.0 (1.7)	27.7 (1.4)	33.3 (3.1)
aPWV (m/s) * # +	5.8 (0.9)	6.3 (1.0)	6.9 (0.8)
cβ # +	4.48 (1.16)	5.10 (1.38)	6.32 (2.52)
cIMT (mm) # +	0.44 (0.08)	0.46 (0.07)	0.53 (0.11)
SBP / DBP (mmHg) # +	122 (9) / 67 (7)	126 (8) / 69 (8)	130 (10) / 75 (11)
aSBP / aDPB (mmHg) # +	103 (11) / 68 (7)	106 (9) / 70 (8)	111 (11) / 76 (11)
cSBP / cDPB (mmHg) # +	114 (10) / 67 (7)	115 (9) / 69 (8)	120 (9) / 75 (11)
bFMD (%)	6.47 (3.14)	7.23 (3.83)	7.22 (4.34)
Peak RH (ml/100 ml tissue/min)	28.52 (8.34)	31.21 (7.92)	29.93 (8.20)

\* lean different from overweight; + overweight different from obese; # lean different from obese

**CONCLUSION:** At a relatively young age, obese FFs show increased central and peripheral BP, cIMT, and arterial stiffness, showing increased cardiovascular risk, while maintaining normal conduit artery and microvascular endothelial function. These data suggest that obesity is detrimental to vascular health in FFs and may increase the risk for acute events during firefighting.

**Vascular Function Changes Following An Acute Bout Of Resistance Exercise In Obese And Non-obese Males**

R Lee Franco, Ronald K. Evans, Laura K. Welch. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: Edmund Acevedo, FACSM)

Email: franco1@vcu.edu

(No relationships reported)

One of the earliest sub-clinical stages associated with atherosclerosis is endothelial dysfunction, which has been shown to predict future cardiovascular events. Chronic exercise is thought to improve vascular function (VF); however, few studies have evaluated the effects of acute resistance exercise (RE) on VF. In addition, there are no studies to date that have compared VF responses in obese and non-obese individuals following acute RE.

**PURPOSE:** The purpose of this study was to evaluate VF, as determined by the assessment of forearm blood flow (FBF) and vascular reactivity (VR) before and after a single bout of RE in obese and non-obese males.

**METHODS:** Seven non-obese ( $21.4 \pm 2.1$  yrs;  $22.5 \pm 1.2$  kg/m<sup>2</sup>) and seven obese ( $23.8 \pm 2.9$  yrs;  $36.3 \pm 2.4$  kg/m<sup>2</sup>) males volunteered to participate. FBF was assessed prior to (PRE) and immediately after (POST) 3 sets of arm curls to fatigue (70% of 1-RM) using strain-gauge plethysmography before and after 5 min of upper arm occlusion and subsequent reactive hyperemia. Total excess flow, calculated as the difference between baseline FBF and FBF during reactive hyperemia, was used as an indicator of VR. A One-Way ANOVA was performed to determine differences within each group. A multivariate ANOVA was used to test between-subject factors.

**RESULTS:** In non-obese males, FBF was significantly increased in response to reactive hyperemia during the PRE ( $P = 0.021$ ) and POST ( $P = 0.007$ ) trials. However, this increase was not observed in obese males (PRE,  $P = 0.147$ ; POST,  $P = 0.341$ ). There was no significant difference observed in VR for both non-obese and obese males PRE and POST. Between-subject analysis revealed that only POST FBF ( $\text{ml } 100 \text{ ml}^{-1} \cdot \text{s}$ ) was significantly different between non-obese and obese subjects at baseline ( $1782.7 \pm 169.6$  vs.  $1272.1 \pm 92.6$ ,  $P = 0.021$ ) and during reactive hyperemia ( $2796.4 \pm 265.8$  vs.  $1503.5 \pm 214.4$ ,  $P = 0.003$ ). Additionally, a significant difference in VR was observed between non-obese and obese males POST ( $1013.7 \pm 208.5$  vs.  $231.4 \pm 220.4$ ,  $P = .024$ ).

**CONCLUSIONS:** VR was increased during reactive hyperemia following a single bout of RE in non-obese, but not obese males. The different responses suggest that adiposity may have a detrimental effect on VF during acute exercise. Future studies that investigate the effects of obesity on cardiovascular health are warranted.

**Adjusting Flow-mediated Dilation For Shear Stress Allows Detection Of Endothelial Dysfunction In A Moderate-risk Population**

Jaume Padilla<sup>1</sup>, Blair D. Johnson<sup>1</sup>, Sean C. Newcomer<sup>2</sup>, Daniel P. Wilhite<sup>1</sup>, Mickleborough D. Timothy, FACSM<sup>1</sup>, Fly D. Alyce<sup>1</sup>, Kieren J. Mather<sup>3</sup>, Janet P. Wallace, FACSM<sup>1</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Purdue University, West Lafayette, IN. <sup>3</sup>Indiana University, Indianapolis, IN.  
Email: jpadilla@indiana.edu

(No relationships reported)

Although normalization of brachial artery flow-mediated dilation (FMD) to individual shear stress (FMD:shear stress ratio) has been proposed to improve this measure of endothelial function, the clinical utility of FMD normalization has not yet been demonstrated.

**PURPOSE:** We tested whether 1) FMD:shear stress ratio would discriminate a population with moderate cardiovascular risk (MR) from a low risk (LR) population; and 2) dose-response profile (slope and y-intercept) relating shear stress to FMD would be different between both populations.

**METHODS:** Five different magnitudes of reactive hyperemia-induced shear stress were applied in a randomized order to 20 MR and 20 LR subjects by manipulating forearm cuff occlusion duration (1, 2, 3, 4, and 5 min). Brachial artery diameters and velocities were measured via high-resolution ultrasound. To quantify the hyperemic stimulus, shear stress area under the curve was individually calculated for the duration to peak dilation.

**RESULTS:** Following 5-min of forearm occlusion, FMD:shear stress ratio ( $p=0.041$ ), but not FMD ( $p=0.286$ ), discriminated MR from LR. The slope of shear stress-FMD regression line was lower in MR compared to the LR ( $p<0.001$ ).

**CONCLUSIONS:** FMD:shear stress ratio distinguishes endothelial dysfunction in a population with MR; and dose-response profile of shear stress-FMD relationship differs between populations of distinct cardiovascular risk.

**Normalization Of Flow Mediated Dilation To Time-to-Peak Improves Measurement Sensitivity**

Blair D. Johnson, Jaume Padilla, Janet P. Wallace, FACSM. Indiana University, Bloomington, IN.  
Email: bj33@indiana.edu

(No relationships reported)

Background: Brachial artery flow-mediated dilation (FMD) has become a popular clinical measure of endothelial function. The ability of the traditional FMD procedure to detect differences between groups with apparently different arterial health remains inconclusive. Time-to-peak dilation (TTP) was introduced as a method able to detect differences between young and old individuals. Although TTP is a simple method, it may not assess nitric oxide (NO) production, which is the concept behind the traditional FMD. TTP may only be assessing the responsiveness of the endothelial and smooth muscle cells to NO. Because a large FMD is reflective of increased NO production and a short TTP is reflective of vascular responsiveness, the FMD/TTP ratio may increase FMD sensitivity in the clinical setting.

**PURPOSE:** To test the hypothesis that subjects with low cardiovascular disease risk (LR) would have a greater FMD/TTP ratio than subjects with moderate cardiovascular disease risk (MR).

**METHODS:** Subjects were categorized as LR ( $n=20$ , age= $23.3 \pm 0.6$  yrs) or MR ( $n=20$ , age= $55.9 \pm 1.9$  yrs) for cardiovascular disease by ACSM guidelines. Subjects were tested using current FMD guidelines. Continuous brachial artery diameters were obtained using high-resolution ultrasound for 1min prior to cuff occlusion and for 2min post occlusion. Edge-detection software was used to analyze brachial artery diameter. An independent sample t-test was used to determine differences in FMD and FMD/TTP ratio between groups with  $p < 0.05$ .

**RESULTS:** There were no differences between LR FMD ( $6.67 \pm 3.0\%$ ) and MR FMD ( $5.63 \pm 3.1\%$ ) ( $p = 0.29$ ). The TTP was significantly different between the LR ( $40.65 \pm 15.2$  s) and the MR ( $53.70 \pm 22.5$  s) groups ( $p = 0.04$ ). When the FMD/TTP ratio was compared, LR ( $0.18 \pm 0.08$ ) had a higher ratio than MR ( $0.13 \pm 0.08$ ) ( $p = 0.04$ ).

**CONCLUSION:** The FMD/TTP ratio may provide a more sensitive clinical marker of endothelial function when compared to traditional FMD. The FMD/TTP ratio may also offer a better perspective on overall conduit artery function when compared to TTP because it accounts for not only the change in arterial dilation but also the TTP (vascular responsiveness).

**As A Bioassay, Should Flow-mediated Dilation Be Measured In Triplicate?**

Ryan A. Harris<sup>1</sup>, Vince Tedjasaputra<sup>1</sup>, D Walter Wray<sup>2</sup>, Russell S. Richardson<sup>2</sup>. <sup>1</sup>University of California, San Diego, La Jolla, CA. <sup>2</sup>University of Utah, Salt Lake City, UT.  
Email: harrisra@ucsd.edu

(No relationships reported)

The flow-mediated dilation (FMD) test is considered by many to be a functional bioassay of NO bioavailability and endothelial function. Typically, bioassays are measured in duplicate or triplicate which allows for removal of outlying values and subsequent data averaging; however, only a single FMD measurement has traditionally been performed. Although there have been multiple studies evaluating the reproducibility of FMD, concern regarding the reliability of this ultrasonic assessment still exists reflected by its absence in the clinical environment.

**PURPOSE:** This study sought to evaluate the impact of applying the typical assay approach of triplicate measurements to reduce variance in FMD, with the ultimate goal of improving both statistical power in research and clinical relevance.

**METHODS:** Eight, young, apparently healthy, college aged males (ages  $23 \pm 1$  years; BMI  $23 \pm 1$  kg/ht<sup>2</sup>) participated in this investigation. On three separate days, FMD was assessed following 5 minutes of forearm ischemia and the single outlier was removed (triplicate approach). Reproducibility of FMD was assessed by coefficient of variation (CV %) and intra-class correlation coefficient (ICC).

**RESULTS:** The initial FMD performed on all subjects (single measurement) revealed an FMD of  $5.4 \pm 0.6$ , which was not statistically different ( $p=.532$ ) from the averaged FMD data utilizing the triplicate approach ( $6.4 \pm 1.3$ ). The mean  $\pm$  SEM CV % for the single FMD assessment was  $34.9 \pm 8.6\%$  and the intra-class correlation coefficient (ICC) was 0.63;  $p=0.07$ . With the triplicate approach the FMD CV % was greatly reduced to  $6.8 \pm 4.3$  while the ICC improved significantly to 0.975;  $p<0.001$ .

**CONCLUSION:** Considering the continued skepticism regarding the robust nature of FMD testing, the results of the present study advocates a triplicate approach when assessing FMD which significantly improves reliability, but does not alter the group mean response. With the previously documented efficacy of 30 minutes between FMD measurements without a carry over effect, and the possibility that the time between measurements can be further reduced, the triplicate approach for FMD can improve the statistical power and may even be suitable for clinical use.

**Normalizing Flow-mediated Dilation For Shear Rate Unveils The Vascular Effect Of A Nutritional Intervention.**

Melissa A. Hayman<sup>1</sup>, John McDaniel<sup>2</sup>, Anette S. Fjeldstad<sup>1</sup>, Stephen J. Ives<sup>1</sup>, Eldon W. Askew<sup>1</sup>, Danielle Bennett<sup>1</sup>, Russell S. Richardson<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>VA Medical Center, Salt Lake City, UT.

Email: melissa.hayman@utah.edu

(No relationships reported)

Endothelium-dependant flow mediated dilation (FMD) of the brachial artery is a frequently used, noninvasive measurement that provides an index of vascular function. However, there is currently uncertainty as to whether the measured FMD should be normalized for the invoked shear stimulus.

**PURPOSE:** This study sought to determine the impact of controlling for shear rate on the FMD response following a relatively high fat nutritional intervention likely to have simultaneous effects upon hyperemia and oxidative stress.

**METHODS:** Thirteen healthy males ( $31.7 \pm 6.0$  yrs) participated in two brachial artery FMD trials before (PRE) and after (POST) ingestion of a 12 ounces of cooked beef. Vessel diameter, blood velocity, and calculated shear rate were determined with ultrasound Doppler following 5 minutes of suprasystolic cuff occlusion of the brachial artery. Differences between PRE and POST measurements were made using paired-samples t-tests.

**RESULTS:** FMD when traditionally expressed as % dilation revealed no difference between PRE FMD ( $10.0 \pm 4.0\%$ ) and POST FMD ( $7.6 \pm 4.9\%$ ). However, when FMD was normalized mathematically to shear rate, POST FMD was significantly reduced compared to the PRE FMD (PRE:  $4.8 \times 10^{-4} \pm 2.3 \times 10^{-4} \% \text{D/s}^{-1}\text{s}$ ; POST:  $3.2 \times 10^{-4} \pm 2.2 \times 10^{-4} \% \text{D/s}^{-1}\text{s}$ ;  $p<0.01$ ).

**CONCLUSION:** Vascular function was significantly reduced following a beef meal (POST) when compared with baseline (PRE) values only when normalized for shear rate. These data reinforce the importance of assessing and normalizing brachial artery FMD for shear rate. Without normalizing FMD for shear rate in the present study, a post-prandial attenuation in FMD following ingestion of the beef meal would not have been unveiled.

**Induced Inflammation Impairs Endothelial Function In Healthy Individuals**

Christopher A. Fahs, Sae-Young Jae, Kevin S. Heffernan, Lindy Rossow, Victoria J. Vieira, Jeffrey A. Woods, Bo Fernhall, FACSM. University of Illinois at Champaign-Urbana, Urbana-Champaign, IL.

Email: CFahs225@yahoo.com

(No relationships reported)

Acute systemic inflammation transiently increases the risk of cardiovascular events, but the mechanism is not clear. Impaired dilation of the brachial artery in response to shear stress is an indication of endothelial dysfunction and has been linked to chronic low grade inflammation in cross-sectional studies. Impaired endothelial function may be the link between inflammation and CVD, but there is a lack of experimental evidence to confirm this hypothesis.

**PURPOSE:** The purpose of this study was to examine the change in endothelial function after induced inflammation in healthy individuals.

**METHODS:** Sixteen ( $25 \pm 9$  yrs; BMI:  $24.6 \pm 3.0$ ) men ( $n=8$ ) and women ( $n=8$ ) volunteered for this study. In a randomized, cross-over design, participants received either a sham placebo shot (Sham) or influenza vaccination (Flu). There was a one-week washout period between the trials. Flow mediated vasodilation (FMD) and C-reactive protein (CRP) were assessed 24-hours before (Pre) and 24- (24-Post) and 48-hours (48-Post) after each treatment condition. CRP data were log transformed and FMD was calculated as the percent increase in brachial artery diameter above baseline (%). Data were analyzed with 2x3 (condition x time) ANOVA.

**RESULTS:** There were significant interactions ( $p<0.05$ ) for changes in both CRP and FMD.

**CONCLUSIONS:** The influenza vaccination increased CRP confirming an acute inflammatory response. Endothelial function decreased following the vaccination, but this decrease occurred before significant changes in circulating levels of CRP. This finding supports the link between inflammation and endothelial dysfunction and indicates that endothelial dysfunction may precede increases in systemic biomarkers of inflammation.

**Acute Effects Of Various Whole-body Vibration Frequencies On Squat Jump In Men And Women**

Margarita Gerakaki, Giorgos Paradis, Stavros Tziortzis. University of Athens, Athens, Greece.

Email: margarita.gerakaki@gmail.com

(No relationships reported)

Whole-body vibration (WBV) has been developed recently as a neuromuscular training method and has been popularly used from/by athletes, as a performance enhancement. However the most optimal / effective protocol / prescription has not been yet determined. **PUPROSE:** To investigate the acute effects of difference vibration frequencies on squat jump (SJ), as well as the differences in gender. **METHOD:** Seventeen trained subjects, 8 males (age  $23.4 \pm 1.5$  yrs, height  $173.4 \pm 4.5$  cm, weight  $72.3 \pm 6.9$  kg) and 9

females (age  $23.9 \pm 3.4$  yrs, height  $165.7 \pm 6.4$  cm, weight  $56.5 \pm 5.5$  kg) after participated in two familiarization sessions, they were randomly assigned into three groups and executed the WBV treatments in three different days, in order to avoid learning effect and fatigue. The WBV treatment consisted of static isometric squat ( $90^\circ$ ) on a vibration platform (PowerPlate<sup>®</sup>) in three different vibration frequencies (30Hz, 40Hz & 50Hz). The vibration amplitude was low (2mm) and each session lasted for 120 s ( $2 \times 60$  s with a rest period of 30 s). Three maximal squat jumps were performed before and 6min after the WBV treatment where the best trial was selected for further analysis.

**RESULTS:** Repeated one-way Anova showed that 50Hz vibration frequency significantly improved SJ performance in men by 7.05% and in women by 2.01% ( $F=13.330$ ,  $p=0.02$ ) whereas there was not significant changes on SJ in 30Hz and 40Hz vibration frequency. Additionally, there was a significant frequency by gender interaction ( $F=6.041$ ,  $p=0.27$ ) indicating that changes in men were greater comparing to women.

**CONCLUSION:** Two minutes isometric squat ( $90^\circ$ ) vibration exposure of 50 Hz produced significant improvements in SJ performance, whereas this vibration frequency was more productive in men than in women.

**Effects Of Whole Body Vibration On Vertical Jump In Female Collegiate Club Volleyball Players**

Jeffery J. Betts, Balie Maak, Elaine F. Betts, FACSM. *Central Michigan University, Mt Pleasant, MI.*

Email: betts1jj@cmich.edu

(No relationships reported)

Studies report an increased vertical jump following whole-body vibration (WBV) with expensive, club-quality platforms. Low-cost versions of WBV platforms have become available.

**PURPOSE:** To determine if acute exposure to WBV using a low-cost vibration platform affects vertical jump height for two jump types in female collegiate volleyball players.

**METHODS:** Seventeen female collegiate club volleyball players completed four trials of two different vibration treatments - WBV for 60 s at 50 Hz on a low-cost WBV platform {Vib}, and non-vibration {NV} for 60 s; and each of two different vertical jumps - the counter-movement jump (CMJ), and one-step jump (1-step). Subjects performed either the Vib or NV trials for both the 1-step or CMJ, followed by 5 min rest, then performed the opposite treatment and repeated the two jump types. The order of vibration treatment, and jump type within a vibration treatment were randomized for each subject.

**SUMMARY OF RESULTS:** Table 1 provides the average  $\pm$  std error of the vertical jump (inches) for the two jump types and vibration treatments.

	NV	Vib	
CMJ (inches)	16.4 $\pm$ 0.48	16.5 $\pm$ 0.50	n.s.
1-step (inches)	17.7 $\pm$ 0.51*	17.6 $\pm$ 0.49*	n.s.

Acute vibration produced no significant effect with either CMJ or 1-step vertical jump ( $P > 0.05$ ). As expected, the 1-step vertical jump was significantly greater than CMJ in both vibration treatment conditions ( $P < 0.001$ ).

**CONCLUSIONS:** Acute WBV (50 Hz for 60 s) with the low-cost WBV platform failed to show an effect on vertical jump in female collegiate club volleyball players. Furthermore, there were no injuries or impairment of vertical jumping performance associated with the acute WBV.

**1640 Board #242 May 27 9:30 AM - 11:00 AM**  
**The Acute Effects Of Whole Body Vibration On Hamstring Flexibility**

David A. Edwards, Elizabeth C. Skidmore, Joseph F. Signorile. *University of Miami, Coral Gables, FL* (Sponsor: Arlette Perry, FACSM)

Email: d.edwards1@umiami.edu

(No relationships reported)

The use of whole body vibration (WBV) platforms has been shown to increase flexibility in acute and chronic exercise studies. However, the vibratory settings used in these studies have varied considerably in terms of the frequency, displacement, and platform type. **PURPOSE:** The purpose of this study is to find the optimal frequency and displacement of WBV that elicits the greatest increase in hamstring range of motion on a triplanar WBV platform.

**METHODS:** Six male (25  $\pm$  6 yrs) and 5 female (22  $\pm$  2 yrs) participants volunteered for this study. Participants attended a total of nine days, with each day used to examine the effects of a unique WBV setting on hamstring flexibility. Conditions were combinations of 4 frequencies (30, 35, 40, and 50Hz) and Low vs. High Amplitudes (2 vs. 5mm), with one day during which stretching was performed with no vibration (NV). During training participants were instructed to bend forward at the waist keeping their knees at a 180 degree angle in an attempt to maximally stretch the hamstring muscle group. Flexibility was assessed using a modified sit and reach test, before vibration (pre), immediately after vibration, one minute post, two minutes post, and five minutes post vibration. A two-way repeated measures ANOVA (condition  $\times$  time) controlling for pre-test measures, was used to analyze the data.

**RESULTS:** The repeated measures analysis revealed no significant differences for stretching condition ( $F(8, 8) = 2.21$ ,  $p=.141$ ) or for time ( $F(3,3) = .932$ ,  $p=.522$ ) however, power levels were .484 and .115, respectfully for the full model. Separate ANOVAs comparing selected stretching conditions over time revealed a significant main effect for condition ( $F(1,8) = 6.23$ ,  $p=.037$ ) but not for time. Post hoc analyses revealed that 50 Hi elicited a significantly greater improvement than NV, ( $p=.040$ ).

**CONCLUSION:** Acute stretching of the hamstrings musculature during WBV resulted in a significant increase in hamstring flexibility over stretching without vibration. The setting 50 Hi condition proved to be the best setting to elicit positive changes in hamstring flexibility. These findings should be considered preliminary, due to the low sample size in this preliminary study.

**Vibration, Split Stretching, And Static Vertical Jump Performance In Young Male Gymnasts**

William A. Sands, FACSM<sup>1</sup>, Jeni R. McNeal<sup>2</sup>, Michael H. Stone<sup>3</sup>. <sup>1</sup>U.S. Olympic Committee, Colorado Springs, CO. <sup>2</sup>Eastern Washington Univ, Cheney, WA. <sup>3</sup>East Tennessee State Univ, Johnson City, TN.

Email: bill.sands@usoc.org

(No relationships reported)

Low frequency vibration has been shown to dramatically improve split range of motion (ROM) and to enhance vertical jumping ability.

**PURPOSE:** To investigate the effects of vibration and stretching-induced increases in ROM on subsequent single-leg static vertical jump (SLSVJ) performance.

**METHODS:** Fifteen male gymnasts [11.1(2.1) yr, 144.3(15.6) cm, 36.5(12.2) kg] participated. All tests were randomized for tests and treatment condition. Pretests consisted of two SLSVJ trials on each leg from 90 deg knee flexion on a force platform. Then two trials of a forward split test were conducted on each leg. In the split test the rear leg was flexed vertically 90 deg at the knee to limit pelvic misalignment. The anterior superior iliac spine (ASIS) was palpated with height from the floor measured as the ROM criterion variable. Both sides forward splits were treated by vibration on a custom device (30 Hz, 2mm displacement) for one minute (10s stretch, 5s rest, four times). The vibration device was placed under the forward ankle and under the rear thigh in each treatment. In the experimental condition the vibration device was turned on (V) while in

the control condition the device was turned off (NV). Following vibration treatment, the gymnasts repeated the split tests and the SLSVJ tests. Analysis consisted of multiple 2x2 ANOVAs with repeated measures of splits ROM, allometrically scaled SLSVJ variables, and descriptive statistics.

**RESULTS:** There was a greater improvement in split ROM in the V [29.4 (6.6) cm pre, 23.4 (6.2) cm post] vs NV [27.7 (7.3) cm pre, 25.0 (5.8) cm post] splits ( $P=0.002$ ), however all SLSVJ variables showed a decrease pre-post ( $P<0.05$ ) with no effect of condition and no significant interaction V by NV (all  $P>0.05$ ).

**CONCLUSION:** Vibration-enhanced stretching improved split ROM but did not show a protective effect nor enhancement of subsequent SLSVJ performance.

**Effects Of Acute Whole Body Vibration On Fatigue During Leg Press Exercise Session**

Ludmila M. Cosio-lima<sup>1</sup>, Thomas S. Marzilli<sup>2</sup>, Lem W. Taylor<sup>3</sup>, Mai-Vi Callahan<sup>1</sup>. <sup>1</sup>University of West Florida, Pensacola, FL. <sup>2</sup>University of Tyler, Tyler, TX. <sup>3</sup>University of Mary-Hardin Baylor, Belton, TX.  
Email: lcosiolima@uwf.edu

(No relationships reported)

**INTRODUCTION:** Often these athletes experience fatigue in between sets and this fatigue leads to poor biomechanics and lesser gains in strength. Whole-body vibration (WBV) training has been used to improve strength and vertical jump height in various athletes. Several studies had suggested an increase in sports performance after whole-body vibration training program either acutely or chronically. However, is of our knowledge that little data exists on the effects of WBV training on mechanisms of fatigue during muscular strength activities.

**PURPOSE:** To examine whether implantation of WBV during normal rest periods affects the fatigue associated with resistance exercise by measures of power, force, velocity and the force-velocity curve during a series of dynamic leg presses until failure.

**METHODS:** Ten sedentary college students ( $N = 5$  males,  $19 \pm 1.3$  yrs), and  $N = 5$  females,  $19 \pm 0.5$  yrs) participated in three trial sessions of 3 sets of dynamic leg press exercise to failure with 3.5 min rest in between sets. Subjects on the WBV trial were exposed to 60 sec vibration and 30 sec rest during their 3.5 min rest. Control subjects were stationary between sets and rest intervals. Statistical analyses utilized a two-way ANOVA with repeated measures for power, force, velocity, and force-velocity curves.

**RESULTS:** No significant differences ( $p > 0.05$ ) were observed for the dependent variables power, force, velocity and force-velocity curve between WBV and CON groups. However, a significant block effect ( $p > 0.05$ ) as well as a significant test x block interaction ( $p > 0.05$ ) was observed. The second block in each set of three blocks/test has the greatest power.

**CONCLUSIONS:** Acute WBV exposure in between sets had no effects on fatigue during leg press exercise as indicated by the measures power, force, velocity and force-velocity curve. The force/velocity curve shows that little resistance at a high velocity will not produce the greatest power, and high force at a slower resistance will not elicit the highest power either.

**Effects Of Muscular Strength, Exercise Order, And Acute Whole-body Vibration Exposure On Bat Swing Velocity**

Gabriel F. Reyes<sup>1</sup>, D. Clark Dickin<sup>2</sup>, Dennis G. Dolny<sup>3</sup>. <sup>1</sup>Northern Illinois University, DeKalb, IL. <sup>2</sup>University of Idaho, Moscow, ID. <sup>3</sup>Utah State University, Logan, UT.

Email: gfreyes@vandals.uidaho.edu

(No relationships reported)

**PURPOSE:** 1) investigate effects of acute WBV exposure and exercise order on bat velocity; 2) examine relationship between muscular strength and bat velocity.

**METHODS:** Male subjects ( $n=16$ ;  $22 \pm 2$  yrs;  $181.4 \pm 7.4$  cm;  $84.7 \pm 9$  kg) were tested for 1-RM strength in squat and bench press. Subjects participated in four randomized trials, each consisting of three sets of five bat swings. Exercises (upper and lower body dynamic and static movements related to bat swing) with or without WBV exposure were applied following sets 1 and 2. Trials were: Control (CTRL), Arm (Arm-NOVIB) followed by Leg (Leg-NOVIB) exercises without WBV (A+L-NOVIB), Arm (Arm-VIB) followed by Leg exercises (Leg-VIB) with WBV (A+L-VIB), and Leg (Leg-VIB) followed by Arm (Arm-VIB) exercises with WBV (L+A-VIB). One-way repeated measures ANOVA assessed statistical differences across sets and trials. Linear regression analyzed relationship between strength and bat velocity.

**RESULTS:** Significant relationship existed between bat velocity and 1-RM squat ( $r^2 = 0.406$ ,  $p = 0.008$ ) but not with bench press. Arm-VIB alone did not significantly change bat velocity ( $p = 0.198$ ), but A+L-VIB significantly increased bat velocity by 2.6% ( $p = 0.02$ ). Performing the identical order of exercises without vibration significantly decreased bat velocity in ensuing sets (Arm:  $p = 0.004$  and with Leg:  $p = 0.039$ ).

Table 1			
A+L-VIB			
Set	Bat Velocity (m/s)	Change from Set #1	p-value
1	$27.85 \pm 2.28$		
2	$28.11 \pm 2.22$	+0.26	0.198
3	$28.58 \pm 1.80$	+0.73	0.020*
A+L-NOVIB			
1	$28.49 \pm 2.58$		
2	$27.88 \pm 2.89$	-0.61	0.004*
3	$27.91 \pm 3.20$	-0.58	0.039*

**CONCLUSIONS:** Leg strength has direct correlation to bat velocity suggesting that increasing leg strength may be beneficial for increasing bat velocity. Adding vibration to total body exercises can provide acute enhancements in bat velocity. This data suggests WBV exercises may enhance bat velocity and perhaps contribute to improving a hitter's performance.

Kenno<sup>3</sup>. <sup>1</sup>Faculty of Human Kinetics - University of Windsor, Windsor, ON, Canada. <sup>2</sup>Faculty of Health and Social Development, University of British Columbia Okanagan, Kelowna, BC, Kelowna, BC, Canada. <sup>3</sup>Faculty of Human Kinetics - University of Windsor, Windsor, ON, Canada.

Email: roberty@uwindsor.ca

(No relationships reported)

Whole body vibration (WBV) platform training studies have reported increases in lower body skeletal muscle electromyography (EMG) activity during both static and dynamic squatting postures, but little if any effect on upper body skeletal muscle activity. In contrast to this, studies using vibrating cables or vibrating dumbbells have reported an improvement in upper body muscular performance. These data suggest that proximity to the vibrating stimulus was critical to the activation of selected muscle groups.

**PURPOSE:** To investigate the effects of vibration stimulus from a WBV platform on the upper body EMG muscle activity of recreationally trained males during the pushup exercise.

**METHODS:** To determine changes in muscle activity during dynamic pushups, EMG data was recorded from the pectoralis major (PM), latissimus dorsi (LD), triceps brachii (TB), & biceps brachii (BB) with results expressed as a % of maximum voluntary exertion (MVE). Subjects (n=15) performed pushups at no vibration (NV) or 6 random pairings of frequency (25, 35 & 45 Hz) and amplitude (2 or 4 mm). Ratings of perceived exertion (RPE) were determined using the Borg RPE scale following each condition.

**RESULTS:** With NV, ANOVA of the PM ( $45.8 \pm 3.4\%$ MVE) and TB ( $42.5 \pm 3.4\%$ MVE) showed significantly greater activity ( $p < .05$ ) than the LD ( $12.0 \pm 3.4\%$ MVE) and BB ( $7.0 \pm 3.4\%$ MVE). There were no statistically significant increases in EMG muscle activity of the PM or LD at any vibration setting over the NV condition. However, the pairing of 45Hz and 4mm resulted in statistically significant increases ( $p < .05$ ) in the EMG muscle activity of the TB ( $4.37 \pm 1.48\%$ MVE), and BB ( $7.64 \pm 2.5\%$ MVE) over the NV condition. RPE data confirmed that subjects perceived the WBV stimulus to be statistically more intense than NV.

**CONCLUSIONS:** Our data indicate that performing pushups on a WBV platform is similar to squatting on a WBV platform with the proximal muscles responding significantly to vibration set at 45Hz and 4mm. However, the data also indicate that the pushup position limited the transmissibility of the vibration stimulus to the muscles furthest away from the platform. Though RPE data indicate a perceived increase in effort during vibration training, an effective posture to increase the transfer of the vibration stimulus to the distal muscles in the upper body core remains unknown.

**Cardiorespiratory Responses During Whole Body Vibration**

Yusuke Osawa, Yuko Oguma, Norimitsu Kinoshita, Fuminori Katsukawa, Hajime Yamazaki, Shohei Onishi, *Keio University, Yokohama, Kanagawa, Japan.*

Email: osawa@z7.keio.jp

(No relationships reported)

Whole body vibration (WBV) has various effects on human. WBV on foot has an effect on human standing posture regulation and makes it difficult to keep the position. Blood pressure, heart rate, and ventilation decrease when local vibration is imposed on the tendon of agonist during isometric contraction; however, little is known whether WBV imposed on foot decreases cardiorespiratory responses in static and dynamic tasks.

**PURPOSE:** To investigate the difference of cardiorespiratory responses in no-vibration (NV), low amplitude vibration (LV, amplitude 2 mm; frequency 35 Hz), and high amplitude vibration (HV, amplitude 4 mm; frequency 35 Hz) and to examine the effects of vibration on three different tasks.

**METHODS:** Five healthy subjects ( $40.2 \pm 18.4$  yrs) kept two different 45 sec static squat positions (knee angle of task I was 60 deg flexion; that of task II was 90 deg flexion) and 45 sec dynamic squat in cycles of four sec to 90 deg knee flexion for three sets respectively on the vibration platform(task III). Each interval was 60 sec in the same task and the interval between two different tasks was 120 sec. They performed these tasks in NV, LV, and HV on separate day and the order of tests was randomized. Breath-by-breath oxygen consumption and heart rate were measured. Statistical analysis was made using two-way ANOVA.

**RESULTS:** In all tasks, HV (Vo2 was  $9.5 \pm 1.9$ ,  $11.9 \pm 4.5$ ,  $13.5 \pm 4.7$  ml/min/kg; heart rate was  $98.2 \pm 21.4$ ,  $107.7 \pm 26.5$ ,  $104.8 \pm 28.3$  bpm, task I to task III respectively) was higher than NV (Vo2 was  $8.8 \pm 1.8$ ,  $10.0 \pm 2.1$ ,  $12.4 \pm 2.7$  ml/min/kg; heart rate was  $87.5 \pm 19.5$ ,  $94.4 \pm 22.6$ ,  $93.9 \pm 22.9$  bpm, respectively) and LV (Vo2 was  $8.5 \pm 1.5$ ,  $10.9 \pm 2.3$ ,  $11.6 \pm 1.9$  ml/min/kg; heart rate was  $89.2 \pm 16.0$ ,  $101.6 \pm 20.4$ ,  $98.1 \pm 23.0$  bpm, respectively) although there were no significant differences.

**CONCLUSIONS:** These data suggest that low frequency-high amplitude WBV imposed on foot increase oxygen consumption and heart rate and low frequency-low amplitude WBV don't increase oxygen consumption as high as no-vibration.

**Effect Of Acute, Whole-body Vibration On An Isometric One Repetition Maximum Biceps Curl**

Elaine F. Betts, FACSM, Julianne Smith, Sarah Wischmeyer, Jeffery J. Betts, *Central Michigan University, Mt. Pleasant, MI.*

Email: betts1ef@cmich.edu

(No relationships reported)

Vibration plates have been used in combination with conventional resistance training to achieve improvements in strength. There is limited published data regarding the acute effects of vibration on absolute strength; most studies focus on the long-term training effects of vibration.

**PURPOSE:** to evaluate the acute effects of whole body vibration (WBV) on muscle strength during a one repetition maximum (1RM) isometric biceps curl.

**METHODS:** 32 college-age (mean age of  $21 \pm 2$  yrs) students (17 male, 15 female) completed two protocols for assessment of isometric biceps strength while undergoing vibration on a low-cost, home-use WBV platform. Subjects were familiarized with the apparatus and testing was completed to establish 1RM for biceps curl on a preacher curl bench. Treatment order was randomized for assessment of 1RM biceps strength during 5 minutes of vibration vs. 1RM measurement directly after a 5 minute session of vibration. A crossover design was used to perform the alternative treatment after 10 minutes of rest.

**RESULTS:** No significant difference in muscle strength was found during vibration vs. immediately post vibration ( $66.9 \pm 5.1$  vs.  $64.4 \pm 4.3$  in females)( $138.2 \pm 10.5$  vs.  $139.4 \pm 8.9$  in males). There was no order effect. As expected, male subjects were significantly stronger than female subjects. ( $138.7 \pm 7.8$ kg males at baseline vs.  $65.8 \pm 4.6$  kg females at baseline,  $p < .001$ ).

**CONCLUSION:** Acute WBV using a low-cost, home-use platform had no significant effect on biceps strength whether applied directly BEFORE or DURING muscle contraction.

(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the effects of combined resistance exercise and Whole Body Low Frequency Vibration (WBLFV) applied prior too, and then intermittently between sets upon select measures of body composition over a seven week period.

**METHODS:** Thirty men (n = 30) aged between 20 and 30yrs completed the study. Subjects were randomly assigned to one of three groups. Group one (CG, n=6) acted as an

active control, only participating in testing sessions. Group two (SQTV, n=13) performed 6 weeks of squat training while receiving WBLFV (50Hz), prior to, and in-between sets. The third group (SQT, n=11) performed six weeks of squats only. Over the training period subjects completed twelve workouts with variable loads (55% - 90% 1RM) and sets (3 - 5) with 4 minutes between sets. Squats were performed twice weekly separated by 72 hours. WBLFV was applied while subjects stood on a vibrating platform holding an isometric quarter squat position (knee angle  $135 \pm 5^\circ$ ). Initially, WBLFV was applied at 50hz for 30 seconds (s) at a low amplitude (2-4 mm) prior to exercise. WBLFV was then applied intermittently (3 X 10 s) at 50 Hz, high amplitude (4-6 mm) at 60s, 120s, and 180s into the 240s rest period. Measures of body composition were collected using DXA (Lunar Prodigy, General Electric) on weeks one and seven and consisted of Body Weight (BW), Total Lean Body Mass (TLBM), Trunk Lean Mass (TLM), Leg Lean Mass (LLM), Trunk Fat percentage (TRF%), and Leg Fat percentage (LF%).

**RESULTS:** Significant differences were seen at week one between groups for TLBM, TLM and LLM. Two way repeated measures ANCOVA (Time (2) X Group (3)) were utilized using the respective week one values as covariates to analyse changes, W1 to W7. Two way repeated measures ANOVA were used to analyse measures of Wt, TF %, and LF % between W1 and W7. A significant group by trial and group effect was seen for TLBM, SQTV > CG at week seven ( $p = .044$ ). A significant main effect for time was seen for LF%, T1 < T2, ( $p = .047$ ). No other significant differences were seen ( $p > .05$ ).

**CONCLUSIONS:** The addition of WBLFV to a six week squat training regimen significantly increased total lean body mass as measured by DXA. Applying WBLFV prior to, and then in between sets of exercise may further facilitate the anabolic effects of resistance exercise resulting in increased total body muscular hypertrophy.

**Can Whole-body Vibration Plus Exercise Improve Functional Deficits In Post Hip Surgery Patients**

C. Nathan Dodge<sup>1</sup>, Johnny W. Galver<sup>2</sup>, Laura J. Shriver<sup>1</sup>, Aaron D. Horowitz<sup>1</sup>, Simon A. Merila<sup>1</sup>, Gianni F. Maddalozzo<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>BPM Physical Therapy Center INC, Salem, OR.

(No relationships reported)

Functional deficits often exist in older adults following hip replacement surgery.

**PURPOSE:** To determine the effect of whole-body vibration (WBV) plus progressive resistance exercise on lower limb power, balance, and physical performance in older adults following hip replacement surgery.

**METHODS:** 37 community dwelling adults, 27 who were 1-3 years post hip replacement surgery, were recruited for this study (mean age =  $69.1 \pm 8.2$ ). The hip replaced participants were randomly assigned to one of two experimental groups: WBV plus exercise ( $n = 14$ ) or No-WBV plus exercise ( $n = 13$ ). The control group, consisted of age-matched non-hip replaced healthy individuals ( $n = 10$ ). The experimental groups exercised 90 min, 2day/ wk for 24-weeks. The WBV group performed supervised progressive resistance exercises on a Pneu-Vibe T vibration platform (Pneumex, Sandpoint, ID), low amplitude (4mm peak to peak) at 30-40 Hz. The No-WBV exercise group performed an identical supervised progressive resistance exercise program. Repeat measures MANOVA was conducted to evaluate between-subjects effects for lower limb power, balance, and physical performance.

**RESULTS:** Whole-body vibration resulted in significant statistical differences among the three experimental groups ( $p < 0.05$ ) with respect to outcome measures of balance (Sensory Organization Test, Neurocom Smart Balance Master), lower limb power (Bassey Power Rig) and physical performance (Timed Get Up & Go). Compared to those in the no-WBV plus exercise or control groups, participants in the WBV plus exercise intervention group showed significant improvement in balance (somatosensory) (meandiff = 0.05 %), Bassey Power Rig (meandiff = 39 Watts), and Timed Get Up & Go (meandiff = 1.99 sec.).

**CONCLUSIONS:** These findings suggest that whole-body vibration training may have potential beneficial effects on balance, lower limb power, and physical performance in individuals having undergone hip replacement surgery. Low injury risk makes whole-body vibration training a beneficial, well-tolerated supplement to exercise interventions intended to accelerate recovery from functional deficits in older adults following surgery.

(No relationships reported)

The combination of WBV and strength training can increase oxygen consumption ( $VO_2$ ); however, limited data exist concerning its effectiveness in older persons.

**PURPOSE:** To examine the effectiveness of WBV at increasing  $VO_2$  in older persons.

**METHODS:** Five untrained men ( $76.0 \pm 5.4$  yrs;  $84.9 \pm 12.2$  kg) took part in the study.  $VO_2$  was collected using 4 different exercise protocols performed on separate days. A 12hr fast preceded each visit. The testing involved three stages: resting (sitting for 15 min), exercise (active squats for 8 min), and recovery (sitting for 15 min). During the exercise stage, six 30s sets of active squatting were performed with one min of passive recovery between sets. Squatting speed was set at one squat per 3 seconds, controlled by matching the sound of a metronome. The four training protocols were the combination of load and vibration: body weight with no vibration (BW-NV), BW with vibration (BW-V), BW plus and additional load of 20% BW with NV (20%-NV) and 20%BW with vibration (20%-V). Triplanar WBV was applied at 35Hz and 2-3mm amplitude and load was applied at shoulder level. Testing order was randomized and testing days were separated by at least 48 hours.

**RESULTS:** Repeated measures analysis for  $VO_2$  revealed stage x vibration ( $p = .003$ ) and stage x load ( $p = .022$ ) interactions. The exercise stage was significantly higher than the resting ( $p < .001$ ) and recovery ( $p < .001$ ) stages; also the recovery stage was higher than the resting stage ( $p < .001$ ). When separate analyses were performed by training stage, no significant differences were seen among conditions at baseline. During the exercise stage, WBV produced a higher  $VO_2$  than NV ( $p = .056$ ). Although no significant vibration x load interaction was seen, pairwise comparisons showed a significantly higher  $VO_2$  for the 20%-V ( $9.8 \pm 1.3 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) compared to the BW-NV ( $8.4 \pm 0.4 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) condition ( $p = .047$ ); while, the 20%-NV condition ( $8.8 \pm 0.7 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) failed to significantly increase  $VO_2$  ( $p = .152$ ). Additionally, the BW-V condition ( $9.20 \pm 0.8 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) produced a higher, albeit non-significant,  $VO_2$  than the 20%-NV condition.

**CONCLUSION:** At the moderate training loads well-tolerated by older individuals, the addition of WBV during resistance training can produce a significantly greater increase in  $VO_2$  than the addition of load alone.

(No relationships reported)

Changes in muscular performance following whole-body vibration (WBV) have been attributed to adaptations in the neuromuscular system. However, due to a lack of standardization of WBV protocols and exposure time used in previous studies, the responsiveness of the muscular system to acute exposure to WBV remains unclear.

**PURPOSE:** To examine the acute effect of WBV on two functional muscular variables [rate of force development (RFD) and electromechanical delay (EMD)].

**METHODS:** Forty young healthy individuals were randomly assigned to an experimental or control groups. The experimental group received acute WBV (3 bouts of 2 minute)

while standing on a vibration platform. The control group adopted the same position (semi squat position) for equal time but received no vibration. During each of the testing sessions (before and after acute WBV), rate of force development and electromechanical delay were measured while subjects were isometrically plantar flexing their ankle on the plate of an isokinetic dynamometer.

**RESULTS:** After 3 bouts of 2 minute WBV, the experimental (WBV) group demonstrated a significant group by test interaction for the EMD ( $p=0.02$ ) and RFD ( $p=0.03$ ). The experimental group decreased EMD by 16% (from  $23.42 \pm 7.54$  ms to  $19.3 \pm 8.08$  ms) and increased RFD by 15.6% (from  $274.13 \pm 137.77$  N/sec to  $323.02 \pm 161.98$  N/sec) while the control group didn't change both EMD (from  $21.25 \pm 7.63$  to  $21.11 \pm 6.49$  ms) and RFD (from  $318.41 \pm 145.42$  to  $315.54 \pm 137.99$ ).

**CONCLUSION:** Our findings suggest that acute WBV had an effect on the functional performance of the soleus muscle as measured with EMD and RFD in young healthy subjects.

#### Effect Of Age On Oxygen Uptake Kinetics, Power Output And Oxygen Pulse.

Jaime S. Milheiro, João Reimão, Rosa Fonseca, João Espregueira-Mendes. *Clinica Saude Atlantica, Sports Center, Oporto, Portugal.*

Email: jaimemilheiro@yahoo.com

(No relationships reported)

**PURPOSE:** To determine which parameter may represent the best indicator of cardiopulmonary capacity along with aging we decided to compare the peak rate of oxygen consumption ( $VO_2$  (peak)), peak power output ( $W$  (peak)) and peak Oxygen pulse ( $VO_2 \times HR(-1)$  (peak)) obtained during incremental cycle exercise tests from three different age groups.

**METHODS:** Fifty male cyclists were carefully matched in which concerns training (12 - 15 hours/week) and tested in a protocol that would achieve maximum uptake or exhaustion in 10 to 12 minutes. They were split in three groups based on their age: twenty one in Group A (under 25 yrs) - age:  $19.1 \pm 3.1$  yrs, body mass:  $66.9 \pm 6.2$  Kg and height:  $174.9 \pm 5.6$  cm; twelve in Group B (between 25 - 34 yrs) - age:  $29.1 \pm 3.3$  yrs, body mass:  $72.0 \pm 7.4$  Kg and height:  $174.0 \pm 4.3$  cm and seventeen in Group C (above 35 yrs) - age:  $41.5 \pm 5.8$  yrs, body mass:  $69.2 \pm 7.7$  Kg and height:  $172.4 \pm 6.0$  cm (means  $\pm$  SD).

#### RESULTS:

Age Group	$VO_2$ (peak) ml/min/kg	W (peak) (watts)	$VO_2 \times HR(-1)$ (peak) (ml/beat)
A (under 25 yrs)	$63.3 \pm 7.6^*$	$369.8 \pm 64.7^*$	$23.6 \pm 3.7^{**}$
B (between 25 - 34yrs)	$53.1 \pm 17.2^*$	$308.2 \pm 90.4^*$	$20.6 \pm 5.3$
C (above 35 yrs)	$44.3 \pm 11.9^*$	$272.4 \pm 64.9^*$	$20.8 \pm 5.3$

\*Significantly greater ( $P < 0.05$ ). \*\*Significantly greater ( $P < 0.01$ ).

The  $VO_2$  (peak) ( $ml \times kg(-1) \times min(-1)$ ) and the  $W$ (peak) ( $W$ ) in group A were significantly ( $p < 0.05$ ) higher than group B and C and in group B were significantly ( $p < 0.05$ ) higher than group C. In which concerns the  $VO_2 \times HR(-1)$  (peak) ( $ml/beat$ ) group A was again significantly ( $p < 0.001$ ) higher than group B and C, however there was no significant difference between the group B and group C.

**CONCLUSIONS:** These data suggest that  $VO_2$  kinetics at the end of an incremental cycle exercise are affected by aging as well as the peak power output, however, in the oxygen pulse, that influence was not reflected suggesting that it may represent the best indicator of cardiopulmonary capacity along with aging.

### 1652 Board #2 May 27 3:30 PM - 5:00 PM

#### Psycho-social Differences In Attainment Of Physiological Criteria For Maximal Oxygen Uptake

Nikhil Satchidanand. *The University of Pittsburgh School of Education, Pittsburgh, PA.* (Sponsor: Elizabeth F. Nagle, FACSM)

Email: Nis9@pitt.edu

(No relationships reported)

**PURPOSE:** Accurate assessment of maximal oxygen uptake ( $VO_{2max}$ ) as an objective measure of aerobic fitness is essential in research and clinical settings. The purpose of this analysis was to examine psycho-social factors among subjects who differ in attainment of physiological criteria for  $VO_{2max}$ .

**METHODS:**  $VO_{2max}$  was assessed in 231 young adults (mean age  $29.0 \pm 1.1$  yrs., 53% female) using a treadmill graded exercise test, with a subject determined end-point corresponding to volitional exhaustion. Attainment of physiological criteria for  $VO_{2max}$  was defined as achieving one or both of the following: a respiratory exchange ratio  $> 1.10$  and heart-rate  $+ 10 b \cdot min^{-1}$  of age-adjusted maximal value. Psycho-social variables assessed were enjoyment of physical activity (PA), social support, self-efficacy, decisional balance, depression, perceived stress, perceived benefits of PA, and perceived barriers to PA.

**RESULTS:** Fifty-one subjects (22%) did not attain physiological criteria for  $VO_{2max}$ . Enjoyment of PA and perceived benefits of PA were significantly ( $p < .05$ ) lower in subjects who did not meet physiological criteria for  $VO_{2max}$ . Additionally, depression and perceived stress were significantly higher in this group ( $p < .05$ ).

Attnd. Crit.	Enjoyment			Perceived Benefits			Depression			Perceived Stress		
	M	p	U	M	p	U	M	p	U	M	p	U
YES	103.5			38			5.5			12		
NO	93.0	.03	3193	36	.005	3342	7.0	.005	2772	17	<.01	2474

\*M = Median Score, U = Mann-Whitney U-value, p = p-value

**CONCLUSIONS:** Findings indicate that individuals who enjoy PA and report more benefits of PA attained physiological criteria for  $\text{VO}_{2\text{max}}$ . In contrast, individuals who report depression and higher levels of perceived stress, at the time of testing were less likely to attain physiological criteria for  $\text{VO}_{2\text{max}}$ .

**Measurement Reproducibility Of Exercise Tolerance And  $\text{VO}_{2\text{peak}}$  In Male Sprague- Dawley Rats**

Steven W. Copp, Robert T. Davis, David C. Poole, FACSM, Timothy I. Musch, FACSM. *Kansas State University, Manhattan, KS.*  
Email: scopp@vet.ksu.edu  
(No relationships reported)

The rat model of exercise performance is an invaluable tool for the investigation of experimentally and pathologically induced alterations in exercise tolerance and  $\text{VO}_{2\text{peak}}$ . Interpretation of such data often presumes knowledge of the within-rat reproducibility of these performance measures, however, the literature is bereft of this information. The development of reliable and reproducible measures of exercise performance in the rat would improve experimental design and strengthen confidence in data interpretation.

**PURPOSE:** We tested the hypothesis that within-rat exercise tolerance and  $\text{VO}_{2\text{peak}}$  are highly reproducible across 5 separate weekly measurements when assessed with specifically designed protocols.

**METHODS:** On a custom motor-driven treadmill, 13 male Sprague-Dawley rats (initial age: 2-3 months, weight:  $352 \pm 13$  g) performed 5 progressive endurance runs to fatigue for determination of exercise tolerance, and 5 maximal exercise tests for determination of  $\text{VO}_{2\text{peak}}$  (ml/min/kg) via a metabolic chamber. The coefficient of variation (CV) was used to assess within-rat reproducibility.

**RESULTS:** There were no differences ( $P = 0.47$ ) in average time or distance run to fatigue among any of the 5 exercise tolerance tests, and the average within-rat CV for the 5 runs was 0.13 (avg. exercise tolerance range, 45.9 - 52.1 min). Additionally, there was no difference ( $P > 0.05$ ) among the average CV from any two consecutive weekly exercise tolerance tests (CV range, 0.06-0.1). As expected with the increase in body mass,  $\text{VO}_{2\text{peak}}$  decreased ( $P < 0.05$ ) over the course of the 5 maximal exercise tests. However, there were no differences ( $P = 0.64$ ) in the average within-rat CV among any of the consecutive  $\text{VO}_{2\text{peak}}$  tests (CV range, 0.03-0.04) and the average within-rat CV for all 5 tests was 0.06 (avg.  $\text{VO}_{2\text{peak}}$  range, 75.8 - 80.1 ml/min/kg).

**CONCLUSIONS:** We have demonstrated that, using the protocols described herein, within-rat measurements of exercise tolerance and  $\text{VO}_{2\text{peak}}$  are highly reproducible. The results of this study mandate the adoption of similar specific, reproducible protocols for use in the rat model of treadmill exercise performance and, therefore, have significant implications for improving and refining exercise testing and experimental designs.

**1654 Board #4 May 27 3:30 PM - 5:00 PM**  
**Estimates Of Cycling Efficiency At Low Power Outputs**

Michaela Reger, Rodger Kram, William Byrnes, FACSM. *University of Colorado at Boulder, Boulder, CO.*  
Email: micky.reger@comcast.net  
(No relationships reported)

Efficiency at low power outputs, comparable to daily living activities, is relevant to understanding obesity. Calculating muscular efficiency has remained controversial due to the difficulties of isolating the energy expenditure associated with the skeletal muscle mass performing mechanical work. While subtracting baselines (e.g. metabolic rate at rest or during zero load cycling) is common, these subtractions are problematic.

**PURPOSE:** To investigate the effects of different baseline subtractions on the calculation of efficiency during cycling, particularly at low power outputs.

**METHODS:** 15 active subjects (age 18-35) completed a one-visit cycle-ergometer protocol. They performed 13, 5-minute trials including: seated rest, motor-driven (passive) cycling, no chain cycling, no load cycling, and cycling at low (10-30W), medium (40-60W), and high (80-120W) power outputs. All cycling trials were performed at 90 revolutions per minute (rpm) on a pan-loaded, mechanically braked cycle ergometer. During each trial, we continuously performed indirect calorimetry.

**RESULTS:**  $\text{VO}_2$  during rest was  $0.29, \pm 0.06$  L/min, and nearly doubled during passive cycling ( $0.57, \pm 0.14$  L/min).  $\text{VO}_2$  values for no chain ( $0.76, \pm 0.12$  L/min) and no load ( $0.79, \pm 0.11$  L/min) trials were not statistically different from each other. Thus, active muscle contraction constituted only about half of the increased cost of no load cycling vs. rest. Regression equation for  $\text{VO}_2$  vs. power output for 10-120 Watt trials was  $0.007x + 0.752$ , ( $R^2 = 0.994$ ). Mean delta efficiency for low power outputs was 68.4%, compared to 36.3% and 36.9% for middle, and high power outputs. Means for gross (3.6%) and net (5.6%) efficiencies were rather low at low power outputs. Furthermore, at low power outputs, delta and work efficiencies demonstrated large individual variations exceeding theoretical values for muscular efficiency.

**CONCLUSION:** No method of baseline subtractions gave satisfactory values for muscular efficiency at low power outputs.

**Age Trends In Professional Tennis Players**

Javier Maquieirain<sup>1</sup>, Alejandro Cerúndolo<sup>2</sup>. <sup>1</sup>*Argentine Tennis Association - CeNARD, Buenos Aires, Argentina.* <sup>2</sup>*Tennis Point Academy, Buenos Aires, Argentina.* (Sponsor: Jorge Franchella, FACSM)  
Email: jmaquieirain@yahoo.com  
(No relationships reported)

**BACKGROUND & OBJECTIVE:** Top-ranked professional tennis players are usually young athletes. Their peak performance age has been previously studied but limited data exist on longitudinal age-related development of tennis players. The objective of this study was to explore the relationship between age and ranking position in tennis players during their professional career.

**MATERIAL & METHOD:** Professional players ranking during five years (2002-2006) were studied. Male and female subjects were divided in four groups according to their year-end ranking position. Their ranking position at the ages of 18, 21 and 24 year and their highest career position were determined and compared (*t*-test for independent samples).

**RESULTS:**

Groups	Age	Ranking Position at 18 y-old	Ranking Position at 21 y-old	Ranking Position at 24 y-old	Highest Ranking Position	Age of Highest Ranking
Male A (1 <sup>st</sup> -10 <sup>th</sup> )	24.8 (sd 3.5; n=50)	297.9 (sd 243.6; n=23)	46.1 (sd 54.7; n=23)	24.8 (sd 28.2; n=21)	3.6 (sd 2.4; n=23)	24.1 (sd 2.7; n=23)
Male B (91 <sup>st</sup> -100 <sup>th</sup> )	24.8 (sd 3.4; n=50)	715.2 (sd 416.3; n=50)	193.8 (sd 175.0; n=49)	134.2 (sd 135.2; n=47)	48.3 (sd 28.7; n=50)	24.6 (sd 2.6; n=50)

p A/B	1.00	0.00003	0.0001	0.0005	0.0000	0.4784
Female C (1°-10°)	23.4 (sd 3.3; n=50)	35.1 (sd 38.8; n=20)	23.3 (sd 30.0; n=18)	9.4 (sd 5.8; n=15)	2.9 (sd 2.3; n=21)	21.5 (sd 3.0; n=21)
Female D (91°-100°)	23.4 (sd 3.2; n=50)	256.5 (sd 218.0; n=46)	147.2 (sd 118.8; n=45)	110.7 (sd 70.5; n=40)	46.2 (sd 22.0; n=50)	23.9 (sd 3.0; n=50)
p C/D	1.00	0.00003	0.00000	0.000001	0.00000	0.0036
p A/C	0.046	0.000024	0.120	0.045	0.341	0.004

**CONCLUSIONS:** Age of peak performance of “top-ten” male and female professional tennis players was  $24.1 \pm 2.7$  and  $21.5 \pm 3.0$  years, respectively. “Top-ten” male and female players ranked significantly higher than other successful players at ages of 18, 21 and 24 years. Female “top-ten” were significantly younger than male athletes at ages of 18 and 24 years; they also reached their highest ranking position at early ages. Analyzing the relationship between age and ranking position could help to identify potential tennis champions and monitor their development during the professional career.

#### Regular Physical Exercise Prevents Age Related Decline In Knee Proprioception

José Oliveira, Fernando Ribeiro. *University of Porto, Faculty of Sport, Research Centre in Physical Activity, Health and Leisure, Porto, Portugal.*

Email: joliveira@fade.up.pt

(No relationships reported)

There is evidence that proprioception decline with age. However, literature indicates that regular exercise might be an effective strategy to attenuate the age-related decline in proprioception.

**PURPOSE:** To investigate the effects of aging and regular physical exercise on the knee joint position sense.

**METHODS:** Fifty male subjects, 28 young and 22 older, were recruited and divided, according to the practice of physical exercise in the year before the study, in 4 groups: young sedentary (N = 10;  $21.1 \pm 2.1$  yrs of age), young active (N = 18;  $21.3 \pm 2.8$  yrs of age), older sedentary (N = 12;  $67.9 \pm 3.3$  yrs of age) and older active (N = 10;  $67.3 \pm 3.9$  yrs of age). The technique of open-kinetic chain and active knee positioning was used to evaluate knee joint position sense. Subjects were seated, with the legs hanging freely, and blindfolded. One test position between  $40^\circ$  and  $60^\circ$  of flexion was investigated. Each subject performed three trials trying to reproduce the target position. The target and the response positions were recorded with a video camera. The Ariel Performance Analysis System software was used to measure the knee angle from videotape records. Joint position sense was reported as: the absolute angular error (AAE), defined as the absolute difference between the target position and the three response positions; and, the relative angular error (RAE), defined as the signed arithmetic difference between the test and the three response positions.

**RESULTS:** The mean AAE score of young active ( $2.1 \pm 0.9^\circ$ ) is significantly inferior to young sedentary ( $4.8 \pm 2.2^\circ$ ,  $p < .001$ ). Likewise, older sedentary ( $7.1 \pm 1.0^\circ$ ) had higher AAE than older active ( $4.5 \pm 2.0^\circ$ ,  $p = .002$ ). Active subjects had better joint position sense, indicated by smaller mean AAE score, than their sedentary counterparts. Differently from the results of the comparison of young active and sedentary active (significant difference,  $p = .001$ ), the comparison of young sedentary and older active indicated no difference in knee AAE. The RAE showed that all the groups ( $3.4 \pm 4.0^\circ$  young active;  $6.5 \pm 4.6$  older sedentary;  $6.5 \pm 4.3$  older active) except young active ( $-0.4 \pm 2.2^\circ$ ) clearly underestimate the test position.

**CONCLUSION:** Aging lead to a significant decrease of the knee proprioception, however regular physical exercise seems to prevent age-related decline in knee proprioception.

#### Acute Effects Of A Low-stretching Dynamic Protocol In The Upper Body Force Production

Daniele G. Leone<sup>1</sup>, Pedro Pizarat-Correia<sup>1</sup>, Maria João Valamatos<sup>1</sup>, Orlando Fernandes<sup>2</sup>. <sup>1</sup>Faculty of Human Kinetics, Lisbon, Portugal. <sup>2</sup>Évora University, Évora, Portugal.

Email: daniel Leone@uol.com.br

(No relationships reported)

Previous research has shown that dynamic stretching in the warm-up can enhance several muscular performance variables, while performing a static stretching protocol has been shown to decrease performance. The dynamic stretching seems to be an effective way of warm-up, although there is a lack of research about this topic.

**PURPOSE:** The purpose of this study was to investigate the acute effect of a low-stretching dynamic protocol on maximal isometric force, time to maximal isometric force, rate of force development, and EMG amplitude of main agonist muscles acting on the bench press exercise.

**METHODS:** 20 participants were randomly allocated into two equivalent groups (no stretch, and dynamic stretch). The maximal voluntary isometric contraction (MVC) on the bench press exercise was measured before and after (immediately, 10 min, 20 min, and 30 min) the dynamic stretching, and nonstretching. The average amplitude of the surface EMG of the pectoralis major, long and lateral heads of the triceps brachii was measured during MVC.

**RESULTS:** There was a significant decrease ( $p < 0.05$ ) in the maximal isometric force from the pre to the post-stretching in the dynamic group. This decrease was nearly 4%, with an initial value of  $762.0 \pm 155.4$  N and achieving  $734.6 \pm 136.6$  N immediately after stretching. There were no significant differences in the time to maximal isometric force, rate of force development and EMG amplitude of the three investigated muscles between the pre to the post-stretching. No significant differences were found in the control group in the force or in the EMG parameters between the pre and the post-stretching. Force did not remain significantly decreased for 30 min in both groups: dynamic and control.

**CONCLUSION:** The results suggest that the dynamic stretching have the ability to adversely affect efforts of muscle maximal strength dependence and that the reduction in performance does not appear to be caused by the reduction of muscle activation.

(No relationships reported)

Diazepam (DZP) is an effective tranquilizing, due to its muscular relaxant and hypnotic properties. Reactive oxygen species (ROS) and other free radicals are produced during the cellular metabolism. Exercise training (ET) modulates positively oxidative stress, by improving antioxidant status (AO) and it could also modulate several functions of the central nervous system, such as behavior.

**PURPOSE:** To investigate the influence of an eight week-exercise training protocol on locomotor behavior (LB) and systemic oxidative stress (OS) in rats treated chronically with DZP.

**METHODS:** Thirty two male Wistar rats (160-180g) were assigned into four groups: sedentary control (SC), sedentary DZP (SD), trained control (TC) and trained DZP (TD). Diazepam, 5mg/kg i.p. was injected daily during eight weeks. ET consisted of running sessions on an adapted rodent treadmill, five times a week at 0.6-0.9Km/h and 0% grade, during 60min, through eight weeks. Exercise was performed at least 8h after drug administration. LB was assessed through the open field (OF) test. Systemic OS was evaluated in erythrocytes through lipid peroxidation (LPO) via a chemiluminescent technic (CL) and antioxidant enzyme activities of catalase (CAT) and glutathione S-transferase (GST). The statistical package Graphpad was used

**RESULTS:** TD animals presented an increase in CL (cps/mgHb) values ( $14.2 \pm 0.5$ ) when compared to SD ( $12.7 \pm 0.3$ ;  $p < 0.05$ ) and TC ( $11.3 \pm 0.5$   $p < 0.01$ ) animals. CAT activity (pmol/mg prot) from TD group has also shown elevated values ( $35.0 \pm 4.0$ ) when compared to SD ( $22.4 \pm 1.5$ ;  $P < 0.05$ ). Not only diazepam but also the exercise training protocol promoted an increase on GST activity, being SD ( $1.5 \pm 0.1$ ;  $P < 0.01$ ) TC ( $1.3 \pm 0.1$ ;  $P < 0.05$ ) and TD ( $1.7 \pm 0.4$   $P < 0.001$ ) when compared to SC ( $0.9 \pm 0.08$ ). DZP training animals showed higher total locomotion values ( $82.6 \pm 4.9$ ) than SD ( $54.5 \pm 4.8$ ) and TC ( $31.4 \pm 6.2$ ) animals. There was no association among the variables studied.

**CONCLUSIONS:** DZP has induced an increase in oxidative damage and a consequent adaptation of the AO defenses, and the ET was not able to avoid these changes. Besides that, the locomotion capacity was not depressed by chronic DZP treatment, and the exercise training protocol significantly improved this values on DZP treated animals.

**Peak Torque And sEMG Responses To 5x10 Exhaustive Knee Extension Exercises In Male College Students**

Shangyi Guan<sup>1</sup>, Liangchou Zou<sup>2</sup>, Jian Lu<sup>1</sup>, Wenliang Nie<sup>2</sup>. <sup>1</sup>*East China Normal University, Shanghai, China.* <sup>2</sup>*Guangzhou Sport University, Guangzhou, China.* (Sponsor: Weimo Zhu, FACSM)

Email: gsyone@hotmail.com

(No relationships reported)

Surface EMG signals (sEMG) are often used to investigate fatigue-induced changes at the muscle fiber membrane level. Post static exercise or isokinetic exercise fatigue sEMG measures have been studied, but little is known about sEMG measures of fatigue muscles caused by dynamic exercise.

**PURPOSE:** To investigate sEMG features of quadriceps femoris during the course of muscular acute fatigue caused by exhaustive dynamic knee extension exercise on isometric torque.

**METHODS:** Ten healthy male college students ( $M \pm SD$ : Age =  $20.80 \pm 1.40$  yr., HT =  $174.3 \pm 7.27$  cm, WT =  $64.99 \pm 5.22$  kg) performed isometric maximal voluntary left knee extension at  $120^\circ$  joint angle (MVC120) with HUR machine (3530) first. After a 5-min rest, they performed five sets of 10-RM exhaustive knee extensions, with a 2-min break between sets. The loads were adjusted during the course of the session due to fatigue so that each subject could perform 5 sets. Post-test MVC120 was then performed. The sEMG signal from the biceps femoris (BF), rectus femoris (RF), vastus lateralis (VL), vastus medialis (VM) and knee extension torques of the left leg were collected during the entire trial, simultaneously with torque.

**RESULTS:** Average peak knee extension torque of each sets declined with the progress of the test ranging from  $419.13 \pm 5.57$  at the 1st set to  $360.62 \pm 5.54$  peak torque at 5<sup>th</sup> set and statistical difference was found from third set ( $p < .05$ ). Correspondingly, there was a reduction in mean power frequency (MPF) and Median Frequency (MF) of EMG signal of VM, RF and VL. Average EMG (aEMG) of VM, RF and VL increased during each set. Peak torque of MVC120 ( $668.70 \pm 50.29$  vs.  $615.90 \pm 52.98$  Nm,  $p < .05$ ) declined significantly after 5x10 knee extension exercise. simultaneously, MPF (VM:  $66.50 \pm 5.13$  vs.  $56.50 \pm 4.90$ ,  $p < .05$ ; RF:  $76.60 \pm 5.74$  vs.  $67.10 \pm 4.28$ ,  $p < .01$ ; VL:  $68.50 \pm 7.98$  vs.  $59.20 \pm 5.65$ ,  $p < .01$ ), MF (VM:  $87.90 \pm 11.41$  vs.  $76.70 \pm 11.46$ ,  $p < .05$ ; RF:  $96.30 \pm 7.24$  vs.  $80.90 \pm 13.91$ ,  $p < .01$ ; VL:  $83.70 \pm 10.40$  vs.  $71.40 \pm 7.59$ ,  $p < .01$ ) of EMG signal in VM, RF and VL decreased significantly after 5x10 knee extensions; significant increase was found only in aEMG of RF ( $308.40 \pm 63.07$  vs.  $387.20 \pm 65.00$ ,  $p < .05$ ).

**CONCLUSIONS:** sEMG is an effective measure to study muscle fatigue during dynamic exercise. The excise mode employed can cause acute muscular fatigue on quadriceps femoris.

**Quadriceps Strength Does Not Decrease With Knee Osteoarthritis Progression**

Abbey C. Thomas, MaryFran Sowers, Carrie Karvonen-Gutierrez, Riann M. Palmieri-Smith. *University of Michigan, Ann Arbor, MI.* (Sponsor: Christopher D. Ingersoll, PhD, ATC, FACSM)

Email: abbeyt@umich.edu

(No relationships reported)

Quadriceps weakness has been implicated as a potential risk factor for the development and progression of knee osteoarthritis (OA); however minimal data are available to demonstrate quadriceps dysfunction is present during the early stages of the disease. Further, if quadriceps weakness is a major determinant of disease progression it follows that muscle strength may diminish as OA severity worsens, but evidence supporting this hypothesis is lacking.

**PURPOSE:** To determine if quadriceps strength decreases as OA severity increases.

**Figure 1.** Average (±SE) knee extension torque (Nm/kg) for each OA grade.

**METHODS:** Ninety-one women (age  $56.49 \pm 2.8$  yrs; height  $1.63 \pm 0.07$  m; mass  $83.51 \pm 14.12$  kg) participated in this study and underwent radiographic evaluation and strength testing. Semi-flexed standing A-P x-rays were taken and graded for tibiofemoral OA severity using the Kellgren-Lawrence scale. Quadriceps strength was assessed isometrically at  $90^\circ$ . Subjects performed three maximum voluntary isometric knee extension contractions and the peak torque values from those trials were averaged. Statistical analysis was performed via a 1x5 ANOVA.

**RESULTS:** Quadriceps strength (Nm/kg) was not statistically different between the five OA grades ( $P > 0.05$ ) (Figure 1). While there appears to be a modest decline in strength associated with great knee OA severity (grade 4), the test for trend was not statistically significant ( $P = 0.09$ ).

**CONCLUSION:** Contrary to our hypothesis, quadriceps weakness did not worsen with increasing OA severity. Albeit the data come from a cross-sectional study design, absence of a statistically significant association calls into question the importance of quadriceps strength in the etiology of tibiofemoral osteoarthritis.

**Supraspinal Fatigue After A Low- Force Fatiguing Contraction In Men And Women**

Jaclyn M. Pruse, Manda L. Keller, Tejin Yoon, Bonnie Schlinder-DeLap, Sandra K. Hunter, FACSM. *Marquette University, Milwaukee, WI.*  
 (No relationships reported)

Supraspinal fatigue contributes to neuromuscular fatigue during a low-force fatiguing contraction; however, the influence of the sex of the individual is not understood.

**PURPOSE:** The purpose was to quantify supraspinal fatigue of men and women before and after performance of a low - force isometric fatiguing contraction.

**METHODS:** Thirteen young men and women (5 men [ $21.20 \pm 2.39$  yrs], 8 women [ $20.4 \pm 4.2$  yrs]) attended one experimental session after a familiarization session. Subjects performed a low-force isometric fatiguing contraction at 20% of maximum voluntary contraction (MVC) force with the elbow flexor muscles until task failure. Voluntary activation was quantified using the force of a superimposed twitch evoked with transcranial magnetic stimulation during MVC's performed before and after the fatiguing contraction.

**RESULTS:** Men had greater MVC torque compared with women ( $90.6 \pm 19.4$  Nm vs.  $36.9 \pm 5.5$  Nm,  $P < 0.05$ ). There was a significant reduction in MVC torque at termination of the task for both men and women ( $P < 0.05$ ); however, men had a greater reduction in strength than women (47% vs. 37% respectively,  $P < 0.05$ ). Women had a longer time to task failure for the fatiguing contraction when compared with men ( $12.3 \pm 5.5$  min vs.  $7.0 \pm 1.3$  min  $P < 0.05$ ). The amplitude of the superimposed twitch (%MVC) increased significantly after the fatiguing contraction ( $P < 0.05$ ), with no difference between men and women ( $P > 0.05$ ). Consequently, voluntary activation was similar for men and women before the fatiguing contraction ( $P > 0.05$ ) and decreased similarly for both sexes after the fatiguing contraction ( $94 \pm 4\%$  before to  $70 \pm 21\%$  after,  $P < 0.05$ ). Force fluctuations (coefficient of variation of force, CV) during the fatiguing contraction increased at a similar rate for both men and women ( $1.6 \pm 0.5\%$  at the start vs.  $4.8 \pm 1.7\%$  at task failure,  $P < 0.05$ ).

**CONCLUSION:** Supraspinal fatigue during a low-force fatiguing contraction with the elbow flexor muscles was not influenced by the sex of the individual.

**1662 Board #12 May 27 3:30 PM - 5:00 PM**  
**Whole Body Vibration: Mapping Of Transmission With High Speed Motion Analysis**

Gerald A. Smith, FACSM, Eadric Bressel, Eric M. Snyder. *Utah State University, Logan, UT.*  
 Email: Gerald.Smith@usu.edu  
 (No relationships reported)

Whole body vibration (WBV) is used for its potential benefits in flexibility training and musculoskeletal strengthening. While bone-pin accelerometers have been used, vibration characteristics typically are assessed using skin mounted accelerometers which require corrections to the signal to minimize the effects of local skin-accelerometer resonance. Recent advances in camera technology allow measurement of small, low-mass skin mounted marker positions to a small fraction of a mm at sufficiently high sampling frequency to characterize local vibration.

**PURPOSE:** Evaluate the capability of a motion analysis system to measure local vibrations over bony landmarks during WBV.

**METHODS:** In this pilot study, two subjects experienced WBV while standing on a Freemotion iTonic machine which was set to vibrate under four conditions: low and high frequency (28 and 42 Hz) with low and high amplitude (about 1.5 and 3 mm displacement). Small (9 mm diameter) reflective markers were mounted on the vibration plate and on bony landmarks (lateral malleolus, tibial tuberosity, ASIS, sternum and forehead). Marker positions were measured using six Vicon T-20 cameras operating at 500 Hz. Each condition involved about 10 seconds of vibration exposure from which 40 consecutive cycles were extracted and analyzed. Mean ( $\pm$ SD) of vertical vibration amplitude was determined for each condition and subject. During measurement, knees were extended and feet were flat on the plate.

**RESULTS:** Motion at the ankle closely matched the plate vibration however attenuation occurred at other points. Tibial vibration was about 0.8 mm and 1.0 - 1.5 mm under low and high amplitude conditions. ASIS and sternum vibrations ranged between 0.2 to 0.6 mm. At the head, high frequency vibrations had amplitude of about 0.7 mm while low frequency was transmitted more strongly ( $1.9 \pm 0.4$  mm for the high amplitude condition).

**CONCLUSIONS:** High speed motion analysis has sufficient spatial precision to easily detect vibration of sub mm amplitude. When used with small, low-mass markers over bony landmarks, vibration transmission can be mapped across the body without the challenges associated with skin or bone mounted accelerometers.

**1663 Board #13 May 27 3:30 PM - 5:00 PM**  
**A Kinematic Comparison Of The Digi-jump Machine Versus Rope Jumping.**

John R. McLester, FACSM<sup>1</sup>, Thomas S. Lyons<sup>2</sup>, Zachary J. Callahan<sup>2</sup>, John C. Faircloth<sup>2</sup>. <sup>1</sup>Kennesaw State University, Kennesaw, GA. <sup>2</sup>Western Kentucky University, Bowling Green, KY.  
 Email: jmcleste@kennesaw.edu  
 (No relationships reported)

Pursuant to the recent Surgeon General's report identifying bone health as priority and its recommendation of repetitive jumping as a preferred exercise for ameliorating this

growing problem, this study investigated kinematic variables with use of the Digi-Jump (DJ) machine. The DJ machine is designed to regulate jumps per minute as well as height per jump in order to simulate rope jumping.

**PURPOSE:** To compare the kinematic parameters of the DJ machine and standard rope jumping.

**METHODS:** Twenty-eight subjects (age: 21.1±1.8 yrs; bf: 12.7±6.4%; ht: 170.7 ±22.6 cm; wt: 75.6±12.9 kg) performed in counterbalanced order both a 120 JPM trial on the DJ machine and a concrete floor (FL). Subjects were required to reach a minimum of 1/2" height for each jump. Cadence was monitored through a series of lights and audible "beeps," while height was regulated by infrared beams. Data were recorded with a three camera motion capture system. The kinematics (joint angles, velocities, and accelerations) for both trials were calculated and compared using repeated measures ANOVA.

**RESULTS:** Overall, the body and segmental motions were similar in both trials. However, significant differences ( $p < 0.05$ ) between trials were found for peak vertical velocity (DJ: 149.1±20.3 mm/sec versus FL: 163.6±23.9 mm/sec), peak angular velocity of the knee (DJ: 296.2±59.5 deg/sec versus FL: 352.5±92.9 deg/sec) and ankle (DJ: 417.6±83.2 deg/sec versus FL: 501.1±106.2 deg/sec), peak angular acceleration of the knee (DJ: -4504.2±1588.4 deg/sec<sup>2</sup> versus FL: -5981.1±2917.8 deg/sec<sup>2</sup>) and ankle (DJ: -7960.9±2426.3 deg/sec<sup>2</sup> versus FL: -8141.2±2426.5 deg/sec<sup>2</sup>), and mean angular acceleration at the knee (DJ: -974.2±172.0 deg/sec<sup>2</sup> versus FL: -1234.4±323.8 deg/sec<sup>2</sup>) and ankle (DJ: -1423.8±353.6 deg/sec<sup>2</sup> versus FL: -1773.9±521.5 deg/sec<sup>2</sup>).

**CONCLUSIONS:** Parameters measured on the DJ machine are similar to standard rope jumping, but not directly equivalent. Peak velocities are higher on a concrete floor versus the DJ machine. This indicates that the floor of the machine may provide some return of strain energy, allowing the subject to maintain the correct jump height and cadence with less energy expenditure. These findings provide indirect evidence that jumping on the DJ machine may be safer due to lower impulse upon landing.

**The Effects Of Whole-body Vibration On Spinal Excitability And Intrinsic Pre-synaptic Inhibition**

Kristof Kipp, Jeffrey R. Doeringer, Sam T. Johnson, Mark A. Hoffman, FACSM. *Oregon State University, Corvallis, OR.*

Email: kristofk@hotmail.com

(No relationships reported)

Researchers have reported that whole-body vibration (WBV) affects neural excitability. However, it is unknown if these effects are due to changes in motor neuron pool excitability (H-reflex) or intrinsic pre-synaptic inhibition (IPI). Further, the time course of these changes remains to be elucidated.

**PURPOSE:** To identify the effect and time course of WBV on H-reflex and IPI.

**METHODS:** H-reflexes and IPI were measured in the soleus muscle of 10 participants during quiet standing using a paired pulse conditioning protocol. Stimulation intensity was set to evoke an H-reflex equivalent to 10% of motor neuron pool output (10% of  $M_{max}$ ). The first stimulation (S1) produced an unconditioned H-reflex that was used as a measure of neural excitability. S1 was followed 100 ms later by a second stimulation of the same intensity (S2). The ratio of S2 to S1 determined the amount of IPI. Prior to WBV, each participant received 10 pairs of stimulations, one every 15 sec. The averaged peak-to-peak H-reflex responses of these stimulations and the IPI ratio served as baseline values. Participants then stood on a vibration plate that vibrated at a frequency of 25 Hz and 2-4 mm amplitude for 5 min. Immediately following WBV, participants received paired stimulations every 15 sec for 10 mins. Reflex responses were averaged at one minute increments. Two 1x4 [baseline, 1-min, 5-min, and 10-min post-WBV] repeated measures ANOVAs were used to test for the effects of WBV across time on H-reflex and IPI means. Post-hoc testing used Bonferroni-corrected paired t-tests.

**RESULTS:** Baseline, 1-min, 5-min, and 10-min H-reflex values were .61±.25, .46±.29, .63±.25, and .72±.34, respectively. The ANOVA detected a significant difference among H-reflex values, but post-hoc tests showed no differences between comparisons ( $p > .053$ ). Baseline, 1-min, 5-min, and 10-min IPI values were .24±.26, .41±.39, .32±.35, and .26±.26, respectively. The ANOVA did not detect differences in IPI values.

**CONCLUSIONS:** Changes in IPI are thought to represent a time-dependent modulation of Ia afferent input from the muscle spindle and may explain previously reported changes in neural excitability after WBV. However, in our study neither excitability nor inhibition changed, which suggests that other mechanisms may also modulate neural excitability after WBV.

**The Short-term Effect Of Whole-body Vibration On The Spinal Reflex Activation**

Jeffrey R. Doeringer, Kristof Kipp, Sam Johnson, Mark Hoffman, FACSM. *Oregon State University, Corvallis, OR.* (Sponsor: Mark Hoffman, FACSM)

Email: doerinj@onid.orst.edu

(No relationships reported)

Whole-body vibration (WBV) training is suggested to cause neuromuscular changes. Investigators report modulation of the soleus H-reflex after WBV, but have not examined simultaneous changes in multiple muscles after a single vibration exposure.

**PURPOSE:** To determine the effects of an acute bout of WBV on the H-reflex of the soleus (Sol), medial head (MG), and lateral head (LG) of the gastrocnemius over time.

**METHODS:** H-reflexes were measured in the Sol, MG, and LG of 10 subjects during quiet standing. Each subject received 10 stimulations at intensity equal to 10% of  $M_{max}$  at an interval of 15s. The reflex responses were averaged and served as baseline. Subjects then stood on a WBV plate (Turbosonic) that vibrated at a frequency of 25 Hz and 2-mm amplitude for 5 min. Immediately after the WBV subjects received a stimulation every 15s for 10 min at the pre-vibration intensity. Peak-to-peak reflex responses were averaged at one minute increments and served as the dependent variable. The independent variables were time (baseline, 1 min, 5 min, and 10 min) and muscle (Sol, MG, LG). A 3x4 (muscle x time) ANOVA ( $\alpha = 0.05$ ) with repeated measures on time was used to analyze the data and followed up with post-hoc paired t-tests.

**RESULTS:** In the Sol the H-reflex amplitude decreased significantly at 1 min and increased at 10 min ( $p < 0.05$ ) [base =  $0.61 \pm 0.25$ , 1 =  $0.46 \pm 0.29$ , 5 =  $0.63 \pm 0.25$ , 10 =  $0.72 \pm 0.34$ ]. In the MG the H-reflex decreased significantly following WBV ( $p < 0.05$ ) [base =  $0.26 \pm 0.26$ , 1 =  $0.19 \pm 0.21$ , 5 =  $0.19 \pm 0.11$ , 10 =  $0.21 \pm 0.15$ ]. In the LG the H-reflex amplitude decreased significantly 1 min and increased at 10 min ( $p < 0.05$ ) [base =  $0.30 \pm 0.18$ , 1 =  $0.24 \pm 0.19$ , 5 =  $0.32 \pm 0.21$ , 10 =  $0.36 \pm 0.22$ ]. The paired t-test showed significant decrease in all muscles below baseline at 1 min. However at the 5 min interval no difference existed between baseline measures in any of the muscles. Sol and LG H-reflexes increased at 10 min post intervention but not in the MG.

**CONCLUSIONS:** Similar changes in H-reflexes were observed in the Sol and LG following WBV. We observed a similar trend between muscles with different fiber types.

**Bilateral Deficit In Peak Cycling O<sub>2</sub> Consumption But Not Maximum Cycling Power**

Jason D. Miller, Steven J. Elmer, Stephen J. Ives, Timothy A. VanHaitisma, L. Nathan Thomas, Melissa A. Hayman, Arwen A. Fuller-Hayes, James C. Martin, FACSM. *University of Utah, Salt Lake City, UT.*

(No relationships reported)

**PURPOSE:** Evidence for the presence of bilateral deficits during assessments of maximal power ( $P_{max}$ ) and maximal aerobic capacity ( $VO_{2peak}$ ) during cycling has been previously reported. To our knowledge bilateral deficits in  $P_{max}$  and  $VO_{2peak}$  have not been assessed in the same individual. The purposes of this study were to 1) compare the summed (right + left leg) unilateral  $P_{max}$  with bilateral  $P_{max}$  and summed unilateral  $VO_{2peak}$  with bilateral  $VO_{2peak}$  and 2) identify the potential difference in unilateral asymmetry when measuring  $P_{max}$  and  $VO_{2peak}$ .

**METHODS:** Seven trained participants ( $VO_{2peak} = 54 \pm 11$  ml·kg<sup>-1</sup>·min<sup>-1</sup>), 6 males and 1 female (27±2 yrs, 176±7 cm, 82±21 kg) volunteered for this investigation.  $VO_{2peak}$  was

assessed during a ramped cycling protocol and  $P_{\max}$  assessed using inertial-load cycling. For  $P_{\max}$  and  $VO_{2\text{peak}}$  trials a 9.9 kg counter weight was attached to the ergometer to facilitate smooth single-leg cycling. Paired  $t$ -tests were used to identify unilateral asymmetry and bilateral deficit for  $P_{\max}$  and  $VO_{2\text{peak}}$ . The unilateral analysis compared the most powerful, most aerobic leg against the least powerful, least aerobic leg for each participant.

**RESULTS:** Bilateral  $P_{\max}$  and summed unilateral  $P_{\max}$  were not different ( $1139 \pm 288$  vs.  $1137 \pm 314$  W,  $p=.94$ ). Unilateral  $P_{\max}$  (strongest vs. weakest) ( $581 \pm 161$  vs.  $555 \pm 154$  W,  $p<.05$ ) as well as unilateral  $VO_{2\text{peak}}$  (more aerobic vs. least aerobic) ( $45 \pm 9$  vs.  $41 \pm 9$  ml $\cdot$ kg $^{-1}\cdot$ m $^{-1}$ ,  $p<.01$ ) differed significantly. Summed unilateral  $VO_{2\text{peak}}$  was significantly greater than bilateral  $VO_{2\text{peak}}$  ( $86 \pm 18$  vs.  $54 \pm 11$  ml $\cdot$ kg $^{-1}\cdot$ m $^{-1}$ ,  $p<.01$ ).

**CONCLUSIONS:** These trained individuals did not exhibit a bilateral deficit in maximum power which supports and extends previous work measuring bilateral deficit in strength training. However, the observed unilateral differences (both  $P_{\max}$  and  $VO_{2\text{peak}}$ ) imply that trained individuals may preferentially rely on one leg during cycling and raises the question of asymmetry during bilateral cycling. The difference in unilateral vs. bilateral  $VO_{2\text{peak}}$  values suggest bilateral aerobic cycling is likely limited by central factors while unilateral lower body cycling may be limited by local muscle factors.

---

**1667 Board #17 May 27 3:30 PM - 5:00 PM**  
**Evaluating Symmetry Of Healthy Participants During Landing**

Michael Wortley, Songning Zhang, FACSM. *The University of Tennessee, Knoxville, TN.*  
Email: mwortley@utk.edu  
(No relationships reported)

Although landing is an important model for examining lower extremity injury mechanisms, little is known about symmetry during the landing. Most landing studies assume bilateral symmetry and use one side to describe landing behaviors.

**PURPOSE:** To investigate the symmetry of healthy subjects during drop landing and landing from a counter-movement jump using symmetry index (SI) and symmetry angle (SA).

**METHODS:** Sixteen healthy subjects (8 male, 8 female) performed drop landings from heights of 30 cm (C1) and 60 cm (C2), and counter-movement jumps to a height of 90% of maximum jump height (C3). Three-dimensional kinematics and ground reaction force (GRF) data were collected. Discrete events were selected from joint angle, velocity, and moment curves of the ankle, knee, and hip, as well as from GRF of both sides during the landing phase. For each of 29 selected variables, SI and SA values were calculated such that 0 would indicate perfect symmetry, negative values would indicate greater magnitude on the right side, and positive values indicate greater magnitude on the left side. Two separate MANOVAs, one for SI values and one for SA values, were used to evaluate the differences among conditions ( $p<0.05$ ).

**RESULTS:** The MANOVA results indicated that there was a difference in symmetry between conditions ( $p=0.0018$  for SI,  $p=0.0001$  for SA.) In the sagittal plane, the largest SI and SA values were for ankle, knee, and hip moments. SA of the second peak knee extension moment was the strongest representation of the trend between conditions (mean values of -9.57, -4.34, and -0.81 for C1, C2, C3 respectively) and the peak vertical GRF followed the same trend (mean values of -8.02, -6.29, and -1.49.) The peak hip adduction moment was the only frontal plane variable to show a significant effect for condition (mean SA values of 33.70, 24.09, and -2.70). Frontal plane SI values were highly variable with standard deviations ranging from 3123.44 to 38.44, most likely due to small values of the frontal plane variables.

**CONCLUSIONS:** The results suggest that healthy subjects tend to land more asymmetrically in drop landing compared to landing from a counter-movement jump. Factors that influence the symmetry of a landing may need to be investigated on an individual basis, due to high inter-subject variability.

**Belly Loads Influence Minimum Cost Of Transport And Speed It Occurs In Walking Women**

Marcella J. Myers<sup>1</sup>, Christine M. Hayes<sup>1</sup>, Andrea L. Hokanson<sup>1</sup>, Jessica A. McCafferty<sup>1</sup>, Sarah M. Meissner<sup>1</sup>, Cara M. Wall-Scheffler<sup>2</sup>. <sup>1</sup>College of St. Catherine, St. Paul, MN. <sup>2</sup>Seattle Pacific University, Seattle, WA. (Sponsor: Mark Blegen, FACSM)  
Email: mjmyers@stkat.edu  
(No relationships reported)

Central fat, insulin resistance and physical inactivity are linked in a pathological positive feedback cycle leading to ever-increasing levels of visceral abdominal fat (VAF). Our ultimate goal is to interrupt this cycle by developing walking regimes for women of different ages and mass distributions that maximize calories burned while minimizing load-induced gait disturbances.

**PURPOSE:** Our specific goal was to determine how the amount of mass carried around a woman's abdominal area (belly) affected her gait kinematics and metabolic cost during walking at different speeds.

**METHODS:** We measured metabolic cost in 10 young females (mean=20.9yr) and 10 older females (mean=51.4yr) as they walked on a treadmill unloaded and belly-loaded (two loads, 8% and 16% of body mass) at four speeds (self-selected from eight options) centered around optimal walking speeds. For each individual, we developed cost of transport (CoT) equations (cost vs speed) for each of the three loading conditions and determined the minimum CoT (minCoT) and the speed of minCoT (SPminCoT) at each loading condition. Kinematic measures were determined from videotape (Kinematic Analysis program) using 5 strides from each trial.

**RESULTS:** Both age cohorts showed the same pattern of significantly higher minCoT ( $p < 0.0001$ ), lower SPminCoT, and lower stride frequency ( $p < 0.0001$ ) as belly load increased. The shape of the metabolic cost vs speed curve was significantly ( $p<0.0001$ ) more acute (higher costs above and below SPminCoT) for loads of 16% body mass than for the unloaded condition, yielding a decidedly smaller range of "comfortable" walking speeds for women with sizable belly loads.

**CONCLUSIONS:** Our results show that the amount of centrally-located mass can influence the metabolic cost and kinematics of walking at a given speed, including the speed at which walking is least costly per distance. These findings will aid in developing individualized exercise prescriptions that could help women with significant visceral body fat maintain exercise levels that lower their risk for type 2 diabetes.

**Concepts For Assessment Of Anterior Knee Pain In Relation To Muscle Function**

Hechmi Toumi<sup>1</sup>, Thomas M. Best, FACSM<sup>2</sup>, Mark Forster<sup>3</sup>, Sleem F'Guyer<sup>4</sup>, John A. Fairclough<sup>1</sup>. <sup>1</sup>University of Wales, Cardiff, United Kingdom. <sup>2</sup>Ohio State University, Ohio State, OH. <sup>3</sup>University of Wales Institute, Cardiff, Cardiff, United Kingdom. <sup>4</sup>University of Illinois at Chicago, Chicago, IL. (Sponsor: Thomas Best, FACSM)  
Email: toumih@cardiff.ac.uk  
(No relationships reported)

**PURPOSE:** Anterior knee pain in the young adult is associated with patello femoral rather than femoral tibial dysfunction (Kristin M Houghton 2007). The relationship between vastus medialis oblique strength and anterior pain and disability has been suggested (S. O'Reilly 1998). The lack of consistent methodology in objective measurement of the quadriceps muscles have made evaluation of the link between pain and altered muscle function difficult to assess. Using a novel methodology we demonstrate a biomechanical protocol to assess the deficiency of the quadriceps muscles in patients with anterior medial knee pain.

**METHODS:** A biomechanical evaluation was conducted on 54 patients with anterior medial knee pain (34 females and 20 males). All patient x-rays were normal (alignment and joint space between the femur and the tibia as well as between the femur and the patella) through interpretation by a blinded radiologist. A Kistler force plate, a VICON

motion analysis system and surface electromyography were used to quantify biomechanical function during isometric, walking and squatting exercises.

**RESULTS:** For 42 of the 54 (78%) subjects, during isometric and walking exercises we observed that activation of the VMO, rectus femoris (RF) and vastus lateralis (VL) muscles of the symptomatic leg was not significantly different from those of the asymptomatic leg ( $p < 0.01$ ). However, for 31 patients (57%) during the eccentric phase of the squat exercises, the symptomatic leg presented with high activation of VL compared to VMO and RF ( $p < 0.01$ ). During the concentric phase, 45 patients (83%) presented with higher activation of the VL compared to the VMO.

**CONCLUSION:** VMO activity during squatting for the symptomatic (patient with anterior medial knee pain) leg differs fundamentally during walking and isometric exercise compared to squatting tasks. Moreover, the relative contribution of the VL compared to the VMO during the eccentric phase of the squat exercises was different to those recorded during the concentric phase. Therefore, we suggest that maximal isometric and/or isokinetic exercises are not sufficient to access the quadriceps function in relation to anterior knee pain. A thorough biomechanical assessment, including functional testing to reproduce the patient's pain and locate the nature of the symptoms is suggested.

### **1670 Board #20 May 27 2:00 PM - 3:30 PM Neighborhood Socioeconomic Status And Changes In Walking Activity Among Adults Aged 50-75**

Naruepon Vongjaturapat<sup>1</sup>, Fuzhong Li<sup>2</sup>, Peter Harmer, FACSM<sup>3</sup>, Bradley J. Cardinal, FACSM<sup>4</sup>, Mark Bosworth<sup>5</sup>. <sup>1</sup>Burapha University, Chonburi, Thailand. <sup>2</sup>Oregon Research Institute, Eugene, OR. <sup>3</sup>Willamette University, Salem, OR. <sup>4</sup>Oregon State University, Corvallis, OR. <sup>5</sup>Portland Metro Regional Services, Portland, OR.  
Email: fuzhongli@ori.org  
(No relationships reported)

Research suggests that built and social environments influence physical activity such as walking, but the role of the neighborhood socioeconomic context is not fully understood.

**PURPOSE:** To examine the influence of neighborhood socioeconomic status on the relationships between built environment and psychosocial factors and changes in walking activity over time.

**METHODS:** Using a multilevel, prospective design, we collected data on walking activity assessed by self-report, both at baseline and 1-year follow-up, from 1,141 residents aged 50-75, across 120 neighborhoods in Portland, Oregon. Neighborhoods were divided into low and high socioeconomic status on the basis of median household income, percentage of population in poverty, and racial/ethnic composition. Within-neighborhood level measures were the objective measure of walkability, and residents' self-report of exercise self-efficacy and social cohesion. Change scores in walking were operationalized as values  $\geq 75^{\text{th}}$  percentile of positive change. The 2-level hierarchical data were analyzed using logistic regression with adjustments on neighborhood- and resident-level sociodemographic characteristics.

**RESULTS:** Among low-socioeconomic neighborhoods, residents living in low-walkable built environments were less likely to increase walking activity (adjusted odds ratio [AOR] = 0.68, confidence interval [CI] = 0.50, 0.95). However, the likelihood increased for residents reporting high exercise efficacy (AOR = 1.07, CI = 1.01, 1.14) and perceiving high neighborhood social cohesion (AOR = 1.22, CI = 1.01, 1.48).

**CONCLUSIONS:** Neighborhoods with low-socioeconomic status and low walkability are likely to be associated with reduced levels of walking. Efforts to increase exercise self-efficacy and foster social cohesion are likely to promote increases in walking activity in these neighborhoods.

### **1671 Board #21 May 27 2:00 PM - 3:30 PM Density Of Neighborhood Public Transit, Built Environment Characteristics, And Residents' Time Spent In Commuting By Public Transit And Utilitarian Walking**

Emily Sectar<sup>1</sup>, Arissa Fitch-Martin<sup>1</sup>, Fuzhong Li<sup>1</sup>, Bradley J. Cardinal, FACSM<sup>2</sup>, Mark Bosworth<sup>3</sup>, Peter Harmer, FACSM<sup>4</sup>. <sup>1</sup>Oregon Research Inst., Eugene, OR. <sup>2</sup>Oregon State University, Corvallis, OR. <sup>3</sup>Portland Metro Regional Services, Portland, OR. <sup>4</sup>Willamette University, Salem, OR.  
Email: fuzhongli@ori.org  
(No relationships reported)

There is a known association between built environment characteristics and physical activity. However, the extent to which features of the built environment are related to transportation use and walking for utilitarian purposes is not well understood.

**PURPOSE:** Determine whether the density of the public transit system (bus, light rail), walkability around people's homes, and people's perceptions of the built environment are related to the amount of time spent commuting (via public transit) and walking (for the purposes of transportation, errands, and social visits).

**METHODS:** We used a cross-sectional design in which we collected one-time observational data on 1221 participants residing in 120 neighborhoods in Portland, Oregon. These data included dependent measures of time spent commuting and walking (min/wk), a neighborhood-level measure of the density of public transportation systems, and resident-level measures of walkability, perceptions of neighborhood street connectivity, accessibility, safety from traffic, and aesthetics. We used multilevel logistic regression to examine associations among these variables in relation to the dependent measures.

**RESULTS:** In neighborhoods with high densities of public transportation, people who resided in highly walkable home environments were more likely to spend time commuting (OR=1.15) and engaging in utilitarian walking (OR=1.19). Perceived traffic safety was related to both behaviors (OR= 1.16 for transportation, OR=1.18 for walking). Participants perceiving high neighborhood street connectivity, accessibility, and aesthetics engaged in more frequent walking trips for utilitarian purposes (ORs ranging: 1.05-1.18).

**CONCLUSIONS:** In communities with well-established public transportation systems, a high-density public transit network and highly walkable neighborhood living environment are related to active commuting and increased walking behaviors among residents. In addition, individuals' perceptions of their built environment are also important to these behaviors, especially for walking activities.

### **1672 Board #22 May 27 2:00 PM - 3:30 PM Relationships Between Objectively-measured Environmental Attributes And Step Counts Among Japanese Adults**

Kenichi Suijo, Shigeru Inoue, Yumiko Ohya, Yuko Odagiri, Tomoko Takamiya, Kaori Ishii, Makiko Kitabayashi, Teruichi Shimomitsu. Tokyo Medical University, Tokyo, Japan.  
Email: suiyo@tokyo-med.ac.jp

(No relationships reported)

Although an increasing number of studies examining the association between physical activity and environment have been reported, there have not been enough studies using objective methods of assessment both in environment and in physical activity.

**PURPOSE:** This study examined the associations between an objectively-measured environment and step counts assessed by pedometer among Japanese.

**METHODS:** A cross-sectional mail survey was conducted in four Japanese cities (Tsukuba, Koganei, Shizuoka and Kagoshima). A sample of 4,000 adults (male: 50%), aged from 20 to 69 yrs, was randomly selected from a registry of residential addresses. The survey consisted of self-administered questionnaire and 7-day accelerometer survey (Lifecorder, Suzuken). Among the 1508 respondents of the questionnaire survey, 819 (male: 46.4%, age: 48.3±14.2 yr) participated in the accelerometer survey. Environmental attributes (residential density, intersection density, existence of a train station, number of convenience stores, existence of parks and existence of exercise facilities) were assessed by the Geographic Information System (GIS), at the half-mile network buffer level. For statistical analysis, the odd ratios of walking ≥10,000 steps/day by environmental attributes were calculated using logistic regression models adjusted for gender, age, educational attainment, employment status and residential city.

**RESULTS:** Residential density (OR, 95% CI: 1.82, 1.30-2.55), existence of a train station (1.64, 1.12-2.41) and number of convenience stores (1.53, 1.10-2.13) were significantly related to walking ≥10,000 steps/day. According to stratified analyses by gender, residential density (2.15, 1.29-3.60) and number of convenience stores (1.65, 1.00-2.70) were related to walking ≥10,000 steps/day among men, while residential density (1.72, 1.06-2.71) and existence of a train station (1.95, 1.14-3.33) were related to walking ≥10,000 steps/day in women.

**CONCLUSIONS:** Associations between environmental attributes and step counts were observed using an objectively-measured environment and physical activity among Japanese.

**1673      Board #23      May 27      2:00 PM - 3:30 PM**  
**Use And Perceptions Of Available Physical Activity Facilities In Sedentary Adults**

Lucas J. Carr<sup>1</sup>, Amy V. Ries<sup>2</sup>, Bess H. Marcus<sup>1</sup>. <sup>1</sup>The Miriam Hospital and Brown Medical School, Providence, RI. <sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC.

Email: Lucas\_Carr@brown.edu

(No relationships reported)

Recent research has increasingly examined the impact of the environment on physical activity (PA) participation. Previous studies have demonstrated associations between PA and the availability of PA facilities. Little is known regarding frequency of use, type and desirable characteristics of neighborhood and community PA facilities in sedentary adults preparing to become more physically active.

**PURPOSE:** To examine perceived availability, frequency of use, type and desirable characteristics of PA facilities in sedentary, healthy adults enrolled in a PA intervention.

**METHODS:** Preliminary baseline survey data assessed perceptions of facility availability, frequency of facility use, and PA in 256 sedentary adults (32 males, 224 females; 18 to 65 years) enrolled in a 12 month PA intervention. Additionally, facility users responded to open-ended questions about the types of facilities used and desirable characteristics of PA facilities. Facility non-users were asked to report reasons for not using PA facilities and types of facilities they would be most interested in using. Analyses of survey data are ongoing but will include associations between change in PA and facility use and availability. Qualitative data were analyzed using the constant comparative method.

**RESULTS:** Based on preliminary analyses, 73% of participants reported using PA facilities for PA in the past year. The most commonly used facilities were walking trails, gyms, parks, and bike paths. The most commonly reported desirable characteristics of PA facilities included convenience, beauty, nature, presence of other people, and availability of multiple activities. Facility non-users cited cost and lack of time as primary reasons for not using PA facilities. The most desirable PA facilities for facility non-users included gyms with many workout options and classes such as aerobics or martial arts.

**CONCLUSION:** A majority of participants enrolled in this PA trial reported using PA facilities such as walking trails and gyms. Convenience was the most desirable facility characteristic while cost was the most common reason for not using PA facilities. Data on the current use and desirable characteristics of PA facilities are useful for the development of environmentally tailored PA promotion programs.

(No relationships reported)

**PURPOSE:** To identify the activities performed by frequently users of parks (PK) and squares (SQ) in the city of Curitiba, BRAZIL.

**METHODS:** Data was obtained by interview with frequently users of PK and SQ. The interviews were conducted in four PK and four SQ representing neighborhoods with different socioeconomic and built environment characteristics using a translated version of the Park Survey questionnaire (Cohen, 2004). In order to identify the activities the subjects should select one or more options from a list of 15 possible activities. The interviews were conducted during two consecutive weeks, in three periods of the day, six days by week, with exception on Fridays. The data analysis was conducted with absolute and relative frequency distribution and users of PK and SQ were compared according the gender.

**RESULTS:** Participants were 438 individuals, 259 men (59.1%) 179 women (40.9%), 152 (34.7%) and 286 (65.3%) were users of PK and SQ respectively. Considering the total of activities reported, the predominance, was walking (men: 45.3% - PK and 37.8 - SQ; women: 73.7% - PK and 58.2% - SQ), stretching (men: 37.9% PK and 40.9% SQ; women: 42.1% PK and 37.7% SQ) and running (men: 40.0% PK and 30.5% SQ). The male SQ users reported the following activities: stretching, seating, reading, exercising in the gymnastics equipment, court sports and skating in higher proportion when compared with PK users. Also, among women, the activities differ from PK to SQ. The women SQ users performed in higher proportion activities as seating, reading, walking the dog, finding friends, exercising with gymnastics equipment, court sports, gymnasium activities and playing soccer, when compared with PK users.

**CONCLUSION:** The predominant activities in the public leisure spaces were walking, stretching and running. However, there are differences in proportion between the activities performed in PK and SQ. The differences observed are likely to be related to built and social characteristics within the public leisure spaces in Curitiba, Brazil.

Cardinal, FACSM<sup>3</sup>, Mark Bosworth<sup>4</sup>. <sup>1</sup>Oregon Research Inst., Eugene, OR. <sup>2</sup>Willamette University, Salem, OR. <sup>3</sup>Oregon State University, Corvallis, OR. <sup>4</sup>Portland Metro Regional Services, Portland, OR.

Email: fuzhongl@ori.org

(No relationships reported)

Current research suggests that neighborhoods with few socioeconomic resources and unsafe conditions impose constant stress on the inhabitants, which can lead to increased risks for poor mental health conditions such as depression.

**PURPOSE:** To examine whether neighborhood walkability, socioeconomic status, and residents' perceptions of their neighborhood environment were associated with depressive symptoms among middle aged and older adults.

**METHODS:** The study used a cross-sectional, multilevel design involving neighborhoods as the primary sampling unit and residents as the secondary unit. A Geographic Information System-based measure of neighborhood walkability was constructed in 120 randomly selected neighborhoods in Portland, Oregon, from which 1145 adult residents 51-76 years of age completed a neighborhood environment and health survey. Depressive symptomatology defined by the Center for Epidemiologic Studies Depression Scale (CES-D) with a cut-off score of  $\geq 10$ . Multilevel logistic regression analyses were used to examine level-specific and cross-level associations between neighborhood-level measures of walkability and socioeconomic status and residents' perceptions of neighborhood safety, aesthetics, and social cohesion, and depressive symptoms.

**RESULTS:** High walkability and socioeconomically advantaged neighborhoods were associated with a reduced likelihood of depressive symptoms. However, residents of low-walkability neighborhoods who perceived their neighborhood as safe and socially cohesive and those in socioeconomically disadvantaged neighborhoods who perceived their neighborhoods as safe and having good aesthetics were also less likely to have depressive symptoms.

**CONCLUSIONS:** These findings provide new evidence of the importance of both the independent and joint influences of urban form and people's perceptions of the built and social environment to the development of depressive symptomatology. Promoting neighborhood built and social environments that are safe, pleasing, and cohesive may be an important intervention for enhancing residents' health and reducing the likelihood of developing depressive symptoms.

**Does The Perceived Home Environment Influence Levels Of Physical Activity In Hong Kong Residents?**

Duncan J. Macfarlane, Anson K.C. Chan, Kelvin S.K. Wong, Chris H.F. Ng, Daniel C.W. Ho. *The University of Hong Kong, Pokfulam, Hong Kong.*

(Sponsor: H. S. S. Wong, FACSM)

Email: DJMAC@HKU.HK

*(No relationships reported)*

There is growing evidence that the neighborhood built environment can play an important role in influencing how residents chose to be physically active. Public health professionals also recognize that the indoor home environment has a role in causing or mediating some human diseases. However, it is not apparent whether the home built environment contributes to public health by helping determine how its residents choose to be physically active.

**PURPOSE:** To use a recently-devised self-completed Building Environment Quality Questionnaire (BEQQ), that has been proven to be valid and reliable, to examine the association between the perceived home environment and the levels of objectively-determined physical activity.

**METHODS:** A total of 85 ethnic Hong Kong Chinese (39 men and 46 women with a mean age = 41.1 years; range 16-66 years), accepted an invitation to participate in this study. They were occupants from 22 residential buildings across Hong Kong that were considered representative examples of four types of neighborhoods that varied in extremes of socio-economic status (high v low) and "walkability" (high v low). Each resident completed a self-report BEQQ and was then asked to wear a uniaxial accelerometer for 7 consecutive days.

**RESULTS:** The 25th and 75th percentiles of the overall average BEQQ score was used to classify the perceived building environment as "High", "Moderate", or "Low", with light and moderate physical activity classified using 694-2019 and 2020-5999 accelerometer counts/minute respectively. ANOVA showed no statistically significant differences between the three levels of perceived indoor quality (high, medium, low) and time residents spent in light or moderate physical activity, nor with the average number of steps accumulated per day. Pearson correlations between accrued activity and the BEQQ scores were also not significant.

**CONCLUSIONS:** These preliminary results suggest there is no association between the perceived quality of the home environment and the levels of light or moderate habitual physical activity of these Hong Kong residents as recorded by accelerometry.

*This research was funded by the University of Hong Kong's URC-Strategic Research Theme (Public Health).*

*(No relationships reported)*

For many years the built environment has been considered to have a significant role in public health, but it is unclear whether the indoor home environment has a significant influence on the levels of habitual physical activity we accrue. Such research is restricted due to the lack of valid and reliable instruments that allow residents to self-report the nature of the home built environment.

**PURPOSE:** To develop a new self-completed Building Environment Quality Questionnaire (BEQQ) on the perceived indoor built environment, and to examine the reliability and validity of the BEQQ.

**METHODS:** After reviewing extant literature and conducting pilot interviews of residents, the new BEQQ was devised to include sections on perceived air and water quality, hygiene, space, lighting, noise, temperature/humidity, and property management. A total of 108 ethnic Hong Kong Chinese (47 men and 71 women with a mean age = 41.9 years; range 16-81 years), were then recruited to participate in the study to examine the reliability and validity of the BEQQ. They were residents from 12 residential buildings that had been audited using a semi-objective Building Health and Hygiene Index (BHHI), and chosen to represent 4 buildings with a high, medium, and low index. Intra-class correlations (ICC) were used to analyze both the reliability and intra-building validity of the BEQQ, with Pearson correlations used to analyze the criterion validity between the BEQQ and BHHI.

**RESULTS:** The BEQQ had good test-retest reliability ( $r = 0.70$ ). The intra-building validity testing generated moderate to high ICC values for all sub-categories ( $r = 0.7-0.9$ ). Furthermore, the BEQQ was significantly correlated with the criterion BHHI ( $r = -0.68$ ,  $p = 0.016$ ).

**CONCLUSIONS:** The BEQQ is a valid and reliable self-report tool for investigating the indoor home environment in a high density Asian city like Hong Kong. Further research examining the possible association between the indoor built environment and the levels of habitual physical activity accrued by the residents is therefore encouraged. This research was funded by the University of Hong Kong's URC-Strategic Research Theme (Public Health).

**Step It Up: A Multi-component Intervention To Increase Stair Use In A University Residence Building**

Erin K. Howie<sup>1</sup>, Deborah R. Young, FACSM<sup>2</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of Maryland, College Park, MD.

Email: howieek@mailbox.sc.edu

*(No relationships reported)*

Few physical activity interventions have targeted college-aged adults. Point-of-decision prompts have increased stair usage in public stairwells such as shopping malls but have had less success in worksites. No stair climbing intervention has been implemented in residential buildings.

**PURPOSE:** To examine the effects of a multi-component intervention on stair usage in a large college dormitory compared with a control dormitory.

**METHODS:** Stair use was measured through direct observation in both dormitories for one week each at baseline, mid-intervention, and one week post-intervention. Observations were made at high traffic times between noon and two in the afternoon and five and seven in the evening. The two week "Step it UP" campaign utilized poster prompts, flyers, and fun/competitive challenges with incentives to promote residents to use the stairs instead of the elevators.

**RESULTS:** A total of 5,711 direct observations were made and coded for gender. Stair use at baseline was equivalent in the experimental and control dormitories (24.9% and 27.8%). Stair use increased in the experimental dorm during the intervention as compared to the control (+8.3%, vs. -2.6%, Chi Square = 14.34,  $p < 0.001$ ). Stair use returned to baseline at follow-up (25.4% vs. 26.3%). There was no significant difference between genders or time of day.

**CONCLUSION:** This short-duration intervention significantly increased stair usage during the campaign in a college population relative to the control dorm, but was unable to sustain stair use. Formative assessment is needed to determine which single component is most cost effective for future interventions. Campaigns to increase sustained stair use are needed.

**Active Commuting At A Large University Campus**

Pamela R. Wittman, Melissa Bopp, Andrew T. Kaczynski. *Kansas State University, Manhattan, KS.* (Sponsor: Thomas J. Barstow, FACSM)  
(No relationships reported)

Regular physical activity (PA) is known to contribute to physical and mental health benefits and recent research has shown several short bouts of leisure-time or transportation PA accumulated daily are effective in obtaining health benefits.

**PURPOSE:** to understand patterns of and influences on active commuting (AC) behavior.

**METHODS:** An online survey of AC patterns was conducted at a large Midwest university campus. Students, faculty, and staff answered questions about frequency of walking, biking, and driving to campus. Respondents were asked about current PA, influences on commuting habits, and geographic characteristics related to commuting. The IR<sup>2</sup> for walking and biking behavior was tested with linear regression for 3 sets of independent variables (demographics, psychosocial, and environmental).

**RESULTS:** 901 respondents participated. 55.7% were female, 50.8% were students, and 75.1% met PA recommendations. The full model explained 31.3% of variance in walking ( $p < 0.01$ ). The demographic set explained 2.8% of variance; meeting PA recommendations was a significant predictor, and age was a negative predictor. The psychosocial set explained 18% of variance; self efficacy for AC was a significant positive predictor, time constraints were a negative predictor. The environmental set explained 10.5% of variance; barriers to parking on campus (cost, availability) were a positive predictor, perceived distance to campus was a significant negative predictor. The full model explained 26.7% of variance in biking ( $p < 0.01$ ). The demographic set explained 3.1% of variance; sex was a significant predictor (males greater AC), age was a significant negative predictor. The psychosocial set explained 23.4% of variance; eco-friendly concerns and self efficacy for AC were positive significant predictors. The environmental set explained .2% of variance; perceived distance to campus was a significant negative predictor.

**CONCLUSION:** Psychosocial variables explained the greatest percentage of both walking and biking. With current economic and ecological concerns, AC should be considered a viable and sustainable behavior to target with future health promotion initiatives. Strategies for the greatest public health impact could include both individual and community level approaches.

**Walkability Of A University Campus**

Marie H. Murphy, FACSM<sup>1</sup>, José M. Saavedra<sup>2</sup>, Yolanda Escalante<sup>2</sup>. <sup>1</sup>*University of Ulster, Jordanstown, Uruguay.* <sup>2</sup>*University of Extremadura, Cáceres, Spain.*  
Email: MH.Murphy@ulster.ac.uk  
(No relationships reported)

**PURPOSE:** Walking is a popular inexpensive physical activity that can be easily incorporated into lifestyle and has therefore become a cornerstone of many workplace physical activity promotion campaigns. A recent study suggests that increasing employee's opportunities to walk in the working day may improve productivity (Gilson et al., 2008). The purpose this study was to audit the walkability audit of Campus of Jordanstown, University of Ulster, Northern Ireland, UK.

**METHODS:** Major pedestrian routes on the university's main campus were audited by five independent observers using pedometer and an established walkability audit tool (Dannenberg et al., 2005) The audit assessed 10 routes on nine individual components (pedestrian facilities, vehicle conflicts, crossings, route-maintenance, walkway width, roadway buffer, universal accessibility, aesthetics and shelter). Each component was scored on a five-point scale (1=poor, 5=excellent). Total scores combined and weighted for each route were used to indicate of poor (20-39), fair (40-69) or good (70-100) walkability.

**RESULTS:** The 10 routes identified ranged in distance from 155-177 steps. 90% provided were considered fair and the remainder good for employee walking (range 51-88). Route averages for individual items were as follows: pedestrian facilities (3.25+1.31), vehicle conflicts (3.27+1.40), crossings (3.58+1.30), route-maintenance (3.41+1.20), walkway width (3.04+1.29), roadway buffers (2.83+1.39), universal accessibility (3.12+1.20), aesthetics (3.10+1.14) and shade (3.35+1.30). Kendall coefficient of concordance among five observers was calculated ( $k > 0.600$ ,  $p < 0.001$ ).

**CONCLUSIONS:** Overall physical infrastructure was found to be well suited to supporting workplace walking at the campus of Jordanstown, University of Ulster. The majority of the routes are safe and agreeable, providing suitable opportunities for university employees and students to engage in workplace walking. The results of the audit will also be used to reduce barriers to walking on the campus. The audit will now be replicated at partner sites and date used to inform the design and evaluation of our multi-site intervention.

**1681 Board #31 May 27 2:00 PM - 3:30 PM**  
**The Illinois Cross-campus Bicycle Program (iccb): Facilitating Lifestyle Physical Activity At A Public University**

Kyungo Kim, Leticia Malavasi, Timothy Wolfe Bretl, Morgan Johnston, Andriana Schwingel, Wojtek Chodsko-Zajko, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.*  
Email: kkim79@illinois.edu  
(No relationships reported)

The Illinois Cross-Campus Bicycle Program (ICCB) is demonstration project designed to assess the feasibility and cost-effectiveness of implementing an environmentally-friendly, healthy, and relatively inexpensive cross-campus transportation system for university employees. The program made available to participating faculty and staff departmentally-owned and maintained bicycles equipped with baskets, lights, and helmets. A key aim of the study was to determine whether employees would be willing to adopt healthier transportation options if they were made available at no cost.

**PURPOSE:** This study was designed to determine employee attitudes and responses to the availability of departmentally-owned bikes on a major university campus.

**METHODS:** Using a mixed method design, we used surveys and focus groups to determine if employees will use bicycles to get around campus on job-related activities and to learn whether some routes were more or less likely to be selected for bicycle transportation. In addition, Global Positioning System (GPS) monitors were attached to each of the

six bicycles and were used to record the details of each bicycle trip taken by the study participants.

**RESULTS:** Eighteen faculty and staff members volunteered to participate in the study. Participants used the bikes to help them get around campus for a variety of purposes including teaching classes, attending meetings, running errands, and taking a lunch break. In addition to interviewing faculty and staff members who used the bikes regularly, focus groups also sought input from infrequent, and never-users of the program. Differences in attitudes and values between the distinct cohorts were identified.

**CONCLUSIONS:** Strategies that encourage staff and faculty to select healthy transportation options while at work have the potential to not only reduce the demand for parking and the university's impact on the environment, but also to improve the health of the participants. The primary reasons given for choosing automobile transportation included time, distance, weather, convenience, and "being too tired to walk." However, others report that bicycle transportation may be an ideal form of transportation on campus that saves time and reduces stress by eliminating wait time for buses and parking woes.

### **1682 Board #32 May 27 3:30 PM - 5:00 PM**

#### **Variability Of Plasma Interleukin-6, Soluble Interleukin-6 Receptor And Soluble Glycoprotein 130 Response To A Run Pre-load Time Trial Protocol**

Paula J. Robson-Ansley, Ian Walshe. *Northumbria University, Newcastle upon Tyne, United Kingdom.*

Email: paula.ansley@unn.ac.uk

(No relationships reported)

During exercise, IL-6 is actively produced. Elevations in IL-6 levels can impair athletic performance and increase sensation of fatigue. Nutritional interventions can alter the IL-6 response to exercise but the impact this may have on performance is yet to be investigated. To test the hypothesis that an altered IL-6 response to exercise influences athletic performance, studies should employ an exercise preload followed by a time trial.

**PURPOSE:** The aim of this study was to provide data on the variability of IL-6 and its signalling molecules; sIL-6R and sgp130 response to a specific pre-load time trial protocol.

**METHODS:** Ten trained fasted runners with mean (SD) age: 27 (5) yr, body mass: 72.4 (8) kg,  $VO_{2max}$  59 (5)  $ml \cdot kg^{-1} \cdot min^{-1}$ , completed a pre-load of 120 min running at 60%  $VO_{2max}$  and followed by a 5 km time trial on 3 occasions separated by one week. The first trial was a habituation trial. Venous blood samples were drawn prior to exercise, immediately following both the pre-load and time trial. Plasma samples were analysed in duplicate for IL-6, sIL-6R and sgp130.

**RESULTS:** Coefficient of variation between trial A and B for time to complete 5 km was 3.8% (see Table 1 for C of V% for IL-6, sIL-6R and sgp130).

**CONCLUSION:** Despite attempts to standardise conditions such as pre-exercise glycogen levels, food intake and exercise training between trials, our results indicate that there is considerable variability in the IL-6, sIL-6R, sgp130 response to exercise. This variability must be taken into account in future studies attempting to explore the relationship between these variables and performance using a pre-load time trial protocol.

*Supported by Biotechnology and Biological Research Council (UK) and GlaxoSmithKline Nutritional Healthcare (UK).*

Table 1. Coefficient of variation % in plasma parameters between trials			
	Pre-ex	Post pre-load	Post time-trial
IL-6	21.8	25.4	27.7
sIL-6R	16.8	14.6	20.5
sgp130	13.9	11.8	6.4

#### **Myeloperoxidase And Neutrophil Responses To Exercise In Healthy, Overweight, And T1dm Children**

Jaime S. Rosa, Stacy R. Oliver, Rebecca L. Flores, Andria M. Pontello, Timothy D. Minh, Shirin Heydari, Milagros Ibarrolaza, Pietro R. Galassetti. *University of California, Irvine, Irvine, CA.* (Sponsor: Dan Cooper, FACSM)

Email: jsrosa@uci.edu

(No relationships reported)

**PURPOSE:** Myeloperoxidase (MPO), an oxidative enzyme mostly derived from neutrophils (PMN), has been associated with the

pathogenesis of cardiovascular disease (CVD), a common outcome in type 1 diabetes (T1DM) and obesity (OW). While regular exercise is believed to reduce CVD risk in these conditions, the role of PMN activation and MPO secretion in this context is unclear, especially in children.

**METHODS:** For 37 T1DM (13.8 $\pm$ 0.2 yrs, 16F), 55 OW (12.7 $\pm$ 0.3 yrs, 25F, BMI% $\geq$ 95<sup>th</sup>), and 43 healthy (CL, 13.4 $\pm$ 0.5 yrs, 25F, BMI% $<$ 85<sup>th</sup>) children, blood PMN and plasma MPO were measured at baseline and after 30-min of intense, intermittent exercise (2-min cycling @ ~80% VO<sub>2</sub>max followed by 1-min rest, x10); all subjects were euglycemic for  $\geq$ 90 min prior to and during exercise.

**RESULTS:** Baseline MPO (ng/mL) was higher in T1DM (143 $\pm$ 23) than OW (76 $\pm$ 6) and CL (89 $\pm$ 10). During exercise, MPO increased in OW and CL but was unchanged in T1DM; nevertheless, end-exercise values were highest in T1DM. The greater MPO levels in T1DM occurred despite slightly lower PMN counts (2.8 $\pm$ 0.2  $\times 10^3/\mu\text{L}$  vs. 3.1 $\pm$ 0.2 in CL and 3.6 $\pm$ 0.2 in OW) and similar exercise-induced PMN increases in all 3 groups.

**CONCLUSION:** Despite normal baseline counts and exercise mobilization pattern of PMNs, both pre- and post-exercise MPO were markedly elevated in T1DM children. This may reflect an enhanced pro-oxidative state throughout the duration of exercise in this group, potentially altering its overall health effects. Our data underscore the importance of a complete characterization of oxidative responses to exercise so that the full benefits of physical activity could be achieved for OW and T1DM pediatric patients.

##### Relationship Between Autonomic Nerve Activity And Distribution Of Leukocyte Subsets During Intensive Training.

Masatoshi Suzui<sup>1</sup>, Kazuyoshi Takeda<sup>2</sup>, Hideo Yagita<sup>2</sup>, Ko Okumura<sup>2</sup>, Pang N. Shek<sup>3</sup>, Roy J. Shephard, FACSM<sup>4</sup>. <sup>1</sup>Meiji University, Tokyo, Japan.

<sup>2</sup>Juntendo University, Tokyo, Japan. <sup>3</sup>Defence R & D Canada, Toronto, Ontario, Canada. <sup>4</sup>Toronto University, Toronto, ON, Canada.

Email: suzui@isc.meiji.ac.jp

(No relationships reported)

The neutrophil and lymphocyte counts in the peripheral blood show opposite circadian patterns. These changes reflect corresponding changes in sympathetic and parasympathetic nerve activity, respectively.

**PURPOSE:** We determined the impact of intensive training on autonomic nerve activity and the distribution of leukocyte subsets, by examining changes in heart rate variability (HRV) and concentrations of catecholamine and cortisol, and leukocyte subset distributions.

**METHODS:** Eight college-level female volleyball players undertook one-month of heavy pre-season training. Volleyball drills were performed 5 h/day, 6 days per week. Four morning resting blood samples were taken pre-training, on the 10th day of training, one day before the end of training and one week after training. Before collecting each blood sample, the R-R interval was also measured in a sitting position.

**RESULTS:** Circulating neutrophil and lymphocyte counts did not change throughout the experiment, except for a small subset of natural killer (NK) cell (CD56<sup>bright</sup> NK cell), that we previously reported. Peripheral blood concentrations of adrenaline, noradrenaline and cortisol also remained unaltered. HRV data showed no changes in natural log transformed (ln) high frequency (HF), low frequency (LF), LF/HF or total power (TP) but when data were pooled and plotted together, the levels of neutrophils ( $r=0.562$ ,  $p<0.001$ ), adrenaline ( $r=0.375$ ,  $p=0.034$ ) and noradrenaline ( $r=0.471$ ,  $p=0.007$ ) were negatively correlated with ln TP.

**DISCUSSION:** Our previous report showed increased CD56<sup>bright</sup> NK cells with decreased cytotoxicity at the end of training. On the other hand, in the present study we found no impact of intensive training on autonomic nerve activity and leukocyte subsets. However, homeostatic regulation might be reflected in the relationships between autonomic nerve activity and neutrophil and catecholamine concentrations.

**CONCLUSION:** The results suggest that one-month of intensive training does not affect HRV indices, concentrations of catecholamines, cortisol or major components of leukocyte at rest.

Supported by the Grant-in-Aid for Scientific Research C-2, 11680058, Japan Society for the Promotion of Science.

#### 1685 Board #35 May 27 3:30 PM - 5:00 PM

##### Phytochemical-induced Cytokine Synthesis By Peripheral Blood Mononuclear Cells Increases From Pre- To Post-vo<sub>2</sub>Max Testing

David S. Sencina<sup>1</sup>, Justus E. Hallam<sup>2</sup>. <sup>1</sup>Drake University, Des Moines, IA. <sup>2</sup>Iowa State University, Ames, IA. (Sponsor: Warren D. Franke, FACSM)

(No relationships reported)

Use of dietary botanical supplements by both recreational and professional athletes has grown in the last decade. Few studies have examined exercise-associated immune responses to supplements.

**PURPOSE:** To examine the effects of a single, intense burst of exercise (VO<sub>2</sub>max test) on *in vitro* production of TNF, IL-1b, and IL-10 in the presence of commonly used herbal medicine extracts.

**METHODS:** Twelve males (24.1  $\pm$  2.9 years of age) not currently taking any supplements participated in a graded VO<sub>2</sub>max test on a cycle ergometer. Blood was drawn pre- and post-testing. Peripheral blood mononuclear cells were isolated, standardized to 1.0  $\times 10^6$  cells/mL, and cultured with purple coneflower (*Echinacea tenesseeensis*) or

bloodroot (*Sanguinaria canadensis*) extracts using multiple extraction schemes, or solvent vehicle controls.

**RESULTS:** The average  $\text{VO}_2\text{max}$  was  $53.5 \pm 6.9$  mL/kg. For all cytokines, there was a main effect of stimulant (all  $p < 0.001$ ) such that *Sanguinaria canadensis* extracts elicited greater cytokine production than *Echinacea tennesseensis* extracts or controls, possibly due to high benzophenanthridine alkaloid content such as berberine and sanguinarine. Both ethanol and water bloodroot flower extracts elicited higher levels of cytokine production than root extracts. For TNF and IL-1b, but not IL-10, there was a main effect of exercise (both  $p = 0.011$ ) such that cytokine production was greater post-testing. No exercise  $\times$  stimulant interactions were uncovered.

**CONCLUSIONS:** Brief, intense exercise such as that experienced during  $\text{VO}_2\text{max}$  testing may be associated with a change in *in vitro* peripheral blood mononuclear cell response to compounds such as those in herbal medicine extracts.

---

**1686 Board #36 May 27 3:30 PM - 5:00 PM**

**Cycling For 90 Minutes At 85% Ventilatory Threshold Decreases Immunogen-induced Cytokine Synthesis By Peripheral Blood Mononuclear Cells**

Justus E. Hallam<sup>1</sup>, David S. Sencina<sup>2</sup>. <sup>1</sup>Iowa State University, Ames, IA. <sup>2</sup>Drake University, Des Moines, IA. (Sponsor: Warren D. Franke, FACSM)  
(No relationships reported)

High school and college athletes are increasingly consuming dietary botanical supplements to improve health or performance although little is known about their effects on immune function in the context of exercise.

**PURPOSE:** To examine the effects of 90 minutes of cycling at 85% ventilatory threshold (VT) on *in vitro* production of TNF, IL-1b, and IL-10 in the presence of immunogenic phytochemicals.

**METHODS:** Eight males ( $24.0 \pm 3.3$  years of age) not currently taking any supplements participated in a graded  $\text{VO}_2\text{max}$  test on a cycle ergometer to determine VT (using the  $\text{VE}/\text{VO}_2$  method) and then in a 90-minute cycling bout at 85% of VT. Peripheral blood mononuclear cells were isolated from pre- and post-exercise blood samples, standardized to  $1.0 \times 10^6$  cells/mL, and cultured with extracts from bloodroot, echinacea, or solvent vehicle controls. Cells were cultured for 24, 48, and 72 h and supernatants were assayed for TNF, IL-1b, and IL-10 production, respectively, via ELISA.

**RESULTS:** The average  $\text{VO}_2\text{max}$  was  $50.3 \pm 5.0$  mL/kg and the average workload corresponding to 85% VT was  $2.1 \pm 0.2$  kP ( $164.0 \pm 28.2$  W). For all cytokines, there was a main effect of exercise (all  $p \leq 0.02$ ) such that the exercise bout decreased cytokine synthesis and a main effect of stimulant (all  $p < 0.001$ ) such that bloodroot extracts were significantly different than all other stimulants or controls, possibly due to presence of benzophenanthridine alkaloids.

**CONCLUSIONS:** Cycling for 90 minutes at 85% VT decreases *in vitro* peripheral blood mononuclear cell production of TNF, IL-1b, and IL-10 in a stimulant-specific manner.

**1687 Board #37 May 27 3:30 PM - 5:00 PM**

**Marathon Running Enhances The Migratory Behavior And Proliferation Of Pc-3 Cells**

Emre Tunca, Marcus Bellin, Anne Hoffmann, Karsten Krueger, Martin Sitko, Frank-Christoph Mooren. *Sports Science, Giessen, Germany.*  
Email: emre.tunca@sport.uni-giessen.de  
(No relationships reported)

Epidemiological studies have shown that physical activity and exercise can reduce the risk to develop cancer and that cancer patients benefit regarding different physiological and psychological aspects. However, our knowledge about the mechanisms and the effect of physical activity/exercise on tumour migration and growth is rather limited.

**PURPOSE:** To analyse the effect of prolonged endurance exercise on the migratory behaviour, proliferation/apoptosis and intracellular calcium homeostasis of the prostate cancer cells PC-3.

**METHODS:** Serum was taken from 10 healthy trained male subjects ( $43 \pm 14$  yrs), pre, 1, and 2 hours after a marathon run. PC-3 tumour cells were incubated with these serums and various cellular functions were analysed. Migratory behaviour was analysed by performing a 3D-migration assay in a collagen type I matrix. For the investigation of proliferation, aliquots of the cells were cultured until one group reached the confluent state. Apoptosis was measured by flow cytometry using annexin V and propidium iodide after 24 h incubation. Intracellular calcium concentration ( $[\text{Ca}^{2+}]_i$ ) was measured using the  $\text{Ca}^{2+}$  sensitive fluorescent dye Fura-2. Statistical significance was calculated using Student's t test (two-tailed, paired).

**RESULTS:** 1 and 2 h post serums increased the relative migratory activity ( $127 \pm 5.8$  &  $117 \pm 5.8$  vs.  $100 \pm 0\%$ ,  $p < 0.05$ ) and the relative migrated distance ( $129 \pm 11.8$  &  $121 \pm 6$  vs.  $100 \pm 0\%$ ,  $p < 0.05$ ) compared to pre serum. The relative velocity of the migrating cells remained unchanged. Treatment of the cells with pre serum lead to a significantly ( $p < 0.01$ ) higher  $[\text{Ca}^{2+}]_i$  level at peak ( $668 \pm 60$  vs.  $437 \pm 59$  nmol/l) and the following plateau compared to 1h post. Incubation with post serums increased the proliferation, but was only significant ( $p < 0.05$ ) for 1h post ( $932,143 \pm 34,810$  vs.  $1,253,571 \pm 96,583$  (1h) &  $1,068,080 \pm 109,505$  (2h) cells/ml). In contrast, measurement of apoptosis revealed a significantly ( $p < 0.05$ ) higher percentage of survived cells by pre serum compared to 1h post serum ( $92.5 \pm 0.7\%$  vs.  $90.8 \pm 0.87\%$ ). There were no significant differences of apoptotic & necrotic cells between all time points.

**CONCLUSIONS:** Prolonged endurance exercise may increase the migratory behaviour and proliferation of PC-3 cells. This enhancement is associated with a reduced  $[\text{Ca}^{2+}]_i$ .

**Aerobic Fitness And Age-related Changes In Human Lymphocytes Mitochondria Respiration And Peroxyde Production**

Maria P. Mota<sup>1</sup>, Francisco M. Peixoto<sup>1</sup>, Jorge F. Soares<sup>1</sup>, Pedro A. Figueiredo<sup>2</sup>, José A. Duarte<sup>2</sup>. <sup>1</sup>UTAD, Vila Real, Portugal. <sup>2</sup>UP, Porto, Portugal.  
Email: mpmota@utad.pt  
(No relationships reported)

**PURPOSE:** To determine the influence of aerobic fitness on age-related changes in mitochondria respiratory chain complex I and II and its relation with peroxide production in healthy human lymphocytes.

**METHODS:** Fifty healthy and nonsmokers men, aged between 19 and 59 yrs ( $35.3 \pm 11.4$  yrs) participated in this study. Maximal aerobic capacity ( $\text{VO}_2\text{max}$ , mL $\cdot$ kg<sup>-1</sup>·min<sup>-1</sup>) was assessed by spirometry until exhaustion according to Bruce protocol. Lymphocyte mitochondria respiration of complex I and II were assessed after permeabilization with digitonin (1%) with a Clark electrode (Hansatech Instruments, Norfolk, UK). Peroxyde release from lymphocyte mitochondria into the overlying medium was assayed by fluorescence in a spectrofluorimeter (Jasco FP 777). A Pearson test was used to find correlation between age,  $\text{VO}_2\text{max}$  and mitochondria complex I, complex II and  $\text{H}_2\text{O}_2$  production.

**RESULTS:**  $\text{VO}_2\text{max}$  decreased significantly with age ( $r = -0.453$ ,  $p = 0.001$ ) and was negatively correlated with  $\text{H}_2\text{O}_2$  production ( $r = -0.346$ ,  $p = 0.01$ ). No correlation was found between age and mitochondria complex I, complex II and  $\text{H}_2\text{O}_2$  production. Mitochondria complex I and II were positively correlated ( $r = -0.400$ ,  $p = 0.003$ ) and complex I was positively correlated with  $\text{H}_2\text{O}_2$  production ( $r = -0.309$ ,  $p = 0.023$ ).

**CONCLUSIONS:** Concerning our results, we may conclude that high aerobic fitness is associated with lower levels of  $\text{H}_2\text{O}_2$  production due to a minor activity of complex I.

**Il-1ra Response To Brief (6-8 Min) Exercise In Asthmatic And Healthy Children**

Christina D. Schwindt, Szu-Yun Leu, Frank Zaldivar, FACSM, Dan M. Cooper, FACSM. *University of California, Irvine, Orange, CA.*

Email: cschwind@uci.edu

(No relationships reported)

Interleukin (IL)-1RA is one of the most powerful endogenous anti-inflammatory agents. It abrogates airway inflammation and bronchial hyper-responsiveness in asthma and may act to modulate asthma expression with therapeutic potential for the treatment of asthma. Exercise is a robust stimulant of IL-1RA and intense exercise can trigger exercise-induced asthma.

**PURPOSE:** To determine if brief exercise, which most closely mimics children at play, would stimulate IL-1RA in healthy and asthmatic children.

**METHODS:** One hundred nineteen children [16-female asthmatics (FA), mean age 13.6 years; 32 female controls (FC), mean age 13.7 years; 39 male asthmatics (MA), mean age 13.6 years; 32-male controls (MC), mean age 14.9 years] performed a standardized test designed to elicit exercise-induced bronchoconstriction (6-8 minutes of cycle ergometry at about 70% peak work rate). Blood was sampled at pre- and end-exercise. IL-1RA levels were measured by ELISA.

**RESULTS:** The median baseline values for IL-1RA were: FA - 138.3 pg/mL, FC - 177.7 pg/mL, MA -180.2 pg/mL, and MC - 131.8 pg/mL. A significant difference was observed between MC versus MA ( $p<0.0001$ ), and MC versus FC ( $p=0.001$ ). A significant increase in IL-1RA was observed in response to acute exercise in FA ( $p=0.004$ ; median D=6.2) and MC ( $p<0.001$ ; median D=4.6) participants. There were no group differences observed in response to exercise.

**CONCLUSIONS:** This is the first study to demonstrate differences in IL-1RA at baseline and in response to exercise between asthmatic and healthy participants. The interplay between inflammatory mediators and exercise may be important in the induction of exercise-induced asthma.

Supported by NIH Grants K23 ES014923, RO1-HL080947, P01HD-048721 and GCRC:MO1 RR00827.

**Resistance Training Decreases C-reactive Protein Without Changing Inflammatory Cytokines Or Body Mass Index**

Melody D. Phillips<sup>1</sup>, Dennis Cheek<sup>1</sup>, Joel B. Mitchell, FACSM<sup>1</sup>, Robert M. Patrizi<sup>1</sup>, Laura Quigg<sup>1</sup>, Laura K. Stewart<sup>2</sup>, Tara M. Henagan<sup>2</sup>. <sup>1</sup>Texas Christian University, Fort Worth, TX. <sup>2</sup>Louisiana State University, Baton Rouge, LA.

Email: m.phillips@tcu.edu

(No relationships reported)

**PURPOSE:** The purpose of this project was to investigate the influence of 12 weeks resistance exercise training (RT) on inflammatory markers associated with cardiovascular disease (CVD) in obese, post-menopausal women (PMW).

**METHODS:** Obese PMW ( $65.6 \pm 2.7$  yr, BMI:  $33 \pm 3.9$  kg\*m<sup>-2</sup>) completed a resistance exercise bout (RE, 10 exercises, 3 sets, 80% estimated 1RM) both before (BT) and after (AT) 12 weeks RT (EX, N=12) or weekly social meetings (CON, N=11). RT consisted of 3 sets of 10 exercises working all major muscle groups (80% estimated 1RM, 3 days/week). Blood samples were collected pre-exercise (PR), immediately post-exercise (PO), and at 2 (2H) and 24 (24H) hr of recovery (same time points for CON) both BT and AT. The following were measured BT and AT by ELISA: plasma IL-6 (PR, PO, 2H, 24H), and resting (PR) LPS-stimulated TNF- $\alpha$  production (LPS-TNF) and plasma C-reactive protein (CRP). TLR-4 mRNA expression was assessed in whole blood at rest BT and AT using real time PCR.

**RESULTS:** We observed no change in body mass or body composition, but saw an exercise x group interaction ( $P<0.001$ ) for plasma IL-6 (pg\*mL<sup>-1</sup>). RE increased IL-6 in EX at PO. By 2H, IL-6 was not different than PR in EX. EX IL-6 was lower than CON at 2H and 24H. IL-6 was greater in CON at 2H compared to other time points. (EX: PR  $1.9 \pm 0.2$ , PO  $2.9 \pm 0.3$ , 2H  $2.3 \pm 0.2$ , 24H  $1.7 \pm 0.1$ ; CON: PR  $2.5 \pm 0.3$ , PO  $2.4 \pm 0.3$ , 2H  $3.4 \pm 0.5$ , 24H  $2.5 \pm 0.3$  (pg\*mL<sup>-1</sup>)). BT and AT LPS-TNF were not different in EX ( $29 \pm 5$  vs.  $42 \pm 6$  fg\*mono<sup>-1</sup>) or CON ( $32 \pm 5$  vs.  $39 \pm 5$  fg\*mono<sup>-1</sup>). RT decreased resting (PR) CRP in EX (N=10,  $P=0.026$ ) while no change occurred in CON (EX: BT  $1.64 \pm 0.6$ , AT  $1.1 \pm 0.5$ ; CON: BT  $2.1 \pm 0.6$ , AT  $2.2 \pm 0.5$  mg/L, N=8). TLR4 mRNA expression was not different between groups when expressed as "fold change" (EX: -1.12, N=7; CON: 1.17, N=7) nor when expressed in arbitrary units and adjusted for number of monocytes in whole blood (EX: BT  $3.6 \pm 0.7$ , AT  $3.1 \pm 0.8$ ; CON: BT  $2.8 \pm 0.7$ , AT  $2.8 \pm 0.8$ ).

**CONCLUSION:** A single bout of RE using major muscle groups increased plasma IL-6 immediately post-exercise, but blunted an apparent diurnal increase observed in resting CON at 2H. Consistent RE training reduces CRP in obese PMW without a concomitant decrease in inflammatory cytokines, body fat or BMI. These positive RT-induced changes in plasma inflammatory profile may reduce the risk of inactivity-related disease.

**Changes In The Frequency Of Senescent Blood T-cells During 6-months Training Preparation For An Ironman Triathlon**

Cormac Cosgrove<sup>1</sup>, Richard J. Simpson<sup>2</sup>, Stuart DR Galloway<sup>3</sup>, Craig Neal<sup>3</sup>, Angus M. Hunter<sup>3</sup>, Brian K. McFarlin<sup>2</sup>, Keith Guy<sup>1</sup>. <sup>1</sup>Napier University, Edinburgh, United Kingdom. <sup>2</sup>University of Houston, Houston, TX. <sup>3</sup>University of Stirling, Stirling, United Kingdom.

Email: c.cosgrove@napier.ac.uk

(No relationships reported)

It is well-known that athletes are at an increased susceptibility to illness when adhering to arduous training regimens in preparation for endurance events. Senescent T-lymphocytes are antigen-experienced cells that accumulate with age and fail to clonally expand following further antigenic stimulation, thus predisposing the individual to a greater risk of infection. Although acute exercise is known to alter the frequency of senescent T-cells in blood, less is known about the effects of long-term endurance training.

**PURPOSE:** To examine the effects of 6-months training preparation for an Ironman triathlon on the frequency of senescent blood T-cells.

**METHODS:** Ten club-level triathletes (9 males; 1 female: Age:  $42.9 \pm 3.1$  yrs) provided a fasted resting blood sample in the morning at 27 (DEC), 21 (JAN), 15 (MAR), 9 (MAY) and 3 (JUN) weeks before the 2008 Zurich Ironman Triathlon. An additional sample was collected 2-weeks post-competition (AUG). Total training hours completed by the participants over the 6-month period was  $284.4 \pm 122.9$ . Isolated blood lymphocytes were labelled with monoclonal antibodies to assess cell surface expression and co-expression of the T-cell senescence markers KLRG1, CD57 and CD28; and the naïve and memory T-cell markers CD45RA and CD45RO on CD3+, CD3+/CD4+ and CD3+/CD8+ T-cells using four-colour flow cytometry. Data was analyzed for time-change using a repeated measures linear mixed model.

**RESULTS:** Compared to DEC, the percentage of CD4+ T-cells expressing KLRG1 increased by 71% (MAR), 20% (MAY) and 71% (AUG). CD4+ T-cells co-expressing KLRG1 and CD57 was 192% greater in AUG compared to DEC. No changes in senescent markers were found on CD8+ T-cells. The proportion of transitional T-cells (CD45RA+/CD45RO+) increased from MAY to JUN by 141% and 115% for CD4+ and CD8+ T-cells respectively. The proportion of memory CD8+ T-cells (CD45RA-/CD45RO+) was 40% (MAY) and 55% (AUG) greater than DEC.

**CONCLUSION:** Adherence to a 6-month training program in preparation for an Ironman triathlon leads to an increased frequency of senescent CD4+ T-cells (KLRG1+/CD57+) and a greater proportion of naïve to memory transitional CD4+ and CD8+ T-cells in blood. These changes could have important implications for athlete infection risk during periods of arduous training.

**Effect Of Exercise On Gene Expression In Peripheral Blood Mononuclear Cells (PBMCs) In Girls**

Shlomit Radom-Aizik, Frank Zaldivar, Szu-Yun Leu, Alladdin Abosaida, Dan M. Cooper. UCI, Irvine, CA.

Email: saizik@uci.edu

(No relationships reported)

In children and adults, both beneficial (e.g., reduced cardiovascular diseases risk) and dangerous (e.g., bronchoconstriction) effects of physical activity are likely mediated by circulating immune cells. Intriguingly, recent studies show that brief exercise alters circulating neutrophil and PBMC gene expression ranging from cell growth to both pro- and anti-inflammatory

processes. These initial observations were made solely in adult males.

**PURPOSE:** To study the effects of exercise on PBMC gene expression in early pubertal (EP) and late pubertal (LP) girls.

**METHODS:** The girls (EP, n=10, range 8-11 y.o.; LP, n=10, 14.5-17 y.o.) performed 10 consecutive 2-min bouts of cycle ergometry (~90% peak HR) interspersed with 1-min rest intervals. Blood was obtained at rest and again after all exercise bouts were completed. RNA was hybridized to Affymetrix Human Genome U133 Plus 2.0 Arrays. Statistical criterion to identify gene expression changes was <5% false discovery rate with 95% confidence.

**RESULTS:** Lactate and PBMCs increased significantly after exercise within each group with no significant difference between groups. Exercise induced significant changes in PBMC gene expression in EP (1321 genes) and LP (878 genes). 622 genes had a similar direction of change in both groups. From this list we identified 6 gene pathways classified by Kegg with an Ease score  $\leq 0.05$ : antigen processing and presentation (11 genes, e.g., HSPA1B, HLA-DOB, HLA-DOA, and CIITA); natural killer cell mediated cytotoxicity (14 genes, e.g., FASLG, KLRD1, CD247, KIR2DL4 and KIR2DL3); B cell receptor signaling (9 genes, e.g., BLNK, BCL10, and NFKBIA); type I diabetes (6 genes, e.g., GLCC1); hematopoietic cell lineage (8 genes, e.g., IL4R, CD19 and CD24); and apoptosis (7 genes, e.g., FADD, CASP3, PIK3CG and CASP10). We corroborated the microarray results, using RT-PCR in 6 genes from the natural killer cell mediated cytotoxicity pathway.

**CONCLUSIONS:** Brief exercise alters PBMC gene expression in early and late pubertal girls. The pattern of change involves diverse genetic pathways, consistent with a global danger-type response, perhaps readying PBMCs for a range of physiological responses from inflammation to tissue repair that would be useful following a bout of physical activity.

**Team Everest: The Immune Response To High Altitude**

Lygeri Dimitriou<sup>1</sup>, Clara Chong<sup>2</sup>, Ryan Dhunokchand<sup>2</sup>, Jonathan Ranney<sup>3</sup>, Ahmed Jehanli<sup>4</sup>, Tom Speedy<sup>4</sup>, Marcus Ranney<sup>2</sup>. <sup>1</sup>London Sport Institute, Middlesex University, London, United Kingdom. <sup>2</sup>Royal Free & University College London, Medical School, London, United Kingdom. <sup>3</sup>University of the West of England, Bristol, United Kingdom. <sup>4</sup>Cozart Bioscience Ltd, Oxon, United Kingdom. (Sponsor: Greg Whyte, FACSM)

Email: Lygeri1@mdx.ac.uk

(No relationships reported)

**INTRODUCTION:** The synergistic effect of the various high-altitude related physiological assaults concomitant with a high exposure to ultraviolet radiation and different strains of common pathogens, crowding, sub-optimal personal hygiene, sleep disturbance, and harsh environmental conditions, may impair immune function.

**PURPOSE:** To examine illness severity in association with immune and hormonal responses to high-altitude exposure.

**METHODS:** Fifty one healthy medical students (26 male and 25 female; age range, 20-28 yrs) consented to be monitored for illness severity (upper respiratory tract (URT), constitutional (CS), gastrointestinal (GI) and oral symptoms), mood and sleep disturbance, perceived exertion (Borg scale), muscle soreness (Visual Analogue Scale), acute mountain sickness (AMS, Lake Louise Score), and concentrations of salivary secretory SIgA, IgG & cortisol (EIA) during a 15-d expedition to the Nepalese Himalayas. Fasting, unstimulated, saliva samples were taken and all other measures were completed at the same time of each data collection day. Data was collected at Sea Level (Baseline) and daily during the 15-d expedition.

**RESULTS:** The severity score of URT ( $P<0.001$ ), CS ( $P=0.022$ ), GI (NS), and oral ( $P=0.026$ ) symptoms increased relatively to high-altitude exposure (1300-5200m). At 5200m cf. 1300m, URT, CS, and oral symptoms severity scores increased by 9-fold, 2.9-fold and 4.5-fold, respectively. Salivary cortisol varied significantly among the different levels of altitude ( $P=0.001$ ). It decreased by 40% at 1300m cf. Sea Level, and steadily increased after 3867m. Both, SIgA and IgG concentrations decreased ( $P<0.05$ ) relatively to high-altitude exposure and coincided with severity of illness. Perceived exertion also increased significantly ( $P=0.012$ ).

**CONCLUSIONS:** The concomitant decrease of SIgA, IgG and cortisol concentrations with the increased severity of illness, suggests an association. The decrease in cortisol might be due to impaired P450 activities. Acute cortisol suppression and increased severity of URT symptoms may predispose to the development of Acute Mountain Sickness.

**Effect Of Acute And Regular Exercise On CD4+ Lymphocyte Activation In Chronic Kidney Disease Patients**

João L. Viana<sup>1</sup>, Alice C. Smith<sup>2</sup>, George Kosmadakis<sup>2</sup>, Emma L. Clapp<sup>1</sup>, John Feehally<sup>2</sup>, Nicolette C. Bishop<sup>1</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>Leicester General Hospital, Leicester, United Kingdom.

Email: j.l.viana@lboro.ac.uk

(No relationships reported)

Chronic kidney disease (CKD) is associated with impaired cellular immunity, leading to a high incidence of infections. In healthy people, it has been shown that acute intensive exercise temporarily depresses many aspects of immune function, whereas moderate exercise exerts little influence on these measures. In addition, it has been suggested that regular moderate exercise participation may enhance immunity. However, it is not clear what effect exercise may have in CKD patients given their compromised immune systems.

**PURPOSE:** To determine the effects of acute and 6 months of regular moderate aerobic exercise on T helper (CD4+) lymphocyte activation in CKD patients.

**METHODS:** Twelve CKD (stage 4 and 5 pre-dialysis) patients (9M and 3F) with a mean age of 59 years (range 50-73 yrs), exercised for 30 min at least 5 times per week for a total period of 6 months. The exercise programme consisted of brisk walking at a Rating of Perceived Exertion (RPE) in the range of 12-14. At baseline and after the 6-month training period patients performed a standard 30 min treadmill exercise test. Venous blood samples were collected before (Pre), immediately after (Post) and 1 h after (1H) the exercise test at baseline and before the exercise test at 6 months (6M). CD4+ lymphocyte activation (CD69 expression) was determined by flow cytometry following 20 h in vitro stimulation by staphylococcal enterotoxin B.

**RESULTS:** Acute exercise induced a transient decrease in the geometric mean of fluorescence intensity (GMFI) of CD69 in CD4+ lymphocytes (mean  $\pm$  SEM, Pre:  $124 \pm 16$  vs. Post:  $110 \pm 14$ ,  $P=0.024$ ), yet values returned to resting levels within 1 h (1H:  $123 \pm 17$ ,  $P=0.914$  vs. Pre). There was no effect of acute exercise on the percentage of CD4+ lymphocytes expressing CD69 (Pre:  $23.7 \pm 3.5\%$ , one-way ANOVA,  $P=0.960$ ). Average RPE response to the exercise test after the training period was lower than at baseline ( $10 \pm 0$  vs.  $13 \pm 0$ ,  $P=0.002$ ). However, the percentage (6M:  $24.2 \pm 2.7\%$ ,  $P=0.775$  vs. Pre) and GMFI (6M:  $122 \pm 14$ ,  $P=0.748$  vs. Pre) of CD4+CD69+ lymphocytes did not change over this period.

**CONCLUSIONS:** These findings suggest that CD4+ lymphocyte function in CKD patients is not compromised by an acute bout of moderate intensity exercise and it is maintained by 6 months of regular moderate aerobic exercise participation.

**Reliability Study Of The Technique To Assess Upper Respiratory Airway Inflammation In A Polluted Environment**

Elisa Couto Gomes, Geraint Florida-James, Vicki Stone. Napier University, Edinburgh, United Kingdom.

Email: e.gomes@napier.ac.uk

(No relationships reported)

Airway inflammation can be detected by an increased influx of inflammatory cells, such as neutrophils, as well as increased expression of inflammatory markers, which include interleukin-6 (IL-6) and Clara cell protein (CC16). When an individual is exercising in a polluted environment, it is useful to be able to assess these variables with a reliable technique. Some of these techniques, such as bronchial biopsies and bronchoalveolar lavage, though frequently used, are relatively invasive procedures. The nasal lavage technique (NL), on the other hand, is a simple and relatively noninvasive

procedure that samples the upper respiratory airway.

**PURPOSE:** To investigate the reliability and sensitivity of the NL when used to assess upper respiratory airway inflammation in a non-polluted environment and compare it to an ozone-polluted environment.

**METHODS:** Six healthy volunteers took part in this study (mean  $\pm$  SD, 27  $\pm$  3 years; 69.6  $\pm$  10.8 kg; 172  $\pm$  7 cm). Once a week, at the same time of day, during a period of 5 weeks, the participants underwent NL. On the 5<sup>th</sup> week, before the NL, they remained seated for 30 min inside a thermoneutral environmental chamber with an ozone concentration of 0.10 ppm. After collection, the nasal lavage was immediately processed in the lab, the supernatant being removed and frozen at -80°C for further analysis of albumin, IL-6 and CC16. The remaining pellet was re-suspended and used for a differential cell count. Data was analysed using Repeated Measures ANOVA with Tukey's post-hoc test.

**RESULTS:** The NL was successful in measuring immune cells, albumin and CC16 from the upper respiratory airway. IL-6, however, was not detectable. During the 4 weeks with no ozone exposure, the inflammatory markers remained unchanged, with a significant inter-subject variability for albumin ( $P = 0.002$ ) and CC16 ( $P = 0.000$ ). The ozone exposure significantly increased the neutrophil counts ( $P = 0.024$ ) in the NL, but did not affect the other inflammatory markers.

**CONCLUSION:** NL is a reliable technique to assess the upper respiratory inflammatory markers. In addition, a short period of exposure to 0.10 ppm of ozone, without exercise, initiates a small inflammatory process in the lungs characterized by increased neutrophil count.

**Effect Of Power Walking Program On The Immune Response In Human Body**

Hea-Gin Choi<sup>1</sup>, Jung-Ho Cho<sup>1</sup>, Chong-Do Lee, FACSM<sup>2</sup>, Mal-Ryun Shin<sup>1</sup>, Ji-Hyun Lee<sup>1</sup>, Bo-In Choi<sup>1</sup>, Hee-Jung Kim<sup>1</sup>, Sun-Min Kim<sup>1</sup>, Jae-Hyun Jung<sup>1</sup>. <sup>1</sup>*Sookmyung Women's University, Seoul, Republic of Korea.* <sup>2</sup>*Arizona State University, Mesa, AZ.*

Email: heagin@yahoo.com

*(No relationships reported)*

Whether the effects of power walking program on immune response in human body remains less clear.

**PURPOSE:** The purpose of this study was to investigate the effect of power walking program on the immune response including interleukin-6 (IL-6), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), c-reactive protein (CRP), white blood cell (WBC) in female adults.

**METHODS:** 31 healthy female adults aged 19 to 22 years were participated in this study and classified as a three groups by light walking group (30-60 HRmax, 3-5d/wk, 30-55min/d), power walking group (40-70 HRmax, 3-5d/wk, 30-55min/d), and control group (non exercise program). They performed power walking program on treadmill for 12 months. IL-6, TNF- $\alpha$ , CRP, WBC were measured before treatment, after 6 months, and 12 months of the program treatment. Cardiorespiratory fitness was indirectly assessed by Harvard 5-minute step test. Repeated Measures Analysis of Variance (ANOVA), Multiple Range Test (Bonferroni), Pearson Product-Moment Correlation, Analysis of Simple Linear Regression, and Dubin Watson Test were used to examine the statistical significance using SPSS 12.0 windows (SPSS Inc., Chicago, IL).

**RESULTS:** There were significant differences on TNF- $\alpha$  for 12 months among three groups and walking period ( $p < .05$ ), but there were no significant differences on IL-6, CRP, and WBC among three groups. Cardiorespiratory fitness was associated with IL-6 ( $r = 0.39$ ,  $p < .05$ ).

**CONCLUSIONS:** In conclusion, power walking program for 12 months may be partly affected on immune response in healthy female adults.

*This work was Supported by Korea Research Foundation Grant funded by the Korean Government (MOEHRD) (KRF-2005-037-G00045). This work was Supported by the SRC Research Center for Women's Diseases of Sookmyung Women's University.*

**Effects Of Tai Chi Chuan On Cytokines Il-4 And Ifn- $\gamma$  Among Middle-aged And Elderly Women**

Jing Liu, Peijie Chen, Ru Wang, San Wang. *Shanghai University of Sport, Shanghai, China.* (Sponsor: Li Li, FACSM)

Email: liujing\_j3@163.com

*(No relationships reported)*

Immunosenescence refers to the decline in the immune response associated with aging in humans and animals. Factors increasing TH1 by mediated immune response (mainly the production interferon gamma [IFN- $\gamma$ ]) are related to suppression of the development of allergic disease. IFN- $\gamma$  and IL-4 have important contribution in immune defense mechanism. In this study, we analyze the effect of Tai Chi Quan on cytokines IL-4 and IFN- $\gamma$  among middle-aged or elder women who practiced for six months **PURPOSE:** The objective of the present study is to reveal the mechanism that Tai Chi promotes health in levels of cytokine.

**METHODS:** 25 women, 60 $\pm$ 6 years old, were required, who have not participated in any exercise ever. Exclusion criteria included major diseases, use of corticosteroids or other hormones. All subjects participated in 24-Type Tai Chi Quan and 42-Type Tai Chi sword exercise for six months, 60mins every time and four times a week. The intensity was regulated every month. Laboratory examinations consisted of the detection of cytokines IL-4 and IFN- $\gamma$  in peripheral blood by flow cytometry three-color method using the commercial sets of Immunotech Comp. Peripheral venous blood samples were withdrawn in the morning (7 - 9am) with fasting. Withdrawals were carried out prior to the commencement of Tai Chi program, after 4 months and after 6 months.

**RESULTS:** IFN- $\gamma$  has increased from 12.58 $\pm$ 4.40 to 16.96 $\pm$ 5.33 ( $P < 0.01$ ) and 16.15 $\pm$ 5.27 ( $P < 0.05$ ), after 4 and 6 months exercise, respectively. IL-4 has increased from 1.74 $\pm$ 1.10 to 2.55 $\pm$ 1.32 ( $P < 0.05$ ), after 4 and 6 months exercise, respectively.

**CONCLUSIONS:** Based on the literature, relation between exercise and IFN- $\gamma$  could be concerned with factors of exercise mode, exercise intensity, exercise time, exercise intermission. Tai Chi Quan is a type of aerobic training, having the characteristic of regulating physiology and psychology. We conclude that the Tai Chi Quan Exercise may affect some aging related physiological characteristics.

**The Menstrual Cycle Effect On The Immune System Response To Acute Exercise.**

Jan E. Redmond, Mary C. Pieklo, MaryAnn Coughlin, Tracey D. Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*

Email: jeredmond08@gmail.com

*(No relationships reported)*

The total number of white blood cells (leukocytes) in circulation tends to increase during and immediately following exercise. However, little is known about the influence of menstrual cycle phase on the response of total leukocytes and leukocyte subsets to an acute bout of exercise.

**PURPOSE:** To compare the response of total leukocytes and leukocyte subsets to 45 min of running and 45 min of recovery between the follicular phase and luteal phase of the menstrual cycle.

**METHODS:** Ten moderately active females taking some form of chemical contraceptive ran for 45 min at 70% of  $\dot{V}O_2$  peak in both the follicular phase and luteal phase of the menstrual cycle. Two 2 X 7 repeated measures ANOVAs were computed for measured and corrected total leukocytes, and five 2 X 7 repeated measures ANOVAs were computed for leukocyte subsets.

**RESULTS:** No significant interaction ( $p > .05$ ) was found between menstrual cycle phase and time for total leukocytes and leukocyte subsets. No significant main effect ( $p > .05$ ) was found for menstrual cycle phase for total leukocytes and leukocyte subsets. A significant main effect ( $p < .05$ ) for time was found for measured total leukocytes across

45 min of exercise and 45 min of recovery, but not for corrected total leukocytes. A significant main effect ( $p < .05$ ) for time was found for lymphocytes, monocytes, and eosinophils across 45 min of exercise and 45 min of recovery, but not for neutrophils and basophils.

**CONCLUSION:** Menstrual cycle phase does not appear to influence changes in total leukocytes and leukocyte subsets in response to an acute bout of exercise while the duration of exercise may induce changes in some of the leukocyte subset values.

#### **Cardiac Interbeat Intervals To Assess Combat Readiness.**

Donovan L. Fogt<sup>1</sup>, Paige J. Cooper<sup>1</sup>, Christine N. Freeman<sup>1</sup>, John E. Kalns<sup>2</sup>, William H. Cooke<sup>1</sup>. <sup>1</sup>The University of Texas at San Antonio, San Antonio, TX. <sup>2</sup>Hyperion Biotechnology, Inc., San Antonio, TX.

Email: donovan.fogt@utsa.edu

(No relationships reported)

**PURPOSE:** Chronic fatigue/physical exhaustion (FPE) impacts combat readiness but is difficult to identify. We tested the hypothesis that resting cardiac interbeat intervals, including both time- and frequency-domain assessments of heart rate variability (HRV), would correlate with hydration status and aerobic capacity in military recruit-age men and women with varying fitness levels.

**METHODS:** Cardiac interbeat intervals were recorded using a Polar R-R monitor during 20 minutes of quiet, supine rest with paced breathing (0.25 Hz). HRV metrics included: R-R intervals (RRI); R-R interval standard deviation (RRISD); the percentage of adjacent R-R intervals varying by  $\geq 50$  ms (pNN50); and integrated areas of R-R interval spectral power at the high (0.15 - 0.4 Hz; RRIHF) and low (0.04 - 0.15 Hz; RRI LF) frequencies. Treadmill  $\text{VO}_2$  peak; segmental bioimpedance estimates of total body water (TBW); and urine specific gravity (USG) were also assessed.

**RESULTS:** All dependent variables of interest were within expected ranges, although absolute ranges of individual values were considerable. RRI correlated with  $\text{VO}_2$  peak ( $r = 0.49$ ;  $p < 0.001$ ), TBW ( $r = 0.38$ ;  $p < 0.001$ ) and inversely with USG ( $r = -0.23$ ;  $p = 0.02$ ). RRISD correlated with  $\text{VO}_2$  peak ( $r = 0.21$ ;  $p = 0.03$ ), but not with TBW or USG. pNN50 correlated inversely with urine specific gravity ( $r = -0.21$ ;  $p = 0.03$ ) but not  $\text{VO}_2$  peak or TBW. R-R interval spectral power at the high and low frequencies correlated poorly with  $\text{VO}_2$  peak, TBW, and USG.

**CONCLUSIONS:** These results provide direction as to how fitness level and hydration status may affect cardiac function via changes in autonomic tone, highlighting the potential utility of applying field-based assessment of various interbeat interval metrics to identify FPE and other aspects of combat readiness.

(No relationships reported)

Survival conditions can occur during military operations. These emergencies situations often need intensive physical performances performed with limited feeding and associated with high psychological stress. Little is known about the physiological, endocrinal and cognitive responses to survival, as well as alteration of physical and mental performances.

**PURPOSE:** To determine consequences of field survival conditions on physical and cognitive performances and examine metabolic and endocrinal responses in well trained soldiers.

**METHODS:** 8 French commando soldiers (age  $28.4 \pm 0.8$ , height  $178 \pm 1$ , body weight (BW)  $74.3 \pm 2.9$ ) were monitored before and after the last 5 days of their field survival instruction. Anthropometric parameters (BW, fat mass), blood samples for metabolic (glycerol (GL), glucose (G) and free fatty acid (FFA) levels) and endocrinal responses (growth hormone (GH), insulin growth factor 1 (IGF-1), IGF-Binding Protein 3 (IGF-BP3)), and muscle strength characteristics were collected in resting conditions and after a 5-days field survival period. Both knee extensor and forearm muscles strength during isometric maximal voluntary contraction (MVC) and endurance time at 20% of MVC (ET20) were measured. Cognitive evaluation was done with a questionnaire. Two reconnaissance missions per day at moderate exercise intensity were performed, while subjects had to find their own food during the survival period.

**RESULTS:** As expected, BW and fat mass were decreased (-5.4%, -13.5%  $p < 0.05$ , respectively). Concerning blood parameters, both GL and G concentrations were unchanged while plasma FFA level increased (+147%,  $p < 0.01$ ). Plasma GH concentration increased (+200%  $p < 0.05$ ), associated with a surprisingly decrease of both IGF-1 and IGF-BP3 levels (-43%, -17%,  $p < 0.05$ , respectively). Neither MVC of both knee extensor and forearm nor ET20 were altered after 5 days of caloric restriction. Cognitive function also remained unaffected by survival conditions.

**CONCLUSIONS:** A short field survival period leads to lypolysis and adaptive response of the GH axis, without detectable alteration of both physical performance and cognitive status. These surprising findings could be explained by the high level of physical training and mental resilience of our subjects.

#### **Ambulatory Monitoring Of Performance And Health In The Military Using Field Labs**

Susan Vrijkotte, Pierre J.L. Valk, Roy J.E.M. Raymann. TNO Defence, Security and Safety, Soesterberg, Netherlands.

Email: susan.vrijkotte@tno.nl

(No relationships reported)

Operations in Iraq, Afghanistan and Bosnia reveal that soldiers are exposed to extreme, complex and sustained operations, crossing the limits of human capabilities. During these operations the operational readiness or status of the soldier is estimated by the commander based on subjective observations of the physical and mental capabilities of the soldier. This commander evaluation can be biased by personal experiences and commanders own physical and mental status. Wrong judgement can have negative consequences for the soldier, which might lead to dangerous and harmful situations. To predict the operational readiness and to guard the safety and health of soldiers, it is important to objectively recognize symptoms of fatigue and exhaustion. Up till now, no methods were available for the Dutch Army to monitor physiological and cognitive status of soldiers during military operations.

**PURPOSE:** Development of a mobile laboratory setting (field lab) to assess physical and cognitive changes throughout sustained operations. The data obtained will be used to develop a model predicting performance and operational status/readiness.

**METHODS:** A field lab has been developed to assess soldiers physiological and cognitive functioning during military operations (for example during education, training and missions). Equivital Life Monitors (Hidalgo, UK) measure physiological parameters like heart rate, skin and core temperature, respiratory rate, and body movements; laptops

are used to assess cognitive performance and to obtain subjective ratings, and a weather station collects environmental data.

**RESULTS:** The variety of parameters measured in our field labs result in data which will be used to develop a multi-parameter model to predict operational readiness/status. The model will give insight in important parameters to guard soldiers' performance and health and will provide the commander with additional information that might be relevant for the decision making process.

**CONCLUSIONS:** By using well equipped and well defined field labs, it is possible to assess cognitive and physiological functioning of soldiers in operational settings. This results in increased ecological validity of the data that give insight in the effect of military operations on physical and mental performance.

**1702 Board #52 May 27 2:00 PM - 3:30 PM**  
**Test-retest Reliability Of Selected Measures Of Soldier Performance**

Marilyn A. Sharp, Stephen C. Allison, Leila A. Walker, Peter N. Frykman, Everett A. Harman, Nathan R. Hendrickson. *US Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Edward Zambraski, FACSM)  
Email: marilyn.sharp@us.army.mil  
(No relationships reported)

**PURPOSE:** To determine the test-retest reliability (TRR) of measures of Soldier performance.

**METHODS:** 7 Soldier performance tests (30-m grenade throw for distance [GT-D] and accuracy [GT-A], maximum box lift [IRM], running long jump with 20.5-kg load [LJ], 2-mile march with 33-kg load [LM], 80-kg dummy drag [DD], repetitive lift and carry of a 20.5 kg box [RLC], and 5-30-m rushes with 20.5 kg load [Rush],) were performed 4 times over an 8 week period, with adequate rest between tests. Repeated measures analyses of variance (RMANOVA) were used to examine changes over time. Intraclass correlation coefficients (ICC) and 95% confidence intervals (CI) were calculated using data from all Soldiers with 4 trials for a test. Models and forms for reliability coefficients were ICC (2,1), except for GT (ICC(2,5)) and LJ (ICC(2,3)).

**RESULTS:** RMANOVA revealed no differences over time for GT-D, LJ, LM, DD or Rush. RLC and IRM stabilized by the second trial and GT-A by the third trial. Table 1 lists the ICC, CI and sample size for each test. Three tests (GT, IRM and LJ) had significantly higher overall TRR compared to 3 tests with lower TRR (CD, RLC, and Rush). By virtue of a CI that overlapped both high- and low-TRR groups, the TRR for LM was not different from either group.

Table 1. Test-Retest Reliability results.

	ICC	95% CI	n
GT-A	0.95	0.92-0.97	34
GT-D	0.94	0.90-0.97	34
IRM	0.94	0.90-0.97	35
LJ	0.93	0.88-0.96	36
LM	0.85	0.75-0.92	26
DD	0.78	0.66-0.87	34
RLC	0.71	0.57-0.83	34
Rush	0.67	0.52-0.80	32

**CONCLUSIONS:** The measures of soldier readiness with the greatest TRR were GT, IRM and LJ. Based on CI overlap, the LM was not different from the higher or lower TRR group. These 4 tests could be used to provide a reliable measure of soldier readiness.

**1703 Board #53 May 27 2:00 PM - 3:30 PM**  
**Army Physical Fitness Test 2-mile Run Correlates With Peak Oxygen Uptake In Infantry Soldiers**

Leila A. Walker<sup>1</sup>, Marilyn A. Sharp<sup>1</sup>, Joseph J. Knapik, FACSM<sup>2</sup>, Roberto E. Marin<sup>3</sup>, Robert P. Mello<sup>1</sup>. <sup>1</sup>U.S. Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD. <sup>3</sup>Womack Army Medical Center, Department of Preventive Medicine, Ft. Bragg, NC.  
Email: leila.walker@us.army.mil  
(No relationships reported)

Active duty Soldiers must be sufficiently physically fit to perform military tasks and maintain physical readiness. The Army Physical Fitness Test (APFT), consisting of a 2 mile run (2MR), sit-ups and push-ups, is used to assess Soldiers' aerobic and muscular fitness. While 2MR times have been correlated to aerobic capacity in a laboratory setting (n=61, r=-.91, Mello et al 1984), the relationship between 2MR time and peak oxygen uptake (peak VO<sub>2</sub>) has not been assessed in a large Infantry population in a field or operational setting. This matter is important due to recent findings of Soldiers entering basic combat training with lower levels of aerobic fitness and increased percent body fat.

**PURPOSE:** To determine whether 2MR time correlates with peak VO<sub>2</sub> in Infantry Soldiers in a field setting. This study will also determine whether 2MR times are influenced by body weight or composition.

**METHODS:** Prior to deploying to Afghanistan, 199 Infantry Soldiers (Mean±SD: 22.9±4.0 yr; 82.1±14.1 kg; 177.1±7.2 cm) were measured for body mass (BM), percent body fat (BF) via dual energy x-ray absorptiometry, and peak VO<sub>2</sub> by indirect spirometry using the Parvo Medics TrueOne<sup>®</sup> 2400 system and an uphill treadmill running protocol. 2MR times from the most recent APFT were obtained. Correlation coefficients were established using Pearson Product Moment correlations (α = 0.05) and prediction equations were determined through a linear regression analysis.

**RESULTS:** Mean±SE values for peak VO<sub>2</sub>(ml/kg/min), 2MR(sec), BM(kg) and BF(%) were 50.9±0.4, 863.4±5.0, 82.1±1.0, and 18.1±0.5, respectively. 2MR time was correlated negatively with peak VO<sub>2</sub> (r=-0.65); and positively with BM (r=0.41) and %BF (r=0.52). The linear regression analysis generated the following equation: Peak VO<sub>2</sub>=95.78 - .052\*2MR time(sec); r=-0.65 r<sup>2</sup>=0.42, p<.001.

**CONCLUSIONS:** Although the correlation is less than determined in the laboratory, in a field setting APFT 2MR times are correlated with and can be used to predict peak VO<sub>2</sub> or aerobic fitness. In addition, greater body weight and percent body fat are associated with slower APFT 2MR times.

**Oxygen Consumption Output Increases During Steady-State Submaximal Prolonged Heavy Load Carriage**

Megan E. Coyne, Leif Hasselquist, Jeffrey M. Schiffman, Karen N. Gregorczyk, Katharine M. Nobes, Albert Adams, Carolyn K. Bensel. *U.S. Army Natick Soldier Research, Development, and Engineering Center, Natick, MA, Natick, MA.*  
Email: megan.coyne1@us.army.mil  
(No relationships reported)

**INTRODUCTION:** Research indicates that oxygen consumption ( $\text{VO}_2$ ) increases seen during prolonged walking with a load depend upon the walk duration, velocity, grade, load carried and  $\text{VO}_2$  sampling frequency during the exercise. The timing when  $\text{VO}_2$  starts to increase as a function of loading and walking conditions remains an open question. Predictive models do not accurately capture this  $\text{VO}_2$  increase over time.

**PURPOSE:** We examined the effects on  $\text{VO}_2$  of continuous walking while carrying a heavy load versus walking without a load.

**METHODS:** Eight male volunteers (24 yrs, 81 kg, 180 cm) participated and walked on a level treadmill uninterrupted for 120-min at 1.35 m/sec. At one session volunteers wore

Figure 1: Interaction between time and load condition.

shorts, t-shirt, and footwear. At a second session, volunteers walked wearing that basic outfit plus an armor vest and a loaded backpack, for a total load of 40 kg.  $\text{VO}_2$  was collected for 3 min at minutes 5, 30, 60, 70, 80, 90, 100, 110, and 117 of the walk, and scaled to percentage of  $\text{VO}_{2\text{max}}$ . A two-way repeated measures ANOVA with nine levels of time and two levels of load (40-kg load, no load) was used to assess differences in percentage of  $\text{VO}_{2\text{max}}$  and appropriate statistics were used for follow-up analyses.

**RESULTS:** A significant interaction effect was found. Follow-up tests revealed increases over time for the loaded condition and also as compared to no load. Across time, energy cost as a percentage of  $\text{VO}_{2\text{max}}$  increased at a greater rate for the loaded condition as compared to the unloaded condition and did not appear to taper off to a steady state (Figure 1).

**CONCLUSIONS:** This study demonstrates that results of energy cost increases due to prolonged load carriage are study dependent and cannot accurately be captured by existing model predictions.

#### The Effects Of Aquatic Exercise On Balance Outcomes In Individuals With Parkinson's Disease

Miwa Kawasaki. *California State University Northridge, Northridge, CA.*

Email: miwa.kawasaki@csun.edu

(No relationships reported)

**INTRODUCTION:** Research has shown that physical activity is beneficial for improving motor performance and the quality of life for people with PD. However, few examined the effects of aquatic exercise on motor outcomes of people with PD.

**PURPOSE:** The purpose of this study was to investigate the effects of aquatic exercise on various balance outcomes of people with PD.

**METHODS:** A total of 24 individuals with PD were recruited initially and randomly assigned to two groups (12 subjects per group). Only 15 of them were able to complete this intervention study. The aquatic group (n=9) participated in a 50-minute therapeutic pool exercise program (90-94° F) 3 times a week for 9 weeks. The control (n=6) was recommended to do similar exercises at home after receiving an on-site orientation initially. Participants were tested on four balance measures: Activities Specific Balance Confidence Scale (ABCS), Berg Balance Score (BBS), static balance (postural sway), and dynamic balance (time of sit-to-stand). The postural sway was measured in two conditions (static standing with eyes closed and eyes open), using a force plate (Quattro Jump 9290, Kistler, 2003). Postural sway was calculated based on the total traveling distance of center of pressure. Time of sit-to-stand (STS) was measured using a force plate in combination with a 2 dimensional motion analysis system (Peak Modus, Vicon, 2007). Both force displacement data and movement trajectory information were used to identify the start and end times of STS.

**RESULTS:** A mixed-model ANOVA showed that there was a significant group interaction in time of STS ( $F=5.671, p < .039$ ). The aquatic group showed a greater decrease in the STS time. However, no significant group differences were noted for other dependent variables: ABC, BBS, static balance with eyes open, static balance with eye closed.

**CONCLUSIONS:** Although no significant differences were found in the ABC, BBS and static balance tests, many participants were able to maintain their balance ability, which still bears clinical significance considering the progressive nature of PD. The result of this study indicated aquatic exercise program can improve dynamic and functional balance of people with PD while it can help them prevent further loss of static balance and balance confidence.

### 1706 Board #56 May 27 2:00 PM - 3:30 PM

#### Motor Unit Conduction Velocity During Sustained Contraction Of The Vastus Medialis Muscle Injured By Eccentric Exercise

Nosratollah Hedayatpour, Deborah Falla, Lars Arendt-Nielsen, Carolina Vila-Chã, Dario Farina. *Aalborg University, Aalborg, Denmark.* (Sponsor: Frank Katch, FACSM)

Email: hedayat@hst.aau.dk

(No relationships reported)

**PURPOSE:** Eccentric contractions induce muscle fiber damage, which is associated with a decreased capacity to generate force. The sarcolemma, which conducts the action potential, is subjected to substantial tears during eccentric contractions. Thus, in this study it is hypothesized that the electrophysiological fiber membrane properties change after muscle damage induced by eccentric exercise. The aim of the study was to investigate the propagation velocity of muscle fiber action potentials in individual motor units following eccentric exercise.

**METHODS:** Multi-channel surface and fine-wire intramuscular EMG signals were concurrently recorded from two locations (proximal and distal) of the right vastus medialis muscle of 10 healthy men during 60-s isometric contractions at 10% and 30% of the maximal force. The measures were performed before (baseline), 24h, and 48h after eccentric exercise.

**RESULTS:** The maximal force decreased by  $26.1 \pm 16.1\%$  ( $P < 0.0001$ ) at 24h and remained reduced by  $23.6 \pm 14.5\%$  ( $P < 0.0001$ ) 48h post exercise with respect to baseline, which was indicative of muscle damage. Muscle fiber conduction velocity (MFCV) was reduced 24h and 48h post exercise with respect to baseline for both contraction forces and both recording locations. The percent reduction in MFCV from day 1 to day 2 and 3 (average for 24h and 48h post exercise) was  $7.7 \pm 2.7\%$  (proximal) and  $7.2 \pm 2.8\%$  (distal).

(distal) ( $P < 0.05$ ) for 10% MVC force, and  $8.6 \pm 3.8\%$  (proximal) and  $6.2 \pm 1.5\%$  (distal) ( $P < 0.05$ ) for 30% MVC force. Moreover, motor unit conduction velocity decreased over time during the sustained contractions at a faster rate when assessed 24h and 48h post exercise with respect to baseline for both levels of force and muscle locations ( $P < 0.05$ ).

**CONCLUSIONS:** These results indicate that the electrophysiological membrane properties of muscle fibers are altered by exercise-induced muscle damage.

**Relationship Between Limb Unloading And Quadriceps Strength Loss After Total Knee Arthroplasty**

Michael J. Bade, Jaclyn E. Balter, Laurel R. Kramer, Wendy M. Kohrt, FACSM, Jennifer E. Stevens-Lapsley. *University of Colorado Denver, Aurora, CO.*

Email: michael.bade@ucdenver.edu

(No relationships reported)

Deficits in muscle strength that compromise functional performance persist years after total knee arthroplasty (TKA). Unweighting or unloading of the involved limb both before and after TKA is a common adaptation to avoid knee pain and instability, but may exacerbate quadriceps strength loss.

**PURPOSE:** To quantify the relationship between changes in involved limb unloading and the amount of quadriceps strength loss after TKA.

**Subjects:** Twenty-four patients with end-stage osteoarthritis were studied ( $68.3 \pm 8.4$  years; 15 women, 9 men). Patients were excluded if they had uncontrolled hypertension, uncontrolled diabetes, body mass index  $> 35$ , or significant neurologic impairments. All subjects underwent a primary, unilateral TKA.

**METHODS:** Maximal voluntary isometric strength (MVIC) of the quadriceps muscle was assessed preoperatively and again 4 weeks after TKA using an isokinetic dynamometer. Static limb unloading was quantified by having patients place each limb on one of 2 electronic scales. Weight on each scale was recorded continuously and averaged over a total of 90 seconds. Patients were asked questions to distract them and encourage habitual stance patterns. All patients participated in a standardized rehabilitation program for 9 weeks following surgery.

**RESULTS:** Average quadriceps strength loss 1 month following TKA was  $37.9 \pm 27.9\%$  (range: 85.5% loss to 30% gain). The average amount of unloading did not change significantly before and after surgery ( $5.7 \pm 6.1\%$  vs  $7.0 \pm 4.4\%$  respectively) ( $p > 0.05$ ), although the changes in unloading by individual were more variable and ranged from a 35.9% decrease to a 29.9% increase in unloading of the involved limb. The change in quadriceps strength was significantly correlated with the change in limb unloading ( $r = 0.47$ ,  $p < 0.05$ ).

**CONCLUSION:** Quadriceps strength loss following TKA was associated with an increase in involved limb unloading. Additionally, limb unloading did not improve following TKA and one month of standard rehabilitation, suggesting that habitual unloading patterns may persist. Further research is required to determine if targeted quadriceps strengthening after TKA would attenuate limb unloading and if other causal factors exist for limb unloading.

**Dynamic Stability During Multi-directional Gait Initiation: Influence Of Age And Disease**

Joe R. Nocera<sup>1</sup>, Srikant Vallabhajosula<sup>1</sup>, Shinichi Amano<sup>1</sup>, Thomas Buckley<sup>2</sup>, Chris Hass<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>Georgia Southern University, Statesboro, GA. (Sponsor: Paul Borsa, FACSM)

Email: jnocera@ufl.edu

(No relationships reported)

Gait initiation (GI) and turning while walking have been widely investigated in older adults and more recently in Parkinson's disease (PD) patients. Previously, we have shown that persons with PD have difficulty initiating gait 90° to the side of the stepping leg. However, whether these findings carry over to other perhaps more functional turning angles (open 45° and cross over 45°) is unknown.

**PURPOSE:** To examine the differences in dynamic stability during multi-directional GI among three groups: Healthy Young Adults (HYA), Healthy Older Adults (HOA) and Persons with Parkinson's (PWP).

**METHODS:** Nine HYA (age:  $28.4 \pm 4$ y), nine HOA (age:  $56.6 \pm 9.7$ y) and 11 PWP (age:  $63 \pm 2$ ; Modified Hoehn & Yahr stage of 1 to 3) participated. An 8-camera motion capture system was used to capture the kinematic data at 120 Hz. Center of pressure (COP) data were collected using two force platforms at 1560 Hz. The whole body center of mass (COM) location was computed as the weighted sum of each body segments COM from a 15 segment biomechanical model using the collected kinematics and subject anthropometrics. Participants performed five GI trials in each of four directions: stepping 45° medially (crossing in front of the body, c45), open-stepping 45° laterally (O45), open-stepping 90° (O90) and straight (ST). The magnitude of the COP-COM moment arm was evaluated in three distinct phases (postural, weight shift, and locomotor) of the GI cycle.

**RESULTS:** The MANOVA results indicated a significant interaction effect in all the three phases. *Postural:* PWP produced the smallest resultant and AP COP-COM moment arms across C45, O45 and ST directions ( $P < 0.05$ ). However, for the O90 direction, the PWP produced the greatest resultant and ML COP-COM moment arm ( $P < 0.05$ ). *Weight shift:* PWP had a smaller AP COP-COM moment arm than HYA and HOA groups across all directions ( $P < 0.05$ ). *Locomotor phase:* PWP exhibited lowest resultant moment arm in all the directions except C45 direction ( $P > 0.05$ ). Similarly, the PWP group had lowest AP moment arms in C45, ST and O45 directions ( $P < 0.05$ ), but the greatest moment arm in O90 direction ( $P < 0.05$ ).

**CONCLUSION:** The results indicate that PWP have deficits in multi-directional GI when compared to their aged-matched counterparts and HYA, placing greater emphasis on maintaining stability than momentum generation.

**Ankle Morphometry In The Chinese Population**

Ching-Ya Huang, Kuo-Wei Tseng, Hon-Wen Cheng, Cheng-Hsiu Lai, Kuan-Ting Lee, Jyun-You Lin. *Taipei Physical Education College, Taipei, Taiwan.*

Email: fossil@tpcc.edu.tw

(No relationships reported)

**INTRODUCTION:** Modern designs are now contributing to a remarkable renewed interest in total ankle arthroplasty (TAA), but TAA is still not as successful as total hip and total knee arthroplasty. Among the remaining issues there is the design of the prosthesis components, which are often claimed to be 'anatomical' or compatible with the bony and ligament structures. However, very little is reported in the literature about the morphology of the distal tibia and proximal talus. Not a single is dedicated to the ankle morphological parameters in the Chinese population, which are expected to be addressed particularly in prosthesis designs dedicated to meeting the requirements of oriental life style.

**PURPOSE:** The purpose of the current study was to bridge the gap.

**METHODS:** Ten ankle/foot cadaver specimens without any trauma or disease (mean foot length: 22cm) were used in the current study. Each specimen was positioned at the neutral position and fixed to the plastic frame before receiving a computerized tomography (CT) scan at a slice thickness of 0.6 mm. The CT data were then used to reconstruct the 3D model of the bones and a MATLAB program was implemented with Geomagic STUDIO to obtain the morphological parameters of the distal tibia and proximal talus.

**RESULTS:** The morphometrical measures obtained are all less than those in a recent study, except for TaW, SRTi and Tiw. The relatively smaller bone mass of the distal tibia in the Chinese population suggests that the tibial bone may not be enough for the tibial component, and the stress fracture of the medial and lateral malleoli may occur.

**CONCLUSIONS:** The success of an ankle prosthesis design depends largely on the morphological data from the ankle joints of its targeted population. The measurements in the current study are expected to contribute to the design of surgical instruments and in particular of the dimensions for the different prosthesis component sizes, which were revealed to be under dimensioned. This is particularly true in post-traumatic ankles, where bones are larger than in normal ankles.

#### **Post-exercise Carbohydrates Increase The Magnitude Of The Inflammatory Response**

Chris M. Depner, Sara J. Frederickson, Kitrick Rhodes, Kelly Bond, Rita Barry, Rochelle Kirwan, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*

Email: depnerc@onid.orst.edu

(No relationships reported)

**PRUPOSE:** To determine the influence of high carbohydrate intake during recovery from eccentric exercise on the inflammatory response.

**METHODS:** The study was a cross-over design. College aged men and women (n=12) completed high carbohydrate and high fat/protein conditions in counterbalanced order. Both conditions consisted of 6 sets of 10 maximal high-force eccentric contractions of the elbow flexors and extensors. The exercise was followed by a controlled diet for the first 8 hours post-exercise based on the condition. Interleukin-6 (IL-6), interleukin-1b (IL-b), and C-reactive protein (CRP) were measured as indicators of inflammation pre-exercise, 1.5, 4, 8, and 24 h post-exercise. Blood glucose and insulin were measured at these same time points to identify differences between diets in the conditions. Creatine kinase (CK), muscle soreness, and isometric strength loss were measured as indicators of muscle damage through 120 h post-exercise.

**RESULTS:** Insulin increased ( $p<0.01$ ) in the high carbohydrate condition compared to the high fat/protein condition at 1.5, 4, and 8 hours post-exercise. Perceived soreness was elevated ( $p<0.001$ ) at all time points post-exercise in both conditions and was higher ( $p<0.05$ ) in the high carbohydrate condition compared to the high fat/protein condition. There was a main effect trend ( $p = 0.064$ ) for IL-6 to be greater in the high carbohydrate condition compared to the high fat/protein condition. IL-1b increased ( $p = 0.05$ ) 24 hours post-exercise in the high carbohydrate condition compared to the high fat/protein condition.

**CONCLUSION:** The inflammatory response following eccentric exercise was higher in the high carbohydrate compared to the high protein/fat condition, as evidenced by augmented IL-1b and IL-6 (trend only) responses. This is consistent with greater perceived muscle soreness post-exercise in the high carbohydrate condition. Additional research is required to investigate whether this response to high carbohydrate intake has the potential to influence recovery from strenuous exercise or the development of chronic diseases related to inflammation.

Email: Mustafa.Atalay@uku.fi

(No relationships reported)

Uncontrolled oxidative stress, a state where the increased production of ROS overwhelms endogenous antioxidant protection, may result in macromolecular damage and perturbation of redox control of signalling and cellular events. The heat shock proteins (HSPs) respond to a wide variety of stress, including oxidative stress. HSPs function primarily as molecular chaperones, but also control protein synthesis and trafficking, as well as regulate cellular adaptation and survival.

**PURPOSE:** Several antioxidant supplementation strategies have been used to cope with exercise-induced oxidative stress and to facilitate adaptations to exercise. While antioxidant supplementation diminishes exercise-induced oxidative stress, there is also a risk of decreasing the normal response of tissues to exercise and blunting the adaptations. In this study we examined the protective role of natural thiol antioxidant, alpha-lipoic acid (LA) supplementation at rest, after exercise and at different recovery points in skeletal muscle in horses.

**METHODS:** Six standardbred trotters were examined on the treadmill and exercised 75 min at individually defined aerobic level. Blood and muscle biopsy samples were taken before and immediately after treadmill exercise, as well as after 2-, 6-, 24- and 48-hour recovery.

**RESULTS:** LA supplementation ( $25 \text{ mg kg}^{-1} \text{ day}^{-1}$ ) for five weeks increased the resting levels of HSP90 and the recovery levels of inducible HSP70 in gluteus medius muscle. In addition, following LA-supplementation, we observed a significant decrease in exercise-induced protein oxidation in plasma and free radical formation in muscle, measured by EPR signals.

**CONCLUSION:** Our findings suggest that LA enhances HSP levels and decreases exercise-induced oxidative stress in skeletal muscle.

#### **The Impact Of Pre Exercise Snacks On Exercise Intensity, Stress, And Fatigue In Children**

Jennifer M. Sacke, Tamar Kafka, Helen Rasmussen, Jeffrey B. Blumberg, Christina D. Economos. *Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA.* (Sponsor: Miriam E. Nelson, PhD, FACSM)

Email: jennifer.sacke@tufts.edu

( J.M. Sacke, California Raisin Marketing Board, Contracted Research.)

**PURPOSE:** Few studies have examined how the composition of snacks affects athletic performance in children. We investigated whether the macronutrient and flavonoid content of 3 pre-exercise snacks differentially affected exercise intensity, stress, and post-game fatigue in young soccer players.

**METHODS:** At 1 h prior to a 50-min soccer game, 115 children ( $9.1 \pm 0.9 \text{ y}$ ) were randomly assigned to consume 1 of 3 isocaloric snacks: 1) nutrient dense/high flavonoid (HF) raisin/nut bar; 2) low flavonoid (LF) peanut butter graham bar; or 3) low flavonoid/high sugar (LF/HS) rice cereal bar. Blood glucose and salivary cortisol and IgA were measured before consuming the snack and immediately following the game. Game exercise intensity was measured by accelerometry. Self-administered questionnaires were used to assess diet quality and physical and mental fatigue after the game.

**RESULTS:** The children spent approximately 33% of the game in moderate to vigorous activity and 49% of the game in sedentary activity. The snack consumed was not related to exercise intensity. Mean post-exercise blood glucose ( $P<0.001$ ) and cortisol ( $P<0.05$ ) increased and IgA levels decreased ( $P<0.001$ ) from pre-game values. The pre-exercise snack did not predict the post-exercise outcome for any of these parameters after controlling for pre-exercise values of the biomarkers, age, gender, BMI, exercise intensity, game-time water consumption, and diet quality. Children who reported symptoms of fatigue were more likely to have consumed the LF/HS snack ( $P<0.05$ ).

**CONCLUSIONS:** The pre-exercise snacks formulated for this study did not affect blood sugar or salivary biomarkers of stress following a soccer game in young children. The nutrient content of the single snack did not differentially influence these biomarkers or the exercise intensity; however subjective feelings of fatigue may be associated with low flavonoid/high sugar snacks. Future investigations are warranted to further explore the effects of pre-exercise snacks on exercise, performance, stress and fatigue in children.

**The Effects Of Three Pre-exercise Meals On Long And Short-term Submaximal Cycling Endurance Exercise.**

Green T. Waggener, 111<sup>1</sup>, Emily M. Haymes, FACSM<sup>2</sup>, J. Derek Kingsley<sup>2</sup>, Inez Nichols<sup>1</sup>, Larry Wiley<sup>1</sup>, Robert Moffatt<sup>2</sup>. <sup>1</sup>Valdosta State University, Valdosta, GA. <sup>2</sup>Florida State University, Tallahassee, FL.

Email: gtwaggen@valdosta.edu

(No relationships reported)

**PURPOSE:** To determine the effects of pre-exercise meals on blood and cardiorespiratory variables during long-term and short-term submaximal endurance cycling.

**METHODS:** Eighteen endurance trained males, ages of 18 - 35 years, participated in this study examining the effects of 200 iso-caloric meals (300 mL) of glucose, whole milk, and an artificially flavored placebo after an overnight fast and 2-day diet high (>60%) in complex carbohydrates fed 30 minutes prior to separate rides at 55% of  $\dot{V}O_{2max}$  for 120 minutes, followed by a 30 minute rest, and a short high intensity ride to exhaustion at 80% of  $\dot{V}O_{2max}$ . Subjects were healthy and each paid \$100 for their participation. Variables measured were blood glucose, glycerol, free fatty acids, and lactate, respiratory exchange ratio, heart rate, rating of perceived exertion, and time to exhaustion. Data were analyzed using a two-way repeated measures ANOVA. Significant differences ( $p < 0.05$ ) were tested using a Bonferroni post hoc test.

**RESULTS:** Only the means of the free fatty acids were significantly different between the long ride trials ( $p < .007$ ) with milk and glucose significantly blunting the rise in free fatty acids with exercise. Over time in the long ride free fatty acids, glycerol, and heart rate increased significantly and glucose, lactate, and respiratory exchange ratio decreased significantly. On the short rides there were no significant differences between any of the variables ( $p < 0.05$ ). While the differences were not significant, time to exhaustion for the carbohydrate meal was 18% longer than milk and 20% longer than the placebo.

**CONCLUSIONS:** These results demonstrate that, following an overnight fast, a 200 kilocalorie meal prior to endurance exercise will not make a difference in time to exhaustion if it is a carbohydrate or whole milk meal. Additionally, a whole milk meal will blunt the free fatty acid response during endurance exercise similar to that of a carbohydrate only meal.

**1714 Board #64 May 27 3:30 PM - 5:00 PM**

**Atkins Diet Has Profound Effects On Mood With Minimal Effects On Physiological Responses During Exercise**

Ronald J. Giachello, Adam Wymore, Nathan Trueblood, Erica Sander, Daryl Parker, Roberto Quintana. CSUS Human Performance Research Laboratory, Sacramento, CA.

Email: rjgorion@comcast.net

(No relationships reported)

Low carbohydrate diets such as the Atkins diet induce weight loss but the combined effects of decreased mood, increased fatigue, increased perception of effort and reduced capacity to exercise may alter submaximal and high intensity exercise responses.

**PURPOSE:** The purpose was to evaluate the effects of the Atkins dietary intervention on mood state and the physiological responses during submaximal and high intensity exercise.

**METHODS:** Twenty-four healthy males volunteered to participate in the study. All subjects performed a graded exercise test to exhaustion (GXT) on a cycle ergometer or treadmill. Subjects were pair-matched and divided into two groups [control(C) and Atkins (A)]. All subjects kept a daily food record for 9 days and provided 24-hr urine samples on protocol days 3, 6 and 9 for evaluating pH and ketones. On protocol day 3 (baseline), subjects answered the Profile of Mood States (POMS) questionnaire, followed by a 40-minute exercise bout at  $58 \pm 10.2$  % of  $\dot{V}O_{2max}$ . Expired gases and RPE were measured at 10-minute intervals. At 40 minutes, intensity was increased to 90% of  $\dot{V}O_{2max}$  and time-to-exhaustion was recorded. Beginning on protocol day 4, the C group consumed their normal diet and the A group followed the induction phase of the Atkins diet for 6 days. On protocol day 9, POMS questionnaire and baseline exercise tests were repeated.

**RESULTS:** Daily CHO intake in the A group was reduced from 48% to 9% ( $p < .05$ ). pH was reduced 9.8% ( $P < .05$ ) in the A group at protocol day 9. POMS TMD was increased 768.5% in the A group ( $p < .05$ ) at protocol day 9. During exercise, fat oxidation increased. RER was reduced by 12.8 % ( $p < .05$ ) in the A group compared to C.  $\dot{V}O_2$  and RPE in the A group were significantly higher than baseline but were not different than the C group. Time-to-fatigue in the A group was also reduced compared to baseline but not different from C.

**CONCLUSION:** The Atkins diet was successful in significantly reducing CHO intake. This had a profound effect on resting urinary markers of ketogenesis and mood. Despite a large shift in substrate utilization during submaximal exercise, there were minimal effects on  $\dot{V}O_2$ , RPE and time to exhaustion during high intensity exercise. This indicates that a 6-day Atkins dietary intervention has large effects on resting mood with minimal effects during submaximal and high intensity exercise.

---

**1715 Board #65 May 27 3:30 PM - 5:00 PM**

**Weight Loss And Liquid Ingestion During Classical Ballet Training**

Cláudia V. Silva, Ana Paula T. Fayh. IPA, Porto Alegre, Brazil.

Email: claudinha\_vi@hotmail.com

(No relationships reported)

Even during moderate exercises, such as classical Ballet, weight loss (WL) due to significant water loss may happen.

**PURPOSE:** To assess WL and liquid ingest during classical ballet training sessions.

**METHODS:** The sample was composed of 21 ballet dancers of a dance school in Porto Alegre, whose average age was  $21.29 \pm 2.53$  years, who participated in three classical ballet training sessions. Initially, WL was evaluated in a 90-minute ballet session with no liquid reposition. Then, in two different training sessions of same duration, dancers received 1L of water or sports drinks, which were consumed *ad libitum*. Dancers body mass was measured in their underwear before and after the three ballet sessions, and different liquid's intake was measured through volume of individual consumption. The room temperature was controlled during the three training sessions, remaining between 20.9 and 22° C. Statistical data analysis was made through the Wilcoxon test, in which liquid ingestion and WL were compared.

**RESULTS:** Data are presented as median, and maximum and minimum values. The dehydration percentage during the session without liquid consumption was  $0.64\% \pm 0.49\%$ . In the session which dancers received water, the liquid intake was 376,19 mL (50-600mL) and the WL was -190g (-500 + 210g). In the session with sports drinks consumption, liquid intake was 226,19 mL (50-500 mL) and WL was -150g(-400g+800g). Significant differences were detected in liquid ingestion, but not in the WL in different sessions (respectively  $p=0.01$  and  $p=0.79$ ).

**CONCLUSION:** Classic ballet exercise induces a low level of dehydration, and dancers voluntarily drink more water than sports drinks during classical ballet training sessions.

**The Effect Of Acculturation And Socioeconomic Status On Dietary Patterns In Mexican-American Women**

John E. Haubenstricker<sup>1</sup>, Simon J. Marshall<sup>1</sup>, Donna Beshgetoor<sup>1</sup>, Barbara E. Ainsworth, Facsm<sup>2</sup>. <sup>1</sup>San Diego State University, San Diego, CA. <sup>2</sup>Arizona State University, Mesa, AZ.

Email: jhaubenstricker@yahoo.com

(No relationships reported)

Obesity has become epidemic among adult Hispanic women in the U.S. Currently over 75% of adult Latinas are either overweight or obese, which is partly attributable to poor dietary patterns. Although dietary patterns may be related to acculturation status, relationships have been inconsistent and are likely confounded by socioeconomic factors.

**PURPOSE:** To examine the effect of acculturation and socioeconomic status on dietary intake patterns in Mexican-American women.

**METHODS:** A community sample of 299 women (mean age = 36.0 ± 9.1 yrs; mean body mass index [BMI] = 31.0 ± 6.4) were recruited from the South Bay region of San Diego County. Participants completed an interviewer-assisted survey regarding education level, family size, household income, a short acculturation scale and a brief dietary questionnaire for Hispanics. To evaluate the combined effects of acculturation and socioeconomic status, indicators were dichotomized, and participants categorized into one of four quadrants (high/high, high/low, low/high, low/low), each reflecting a different combination of acculturation and socioeconomic status. Data were analyzed using MANCOVA to determine the effect of acculturation/socioeconomic groupings on dietary fat intake, fast food intake, and fruit and vegetable intake.

**RESULTS:** No significant differences were observed between the acculturation/socioeconomic groupings and dietary fat intake or fruit and vegetable intake. While the difference between the frequency of fast food intake per week was statistically significant between the high acculturation/above poverty group and the low acculturation/poverty group (1.18 vs. 0.99;  $P < 0.05$ ), it is doubtful this small difference has practical significance.

**CONCLUSION:** Limited evidence was found for an interaction between acculturation, socioeconomic factors and dietary intake. Relationships between acculturation, income, and fast food consumption appear complex and need further study in understanding the dietary habits of underserved populations.

Supported by a SIP 09-04 Cooperative Agreement (U48 DP000036-01S1) between the Centers for Disease Control and Prevention (CDC) and the San Diego Prevention Research Center.

**Effect Of Dash Diet On Pre- And Stage-1 Hypertensive Individuals In A Free-living Environment**

Joan Malloy-McFall, Jacob E. Barkley, Karen Lowry Gordon, Nancy Burzminski, Ellen L. Glickman, FACSM. Kent State University, Kent, OH.

Email: jmcfall@kent.edu

(No relationships reported)

**BACKGROUND:** Dietary Approaches to Stop Hypertension (DASH) has been shown to successfully reduce systolic (SBP) and diastolic blood pressure (DBP) when evaluated in clinically controlled environments but little is known about the efficacy of the DASH diet when it is applied in a free-living environment.

**PURPOSE:** To determine if following the DASH diet in a free-living environment for a 4-week duration decreased SBP and DBP.

**METHODS:** Twenty, pre- and stage-1 hypertensive participants were split into 2 groups; DASH (males N = 5, females N = 5, age = 38.1 ± 11.1) and control (males N = 7, females N = 3, age = 38.5 ± 10.5). The DASH group was instructed how to follow the DASH diet on their own for a 4-week duration while the control group continued their normal diet. SBP, DBP, bodyweight, 3-day food diaries and physical activity questionnaire data were collected pre and post intervention.

**RESULTS:** Group (DASH, control) by gender (males, females) by time (pre, post-intervention) ANCOVAs, with weight change as a co-variate, demonstrated a significant group by time interaction for changes in SBP ( $p = 0.003$ ) and no significant effects for DBP. The interaction was due to a significant reduction ( $p = 0.001$ ) in SBP in DASH (pre: 141.3 ± 11.3 mmHg vs. post: 130.7 ± 9.1 mmHg) with no change in SBP in control (pre: 133.5 ± 6.6 mmHg vs. post: 131.9 ± 8.9 mmHg). Bodyweight change was entered as a covariate to ensure significant changes in SBP and DBP were independent of weight loss. Chi-square demonstrated no significant differences in the number of participants per group ( $n = 4$  DASH,  $n = 1$  control) who indicated increasing physical activity during the intervention. Group by time ANOVAs demonstrated significant interactions for K<sup>+</sup>, total and saturated fat ( $p \leq 0.02$ ). These interactions were the result of a significantly greater increase in dietary intake of K<sup>+</sup> and decrease in dietary intake of total and saturated fat ( $p \leq 0.02$ ) in DASH (D 1267.8 ± 1103.2mg K<sup>+</sup>, -68.4 ± 35.9g total fat, -22.1 ± 13.1g saturated fat) relative to control (D -40.0 ± 1103.2mg K<sup>+</sup>, -18.8 ± 19.7g total fat, -3.1 ± 10.0g saturated fat).

**CONCLUSION:** DASH diet followed in a free-living environment significantly reduced SBP independent of weight loss and without significant differences in self-reported physical activity. These changes may be due to differences in K<sup>+</sup>, total and saturated fat intake.

Brown, FACSM<sup>3</sup>. <sup>1</sup>Tshwane University of Technology, Pretoria, South Africa. <sup>2</sup>Vaal University of Technology, Vanderbijlpark, South Africa. <sup>3</sup>Human Performance Laboratory, University of Nebraska at Kearney, Kearney, NE.

Email: shawbs@tut.ac.za

(No relationships reported)

Obesity is increasingly becoming a world-wide health concern leading to a variety of diseases, disorders and metabolic abnormalities such as coronary artery disease (CAD).

**PURPOSE:** To evaluate the effects of 16 weeks of endurance (ET) and concurrent endurance and resistance training (CT) on anthropometric measures of fatness in inactive males.

**METHODS:** Thirty-seven males were randomly assigned to an ET (N = 12), CT (N = 13) or non-exercising control (NE) group (N = 12). ET subjects utilized a combination of aerobic equipment, while the CT subjects utilized both endurance and whole-body resistance training in equal proportions.

**RESULTS:** While the NE group only found an unfavourable increase in the waist to stature ratio (WSR), ET improved ( $P \leq 0.05$ ) five of the six anthropometric measures of total fatness (i.e. body mass, fat mass, sum of skinfolds, percentage body fat (%BF) and body mass index) and two of the four anthropometric measures of intra-abdominal visceral fat mass (i.e. conicity index (CI) and WSR). CT resulted in an improvement in three of the six measures of total fatness (i.e. fat mass, sum of skinfolds and %BF) and all four measures of intra-abdominal visceral fat mass (i.e. CI, waist circumference, waist to hip ratio and WSR).

**CONCLUSIONS:** This study highlighted the superiority of endurance training over concurrent endurance and resistance training when assessing anthropometric indices of total fatness. However, concurrent endurance and resistance training was found to be more effective than endurance training at improving anthropometric measures of intra-

**Prevalence And Trends In Overweight, Obesity And Fitness In University And Government Employees.**

Francisco J. Diaz<sup>1</sup>, Donald t R. Hagan, FACSM<sup>2</sup>, María R. García<sup>1</sup>, Teresa Melchor<sup>1</sup>, José G. Montañó<sup>1</sup>, Marco A. Sanchez<sup>1</sup>, Luis A. Garcidueñas<sup>1</sup>, Magdalena Najera<sup>1</sup>, Humberto Guerrero<sup>1</sup>, Flora Moreno<sup>1</sup>, Agustín Moreno<sup>1</sup>. <sup>1</sup>University of Guanajuato, Leon, Mexico. <sup>2</sup>Houston Space Center, NASA, Houston TX, Houston, TX.

Email: fisiol@prodigy.net.mx

( F.J. Diaz, University of Guanajuato, Salary.)

**PURPOSE:** To determine prevalence and trends in overweight, obesity, Metabolic Syndrome (MS) and Maximal Aerobic Capacity (VO2Max.) in Mexican people.

**METHODS:** Data from 761 subjects (431 men and 330 women) studied in 1997-8 were compared with another group of 769 subjects (529 men and 240 women) studied in 2007-8. All subjects were government and university employees. Prevalence of overweight was defined by Body Mass Index (BMI > 24 and < 30), obesity by BMI ≥ 30, MS equal ATP III criteria and VO2Max on a treadmill.

**RESULTS:** There were no significant differences between groups in age and height (37.5±9 vs 39.4±8 years, 164±8 vs 168±8 cms for 1997-8 and 2007-8 respectively). Subjects from 2007-8 were heavier and with higher BMI (78.3±12 vs 67.7±14 Kg. and 28±4 vs 25±4 respectively.) (p<0.05). Prevalence of overweight increased from 55 to 58% and prevalence of Obesity increased from 10 to 29% respectively. These changes were observed in both genders; although women tended to present greater changes. Prevalence of MS did not change significantly (33.6 to 32.7%). There were only two variables of MS that increased significantly; waist circumference increased from 88 to 96 cms (90 to 99 for men and 85 to 90 from women) and blood glucose also increased from 86 to 95 mg/dl. (87 to 98 for men and 82 to 90 mg/dl for women)(p<0.05). In ten years VO2Max in men decreased 5 ml\*kg/min (42.3 to 37.0 ml/kg\*min) meanwhile in women did not change significantly (30 to 32 ml/kg\*min).

**CONCLUSIONS:** These data clearly demonstrate that overweight, obesity, hyperglycemia and low cardiovascular fitness are worse than ten years ago and also are mayor problems for public health in our people. These risk factors are probably deeply related to elevated morbidity and mortality from cardiovascular diseases. We need to establish urgently program of fitness related to health.

**1720 Board #70 May 27 3:30 PM - 5:00 PM**

**The "Fit But Fat" Concept Revisited: Population-based Estimates Using Nhanes**

Glen E. Duncan, Andy Bogart. University of Washington, Seattle, WA.

Email: duncag@u.washington.edu

(No relationships reported)

Low cardiovascular fitness is an independent risk factor for developing type 2 diabetes and of all-cause and cardiovascular disease mortality in adults. The so-called "fit but fat" concept suggests that cardiovascular fitness attenuates risk of metabolic and cardiovascular disease independent of body mass index (BMI), even among individuals classified as obese. However, the proportion of the U.S. population that is both fit and obese is unknown.

**PURPOSE:** To estimate the proportion of U.S. adults who are clinically obese yet have a high cardiovascular fitness level, and determine the independent effect of obesity on cardiovascular fitness.

**METHODS:** Analysis of data on 4,675 adults (20-49 years) who had completed a submaximal exercise test, from the National Health and Nutrition Examination Survey (1999-2002), a cross-sectional health survey of a nationally representative sample of the non-institutionalized U.S. population. Cardiovascular fitness and body weight were expressed as continuous (estimated VO<sub>2max</sub> [ml\*kg<sup>-1</sup>\*min<sup>-1</sup>] and BMI [kg/m<sup>2</sup>]) and categorical variables (low, moderate, and high cardiovascular fitness level; and normal weight, overweight, and obese), the latter using sex and age-specific criteria established in the Aerobic Center Longitudinal Study and standard BMI cut-points, respectively.

**RESULTS:** The prevalence of meeting the "fit but fat" definition among U.S. adults aged 20-49 was 8.9% (95% C.I. = 6.9-10.9%). The proportion of low, moderate, and high cardiovascular fitness differed significantly (P < 0.05) by body weight category. Overall, 8.9% were obese and had a high cardiovascular fitness level, 17.4% were overweight and high fit, and 30% were normal weight and high fit. In multiple regression, obesity was associated with a 9.2% lower estimated VO<sub>2max</sub> compared to a normal weight adult, controlling for age, sex, race, and income.

**CONCLUSION:** A small proportion of U.S. adults can be considered "fit but fat", and obesity is significantly and independently associated with reduced cardiovascular fitness. These results suggest that obese adults in the U.S. population may be at increased health risk due to low cardiovascular fitness.

Analyses Supported by U01CA114642.

**1721 Board #71 May 27 3:30 PM - 5:00 PM**

**The Effect Of Percent Body Fat On Mets During Self-paced Activities Of Daily Living**

Bryce L. Jones, Cheryl A. Howe, Sarah L. Kozey, John W. Staudenmayer, Patty S. Freedson, FACSM. University of Massachusetts, Amherst, MA.

(No relationships reported)

Activities of daily living (ADLs) are examples of lifestyle activities that can be performed at a moderate intensity to achieve physical activity recommendations. However, previous data suggest that obese individuals do not consistently perform ADLs at a moderate intensity. Variability in the self-selected intensity of performing ADLs needs further investigation in order to include them as examples of moderate intensity activities in the physical activity guidelines for the general public.

**PURPOSE:** To determine the effect of percent body fat on oxygen consumption and corresponding metabolic equivalents (METs) during self-paced ADLs in women.

**METHODS:** Forty-three healthy women (normal weight, < 30 % body fat, n=23; overweight/obese, ≥ 30% body fat, n = 20) between the ages of 30-60 completed a series of self-paced ADLs that were seven minutes in duration. ADLs were grouped into intensity categories (moderate = 3-6 METs, vigorous > 6 METs). Oxygen consumption was measured with a portable indirect calorimeter for each activity. To evaluate the relationship between percent body fat group and METs during ADL, a two-way repeated measures analysis of variance (RMANOVA) was performed.

**RESULTS:** The mean +/- SD percent body fat for the normal weight and overweight/obese groups were 23.7 ± 5.25 and 38.9 ± 6.40, respectively. The mean MET levels reported for moderate ADLs were > 3 METs for both normal weight and overweight/obese groups (4.5 METs ± 0.11 vs. 3.7 METs ± 0.15, respectively). However, the overweight/obese group performed moderate and vigorous ADL's at a significantly lower intensity compared to the normal weight group (moderate= 15% lower, p < 0.001; vigorous = 17.8% lower, p = 0.001).

**CONCLUSION:** Both normal weight and overweight/obese women performed self-paced ADLs at a moderate intensity. Although the overweight/obese group performed ADLs at a lower absolute intensity compared to their normal weight counterparts, the mean MET level was above the lower boundary for moderate intensity activities. The promotion of self-paced ADLs may be a successful and achievable strategy for increasing physical activity among overweight/obese women, a population at risk for chronic diseases.

**Discrepancy Between The IOTF-BMI Criteria And The Body Fat Criteria For Classifying Chinese Childhood Obesity**

Stanley Sai-chuen Hui, FACSM, Daniel C. S. Yeung. *The Chinese University of Hong Kong, Shatin, Hong Kong, Hong Kong.*  
Email: hui2162@cuhk.edu.hk  
(No relationships reported)

Age and gender specific body mass index (BMI) cut-off criteria for screening overweight and obese children has been introduced by the International Obesity Task Force (IOTF) (Cole, 2000), and has been claimed to be appropriate for Asian children. This children specific BMI criteria was developed from extrapolating the adult BMI of 25 (overweight) and 30 (obesity) to the children's BMI distribution. Its sensitivity to identify %fat-determined overweight and obesity in Chinese children is unknown.

**PURPOSE:** To evaluate the association between BMI and %fat in Chinese children and to examine the sensitivity of the IOTF-BMI criteria for screening overweight and obese children as compared to %fat criteria.

**METHODS:** A heterogeneous sample of Chinese children (N=230; BMI=13.9-37.4; Age=9-19 yrs-old) was recruited to participate in measurement of height and weight, and body fat criterion using Plethysmography (Bod-Pod). The sample was then screened for overweight and obesity using both the IOTF-BMI criteria and the %fat criteria (overweight: 25%fat for boys, 30%fat for girls; obesity: 30%fat for boys, 35%fat for girls). Difference in prevalence of overweight and obesity was compared by chi-square test. Moreover, regression equations were developed to estimate %fat from BMI and age. Using IOTF-BMI cut-off values, estimated %fat was computed using the developed equations and to compare with the measured %fat.

**RESULTS:** Using the IOTF BMI criteria, the prevalence of overweight and obesity in this sample was 20% and 6% respectively; versus the %fat determined overweight and obesity prevalence was 27.8% and 15.7%, respectively. Significant differences existed ( $p<.05$ ). From the regression analysis, mean %fat estimated from IOTF-BMI<sub>(overweight)</sub> was 23.6% for boys and 31.9% for girls; whereas mean %fat estimated from IOTF-BMI<sub>(obese)</sub> was 32.2% for boys and 40.1% for girls, which yielded large discrepancies with the %fat criteria for overweight and obesity ( $p<.05$ ). It is also noted that the predicted %fat decreases linearly as age increases in boys, whereas predicted %fat increases curvilinearly as age increases in girls.

**CONCLUSION:** There is a lack of sensitivity of IOTF-BMI criteria for screening obese Chinese children. The use of IOTF-BMI criteria as a screening tool for obesity of Chinese children is questioned.

**Self Reported Weight Category Vs. Actual Weight Category Within College-aged Students**

Rickie Lee Marker-Hoffman, Jeanne D. Johnston, Alice K. Lindeman, Matt G. Hinman. *Indiana University, Bloomington, IN.* (Sponsor: Georgia C. Frey, FACSM)  
Email: Miss\_Rickie@hotmail.com  
(No relationships reported)

Determining the most appropriate standard to measure body composition in the young adult population (18-20 yrs) may lead to more accurate classification of weight category and awareness of health status.

**PURPOSE:** To examine weight category (WC) classifications, body mass index (BMI) and percent body fat (%BF), and compare actual to perceived WC in young adults.

**METHODS:** 121 male and 162 female students from a Midwestern university were assessed for BMI and %BF via standard procedures. Subjects in the 95<sup>th</sup> percentile or higher (BMI) for age and sex were classified as obese. A questionnaire elicited self-reported and peer perceptions of WC.

**RESULTS:** Subjects were classified as overweight (OW) or obese (OB) based on BMI or %BF. BMI results for men were 13.2% OW and 18.2% OB; 24.8% OW and 7.4% OB using %BF. For women BMI values were 11.7% OW and 8.0% OB and 43.8% OW and 16.7% OB using %BF method. Men more accurately self reported WC regardless of BMI or %BF classification. 34.7% self categorized as OW/OB similar to BMI (37.3%) and %BF (38%) results. Women were not as accurate, with 39.9% self categorizing as OW/OB, lower than BMI (44.7%) or %BF (62%) findings. Regardless of sex, OB individuals indicated that their peers would view them as obese, but the OW were less likely to think their peers would categorize them OW.

**CONCLUSION:** Current methods of weight categorization appear to misclassify college men and women. Using an appropriate standard to classify this population into weight categories is important when addressing risk factors associated with body composition. The young adult population can modify lifestyle behaviors to maintain health by utilizing appropriate classifications and increasing awareness of suitable body composition values.

**On Campus Living Decreased Body Weight In Hispanic Female During College Freshman Year.**

Kyung-Shin Park, Sukho Lee. *Texas A&M International University, Laredo, TX.*  
Email: kpark@tamiu.edu  
(No relationships reported)

It is known that the freshman year of college is a critical period for weight gain and also behavioral patterns such as unhealthy diet and physical inactivity obtained during this period may contribute to overweight and obesity after graduation.

**PURPOSE:** To examine changes in body weight, body composition and diet pattern in Hispanic female during freshman year in the college.

**METHODS:** 43 Hispanic women (19 on campus living and 24 off campus living) in college freshman year participated in this study and completed two test sessions held at the beginning and end of freshmen year. In each session, participants completed three day diet log and health screening test including height, weight, body mass index (BMI), waist-hip ratio, % body fat, blood glucose and cholesterol. Level of physical activity measured using a pedometer was only taken at the end of freshmen year. Diet pattern was analyzed using Diet Power program (Danbury, CT).

**RESULTS:** From students living on campus, we observed decreased level of cholesterol (177mg/dL $\pm$ 6.1(SE) vs. 131 $\pm$ 3.7,  $p<.05$ ), body weight (140 lbs $\pm$ 3.1 vs. 131 $\pm$ 3.2,  $p<.05$ ), and daily caloric intake (1724 $\pm$ 10582 kcal/day vs. 1366 $\pm$ 55,  $p<.05$ ). BMI, waist-hip ratio, and %body fat were also slightly decreased but not significantly. We could not see any significant difference from students living off campus except decreased cholesterol level (161 $\pm$ 5.8 vs. 133 $\pm$ 4.1). Daily caloric intake was increased in this population but not significantly (1384 $\pm$ 108 vs. 1569 $\pm$ 103). Furthermore, level of physical activity was significantly higher in students living on campus as compared to students living off campus (89,600 $\pm$ 18,930 steps/week vs. 41,700 $\pm$ 5720;  $p<.05$ ).

**CONCLUSIONS:** We concluded that Hispanic female students don't gain body weight during freshman year. Results indicate that on campus living induces decrease in daily caloric intake and increase in level of physical activity in Hispanic female students during freshman year. Students living on campus may have difficulty to have food other than during University dining hours. Students who commute may experience lack of physical activity as opposed to students living on campus who walk to campus and have easy access to exercising facilities on campus.

**Body Composition And Cardiovascular Risk Factors Within College-aged Students**

Jeanne D. Johnston, Alice K. Lindeman, Rickie Lee Marker-Hoffman, Matt G. Hinman. *Indiana University, Bloomington, IN.* (Sponsor: Georgia Frey, FACSM)  
Email: jldjohnst@indiana.edu

(No relationships reported)

Identifying cardiovascular risk factors (CRF) in the young adult population (18 - 20 years) may lead to a delay of adult-onset cardiovascular disease.

**PURPOSE:** To examine the prevalence of CRF within the college-aged population and describe the relationship between CRF and body composition measures.

**METHODS:** 57 male and 81 female students from a Midwestern university were assessed. Body mass index (BMI), percent body fat (%BF), waist circumference (WC), and waist-to-hip ratio (WHR) were determined via standard procedures. Subjects in the 95<sup>th</sup> percentile or higher (BMI) for age and sex were classified as obese. Serum lipid profile (TC, HDL, LDL, TG) and glucose were determined following a 12-hr fast. The number of cardiovascular risk factors was determined utilizing American Heart Association (AHA) standards. An ANOVA was performed to examine sex differences in the variables studied.

**RESULTS:** Men had significantly higher BMI ( $24.0 \pm 3.4$ ;  $22.9 \pm 2.9$ ), WC ( $81.8 \pm 8.3$ cm;  $73.6 \pm 7.5$ cm), WHR ( $0.85 \pm 0.05$ ;  $0.78 \pm 0.06$ ) and lower %BF ( $13.7 \pm 6.2$ ;  $25.3 \pm 6.7$ ) compared to women. Women had significantly higher TC ( $173.8 \pm 33.4$  mg-dl<sup>-1</sup>;  $157.2 \pm 28.8$  mg-dl<sup>-1</sup>) and HDL ( $62.3 \pm 13.7$  mg-dl<sup>-1</sup>;  $54.9 \pm 11.9$  mg-dl<sup>-1</sup>) as compared to men. Low HDL levels were found in 25.4% of the population, followed by high TC (18.1%), TG (13%), and LDL (8%). According to AHA standards, 63% of students had at least 1 CRF, with 26% having 2 CRF, and 13% with  $\geq 3$  CRF. A significant ( $p < 0.01$ ) correlation was noted between WHR and all of the lipid values for men. For women, only HDL demonstrated a significant correlation with body composition measures (BMI, - 0.38; WC, - 0.34; %BF, - 0.23).

**CONCLUSION:** The occurrence of CRF in the young adult population predisposes them to elevated risk of cardiovascular disease (CVD) in adulthood. Efforts to encourage young adults to monitor, achieve and maintain optimal CRF levels might lead to a decreased risk for CVD in mid life. These findings reinforce the importance of lifelong health behaviors which may be established during the transition from adolescence to adulthood.

### Body Mass Index And Physical Activity As Predictors Of Mortality In Adult Women

Christopher M. Torres<sup>1</sup>, Carlos J. Crespo, FACSM<sup>1</sup>, Ross Andersen, FACSM<sup>2</sup>, Gloria C. Diaz<sup>1</sup>. <sup>1</sup>Portland State University, Portland, OR. <sup>2</sup>McGill University, Montreal, QC, Canada.

Email: cmtorres@pdx.edu

(No relationships reported)

**PURPOSE:** Physical inactivity and obesity may be independently related to all cause and cardiovascular mortality. As these conditions continue to increase in the population it is important to assess the independent effect they have in women and other segments of the population that may be disproportionately affected by them. Therefore, the purpose of this study is to examine the effects of body mass index (BMI) and leisure time physical activity (LTPA) on all cause and cardiovascular mortality using a nationally representative sample of Non-Hispanic White, Non-Hispanic Black, and Mexican American women.

**METHODS:** This study uses data from the NHANES III conducted between 1988 and 1994 and the mortality follow up (2002) in adults 20+ yrs/old. Anthropometric measurements were obtained at a mobile examination center and leisure time physical activity was obtained via a questionnaire. Other covariates analyzed were age, education, smoking, and presence of chronic disease conditions. SAS and SUDAAN software programs were used estimate relative risk of mortality and to take into account the complex sample design.

#### RESULTS:

Relative Risk ratio with 95% confidence interval of all cause mortality among non-Hispanic White, non-Hispanic Black and Mexican American women, 20 yrs and older.

	Non-Hispanic White		Non-Hispanic Black		Mexican American	
	BMI no PA	BMI with PA	BMI no PA	BMI with PA	BMI no PA	BMI with PA
Women						
Normal weight	1.0	1.0	1.0	1.0	1.0	1.0
Overweight	1.05 (0.83-1.31)	1.50 (0.84-1.32)	0.96 (0.67-1.39)	0.94 (0.64-1.37)	1.23 (0.80-1.89)	1.22 (0.80-1.87)
Obese	1.26 (1.00-1.59)	1.20 (0.96-1.49)	0.98 (0.70-1.39)	0.95 (0.68-1.32)	1.20 (0.84-1.70)	1.14 (0.79-1.64)
Physical Activity						
Frequent Active*		1.0		1.0		1.0
Infrequent Active**		1.16 (0.91-1.47)		1.10 (0.69-1.74)		1.16 (0.60-2.22)
Sedentary***		1.92 (1.55-2.39)		2.06 (1.33-3.20)		1.74 (1.10-2.76)

\* 5+ times per week \*\*1-4 times per week \*\*\* < 1 time per week

**CONCLUSION:** Sedentary behavior was an independent predictor of all cause mortality and cardiovascular mortality. Overweight status in women was not a predictor of all-cause mortality or cardiovascular mortality with physical activity or without physical activity in the model. Subsequent statistical analysis, including the combination of BMI and waist-to-hip ratio (WHR) and the division of obesity into categories (Obesity I, II, III) did not alter our findings.

### Traditional And Nontraditional Cardiorespiratory Fitness, Percentage Body Fat And All-cause Mortality In Women

Vaughn Barry, Duck-chul Lee, Xuemei Sui, J. Larry Durstine, FACSM, Russell R. Pate, FACSM, Blair N. Steven, FACSM. University of South Carolina, Columbia, SC.

Email: barryvw@mailbox.sc.edu

(No relationships reported)

**PURPOSE:** Low cardiorespiratory fitness (CRF) is inversely associated with mortality. Most previous studies have assessed CRF in ml/kg/min which accounts for body weight, and does not distinguish between fat free mass and fat mass. We investigated the independent and joint associations of two measures of CRF (ml/kg/min vs. ml/kg

FFM/min) and percentage body fat on all-cause mortality in women.

**METHODS:** We followed 10,259 women (age  $43.2 \pm 10.3$  y, % body fat  $26.7 \pm 7.0$  %), who completed a baseline maximal treadmill exercise test and percentage body fat measures during 1974-2003, for an average of  $14.5 \pm 7.6$  y follow-up. Mortality surveillance was completed through December 31, 2003. CRF was reported using traditional (ml/kg/min) and non-traditional methods (ml/kg FFM/min) and both exposures were grouped into tertiles. The lowest third was defined as unfit and the upper two thirds as fit. Percentage body fat was categorized to normal fat ( $<30\%$ ) and overfat ( $\geq 30\%$ ). Cox regression analyses were used to estimate relative risks (RRs) and 95% confidence intervals (CIs).

**RESULTS:** We identified 304 deaths during the 148,322 woman-yr of observation. Middle and high tertiles of traditional CRF (ml/kg/min) showed 21% (95% CI: 0.60-1.03) and 32% lower risk (95% CI, 0.50-0.93) for all-cause mortality after multivariable adjustments (age, examination year, smoking status, alcohol drinks, chronic diseases, and family history of CVD) compared with low CRF, respectively ( $P$  trend=0.03). After adjusting for the same variables, a 24% (95% CI: 0.58-1.00) and 27% (95% CI: 0.54-0.99) all-cause mortality risk reduction was observed using the non-traditional CRF (ml/kg FFM/min) method. Additional adjusting for percentage body fat did not materially change the results. Over-fat women had a 32% higher risk (95% CI, 1.04-1.67) of death when comparing with normal fat individuals. This relationship was no longer significant after further controlling for CRF. Unfit over-fat women were at the highest risk of death compared to fit and normal fat women, regardless of CRF method used.

**CONCLUSIONS:** Fitness was inversely associated with all-cause mortality in women even after adjusting for adiposity. The two CRF methods (ml/kg/min and ml/kg FFM/min) were similar in their association with all-cause mortality.

**Associations Between Anthropometrics, Adiposity And Mortality In Individuals With A History Of Weight Cycling**

Elmira Raeifar, Jennifer L. Kuk, Chris I. Ardern. *York University, Toronto, ON, Canada.*

Email: elmira.raeifar@gmail.com

(No relationships reported)

**Background:** The cycling of body weight is associated with increased weight gain (Van wye et al., 2007) as well as changes in body composition (Manore et al., 1991) and fat distribution (Rodin et al., 1990). Although some studies have found negative metabolic effects (Vergnaud et al., 2008) and increased mortality risk (Folsom et al., 1996) consequent to weight cycling, others do not (Montani et al., 2006). Thus, whether individuals with a history of weight cycling are at increased adiposity or elevated health risk for a given body weight requires further study.

**PURPOSE:** To quantify the impact of weight cycling on body composition and investigate its effects on the relative risk of cardiovascular disease (CVD) and all-cause mortality.

**METHODS:** Data from the Women's Health Initiative (WHI) observational study was obtained from the NHLBI (N=5675; age 50 - 79 y) and used for the analysis. Participants were classified as weight cyclers (WgtC; 37%) if they had reported that their weight had gone up and down by  $\geq 10$ lb. Multiple linear regression was used to quantify the relationship between waist circumference (WC; cm), % body fat (%BF - assessed by dual energy x-ray absorptiometry), and body mass index (BMI;  $\text{kg}\cdot\text{m}^{-2}$ ). To assess subsequent risk of mortality, Cox regressions were used to examine the effect of weight cycling for a given BMI, %BF or WC, adjusting for age, physical activity, and dietary fat consumption.

**RESULTS:** For a given BMI, %BF and WC were higher in WgtC than non-WgtC ( $P<0.001$ ). Similarly, risk for all-cause mortality was significantly higher in WgtC as compared to non-WgtC for a given BMI (HR: 1.21, 95% CI: 1.01-1.46), but not WC (HR: 1.19, 95% CI: 0.99-1.42). Alternatively, CVD mortality risk was not different between WgtC and non-WgtC for a given BMI (HR: 1.31, 95% CI: 0.94-1.83) or WC (HR: 1.31, 95% CI: 0.94-1.83). With respect to %BF, risk for both all-cause and CVD mortality was higher in WgtC versus non-WgtC (HR: 1.32, 95% CI: 1.09-1.58; HR: 1.57, 95% CI: 1.12-2.18, respectively). Implications: For a given BMI, women with a history of weight cycling have a higher %BF and WC. As weight cycling is associated with a higher risk of CVD and all-cause mortality even after adjusting for increased adiposity, these results have implications for the prediction of health risk within current obesity management guidelines.

**PURPOSE:** General obesity is a major risk factor for the development of hypertension (HTN). It is not well-studied whether central obesity and fat distribution are also related to the future HTN.

**METHODS:** 13,925 healthy normotensive men aged 20-100 years completed a baseline examination during 1976-2004, and were followed for HTN incidence. Incident HTN was identified via follow-up mail-back surveys. Obesity was defined as Body mass index (BMI)  $\geq 30 \text{ kg/m}^2$ , waist circumference (WC)  $\geq 102 \text{ cm}$ , and percent body fat  $\geq 25\%$ .

**RESULTS:** A total 1,697 men reported HTN during a mean 15.5 years of follow-up. We observed a positive gradient ( $p$  trend  $< .0001$ ) of HTN incidence rates across incremental fifths of BMI, WC, and percent body fat groups. After adjusting for potential confounders, higher baseline BMI, WC, and percent body fat was associated with greater risk of developing HTN, respectively ( $p$  trend  $< 0.0001$  for each). Additional adjusting for the other adiposity factors did not alter the relationships significantly ( $p$  trend  $< 0.01$  for each). When adiposity factors were grouped based on the clinical cutpoints, HTN incidence risk was significantly higher in BMI-defined overweight (HR, 1.53; 95% CI, 1.38-1.70) and obese (HR, 2.16; 95% CI, 1.84-2.53) compared with normal weight men; in WC-defined abdominal obese (HR, 1.61; 95% CI, 1.06-2.43) compared with normal WC men; in percent body fat-defined obese (HR, 1.47; 95% CI, 1.32-1.65) compared with normal percent body fat men, respectively. After further adjustment for the other adiposity measures, the direct association between BMI and HTN attenuated, but remained statistically significant ( $p$  trend = 0.004). However, the associations between abdominal obesity and HTN, and between percent body fat-defined obesity and HTN were no longer significant ( $p$  trend  $> 0.05$ , for each).

**CONCLUSION:** We conclude that the risk for HTN may be better identified by obesity defined by higher BMI than higher WC or higher percent body fat.

**The Association Of Abdominal Obesity With Endothelial Function In Adults With Type 2 Diabetes**

Bethany B. Barone, Jeanne M. Clark, Dhananjay Vaidya, Sandra Lima, Kerry J. Stewart, FACSM. *John Hopkins University, Baltimore, MD.*

Email: bbbbarone@jhsp.edu

(No relationships reported)

**PURPOSE:** Obesity is associated with impaired endothelial function, an early marker of cardiovascular disease. Mounting evidence suggests that abdominal obesity is especially harmful to cardiovascular health. We evaluated the relationship between general and abdominal obesity with endothelial function in persons with type 2 diabetes.

**METHODS:** 107 non-smoking, sedentary persons with type 2 diabetes controlled by diet or oral medication, aged 45-65 years old, with mild hypertension, were examined at baseline after being recruited for an exercise trial. Body mass index (BMI) was used as a measure of general obesity. Abdominal subcutaneous and visceral fat were assessed by magnetic resonance imaging. Endothelial function was measured by maximal flow-mediated dilation (FMD) of the brachial artery in response to reactive hyperemia following 5 minutes of upper arm occlusion. Bootstrap linear regression was used to assess the association of measures of obesity with FMD.

**RESULTS:** The mean (SD) age was 60.0 (5.8) years and 64% of participants were men. Mean HbA1c was 6.2% and mean BMI was 32.5 (4.3) kg/m<sup>2</sup>. Mean subcutaneous and visceral fat were 384 (121) cm<sup>2</sup> and 165 (74) cm<sup>2</sup>, respectively. Mean FMD was 5.7% (3.8%). BMI was correlated with subcutaneous ( $r=0.79, p<0.001$ ) and visceral ( $r=0.36, p<0.001$ ) abdominal fat. In a multivariate regression model with adjustment for baseline brachial artery diameter, age, and gender, we found that a -1% difference in FMD was somewhat associated with each additional 9.1 kg/m<sup>2</sup> of BMI ( $p=0.19$ ) and each additional 208 cm<sup>2</sup> of abdominal subcutaneous fat ( $p=0.16$ ). However, a -1% difference in FMD was significantly associated with each additional 91 cm<sup>2</sup> of visceral fat ( $p=0.036$ ).

**CONCLUSIONS:** Among those with type 2 diabetes, greater visceral abdominal obesity, rather than general obesity and subcutaneous fat, was associated with impaired FMD. Because of the prognostic importance of impaired endothelial function on cardiovascular health, these data suggest that strategies designed to reduce abdominal visceral fat loss need to be incorporated into preventive treatments for cardiovascular risk reduction in persons with diabetes.

**Combined Effects Of Cardiorespiratory Fitness, Not Smoking, And Normal Waist Girth On Morbidity And Mortality.**

Chong-Do Lee<sup>1</sup>, Xuemei Sui<sup>2</sup>, Steven N. Blair, FACSM<sup>2</sup>. <sup>1</sup>Arizona State University, Gilbert, AZ. <sup>2</sup>University of South Carolina, Columbia, SC.

(No relationships reported)

Physical inactivity, cigarette smoking, and obesity are key modifiable risk factors for coronary heart disease (CHD). Little is known about the relations between these combined risk factors and incident CHD and mortality.

**PURPOSE:** We investigated the combined effects of cardiorespiratory fitness, not smoking, and normal waist girth on incident CHD and mortalities from cardiovascular disease (CVD), cancer, and all causes in men.

**METHODS:** We followed 40,397 men, ages 20-79 yr, who completed a medical evaluation including a maximal treadmill exercise test and self-reported health habits at baseline examination. We defined a low-risk profile as not smoking, moderate- or high-fitness, and normal waist girth (<94 cm), respectively. The combined low-risk group was defined as satisfying all three above factors. There were 1,147 incident CHD (fatal and nonfatal CHD events) and 2,682 deaths (862 CVD, 985 cancers, and 835 others) during an average of 17.8 yr of follow-up (717,404 man-yr).

**RESULTS:** After adjustment for age, examination year, alcohol intake, and family history of CHD, men who were at low-risk for these 3 factors had 70% lower risk of incident CHD (95% CI: 57%, 79%), 84% lower risk of CVD mortality (95% CI: 77%, 89%), 72% lower risk of cancer mortality (95% CI: 58%, 81%), and 75% lower risk of all-cause mortality (95% CI: 69%, 80%), respectively, as compared with men who had none of these low-risk factors (all  $p$  for trend <0.001). Associations persisted after additional adjustment for hypertension, diabetes, and high cholesterol (all  $p$  for trend <0.001). The CHD events in this population might have been reduced by 20% (95% CI: 11%, 29%) if they had been physically fit, not smoking, and had normal waist girth. Men with all three exposures had 2.2 times the risk of CHD (95% CI: 1.52, 3.09  $p<0.001$ ) compared with men with none of these risk factors. This was equivalent to being 10.4 years older in chronological age.

**CONCLUSIONS:** Moderate and high levels of cardiorespiratory fitness, not smoking, and normal waist girth are associated with a reduced risk of incident CHD and much lower mortality from CVD, cancer, and all causes in men.

**Relation Between Muscular Strength and the Prevalence of Obesity: A Cross Sectional Analysis**

Allen W. Jackson, FACSM<sup>1</sup>, Duck - Chul Lee<sup>2</sup>, James R. Morrow, Jr., FACSM<sup>1</sup>, Xuemei Sui<sup>2</sup>, Shannon J. FitzGerald<sup>3</sup>, Steven N. Blair, FACSM<sup>2</sup>.

<sup>1</sup>University of North Texas, Denton, TX. <sup>2</sup>University of South Carolina, Columbia, SC. <sup>3</sup>The Cooper Clinic, Dallas, TX.

Email: Allen.Jackson@unt.edu

(No relationships reported)

Recent physical activity recommendations have included resistance training due to positive effects of increased muscular strength (MS), lean body mass and resting metabolic rate, and reduction in percent body fat (PFAT). The research that supports these recommendations tends to be of limited duration with little information on MS relations with health-related body composition parameters.

**PURPOSE:** To determine the relations between MS and the prevalence of indicators of obesity as measured by PFAT and waist girth (WG).

**METHODS:** The participants were men ( $n = 3,258$ , age range = 20 - 79 yrs) from the Aerobics Center Longitudinal Study that completed clinical examinations at The Cooper Clinic in Dallas, TX between 1980 and 1989. During the exam, PFAT, estimated through skinfold or hydrostatic weighing techniques, and WG were measured. Participants were considered to have excessive body fat (EBF) if PFAT was  $\geq 25\%$  and excessive abdominal fat (EAF) if WG > 102cm. The participants completed a treadmill test to estimate cardiorespiratory fitness (CRF) and 1 repetition maximums of the bench press and leg press on rack mounted weight equipment as measures of MS. An index of MS was calculated, which combined the two MS tests after controlling for age and body weight. The MS was then divided into quintiles (Q1 lowest - Q5 highest). Logistic regression was used to model the MS relations with EBF and EAF controlling age, body weight, smoking status, and CRF and produce relevant odds ratios (OR).

**RESULTS:** Prevalence (%) of EBF and EAF, respectively, were Q1 (27, 15.2), Q2 (18, 11), Q3 (15, 9), Q4 (12, 10), and Q5 (8, 9). There was a strong inverse gradient ( $p<.001$ ) between quintiles of MS and EBF with Q1 as the referent, ORs (95% CIs) were 0.55 (0.39-0.78) in Q2, 0.47 (0.32-0.68) in Q3, 0.33 (0.23-0.48) in Q4, and 0.19 (0.12-0.29) in Q5. A significant inverse gradient ( $p<.01$ ) between MS and EAF was present but only the OR (0.32, 95% CI = 0.18-0.59) for Q5 was significantly lower than Q1.

**CONCLUSION:** MS demonstrated a significant inverse gradient with two indicators of obesity, EBF and EAF. This association was present after controlling important confounders including CRF and supports the use of resistance training to increase strength, lean body mass, resting metabolic rate and improve health-related body composition.

(No relationships reported)

Resistance training to increase muscular strength (MS), lean body mass, and resting metabolic has been recommended to aid in weight loss and maintenance programs.

**PURPOSE:** To determine the relations between MS and the incidence of two indicators of obesity, excessive body fat (EBF) and abdominal fat (EAF).

**METHODS:** The participants were men ( $n = 2,623$ , age range = 20 - 79 yrs) from the Aerobics Center Longitudinal Study that completed at least two or more (baseline, follow-ups) clinical examinations at The Cooper Clinic in Dallas, TX between 1980 and 2006. At baseline, estimates of percent body fat (PFAT) were gathered from skinfold or hydrostatic weighing methods with PFAT  $\geq 25\%$  indicating EBF. Measured waist girths (WG) >102 cm indicated EAF. Participants completed a treadmill test to estimate cardiorespiratory fitness (CRF) and two tests of muscular strength (MS), 1 repetition maximums of the bench press and leg press on rack mounted weight equipment. An index of MS was calculated, which combined the two MS tests after controlling for age and body weight. The MS was then divided into quintiles (Q1 lowest - Q5 highest). At baseline, all participants had measures of PFAT and WG below the standards for EBF and EAF set for the study. PFAT and WG were again measured in follow-up clinical exams to determine if EBF and EAF were present. Cox proportional hazards regression analysis was used to model the MS relations with EBF and EAF controlling age, body weight, smoking status, and CRF and produce relevant hazard ratios (HR).

**RESULTS:** There was a strong inverse gradient ( $p<.001$ ) between quintiles of MS and EBF with Q1 as the referent, HRs (95% CIs) were 0.57 (0.44-0.73) in Q2, 0.58 (0.45-0.75) in Q3,

0.42 (0.32-0.55) in Q4, and 0.28 (0.20-0.37) in Q5. A significant inverse gradient ( $p<.001$ ) between MS and EAF was present with HRs (95% CIs) of 0.73 (0.48-1.10) in Q2, 0.60 (0.39-0.93) in Q3, 0.55 (0.36-0.85) in Q4, and 0.35 (0.22-0.54) in Q5. Incidence rates per 1,000 man-years adjusted for age and body weight (EBF, EAF) were Q1 (50.1, 17.6), Q2 (28.0, 12.5), Q3 (26.2, 9.7), Q4 (19.5, 9.5), and Q5 (11.5, 5.5).

**CONCLUSIONS:** In adult men, MS demonstrated a strong inverse gradient with the incidence of two indicators of obesity, EBF and EAF. Resistance training to increase MS should be considered for obesity prevention.

Limited data are available on the relationship between fitness, fatness and cancer mortality.

**PURPOSE:** To investigate the influences of fitness and fatness on cancer mortality among Japanese men.

**METHODS:** We evaluated fitness (cardiorespiratory fitness: CRF) and fatness (percentage of body fat: %FAT) in relation to cancer mortality in 9,039 healthy Japanese men (Age: 19-59 yr). These men completed a submaximal exercise test, a medical examination, and questionnaires on their health habits between 1982 and 1988. CRF and %FAT were estimated using a cycle ergometer test and skin fold measurements. Men were divided into tertiles based on CRF and %FAT. The mean follow-up period was more than 18 years (165,468 man-years of observation). There were 148 cancer deaths during follow-up.

**RESULTS:** Relative risks (RR) and 95% confidence intervals (95% CI) for cancer mortality were obtained using the Cox proportional hazards model while adjusting for age, systolic blood pressure, cigarette smoking, and alcohol intake. Using the least fit group (first tertile) as reference, the RR and 95% CI for second tertile and third tertile were 0.60 (0.41-0.88) and 0.60 (0.37-0.99) ( $p$  for trend=0.010). Also, using the lean group (first tertile) as reference, the RR and 95% CI for second tertile and third tertile were 0.98 (0.66-1.44) and 1.02 (0.69-1.52) ( $p$  for trend=0.926). Moreover, we calculated RR for cancer mortality according to groups of men cross-tabulated by tertile of %FAT and "Unfit group" (first tertile) and "Fit group" (second and third tertiles) (Table).

**CONCLUSION:** These results suggest that low CRF is a risk factor for cancer mortality in Japanese men which was present in the low fatness and high fatness categories.

	Low-%FAT(7-12%)	Mid-%FAT(13-15%)	High-%FAT(16-40%)
Fit	1 (reference)	1.12 (0.65-1.94)	0.87 (0.44-1.75)
Unfit	2.04 (1.20-3.47)	1.46 (0.86-2.48)	1.64 (0.99-2.71)

 (No relationships reported)

**PURPOSE:** To investigate the influence of physical activity (PA) during days when not participating in a supervised exercise class (Ex-CL) on weight reduction.

**METHODS:** Twenty one Japanese obese men (body mass index:  $30.1 \pm 4.8$  kg/m<sup>2</sup>,  $52.9 \pm 9.3$  years) performed 90-min exercise sessions on 3 days per week for 12 weeks. They were also urged to self-initiate increases in PA during daily living. The amount of PA above an intensity of 3 metabolic equivalents (METs) was measured using a triaxial accelerometer which could classify PA to locomotive or lifestyle activity. Participants wore the accelerometer constantly for 2 weeks prior to and during the entire exercise program. PA was expressed as METs and multiplied by activity time (METs-h). A 3-day food record was used to estimate energy intake (EI).

**RESULTS:** EI remained unchanged during the exercise program (from  $2069 \pm 367$  to  $2022 \pm 336$  kcal/day). During non-Ex-CL days, the amount of lifestyle activity remained unchanged (from  $1.0 \pm 0.6$  to  $1.0 \pm 0.6$  METs-h/day) but locomotive activity increased (from  $2.4 \pm 1.8$  to  $3.8 \pm 2.5$  METs-h/day,  $P < 0.05$ ). There was also a relationship between change (D) in PA during non-Ex-CL days and D in weight ( $r = -0.70$ ,  $P < 0.01$ ), although no relationship was observed between D in PA during Ex-CL days and D in weight ( $r = -0.36$ ,  $P = 0.11$ ).

**CONCLUSIONS:** The increase in PA appears to be due to locomotive activity and not lifestyle activity in men. These results suggest that increased PA during non-Ex-CL days strongly contributes to weight reduction during an exercise program.

**High Fatness And Low Fitness Are Associated With Elevated Serum Vaspin Level In Young Korean Adults**

Soo-Hyun Park, Jin-Kyung Cho, Tae-Kyung Kim, Soo-Jin Lee, Hyun-Sik Kang. Sungkyunkwan University, Suwon, Republic of Korea.  
 Email: otajulia@gmail.com  
 (No relationships reported)

Visceral adipose tissue-derived serine protease inhibitor (vaspin) is a novel adipocytokine with insulin-sensitizing effects that may have some critical roles in the development of obesity, and insulin resistance, and type 2 diabetes.

**PURPOSE:** To investigate if body fatness and fitness are associated with serum vaspin levels in Korean adults.

**METHODS:** In a cross-sectional study, we examined 396 young Korean men (age,  $23.8 \pm 2.5$  years; BMI,  $23.2 \pm 2.8$  kg/m<sup>2</sup>) who were recruited from our institute. Body fatness and fasting levels of serum insulin, adiponectin, and vaspin were measured. Cardiorespiratory fitness (CRF) was quantified as minute volume of oxygen consumption (VO<sub>2</sub>) measured during a graded treadmill test. In the present analyses, we assigned individuals to either lowest, middle, and top third CRF tertiles based on age-adjusted VO<sub>2</sub>max values or lean weight (LEAN) and obese (OB) groups based the BMI criterion (BMI = 25 kg/m<sup>2</sup>) for Pacific-Asian obesity.

**RESULTS:** In the total study population, serum vaspin was positively associated with BMI ( $R=0.139$ ,  $P=0.003$ ) and waist circumference ( $R=0.116$ ,  $P=0.021$ ) and inversely associated with CRF ( $R=-0.103$ ,  $P=0.040$ ). Further, the OB group had significantly higher serum vaspin ( $P=0.030$ ), insulin ( $P<0.001$ ), and homeostasis model assessment insulin resistance ( $P<0.001$ ) along with a lower adiponectin ( $P=0.043$ ) than the LEAN group in the low CRF tertile only, but not in either middle or top CRF tertile.

**CONCLUSION:** The current findings of the study suggest that both body fatness and fitness may modulate serum vaspin levels in young Korean adults.

**Gender And Body Mass Index Related Differences In Predictors Of Physical Activity Among White Collar Workers**

Yun-Ping Lin<sup>1</sup>, Kimberlee A. Gretebeck<sup>1</sup>, Tatiana Bailey<sup>2</sup>, David Ronis<sup>1</sup>, Randall J. Gretebeck, FACS<sup>3</sup>. <sup>1</sup>The University of Michigan, Ann Arbor, MI. <sup>2</sup>Corporation for a Skilled Workforce, Ann Arbor, MI. <sup>3</sup>Wayne State University, Detroit, MI.

Email: yunping@umich.edu

(No relationships reported)

Understanding the correlates of physical activity (PA) in a worksite setting is crucial for developing interventions tailored to the needs of that group.

**PURPOSE:** To determine PA correlates and its predictors among white-collar workers. **METHOD:** 320 white-collar workers (124 women, 196 men) participated in this study (25-65 years old;  $M$  age=43±8.3). Questionnaires were completed with items including PA (Baecke PA Questionnaire), stress, self-efficacy (SE), and dietary habits. Simultaneous multiple regression analyses were stratified by gender and body mass index (BMI) and adjusted for age. BMI categories included normal weight (BMI 18.5-24.9;  $M$ =22.7±1.7), overweight (BMI 25.0-29.9;  $M$ =27.5±1.4), and obese (BMI ≥ 30;  $M$ =34.7±4.2).

**RESULTS:** Regression analyses for the total sample revealed that BMI, SE for exercise, gender, stress, and dietary habit ( $b$  =-.27\*\*,  $b$  =.26\*\*,  $b$  =-.13\*,  $b$  =-.12\*,  $b$  =.11\* respectively) predicted PA ( $R^2$  =.21\*\*). For women, BMI and SE for exercise ( $b$  =-.42\*\*,  $b$  =.33\*\* respectively) predicted PA ( $R^2$  =.31\*\*). For men, SE for exercise, BMI and stress ( $b$  =.22\*\*,  $b$  =.17\*,  $b$  =-.15\* respectively) predicted PA ( $R^2$  =.12\*\*). For obese participants, gender, stress, SE for exercise and dietary habit ( $b$  =-.25\*\*,  $b$  =-.24\*,  $b$  =.20\*,  $b$  =.19\* respectively) predicted PA ( $R^2$  =.20\*\*). For overweight, SE for exercise and gender ( $b$  =.29\*\*,  $b$  =-.18\* respectively) predicted PA ( $R^2$  =.14\*\*), and SE for exercise ( $b$  =.34\*\*) predicted PA in normal weight participants ( $R^2$  =.19\*\*).

**CONCLUSION:** SE for exercise was the most common predictor of PA across all gender and BMI categories. Men were more physically active than women. People with higher BMI were less active than those that weighed less. Efforts to increase PA among white-collar workers should consider programs that focus on increasing SE for exercise based on gender and weight status. \* $p$ <.05, \*\* $p$ <.01

(No relationships reported)

It has been suggested that severe-intensity runs conducted at a constant speed until exhaustion (on a treadmill) or during middle-distance competitions are likely to induce a decrease in oxygen uptake ( $\dot{V}O_2$ ) at the end of the exercise. The impairment of the respiratory system due to high ventilatory flow or exercise-induced arterial hypoxemia in highly trained-endurance athletes have been proposed as potential underlying mechanisms. However, the influence of subjects' aerobic fitness level on  $\dot{V}O_2$  response and the amplitude of this  $\dot{V}O_2$  decrease have not been investigated.

**PURPOSE:** To examine  $\dot{V}O_2$  kinetics to a 5-km run test according to the training status of the runner.

**METHODS:** On a 200-m track, six highly- (H) and six well-trained (W) triathletes completed an incremental test to determine their maximal oxygen consumption ( $\dot{V}O_{2max}$ ; 68.8±7.2 vs. 57.1±4.3 ml.min<sup>-1</sup>.kg<sup>-1</sup> in H and W, respectively) and a 5-km self-paced race (mean performance: ~16 min 20 s and 18 min 40 s in H and W, respectively). The  $\dot{V}O_2$  response was measured breath-by-breath (Cosmed K4b2, Italy) and fit subsequently with a model including three exponential functions (primary, slow component and downward linear phases).

**RESULTS:** No significant ( $P>0.05$ ) changes in amplitude (47.4±6.4 vs. 44.7±3.6 ml.min<sup>-1</sup>.kg<sup>-1</sup>), time delay (3.0±1.5 vs. 2.0±0.0 s) or time constant (23.0±3.7 vs. 20.5±2.7 s) of the primary phase were observed when comparing H and W. Similarly, there was no difference between groups ( $P>0.05$ ) in parameters characterizing the slow component (amplitude: 10.8±3.3 vs. 11.2±3.7 ml.min<sup>-1</sup>.kg<sup>-1</sup>; time delay: 117.8±8.3 vs. 136.6±38.8 s; time constant: 189.8±21.0 vs. 153.3±107.7 s in H and W, respectively) and downward linear (amplitude: 11.1±5.3 vs. 9.0±3.5 ml.min<sup>-1</sup>.kg<sup>-1</sup>; time delay: 395.7±51.4 vs. 409.5±55.9 s; time constant: 217.7±123.1 vs. 359.7±172.0 s in H and W, respectively) phases.

**CONCLUSION:** These data support the occurrence of a new phase in oxygen kinetics characterized by a marked decrease in  $\dot{V}O_2$  during severe-intensity running but the observed decrease was not affected by runners' performance level. This  $\dot{V}O_2$  race profile is in good agreement with those observed during supramaximal run tests such as 800-m and 1500-m races. Nevertheless, further studies are needed to understand which mechanisms are responsible for this phenomenon.

**$\dot{V}O_2$  And Leg Blood Flow Kinetics During Moderate-intensity Exercise: Effect Of Hyperventilation With And Without Added  $CO_2$**

Lisa M. K. Chin<sup>1</sup>, George J. F. Heigenhauser<sup>2</sup>, Donald H. Paterson, FACS<sup>1</sup>, John M. Kowalchuk<sup>1</sup>. <sup>1</sup>The University of Western Ontario, London, ON, Canada. <sup>2</sup>McMaster University, Hamilton, ON, Canada.

Email: lmchin@uwo.ca

(No relationships reported)

Hyperventilation-induced hypocapnic alkalosis slows the activation of the mitochondrial pyruvate dehydrogenase complex and pulmonary  $O_2$  uptake ( $\dot{V}O_2$ ) kinetics during the transition to moderate-intensity exercise (MOD). However, the effect of hyperventilation without the associated hypocapnic alkalosis during the transition to MOD has not been established.

**PURPOSE:** To examine the effect of hyperventilation with and without hypocapnic alkalosis on  $\dot{V}O_2$  and LBF kinetics at the onset of MOD.

**METHODS:** Seven young male subjects (25 ± 6 yrs; mean ± SD) performed alternate-leg knee-extension exercise during a step increase in work rate from baseline (3W) to MOD (80% of estimated lactate threshold). Subjects completed 4-6 repetitions each of the following 3 conditions: i) Control (CON,  $P_{ET}CO_2$  ~40 mmHg): Normal breathing with regular levels of  $CO_2$  (0.03%); ii) Hypocapnia (HYPO,  $P_{ET}CO_2$  ~20 mmHg): Sustained hyperventilation with regular levels of  $CO_2$  (0.03%); and iii) Normocapnia (NORMO,  $P_{ET}CO_2$  ~40 mmHg): Sustained hyperventilation with elevated levels of  $CO_2$  (5%).  $\dot{V}O_2$  was measured breath-by-breath by mass spectrometry and volume turbine. LBF was calculated using mean blood velocity and femoral artery diameters measured by Doppler ultrasound. The adaptation of  $\dot{V}O_2$  and LBF were modeled using a mono-exponential equation by non-linear regression.

**RESULTS:** The phase 2  $\text{VO}_2$  time constant ( $t\text{VO}_2$ ) was different ( $P < 0.05$ ) amongst all 3 conditions: CON ( $19 \pm 7$  s), HYPO ( $43 \pm 17$  s), NORMO ( $30 \pm 8$  s);  $\text{VO}_2$  amplitude was not different amongst conditions. The adaptation of LBF ( $t\text{LBF}$ ) was slower ( $P < 0.05$ ) during HYPO ( $31 \pm 9$  s) compared to both CON ( $19 \pm 3$  s) and NORMO ( $20 \pm 6$  s), and the LBF amplitude was lower during HYPO ( $1.1 \pm 0.2$  L/min) compared to NORMO ( $1.2 \pm 0.2$  L/min;  $P = 0.049$ ) and CON ( $1.2 \pm 0.2$  L/min;  $P = 0.08$ ).

**CONCLUSION:** While hyperventilation + hypocapnia (HYPO) was associated with slower  $\text{VO}_2$  and LBF kinetics compared to CON, preventing the fall in  $P_{\text{ET}}\text{CO}_2$  (NORMO) restored LBF kinetics but  $\text{VO}_2$  kinetics remained "slowed" relative to CON. These data suggest that some factor associated with the hyperventilation maneuver itself (i.e., independent of the induced hypocapnic alkalosis) may contribute, in part, to slowed  $\text{VO}_2$  kinetics during the transition to MOD.

**$\text{O}_2$  Uptake Kinetics During Knee Extension And Leg Cycling Exercise In The Moderate-intensity Domain**

Andrea D. Marjerrison, Jonathan P. Pace, Nicholas J. Petrella, Donald H. Paterson, FACSM, John M. Kowalchuk. *the University of Western Ontario, London, ON, Canada.*

Email: amarjerr@uwo.ca

(No relationships reported)

During the transition to the same relative intensity of exercise in the moderate-intensity domain the phase II time constant for  $\text{O}_2$  uptake ( $t\text{VO}_2$ ) and the  $\text{VO}_2$  gain ( $\text{DVO}_2/\text{DWR}$ ) tend to be greater with knee-extension (KE) than with leg cycling exercise (CE), however, the response at the same absolute work rate (WR) has not been established.

**PURPOSE:** To examine the adaptation of pulmonary  $\text{VO}_2$  during the transition to the same relative and same absolute WRs in the moderate-intensity domain.

**METHODS:** Four younger subjects completed an incremental exercise test to volitional fatigue during both alternate-leg KE and CE to estimate lactate threshold ( $\theta_L$ ) and peak  $\text{VO}_2$ . Subjects then completed four step transitions in WR from light- to a moderate-intensity exercise corresponding to 90%  $\theta_L$  (KErel, CErel), as well as four step transitions during CE from light-intensity to an absolute WR equal to that used during KErel (CEabs). A cadence of 50 rpm was maintained throughout all testing with KE and CE.  $\text{VO}_2$  was measured breath-by-breath using a volume turbine and mass spectrometer. The phase II  $\text{VO}_2$  response was modeled using a monoexponential function and non-linear regression techniques.

**RESULTS:** The  $t\text{VO}_2$  was greater ( $p < 0.05$ ) in KErel (28 (7) s; mean ( $\pm$  SD)) than in CErel (15 (2) s) and in CEabs (16 (4) s). The  $\text{VO}_2$  gain was greater ( $p < 0.05$ ) in KErel ( $15.3$  ( $2.?$ )  $\text{ml} \cdot \text{min}^{-1} \cdot \text{W}^{-1}$ ) than in CErel ( $8.5$  ( $3.1$ )  $\text{ml} \cdot \text{min}^{-1} \cdot \text{W}^{-1}$ ), but not different from that found in CEabs ( $11.5$  ( $6.6$ )  $\text{ml} \cdot \text{min}^{-1} \cdot \text{W}^{-1}$ ).

**CONCLUSION:** The tendency for a greater  $t\text{VO}_2$  and  $\text{VO}_2$  gain during the transition to the same relative and same absolute intensity of exercise using KE compared to CE may be related to biomechanical differences or to the different muscle fibres or muscle groups recruited during the exercise transition within each modality.

**Effect Of Respiratory-alkalosis On  $\text{Vo}_2$ , Femoral Artery Diameter And Leg Blood Flow During Moderate-intensity Exercise**

John M. Kowalchuk<sup>1</sup>, Lisa M. K. Chin<sup>1</sup>, George J. F. Heigenhauser<sup>2</sup>, Donald H. Paterson, FACSM<sup>1</sup>. <sup>1</sup>*The University of Western Ontario, London, ON, Canada.* <sup>2</sup>*McMaster University, Hamilton, ON, Canada.*

Email: jkowalch@uwo.ca

(No relationships reported)

Hyperventilation-induced respiratory alkalosis (RALK) may reduce vascular conductance and muscle perfusion (through a  $\text{CO}_2$ -linked process) which may explain, in part, the slower adaptation of pulmonary  $\text{O}_2$  uptake ( $\text{VO}_2$ ) observed during moderate-intensity exercise (MOD).

**PURPOSE:** To study the effect of RALK on  $\text{VO}_2$ , leg blood flow (LBF), mean blood velocity (MBV), femoral artery (FA) diameter and muscle deoxygenation kinetics at the onset of MOD.

**METHODS:** Eight male subjects ( $26 \pm 5$  yrs; mean  $\pm$  SD) completed 4 - 6 repetitions of alternate-leg knee-extension exercise during normal breathing (CON;  $P_{\text{ET}}\text{CO}_2 \sim 40$  mmHg) and sustained hyperventilation (RALK;  $P_{\text{ET}}\text{CO}_2 \sim 20$  mmHg). Instantaneous increases in work rate were made from baseline (3W) to MOD (80% estimated lactate threshold).  $\text{VO}_2$  was measured breath-by-breath by mass spectrometry and volume turbine. MBV and FA diameter were measured simultaneously by Doppler ultrasound and used to calculate LBF. The change in concentration of vastus lateralis muscle deoxyhemoglobin (D[Hb]) was measured continuously by near-infrared spectroscopy (NIRS; Hamamatsu, NIRO 300). The adaptation of  $\text{VO}_2$ , MBV, LBF, FA diameter and D[Hb] were modeled using a mono-exponential equation by non-linear regression.

**RESULTS:** The phase 2  $\text{VO}_2$  time constant ( $t\text{VO}_2$ ) was greater ( $P < 0.05$ ) in RALK ( $49 \pm 26$  s) compared to CON ( $28 \pm 8$  s). FA diameter was reduced ( $P < 0.05$ ) after 20 min resting accommodation in RALK ( $9.8 \pm 1.2$  mm) compared to pre-hyperventilation values ( $10.5 \pm 1.1$  mm) and CON ( $10.5 \pm 1.1$  mm). During the transition to MOD, FA diameter increased ( $P < 0.05$ ) in an exponential manner towards a new steady-state ( $10.3 \pm 1.2$  mm); FA diameter did not change in CON. As a consequence, although MBV kinetics ( $t\text{MBV}$ ) were not different between RALK ( $30 \pm 13$  s) and CON ( $23 \pm 6$  s), LBF kinetics ( $t\text{LBF}$ ) were slower ( $P < 0.05$ ) in RALK ( $46 \pm 16$  s) than CON ( $23 \pm 6$  s). The mean response time for muscle deoxygenation (Time Delay-D[Hb] +  $t\text{D[Hb]}$ ) were similar in RALK ( $23 \pm 5$  s) and CON ( $24 \pm 3$  s).

**CONCLUSION:** Collectively, the slower adaptation of LBF with unchanged D[Hb] kinetics in RALK suggests that slower conduit artery and microvascular blood flow kinetics may contribute, in part, to the slower  $\text{VO}_2$  kinetics in RALK.

**Cocaine Does Not Alter Microvascular  $\text{Po}_2$  On-kinetics In Rat Hindlimb Skeletal Muscle**

Emily L. Keeslar, Marc A. Engelbrecht, C. J. Harp, William L. Sexton, FACSM. *A.T. Still University-KCOM, Kirksville, MO.*

Email: ekeeslar@atsu.edu

(No relationships reported)

Cocaine abuse in athletes and the associated morbidity and mortality has piqued interest in its mechanisms of action. Acute cocaine intoxication initially enhances muscle performance, but ultimately leads to premature muscle fatigue and may precipitate renal failure, and death. In rats, cocaine administration accelerates muscle glycogen utilization and fatigue during treadmill exercise. Blood flow to rat hindlimb muscles during exercise is not reduced after cocaine administration (Hagen et al., MSSE 29: S218, 1997), suggesting that cocaine may elevate muscle metabolism.

**PURPOSE:** To determine whether acute cocaine administration increases skeletal muscle metabolism and oxygen uptake, thereby accelerating microvascular  $\text{PO}_2$  ( $\text{PO}_{2\text{m}}$ ) on-kinetics.

**METHODS:**  $\text{PO}_{2\text{m}}$  was measured by phosphorescence quenching in the extensor digitorum longus muscle (EDL) of anesthetized female Sprague-Dawley rats at rest and during the rest-to-contraction transition (1 Hz, 6V). In each rat,  $\text{PO}_{2\text{m}}$  was measured during a control stimulation (STIM 1) and after administration of either cocaine (C,  $n=13$ ; 5 mg/kg i.v.) or an equivalent volume of saline (S;  $n=10$ ) (STIM 2). EDL twitch tension was measured during each contraction bout using a muscle tension analyzer.

**RESULTS:** During STIM 1, resting  $\text{PO}_{2\text{m}}$  ( $R\text{-PO}_{2\text{m}}$ ), the time delay (TD) between the onset of contractions and the fall in  $\text{PO}_{2\text{m}}$ , the time constant ( $\text{Tau}$ ) and the magnitude

and of the fall in  $PO_2m$  at the onset of contractions (D- $PO_2m$ ) were the same in the S and C groups. Cocaine administration had no effect on R- $PO_2m$  during prior to STIM 2 (S,  $23 \pm 2$ ; C,  $26 \pm 1$  mmHg). Further, cocaine had no effect on D- $PO_2m$  (S,  $-12 \pm 2$  vs. C,  $-15 \pm 1$  mmHg), TD (S,  $6 \pm 1$ ; C,  $6 \pm 1$  s) or Tau (S,  $8 \pm 2$ ; C,  $9 \pm 2$  s). Neither twitch tension (S,  $31 \pm 7$ ; C,  $28 \pm 7$  N) nor any other indices of muscle contractile function were different during STIM 2.

**CONCLUSION:** The results of this study indicate that acute cocaine administration does not alter resting  $PO_2m$ ,  $PO_2m$  on-kinetics, or contractile function in the rat EDL muscle. Thus, these data do not support the notion that cocaine enhances muscle metabolism in contracting skeletal muscle.

The Effects of reduced blood volumes on Oxygen Uptake Kinetics

**PURPOSE:** The purpose of this study was to test the hypothesis that a reduced total blood volume will influence the ( $VO_2$ ) on-kinetic response during both moderate (MOD) and heavy (HVY) intensity exercise. **METHOD:** Following University Institutional ethics approval twelve subjects volunteered and agreed to participate (age,  $21 \pm 2$  yrs; height,  $175.2 \pm 5.1$  cm; weight,  $66.4 \pm 2.8$  kg;  $VO_{2max}$ ,  $53.0 \pm 4.1$  ml.kg<sup>-1</sup>.min<sup>-1</sup>). The subjects completed two exercise trials, un-bled (UBL) and bled (BLL) which were interspersed by a period of 48h. The trials consisted of an initial phase of 4-min of unloaded cycling followed by 2 bouts of 6-min constant load cycling at D 80% base-line  $VO_2$  -  $VO_2$  at ventilatory threshold (MOD), which were separated by 10-min of recovery unloaded cycling. Following the same recovery phase the subjects completed a third bout of 6-min constant load cycling at D50% ventilatory threshold -  $VO_{2max}$  (HVY). Between the two exercise trials the subjects donated 500ml<sup>3</sup> of blood. For both the UBL and BL trials  $VO_2$  was recorded on a breath-by-breath basis using a pre-calibrated metabolic cart, haemodynamic responses were recorded throughout the trials and haematological variables were recorded pre-exercise. For both UBL and BLL trials the  $VO_2$  on-kinetic response data were fitted with a 3-component exponential model for analysis of the primary time component and mean response times.

**RESULTS:** There were significant differences between UBL and BLL for Hb gdl<sup>-1</sup> ( $p < 0.005$ ), HcT % ( $p < 0.001$ ) and RBC  $\mu l^{-1}$  ( $p < 0.013$ ) with Hb showing a decrease of 9.7% from  $14.5 \pm 5.5$  gdl<sup>-1</sup> to  $13.1 \pm 14.9$  gdl<sup>-1</sup>. There were non-significant differences between UBL and BLL for either the time constant or the amplitude of the phase II/III  $VO_2$  responses in both the MOD and HVY conditions ( $p > 0.05$ ). However there was a significant increase in the D pulse pressure for phase II between UBL and BLL in both MOD ( $10.4 \pm 24.1$ mmHg) ( $p < 0.037$ ) and HVY domains ( $21.2 \pm 4.1$ mmHg) ( $p < 0.042$ ).

**CONCLUSION:** The data highlights the capability of the cardiovascular system in compensating for a reduction in the  $O_2$  carrying capacity of the blood through central alterations of cardiovascular function suggesting that exercise in the MOD and HVY domains does not appear to be limited by  $O_2$  delivery in healthy young individuals.

**Oxygen Kinetics During Specific Intermittent Work**

Galo E. Narvaez Perez, Galo E. Narvaez Alban, Jr., Rafael Santelices. *Comite Olimpico Ecuatoriano, Guayaquil, Ecuador.* (Sponsor: George Brooks, FACSM)

Email: gnarvaez@coe.org.ec

(No relationships reported)

**PURPOSE:** The time (t) discriminates the speed of activation of the oxidations mechanisms, during an intermittent work (IW) 95 - 100% of the  $VO_2$  Max. The deficit of oxygen ( $DO_2$ ) of the fast phase of the  $O_2$  kinetics ( $O_2K$ ) represents the anaerobic work participation.<sup>1</sup>

**PURPOSE:** to analyzer the  $DO_2$  utility during specific intermittent work (SIW)<sup>2,3</sup>.

**METHODS:** Olympic athletes: 4 boxers and 4 judokas. Age (18-24 years); weight (60-75 kg) and height (170-185 cm). SIW on treadmill (slope 2%; heating 2 min; 4 repetitions of 2 min by 1 of rest). Each repetition represents one round and in the rest the subject remains seated; thus the test is considered specific for boxing.  $VO_2$  Max was measured with  $K_4b^2$  and  $DO_2$  by COSMED software. It was applied ANOVA TWO WAY with and without replications.

**RESULTS:** In boxing:  $DO_2 = 1905 \pm 597$  ml F NS between three evaluations. The  $DO_2$  between subjects (BS) and rounds was different  $F = 3.24$   $p < 0.003$  and  $F = 4.83$   $p < 0.003$  respectively; interaction NS. In judo  $DO_2 = 2050 \pm 769$  ml BS  $F = 6.48$   $p < 0.007$ ; between repetitions N.S.

**CONCLUSIONS:** the  $DO_2$  differences BS, demonstrate that the functional answer would be modulated by the characteristics of the box and by the individual variability. The fast phase of the  $O_2$  kinetics ( $O_2K$ ) is considered dependent of the type of muscular fiber with recruitment of fast motor units, we could think that the results, express the functional answer to specific metabolic requirements of box. The SIW designed originally for boxing, demonstrated a relative utility in judo, possibly due to that competition times are different.

**Change In Intracellular  $PO_2$  During Muscle Contraction Under Hb-free Medium Perfusion**

Hisashi Takakura<sup>1</sup>, Kazumi Masuda<sup>1</sup>, Satoshi Iwase<sup>2</sup>, Jue Thomas<sup>3</sup>. <sup>1</sup>Kanazawa University, Kanazawa, Japan. <sup>2</sup>Aichi Medical University, Aichi, Japan. <sup>3</sup>University of California Davis, Davis, CA.

Email: takakura@ed.kanazawa-u.ac.jp

(No relationships reported)

**PURPOSE:** Regulation of  $O_2$  transport to the mitochondria is a fundamental issue, particularly in exercising muscle, where  $O_2$  consumption can vary over a wide range.

Although the  $O_2$  gradient from the capillary to the mitochondria is one of the key factors regulating  $O_2$  transport to the mitochondria, intracellular  $O_2$  dynamics during muscle contraction remain unclear. We recently developed an experimental perfusion model in order to investigate intracellular  $O_2$  utilization during muscle contraction using near infrared spectroscopy (NIRS). The purpose of the present study is, therefore, to examine the kinetics of myoglobin (Mb) saturation ( $S_{mb}O_2$ ) and intracellular  $PO_2$  ( $P_{mb}O_2$ ) during muscle contraction.

**METHODS:** The hindlimbs of male Wistar rats (9 weeks old,  $n = 6$ ) were perfused from the abdominal aorta with the Hb-free Krebs-Henseleit buffer equilibrated with 95%  $O_2$  + 5%  $CO_2$  gas. During perfusion, muscle contraction was evoked by electrostimulation via the sciatic nerve. The kinetics of D[deoxy-Mb] during muscle contraction were monitored using NIRS. After the exercise protocol, buffer equilibrated with 95%  $N_2$  + 5%  $CO_2$  gas was perfused in order to determine the maximal deoxygenation state.  $S_{mb}O_2$  was also converted into  $P_{mb}O_2$  using the  $O_2$  dissociation curve of Mb. Estimated kinetics of  $S_{mb}O_2$  and  $P_{mb}O_2$  were evaluated by fitting the data to the exponential function.

**RESULTS:** The kinetics of  $P_{mb}O_2$  (RT (response time) =  $25.64 \pm 3.25$  sec) were more rapid than those of  $S_{mb}O_2$  (RT =  $42.26 \pm 8.55$  sec). In addition,  $DS_{mb}O_2$  during muscle

contraction increased and  $P_{mb}O_2$  at the steady state decreased progressively as oxygen demand increased ( $S_{mb}O_2$ :  $r = -0.47$ ,  $p = 0.05$ ,  $P_{mb}O_2$ :  $r = -0.54$ ,  $p < 0.05$ ), while  $S_{mb}O_2$  and  $P_{mb}O_2$  at the maximal twitch under buffer-perfused condition were 48% and 2.7 mmHg, respectively. Moreover, the decremental ratio of  $S_{mb}O_2$  kinetics was accelerated with oxygen demand ( $r = -0.82$ ,  $p < 0.01$ ).

**CONCLUSIONS:** These results suggest that Mb desaturated immediately at the onset of the muscle contraction, reflecting a fall in intracellular  $PO_2$ , and that this intracellular response was accelerated along with oxygen demand to increase muscle oxygen consumption.

**Estimation of Oxygen Uptake Dynamics During Walking By Using A Triaxial Accelerometer**

Kyuichi Niizeki, Yuuki Takahashi, Tadashi Saitoh. *Yamagata University, Yonezawa, Japan.*

Email: nzq@yz.yamagata-u.ac.jp

(No relationships reported)

The use of accelerometry to assess physical activity has become more common in recent years. However, accelerometer devices are unable to determine dynamics of energy expenditure (EE) due to the lack of precision and temporal resolution in estimating EE. This may be attributed to that the assessment of EE is based on the activity counts per time without using raw acceleration signals.

**PURPOSE:** In this study, we developed a novel method to predict dynamics of oxygen uptake ( $VO_2$ ) during walking from triaxial accelerometer signals by using transfer function estimate between breath-by-breath  $VO_2$  and the instantaneous amplitude or envelope (Ae) of a 3D vector of accelerometer signals.

**METHODS:** Seven healthy subjects (3 male and 4 female) were participated. From the oscillatory signal of a 3D vector of accelerometer signals, Ae was calculated in the complex unit circle based on the Hilbert-transform. The transfer function between the Ae and the  $VO_2$  was estimated by applying autoregressive exogenous model to the simultaneously obtained accelerometer signals and  $VO_2$  during treadmill walking, in which treadmill speed was varied between 2.5km/h and 5.5km/h in a pseudo-random binary sequence manner for 20 min. The best-fit model parameters were selected by searching for the minimum AIC value. Then, cross-validation was performed by identifying  $VO_2$  response to stepwise change in work rate from 2.5km/h to 5.5km/h by convolving corresponding Ae with the impulse response.

**RESULTS:** By using an individual transfer function estimate,  $VO_2$  dynamics was successfully estimated from the changes in Ae. The predicted  $VO_2$  response was in close agreement with the observed response in each subject (residual sum of squares was 7.6% on average).

**CONCLUSIONS:** Proposed method should be useful for estimating EE dynamics of walking. Further validation is needed whether the method could be applied in the field-based walking activity.

**Oxygen Uptake Kinetics During Arm Cranking Within The Moderate Intensity Domain**

Surendran Sabapathy<sup>1</sup>, Norman R. Morris<sup>1</sup>, Donald A. Schneider<sup>1</sup>, Donald H. Paterson, FACSM<sup>2</sup>. <sup>1</sup>Griffith University, Gold Coast campus, Queensland, Australia. <sup>2</sup>University of Western Ontario, London, ON, Canada.

(No relationships reported)

Recent studies have demonstrated that on-transient oxygen uptake ( $VO_2$ ) kinetics are slowed when constant-load exercise is initiated from the upper compared to lower region of the moderate intensity domain (below the lactate threshold, LT). These studies, focusing exclusively on lower limb exercise, attributed this intensity-dependent slowing of  $VO_2$  kinetics during moderate-intensity exercise to different muscle fiber recruitment patterns or altered oxygen transport dynamics.

**PURPOSE:** To determine if pulmonary  $VO_2$  and heart rate (HR) kinetics are slowed during constant-load arm exercise (arm-cranking) performed in the upper (90%LT) compared to lower (45%LT) regions of the moderate intensity domain.

**METHODS:** Seven healthy male subjects ( $26 \pm 3$  yr) performed 4-8 repetitions of arm-cranking exercise involving: 1) a single, 6-min step transition from 9 W to 90% of the estimated LT ( $AC_{90\%}$ ); two continuous, equal, 6-min step transitions from 9 W to 45% LT ( $AC_{45\%}$ ), and then to 90% LT ( $AC_{45-90\%}$ ); and 3) the  $AC_{90\%}$  protocol superimposed upon low-intensity leg-cycling ( $AC_{90\%+LC}$ ), where baseline HR >100 beats·min<sup>-1</sup> (range: 100-120 beats·min<sup>-1</sup>).

**RESULTS:** The time constants (t) of the  $VO_2$  and HR responses were longer ( $P < 0.05$ ) during  $AC_{45-90\%}$  ( $tVO_2$ :  $70 \pm 5$  s;  $tHR$ :  $59 \pm 4$  s) compared to  $AC_{45\%}$  ( $tVO_2$ :  $54 \pm 6$  s;  $tHR$ :  $47 \pm 5$  s) and  $AC_{90\%}$  ( $tVO_2$ :  $53 \pm 4$  s;  $tHR$ :  $46 \pm 3$  s). The gain ( $DVO_2/DW$ ) and blood lactate concentration were also significantly greater ( $P < 0.05$ ) for  $AC_{45-90\%}$  than  $AC_{45\%}$ . During arm-cranking superimposed upon leg-cycling ( $AC_{90\%+LC}$ ), HR kinetics were significantly slowed when compared to  $AC_{90\%}$  (mean difference for  $tHR$ :  $9 \pm 4$  s,  $P < 0.05$ ) and  $AC_{45\%}$  (mean difference for  $tHR$ :  $9 \pm 5$  s,  $P < 0.05$ ). Similar comparisons between conditions for  $tVO_2$  yielded no significant differences.

**CONCLUSION:** During arm exercise performed within the moderate intensity domain,  $VO_2$  and HR kinetics do not conform to a dynamically linear model. Since HR, but not  $VO_2$  kinetics were slowed during  $AC_{90\%+LC}$ , factors other than convective oxygen delivery (e.g. those intrinsic to the exercising muscle) may explain the slower  $VO_2$  response in the upper reaches of the moderate intensity domain for arm exercise.

**The Significance of the Bohr Effect for Muscle Oxygen Extraction: Evidence from Exercise in McArdle Disease**

Katja Heinicke<sup>1</sup>, Phillip S. Wyrick<sup>2</sup>, Ronald G. Haller<sup>1</sup>. <sup>1</sup>IEEM, Presbyterian Hospital & University of Texas Southwestern Medical Center, Dallas, TX. <sup>2</sup>IEEM, Presbyterian Hospital, Dallas, TX.

Email: KatjaHeinicke@TexasHealth.org

(No relationships reported)

In McArdle disease (MD), complete absence of myophosphorylase (MP) blocks glycogen breakdown, thus restricting anaerobic metabolism. We have shown that impaired glycogenolysis also limits substrate availability for oxidative metabolism. Since patients lack the ability to increase lactate during exercise, an additional factor in impaired  $O_2$  utilization may be an absent Bohr effect -the rightward shift in the oxyhemoglobin dissociation curve caused by the increase in lactic acid and  $H^+$ , that facilitates  $O_2$  extraction during intensive exercise.

**PURPOSE:** To assess the importance of the Bohr effect on muscle  $O_2$  extraction employing patients with typical McArdle disease (glycogenolysis completely blocked) and an unusual patient with a small amount of residual MP who we have shown to have a 2-fold higher peak  $VO_2$  than typical patients.

**METHODS:** Three MD patients with complete MP deficiency, 1 variant MD patient with 3% of normal MP activity, and 13 healthy control subjects performed an aerobic forearm exercise test, consisting of 5 sec isometric grip force alternating with 5 sec of rest for 6 min. We measured lactate, pH, partial pressure of  $O_2$  ( $pO_2$ ) and  $CO_2$  ( $pCO_2$ ) in effluent venous blood at rest, and at the end of exercise with a target grip force of 50% of maximal voluntary contraction.

**RESULTS:** Plasma lactate decreased during exercise in typical MD patients ( $0.6 \pm 0.1$  to  $0.5 \pm 0.1$  mmol/L), but increased slightly in the variant MD patient ( $1.03$  to  $1.14$  mmol/L) and substantially in controls ( $0.9 \pm 0.2$  to  $2.9 \pm 1.1$  mmol/L). Correspondingly, pH decreased in controls ( $7.37 \pm 0.02$  to  $7.28 \pm 0.04$ ) and to a lesser degree in the variant MD patient ( $7.35$  to  $7.32$ ), but increased in typical MD patients ( $7.38 \pm 0.04$  to  $7.40 \pm 0.03$ ). During exercise, venous  $pO_2$  was increased in typical MD patients compared with controls ( $37.3 \pm 3.1$  vs.  $26.8 \pm 2.6$  mmHg). The  $pO_2$  level in the variant MD patient was comparable to controls ( $26.0$  mmHg).  $pCO_2$  was increased at the end of exercise in both controls ( $68.2 \pm 9.0$  mmHg) and variant MD patient ( $55$  mmHg), compared with typical MD patients ( $39.3 \pm 9.3$  mmHg).

**CONCLUSIONS:** This study suggests that absence of the Bohr effect in typical MD patients may contribute to impaired  $O_2$  extraction. Minimal residual MP activity in the

**Validation Of A Continuous-wave, Single-distance Nirs Oxymeter For The Determination Of Muscle Oxygenation During Cycling**

Silvia Pogliaghi<sup>1</sup>, Casiello Lorenzo<sup>1</sup>, Andrea Bandera<sup>2</sup>. <sup>1</sup>Università di Verona, Verona, Italy. <sup>2</sup>Nirox srl, Brescia, Italy.

Email: [silvia.pogliaghi@univr.it](mailto:silvia.pogliaghi@univr.it)

(No relationships reported)

An Italian company recently developed a relatively inexpensive continuous-wave (CW), single-distance near-infrared spectroscopy (NIRS) oxymeter that allows the calculation of absolute values of deoxygenated haemoglobin (*deoxyHb*). This absolute quantification is made possible by an in-vivo estimate of the scattering coefficient (based on direct measures of the scattering at the water absorption peak and on its linear extrapolation to the near-infrared range). The calculated scattering coefficient is assumed not to change over the time of the experiment.

**PURPOSE:** We tested the possible correspondence between non-invasive measures of muscle *deoxyHb* obtained using this CW device and a frequency-domain (FD) multi-distance NIRS system, used as a reference method.

**METHODS:** 11 healthy sedentary males (27±5 years, 176±1 cm, 73±8 kg, 54±4 ml·kg<sup>-1</sup>·min<sup>-1</sup> VO<sub>2max</sub>) performed an incremental cycling test. Following a 3-min rest, subjects pedaled at 50 watt for 3 min. Thereafter, the workload was increased stepwise, 20 watt per minute, up to voluntary exhaustion. During the tests, muscle *deoxyHb* was monitored continuously on the vastus lateralis of the right leg, using the reference FD device (FD*deoxyHb*), and on the right leg, using the CW instrument (CW*deoxyHb*). The average values of the last 30s of rest and warm-up cycling, and the last 10 s of each stage were used for statistical analysis. Agreement between the two instruments was tested by Bland Altman analysis (significance ≤0.05).

**RESULTS:** Resting CW*deoxyHb* and FD*deoxyHb* were 27±6 and 29±5 mmol·l<sup>-1</sup> respectively (not different). As expected, *deoxyHb* increased as a function of exercise intensity reaching 43±9 (CW*deoxyHb*) and 44±10 mmol·l<sup>-1</sup> (FD*deoxyHb*) upon exhaustion (not different). At all exercise intensities, CW*deoxyHb* was not significantly different from FD*deoxyHb* (bias 0.93, not different from 0; precision 7.6 mmol·l<sup>-1</sup>).

**CONCLUSIONS:** The main finding of this study is that there is a very good agreement between muscle *deoxyHb* values measured by the evaluated CW device and the reference FD oxymeter. Compared to the reference device, the new, relatively inexpensive oxymeter yields unbiased and precise *deoxyHb* values during incremental cycling exercises in healthy sedentary males.

The study was Supported by Nirox srl, Italy

**Prior Exercise And Ischemia Affect Blood Flow And Oxygen Uptake During Subsequent Heavy Forearm Exercise**

Azmy Faisal, Kenneth S. Dyson, Richard L. Hughson. University of Waterloo, Waterloo, ON, Canada.

(No relationships reported)

Enhanced blood flow (BF) by prior exercise is associated with acceleration of muscle oxygen uptake (VO<sub>2muscle</sub>) kinetics during subsequent heavy exercise.

**PURPOSE:** We tested the influence of enhanced forearm BF by exercise and circulatory occlusion on VO<sub>2muscle</sub> onset kinetics.

**METHODS:** Seven varsity ice hockey players completed three heavy forearm exercise bouts (5-min at 30 % MVC 14.1 ± 1.2 kg) in two different sessions: [1] control, heavy exercise followed immediately by 2 minutes of circulatory occlusion; [2] heavy bout 8-min after control; [3] heavy bout 3-min after release of 5-min forearm occlusion that included 1-min moderate hand-grip exercise. BF was measured continuously using Doppler ultrasound and venous blood was sampled every 15 seconds from a deep forearm vein to determine O<sub>2</sub> extraction.

**RESULTS:** BF was elevated prior to bout [2] and [3] compared to the control at baseline ([2], 318.2 ± 51.7; [3], 282.1 ± 30.9 vs. control, 69.0 ± 13.4 mL/min, *P* < 0.01), however baseline VO<sub>2muscle</sub> was significantly higher only prior to bout [2] (10.1 ± 2.6 vs. 4.0 ± 1.0 mL O<sub>2</sub>/min, *P* < 0.01). Neither BF nor VO<sub>2muscle</sub> were different at end exercise among the three heavy bouts. BF and VO<sub>2muscle</sub> were significantly higher during the first 2-min of bout [2] compared to both bout [3] and control. Prior occlusion slightly enhanced the onset BF and VO<sub>2muscle</sub> kinetics during bout [3] with a significant increase at 45 sec compared to control (BF: 375.8 ± 75.4 vs. 312.9 ± 79.9 mL/min; VO<sub>2muscle</sub>: 51.2 ± 15.9 vs. 41.9 ± 16.1 mL O<sub>2</sub>/min, *P* < 0.05). The calculated VO<sub>2muscle</sub> area during the first two minutes of exercise was significantly greater in bout [2] than the areas of both bout [3] and control ([2], 113.9 ± 39.1 vs. [3], 93.7 ± 28.7; control, 84.3 ± 30.2 mL O<sub>2</sub>, *P* < 0.01). These results indicate a greater contribution from oxidative phosphorylation at the onset of a heavy bout that followed heavy exercise and occlusion compared to that which followed occlusion with moderate exercise.

**CONCLUSION:** We employed two protocols which enhanced BF prior to a subsequent heavy exercise bout (heavy exercise followed by occlusion and moderate exercise during occlusion); however the major impact on oxidative metabolism was seen only following heavy exercise.

**Muscle And Pulmonary Oxygen Uptake Kinetics During Moderate And High-intensity Knee-extensor Exercise In Humans**

Andrew M. Jones, FACSM<sup>1</sup>, Peter Krstrup<sup>2</sup>, Daryl P. Wilkerson<sup>1</sup>, Jose Calbet<sup>3</sup>, Jens Bangsbo<sup>2</sup>. <sup>1</sup>University of Exeter, Exeter, United Kingdom.

<sup>2</sup>University of Copenhagen, Copenhagen, Denmark. <sup>3</sup>University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain.

Email: [a.m.jones@exeter.ac.uk](mailto:a.m.jones@exeter.ac.uk)

(No relationships reported)

**PURPOSE:** To determine the contribution of muscle O<sub>2</sub> uptake (mVO<sub>2</sub>) to pulmonary O<sub>2</sub> uptake (pVO<sub>2</sub>) during both low-intensity (LI) and high-intensity (HI) knee extension exercise, and during subsequent recovery, in humans.

**METHODS:** Seven healthy male subjects (age 20-25 years) completed a series of LI and HI square-wave exercise tests in which mVO<sub>2</sub> (direct Fick technique) and pVO<sub>2</sub> (indirect calorimetry) were measured simultaneously. The mean blood transit time (MTT) from the muscle capillaries to the lung was also estimated (based on measured blood transit times from femoral artery to vein and vein to artery). The kinetics of mVO<sub>2</sub> and pVO<sub>2</sub> were modeled using non-linear regression.

**RESULTS:** The time constant (t) describing the phase II pVO<sub>2</sub> kinetics following the onset of exercise was not significantly different from the mean response time (initial time delay + t) for mVO<sub>2</sub> kinetics for LI (30 ± 3 vs. 30 ± 3 s) but was slightly higher (*P* < 0.05) for HI (32 ± 3 s vs. 29 ± 4); the responses were closely correlated (*r* = 0.95 and *r* = 0.95; *P* < 0.01) for both intensities. In recovery, limited agreement between the responses was observed with pVO<sub>2</sub> kinetics tending to be slower than mVO<sub>2</sub> kinetics both for LI (36 ± 4 vs. 18 ± 4 s, *P* < 0.05; *r* = -0.01) and HI (33 ± 3 vs. 27 ± 3, *P* > 0.05; *r* = -0.04). MTT was approximately 17 s just before exercise and decreased to 10 s and 12 s after 10 s of exercise for LI and HI, respectively. The increase in mVO<sub>2</sub> above baseline accounted for 100% and 95% of the increase in pVO<sub>2</sub> during LI and HI, respectively.

**CONCLUSIONS:** These data indicate that the phase II pVO<sub>2</sub> kinetics reflect mVO<sub>2</sub> kinetics during exercise but not during recovery where caution in data interpretation is advised.

## Pulmonary Oxygen Uptake Kinetics In Trained And Untrained Male Adolescents

Simon Marwood<sup>1</sup>, Denise Roche<sup>1</sup>, Thomas Rowland<sup>2</sup>, Max Garrard<sup>1</sup>, Vishwanath Unnithan, FACSM<sup>1</sup>. <sup>1</sup>Liverpool Hope University, Liverpool, United Kingdom. <sup>2</sup>Baystate Medical Centre, Springfield, MA.

Email: marwoos@hope.ac.uk

(No relationships reported)

Exercise training results in a speeding of pulmonary oxygen uptake (VO<sub>2</sub>) kinetics at the onset of exercise in adults, however only limited research has been conducted with physiologically immature subjects.

**PURPOSE:** The aim of the present study was to examine VO<sub>2</sub> and muscle deoxygenation kinetics in trained and untrained male adolescents. **METHOD:** 16 trained (14.5 ± 0.2 yrs, VO<sub>2peak</sub>: 54.7 ± 1.6 ml.kg<sup>-1</sup>.min<sup>-1</sup>, Self-assessed Tanner stage range 2 - 4) and 9 untrained (15.4 ± 0.2 yrs, VO<sub>2peak</sub>: 43.1 ± 1.7 ml.kg<sup>-1</sup>.min<sup>-1</sup>, Tanner stage range 2 - 4) male adolescents performed two 6-min exercise transitions from a 3-min baseline of 10W to a workload equivalent to 80% lactate threshold separated by a minimum of 1 hour passive rest. Oxygen uptake (breath-by-breath) and muscle deoxygenation (deoxyhaemoglobin signal from near infrared spectroscopy) were measured continuously throughout baseline and exercise transition.

**RESULTS:** The time constant of the fundamental phase of VO<sub>2</sub> kinetics was significantly faster in trained versus untrained subjects (Trained: 22.3 ± 1.8 s vs Untrained: 29.8 ± 2.8 s, p=0.03). In contrast, neither the time constant (Trained: 9.7 ± 0.7 s vs Untrained: 10.1 ± 1.1 s, p=0.78) or mean response time (Trained: 17.4 ± 0.6 s vs Untrained: 18.3 ± 0.8 s, p=0.39) of muscle deoxygenation kinetics was altered according to training status.

**CONCLUSION:** The present data suggest that exercise training results in faster VO<sub>2</sub> kinetics in male adolescents, though inherent capabilities cannot be ruled out. Since muscle deoxygenation kinetics were unchanged, it is likely that faster VO<sub>2</sub> kinetics were due to adaptations to both the cardiovascular system and the peripheral musculature.

#### Effects Of A Promotora Mediated Physical Activity Intervention For Immigrant Latinas

Karen Therese D'Alonzo. Rutgers University, Newark, NJ. (Sponsor: Barbara A. Smith, FACSM)

Email: kdalonzo@rutgers.edu

(No relationships reported)

Physical activity is widely recognized as an important health promoting behavior for women. Levels of physical activity among immigrant Hispanic women (Latinas) decrease following arrival in the US and Latinas born in the US are more likely than other groups to report no leisure time physical activity. Latinas are often socialized to place family needs above their own needs throughout their lives. This construct, referred to as *marianismo*, may contribute to feelings of low self-efficacy for physical activity and depression among Latinas.

**PURPOSE:** To test the effects of a 12-week physical activity intervention for immigrant Latinas using *promotoras* (Latina community health workers). PAIL (Physical Activity Intervention for Latinas) is based upon Paulo Freire's Community Based Participation Research (CBPR) model and is designed to empower women to embrace physical activity as a health promoting behavior by: 1) Enhancing physical and exercise self-efficacy and collective self-efficacy (empowerment) and 2) Decreasing depressive symptoms.

**METHODS:** Sixty-eight immigrant Hispanic women, 18-55 years of age, were recruited to participate in the intervention which utilized an experimental pretest-posttest lag-group design. The intervention consisted of twice weekly, low impact aerobics/Latin dance classes taught by *promotoras*. Dependent variables were physical and exercise self-efficacy, depression and fitness (aerobic capacity, muscle strength, flexibility, percentage of body fat and body mass index). All dependent variables were measured pre-intervention and at 4, 8 and 12 weeks during the intervention.

**RESULTS:** Baseline data (n = 27, mean age= 30.5 yrs, mean length of stay in US= 8 yrs) confirm concerns about obesity and sedentarism. Mean BMI= 30.50 kg/m<sup>2</sup>, mean percentage of body fat = 36.8%. Results of IPAQ and PA-R indicate that walking is only form of physical activity. Mean non-exercise estimate of VO<sub>2 max</sub> was 25.01 ml/kg/min.

**CONCLUSIONS:** Preliminary results indicate that *promotoras* can be highly effective in encouraging adherence to a culturally attuned physical activity intervention and in assisting immigrant Latinas to achieve a balance between responsibilities toward others (*marianismo*) and healthy self-care activities, particularly physical activity.

Supported by NIH grant K01 NR009381.

#### Resistance And Family-support Program To Improve Functional Fitness And QoLs For Japanese Community-dwelling Elderly

Hiroshi Kohno<sup>1</sup>, Hidenori Asai<sup>2</sup>. <sup>1</sup>Toyo University, Asaka-Shi, Saitama, Japan. <sup>2</sup>Ehime University, Matsuyama-Shi, Ehime, Japan.

Email: kohno@toyonet.toyo.ac.jp

(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the effect of a combined health promotion program composed of resistance training and a family support program to improve functional fitness and QOLs for frail community-dwelling elderly.

**METHODS: PARTICIPANTS:** Subjects were 44 elderly females (69.4±6.0 yrs) The intervention group(IG) were 14(69.4±6.2 yrs, BMI:25.1±3.1) and the control group(CG) were 30 females(69.4±6.0yrs, BMI: 23.1±2.9). **Intervention:**The program was constituted of a home-based exercise program and group learning of resistance training. The intervention program consisted of an exercise program and family support program. The exercise program was composed of resistance training to improve upper, lower and trunk stability. The family support program was composed of learning support skills using behavioral science for the exercise program by the family. The classes were held twice a week over a period of 3 months. **Measurements:** height, body weight, %Fat, one leg standing with eyes open, functional reach, leg extension strength, geriatric depression scale (GDS),QOL score(SF36) and VAS scale of life satisfaction were obtained using standardized tests and questionnaire before and after the intervention period.

**RESULTS:** After the intervention period, measurements of leg extension strength(IG: 19.2±7.8kg to 25.2±7.2kg,P<0.05, CG: 21.4±4.9kg to 22.2±5.5kg,NS, deltaP<0.05), functional reach(IG: 17.9±4.5cm to 23.0±2.5cm,P<0.05, CG: 22.2±3.0cm to 26.3±2.8cm,P<0.05, deltaP<0.05) were improved significantly. QOL scores( Physical Function, Vitality), and VAS scales of life satisfaction in IG were also improved significantly compared to CG( deltaP<0.05).

**CONCLUSIONS:** These results suggest that a combined health promotion program composed of resistance training and a family support program was effective for improving physical function and QOLs in community-dwelling elderly women.

---

### 1755 Board #105 May 27 3:30 PM - 5:00 PM

## A Physical Activity And Lifestyle Education Intervention In Irish Adolescent Females

Deirdre M. Harrington, Alan E. Donnelly. *University of Limerick, Limerick, Ireland.* (Sponsor: Randall Jensen, FACSM)

Email: deirdre.harrington@ul.ie

(No relationships reported)

It has been widely reported that adolescents are not meeting physical activity (PA) guidelines with females often being highlighted as most 'at risk'. The Irish Obesity Taskforce Report 2005 recommended the development of "opportunities for physical activity...that concentrate on increasing physical activity among teenage girls".

**PURPOSE:** To engage a group of 'at risk' adolescent females (age 16yr 3mo±8mo) in a PA and lifestyle education (LE) intervention which would increase their Moderate to Vigorous Physical Activity (MVPA) during and also outside the intervention.

**METHODS:** Participants were randomly allocated to an intervention (n=17) and a control (n=16) group. The intervention group undertook a 32 week PA and LE intervention for 40 minutes 3 times a week. The PA component consisted of activities chosen by the participants (aerobics, kick boxing etc) and the LE component consisted of standard psychological tools such as goal setting and barrier identification. Pre and post tests included two body composition measures, 20 meter shuttle run to estimate  $\text{VO}_{2\text{max}}$  and a 3-5 day measure of PA using recording accelerometry. Accelerometry counts were recorded, and data was processed to identify continuous blocks of MVPA over 10 minutes duration.

**RESULTS:** The intervention did not alter either body composition measures. Estimated  $\text{VO}_{2\text{max}}$  of the intervention group increased significantly ( $p<0.001$ , t-test) from 27.6 ( $\pm 3.6$ ) to 33.6 ( $\pm 4.7$ )  $\text{ml.kg}^{-1}.\text{min}^{-1}$  whilst the control group showed no significant change. PA levels were determined to be below the acceptable level in both groups at pre test (which is as expected since they were chosen due to their sedentary patterns). PA levels increased significantly at the end of the intervention ( $p<0.01$ , t-test) in the intervention group with average minutes of PA per day increasing from 11 ( $\pm 7$ ) to 20 ( $\pm 15$ ) minutes. The control group showed no significant change in MVPA levels. PA patterns were also analysed.

**CONCLUSION:** The PA intervention significantly increased participants PA levels but not enough to reach adult (ACSM, 2007) or child (NASPE, 2005) recommendations. The increase is noteworthy since the group started from a sedentary base and this is combined with an increase in cardiovascular fitness. Data suggests that this type of targeted school based intervention may be successful.

#### Responses Of Postmenopausal Women To Focus Group Inquiries Of Desired Characteristics Of Physical Activity Intervention

Karen Derzic, Andrea M. Kriska, FACSM, Rachel S. Casas, Molly B. Conroy. *University of Pittsburgh, Pittsburgh, PA.*

Email: kld42@pitt.edu

(No relationships reported)

**PURPOSE:** Little participant-centered data exists on appealing characteristics of desirable physical activity (PA) programs for postmenopausal women. Such data may assist in planning PA programs to increase adherence.

**METHODS:** We conducted focus groups (FG) and telephone interviews (TI) for overweight, inactive postmenopausal women aged 45-65. Participants were asked "If you were to create the perfect [PA] program, what would it look like?" FG employed Nominal Group Technique (NGT); women individually listed ideas and voted to elicit the most desired characteristics. Information from FG and TI was reviewed by a research team member using grounded theory approach. Characteristics were reviewed and sorted into categories using open coding.

**RESULTS:** 32 women (average age=57.5 years) participated in FG (n=25) and TI (n=7). Four major themes emerged during review of FG and TI data: 1) Motivating features: "one on one sessions with a pro...I never know what to do or how to do exercises that are good for me," "group activity - with a facilitator who also motivates" and "the program was one in which results were easy to see." 2) Accountability: "requirements for activities to be done at home between sessions," and "a chart or log for keeping track of activities eventually a chart or log to track weight loss and other physical measurements." 3) Variety of PA options: "Varied things (gets bored doing same thing)," "Bikram yoga," "dancing" and "interval training including jogging/walking, calisthenics, weight training." 4) Convenience: "Convenience with regard to work schedule (i.e., noon, after work)" and "Easy parking: can't be so hard to get there that it's not worth it." Motivational factors, both intrinsic and extrinsic, seemed to be the most important factor for the women in our study based on both the frequency of responses and the ranking of these responses by the women in the focus groups.

**CONCLUSIONS:** Physical activity programs for postmenopausal women should include motivational support and a variety of activities in order to attract and retain participation. These characteristics, deemed important to the success of activity intervention participation in postmenopausal women, should be considered when developing an activity intervention program.

#### Effect Long Term Of Physical Exercise On The Nitrate\_nitrite Levels In Hypertensive Obese Postmenopausal

Pedro R. Zaros<sup>1</sup>, Carla E.M. Romero<sup>1</sup>, Camila de Moraes<sup>2</sup>, Angelina Zanesco<sup>1</sup>, Maurício Bacci Junior<sup>1</sup>. <sup>1</sup>UNESP/SP, Rio Claro, Brazil. <sup>2</sup>Cruzeiro do Sul University, São Paulo, Brazil.

Email: przaros@uol.com.br

(No relationships reported)

Shear stress induced by physical exercise is a powerful stimulus to increase NO production in vascular beds either in human or laboratory animals. Cardiovascular disease in women increases after postmenopausal years, mainly arterial hypertension. Furthermore, more women than men die each year of coronary heart disease. Thus, preventive actions to avoid high incidence of cardiovascular disease are extremely necessary for postmenopausal women.

**PURPOSE:** The aim of this study was to investigate the effects of 24 weeks of dynamic exercise training on plasma nitrate/nitrite concentration in hypertensive obese women.

**METHODS:** Eleven volunteers were included in this study with mean age were 50  $\pm$  4 years, BMI 33  $\pm$  6  $\text{Kg/m}^2$ . Participants were submitted to an aerobic exercise program on a cycle ergometer for 3 days a week, each session consisting of 60 minutes during 24 weeks at intensity of 50% of heart rate reserve. Lipid profile and nitrite/nitrate levels were evaluated at baseline and after 24 weeks of exercise training.

**RESULTS:** Neither BMI (33  $\pm$  6 vs 32  $\pm$  6  $\text{Kg m}^{-2}$ ) nor WHR (0.88 $\pm$ 0.06 vs 0.87  $\pm$  0.05 cm) were altered by exercise training. On the other hand, a significant reduction in both systolic (basal: 141 $\pm$ 10, after: 123 $\pm$ 8 mmHg, approximately 13%) and diastolic (basal: 90 $\pm$ 5, after: 80 $\pm$ 5 mmHg, approximately 12%) blood pressure values was seen after aerobic exercise training in hypertensive postmenopausal women. Similarly, heart rate was reduced, approximately 9% (basal: 83 $\pm$ 5, after: 76 $\pm$ 6 beats/min). Total cholesterol was reduced as well, approximately 20%. Physical training did not modify triglycerides levels as well as plasma nitrate/nitrite concentration (basal: 22 $\pm$ 6 after 25  $\pm$  4  $\mu\text{M}$ ).

**CONCLUSION:** Our findings show that exercise training promotes a beneficial effect on the arterial blood pressure which was not associated with plasma nitrate/nitrite levels in hypertensive obese women.

#### Effects Of Exercise Training Intensity On Metabolic Syndrome Components: A Preliminary Study Of Japanese Men

Hiroyuki Sasai<sup>1</sup>, Yasutomi Katayama<sup>2</sup>, Yoshio Nakata<sup>1</sup>, Miki Eto<sup>1</sup>, Takehiko Tsujimoto<sup>1</sup>, Hiroyuki Ohkubo<sup>1</sup>, Kiyoji Tanaka, FACSM<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Ibaraki, Japan. <sup>2</sup>Kogakkan University, Ise, Mie, Japan.  
Email: sasai@stat.taiiku.tsukuba.ac.jp  
(No relationships reported)

Many studies have reported that regular exercise could improve various components of the metabolic syndrome (MetS). However, it is unclear whether intensity of exercise training affects MetS-component improvements in Japanese obese men.

**PURPOSE:** To examine the effects of exercise training intensity on the components of MetS in obese men.

**METHODS:** Thirty-eight obese men aged 32 to 60 years participated in this study. They were divided into two groups (non-random design): moderate exercise (ME) group ( $n = 31$ , age:  $45.4 \pm 8.4$  yr, body mass index [BMI]:  $30.4 \pm 4.0$  kg/m<sup>2</sup>) and vigorous exercise (VE) group ( $n = 7$ , age:  $47.6 \pm 10.9$  yr, BMI:  $29.2 \pm 1.3$  kg/m<sup>2</sup>). All participants engaged in a 3-month exercise training program consisting mainly of aerobic exercise. The program was 90 minutes per session on 3 days per week. Main exercise modes were brisk walking for ME group and jogging for VE group. Measures of visceral fat area (VFA) by computed tomography, systolic and diastolic blood pressure (SBP, DBP), triglycerides (TG), high-density lipoprotein cholesterol, and fasting blood glucose were performed before and after the program. Relative exercise intensity (percentage of heart rate reserve) was also assessed during exercise sessions by a wireless heart rate monitor.

**RESULTS:** Exercise training reduced body weight by approximately 3 kg in both ME and VE groups. VFA significantly decreased from  $206.4 \pm 53.1$  cm<sup>2</sup> to  $172.1 \pm 44.4$  cm<sup>2</sup> for ME group and from  $167.1 \pm 46.1$  cm<sup>2</sup> to  $135.9 \pm 40.4$  cm<sup>2</sup> for VE group in response to exercise training. Significant reductions in SBP, DBP and TG were detected after the program in the ME group, but not in the VE group. Two-way (time by group) repeated ANOVA revealed no significant interactions ( $P = 0.11$  to  $0.92$ ) for all components of MetS. The results remained unchanged after controlling for weight change and each baseline value. In the pooled samples ( $n = 33$ ), relative exercise intensity did not correlate to improvements in the components of MetS ( $P = 0.13$  to  $0.98$ ). Similar results were also obtained after adjustments for each baseline value ( $P = 0.28$  to  $0.95$ ).

**CONCLUSION:** In this preliminary study, the intensity of exercise training might not influence MetS-component improvements in Japanese obese men.

**Effectiveness Of A Lifestyle-modification Program In Overweight Adults**

Gabriela K. Castanho<sup>1</sup>, Monica Y. Morelli<sup>1</sup>, Eric B. Rimm<sup>2</sup>, Roberto C. Burini<sup>1</sup>. <sup>1</sup>Unesp Medical School, Botucatu, Brazil. <sup>2</sup>Harvard School of Public Health, Boston, MA.

Email: gabikaizer@hotmail.com

(No relationships reported)

Brazil ranks 6<sup>th</sup> with 10% of obese (Ob) and 40% of overweight (Ow) individuals. There are no official data about the expenditure on body weight (BW)-reducing drugs, but it is estimated that chronic diseases associated with fattness cost US\$ 45.45 per person/yr to the health care system. Alternative to drugs, lifestyle intervention can prevent or control the disease.

**PURPOSE:** To evaluate the cost-benefit relationship of a feasible low-cost lifestyle-change program (LISC) for adults.

**METHODS:** The study included retrospective data on 116 adults ( $53.2 \pm 7.8$  yrs, 53.4% males that fulfilled the criteria of not taking medicines or not being on energy-restricted diets, accomplishing 3-5 sessions/wk of supervised exercises (60%-70% VO<sub>2</sub>max, 75 min), dietary-counseling sessions (monthly) and anthropometric assessments (every two months). LISC was conducted during two 6-month periods (P<sub>1</sub> and P<sub>3</sub>), intermediated by a counseling exercise period of 2 mo. (P<sub>2</sub>). The two physical-exercise and nutrition professionals with two students earned US\$ 636/mo. Body Mass Index (BMI) was classified as eutrophic (Eu), Ow and Ob (WHO, 1998), and body fatness (%BF) and the waist/hip ratio (W/H) by NHANES III (1996). The statistics included ANOVA, with  $p=0.05$ .

**RESULTS:** At baseline, Ow was more frequent (45.7%) than Ob (37.9%), and Eu (16.4%) with abdominal fat (W/H) predominated (81%) over body fatness (59.5%), with the latter being more frequent in Ob (58%) and the former in Ow (44.7%). Males were predominantly Ow (48.4%) with abdominal fatness (93.5%) whereas females were equally Ob and Ow (42.6%) with high body fat (77.8%). Ow males responded to LISC better in P<sub>1</sub> by losing BW ( $P_{95}=-4.5\%$ ), %BF (-12.9%) and W/H (-3.2%) whereas Ow females responded better in P<sub>3</sub> by losing %BF (-18.5%) and W/H (-5.5%). The loss of benefits in P<sub>2</sub> led the females to increase Ob (1.9%), %BF (2.4%) and W/H (5.6%). The overall program (P<sub>1</sub>+P<sub>2</sub>+P<sub>3</sub>) reduced 20% of Ob, but increased Eu only over Ow (13.8%). Fatness normalization reached 9.7% and 6.7% for %BF and W/H, respectively.

**CONCLUSION:** If applied nationwide for the 70mi. adult-Ow Brazilians, the present LISC (costing US\$ 7632/yr) with an efficiency of 13.8% would save US\$ 439mi/yr, which would be enough to replicate such LISC program 10 times in all the 5.564 Brazilian cities.

**Tailored Messaging And Its Effect On Health And Lifestyle Improvement**

Erin E. Raymond<sup>1</sup>, Steven M. Schwartz<sup>2</sup>, Richard B. Parr, FACSM<sup>1</sup>, Roop C. Jayaraman<sup>1</sup>. <sup>1</sup>Central Michigan University, Mount Pleasant, MI. <sup>2</sup>Health Media Inc., Ann Arbor, MI.

(No relationships reported)

The rising cost of healthcare has driven employers to develop effective health education and communication strategies designed to improve health outcomes. There is growing evidence for the use of computer-tailored, online behavioral health interventions.

**PURPOSE:** To determine the effectiveness of a computer-tailored, online behavioral health intervention promoting healthy lifestyle changes.

**METHODS:** Participants were recruited staff from a large mid-western college campus to participate in the computer-tailored wellness program. Information collected was based on epidemiological need, stage of change, motivation, self-confidence, barriers and demographics, the automated system recruits participants into follow-up behavior change interventions. Self-reported baseline and follow-up biometric, health risk behaviors, lifestyle scores, quality of health and life, motivation, and self efficacy data were analyzed using either CHI squared ( $\chi^2$ ) for categorical variables or t tests for continuous variables.

**RESULTS:** Of the 432 employees enrolled, 23.8% ( $n = 129$ ) completed the one-year follow up health risk assessment. The participants in this study were predominately women (78%), middle-aged, white/non-Hispanic and college graduates. At 1yr follow up, body mass index (BMI) data showed proportionally fewer men in extremely obese (-5.6%), and overweight categories (-5.5%) and more men in the obese category (5.6%). Women showed little proportional change in the BMI risk category except for the significant increase in the extremely obese category (4.6%,  $p<0.05$ ). Physical activity, nutrition, weight management, skin protection and mental health were the 5 behaviors with the highest risk at enrollment and there were strong trends toward improving health in these areas at year end. The lifestyle scores indicated a significant shift towards a healthier lifestyle. However, perceived quality of health and life did not significantly change with participation. Overall motivation and self-efficacy to change risk behaviors showed a strong positive trend.

**CONCLUSION:** Participation in the computer-tailored wellness program resulted in a moderate shift towards a healthier lifestyle. The low program retention contributed to the suboptimal program performance on risk modification.

**Effect Of Lifestyle Health Coaching On Risk Factors In Normal Weight, Overweight And Obese Participants**

Barry A. Franklin, FACSM<sup>1</sup>, Richard D. Salmon<sup>2</sup>, Terri L. Gordon<sup>2</sup>, David A. Alter<sup>3</sup>, Neil F. Gordon, FACSM<sup>3</sup>. <sup>1</sup>William Beaumont Hospital, Royal Oak, MI. <sup>2</sup>Nationwide Better Health, Savannah, GA. <sup>3</sup>INTERVENT Canada, Toronto, ON, Canada.  
Email: bfranklin@beaumont.edu  
(No relationships reported)

Lifestyle health coaching (LHC) has gained increased popularity as a strategy to facilitate behavior change. Scarce comprehensive data are available on the effect of LHC on multiple cardiovascular disease (CVD) risk factors in normal weight, overweight and obese adults.

**PURPOSE:** In this study, we evaluated the effect of LHC on multiple CVD risk factors in 7,281 adults, of whom 3,784 were obese (Group I, baseline body mass index [BMI] >30 kg/m<sup>2</sup>), 2,134 were overweight (Group II, baseline BMI = 25-29.9 kg/m<sup>2</sup>) and 1,363 were normal weight (Group III, baseline BMI <25 kg/m<sup>2</sup>).

**METHODS:** Outcome measures were assessed at baseline and after approximately 1 year of LHC. LHC included individualized coaching on exercise, nutrition, weight management, stress management and smoking cessation.

**RESULTS:** Weight (Group I, -6.9 lbs; Group II, -2.3 lbs; Group III, 0.1 lbs) and BMI (Group I, -1.1 kg/m<sup>2</sup>; Group II, -0.4 kg/m<sup>2</sup>; Group III, 0 kg/m<sup>2</sup>) decreased significantly (p <0.05) in the overweight and obese participants (p <0.05 for Group I versus Groups II and III; p <0.05 for Group II versus Group III). For participants with abnormal baseline risk factors, significant improvements (p <0.05) were observed for multiple additional variables in all 3 groups, as follows: blood pressure (Group I, -8/7 mmHg; Group II, -8/7 mmHg; Group III, -11/8 mmHg); LDL cholesterol (Group I, -19 mg/dl; Group II, -21 mg/dl; Group III, -21 mg/dl); HDL cholesterol (Group I, 4 mg/dl; Group II, 4 mg/dl; Group III, 6 mg/dl); triglycerides (Group I, -39 mg/dl; Group II, -46 mg/dl; Group III, -58 mg/dl); and fasting glucose (Group I, -9 mg/dl; Group II, -6 mg/dl; Group III, -14 mg/dl). In participants with a baseline Framingham 10-year coronary heart disease risk score >10%, the score decreased significantly (p <0.05) in participants in all 3 groups (Group I, -20.8%; Group II, -21.3%; Group III, -17.2%; p=NS for the differences among groups).

**CONCLUSIONS:** These data serve to document the magnitude of improvement in multiple CVD risk factors in normal weight, overweight and obese individuals in response to participation in 1 year of LHC. Although weight loss is greatest for obese participants, the magnitude of improvement in the Framingham 10-year coronary heart disease risk score is similar for all participants.

## 1762 Board #112 May 27 3:30 PM - 5:00 PM

### Effect Of Gender On Responsiveness Of Multiple Cardiovascular Disease Risk Factors To Lifestyle Health Coaching In Adults With Prediabetes

Neil F. Gordon, FACSM<sup>1</sup>, Richard D. Salmon<sup>1</sup>, Terri L. Gordon<sup>1</sup>, David A. Alter<sup>2</sup>, Barry A. Franklin, FACSM<sup>3</sup>. <sup>1</sup>Nationwide Better Health, Savannah, GA. <sup>2</sup>INTERVENT Canada, Toronto, ON, Canada. <sup>3</sup>William Beaumont Hospital, Royal Oak, MI.  
Email: gordonn1@nwbetterhealth.com  
( N.F. Gordon, PrevCan, Ownership Interest.)

Prediabetes affects ~33.5% of men and ~22.6% of women in the U.S. Scarce data are available on the effect of gender on the responsiveness of cardiovascular disease (CVD) risk factors to lifestyle health coaching (LHC) in adults with prediabetes.

**PURPOSE:** In this study of 967 men (n = 399; age = 57 years) and women (n = 568; age = 55 years) with prediabetes, we evaluated the effect of gender on the responsiveness of multiple CVD risk factors to LHC.

**METHODS:** At baseline, all participants met the American Diabetes Association's (ADA) criteria for prediabetes. Participants were evaluated at baseline and after an average of ~4 months of LHC. LHC included individualized coaching on exercise, nutrition, weight management, and smoking cessation.

**RESULTS:** In men, baseline fasting glucose (108 mg/dl) decreased by 5 mg/dl (p <0.05) with LHC. Similarly, baseline fasting glucose (107 mg/dl) decreased by 5 mg/dl (p <0.05) with LHC in women. Based on ADA criteria, 172 (43.1%) men and 250 (44.0%) women normalized their fasting glucose (i.e., fasting glucose below 100 mg/dl). For participants with abnormal baseline risk factors, significant (p <0.05) improvements were observed for multiple additional variables, as follows: blood pressure (Men, -9/7 mmHg; Women, -9/7 mmHg); LDL cholesterol (Men, -25 mg/dl; Women, -15 mg/dl; p <0.05 for Men versus Women); HDL cholesterol (Men, 2 mg/dl; Women, 3 mg/dl); triglycerides (Men, -56 mg/dl; Women, -35 mg/dl; p <0.05 for Men versus Women); and weight (Men, -8 lbs; Women, -7 lbs). Of the participants who smoked cigarettes at baseline, 19.6% of men and 0% of women quit smoking. In participants with a baseline Framingham 10-year coronary heart disease risk score >10%, the score decreased significantly (p <0.05) in men and women (Men, -22.8%; Women, -18.1%; p <0.05 for Men versus Women). Thus, while the magnitude of reduction in fasting glucose was similar in men and women, men derived a slightly greater benefit in terms of overall CVD risk reduction.

**CONCLUSIONS:** The present study adds to previous research by reporting on the effectiveness (rather than the efficacy) of LHC in adults with prediabetes. The data show that many adults with prediabetes can normalize their fasting glucose with LHC but suggest that there may be gender-related differences in the therapeutic responsiveness of certain risk factors.

## 1763 Board #113 May 27 3:30 PM - 5:00 PM

### Evidence-based Practice Improves Health Outcomes In A Community-based Fitness Program

Jessica S. Tischendorf, Lance C. Dalleck. *University of Wisconsin - Eau Claire, Eau Claire, WI.*  
Email: TISCHEJS@uwec.edu  
(No relationships reported)

Evidence-based practice (EBP) refers to the integration of current best clinical evidence, clinical expertise, and client choice in making decisions about the care of individuals. It has been noted that EBP exercise interventions have not been widely applied in non-research settings (Glasgow et al., 2003).

**PURPOSE:** The purpose of this study was to implement an EBP exercise intervention into a local community fitness program following the specific exercise dose (14-23 kcal/kg/wk) and intensity (40-60% heart rate reserve - HRR) guidelines reported in a recent randomized, controlled study (Kraus et al., 2002) to elicit positive health outcomes.

**METHODS:** Participants (N = 238; men = 101 and women = 137) with a mean age of 62.4 yr (range = 29-86 yr) completed a 14-wk community fitness program. Baseline (BL) and post-program measures included energy expenditure, systolic and diastolic blood pressure, cardiorespiratory fitness, body mass, waist circumference, and fasting lipid/blood glucose profile.

Outcome variable	Baseline	Post-Program	14 kcal/kg/wk % change	23 kcal/kg/wk % change
Absolute EE (kcal/d)	461 ± 244	1010 ± 409	Not reported	Not reported
Relative EE (kcal/kg/d)	5.0 ± 1.1	17.8 ± 8.7	Not reported	Not reported
Waist Circumference (cm)	103.2 ± 18.2	101.2 ± 18.3	-1.5%	-1.9%
Body mass (kg)	82.3 ± 21.3	81.6 ± 21.1	-0.7%	-0.1%
Cardiorespiratory Fitness (mL/kg/min)	28.7 ± 9.9	32.4 ± 11.2	+11.0%	+12.9%
Cardiorespiratory Fitness (L/min)	2.63 ± 0.91	2.97 ± 0.95	+11.3%	+12.1%
Systolic BP (mmHg)	123.2 ± 13.4	120.1 ± 12.3	Not reported	Not reported
Diastolic BP (mmHg)	76.4 ± 10.9	74.9 ± 8.7	Not reported	Not reported
Total cholesterol (mg/dL)	180.6 ± 40.6	183.7 ± 41.8	+2.3%	+5.5%
HDL (mg/dL)	45.6 ± 18.4	48.3 ± 17.8	+6.6%	+8.8%
LDL (mg/dL)	121.2 ± 36.7	121.4 ± 32.1	+0.3%	-1.4%
Triglycerides (mg/dL)	140.6 ± 77.8	118.1 ± 71.9	-16.1%	-17.0%
Fasting Glucose (mg/dL)	106.8 ± 36.4	89.3 ± 34.9	+2.8%	-7.0%

**RESULTS:** BL and post-program health outcome data (mean ± SD) pooled from six separate semesters between fall 2005 and spring 2008 are presented in the table. Percent (%) change from BL to post-program for our community fitness program and the two exercise volume groups (14 and 23 kcal/kg/wk) from the literature used to guide our intervention are also reported in the table. Mean relative energy expenditure and exercise intensity were 17.8 kcal/kg/wk and 42.3% HRR, respectively.

**CONCLUSION:** Our data indicates that participants in an EBP community fitness program have comparable health outcomes to participants in a research setting. Overall, these findings suggest that EBP exercise guidelines can successfully be translated into a community setting.

**Self-efficacy Moderates The Effect Of Moderate Intensity Exercise On Smoking Cessation Outcomes Among Women**

David M. Williams. *Brown Medical School/The Miriam Hospital, Providence, RI.*  
Email: [dwilliams2@lifespan.org](mailto:dwilliams2@lifespan.org)  
(No relationships reported)

There has been mixed support for exercise as a treatment adjunct for smoking cessation programs, suggesting that certain moderators may help to identify participants for whom such programs are more likely to be effective.

**PURPOSE:** To examine smoking cessation self-efficacy as a potential moderator of smoking cessation outcomes among women enrolled in a randomized clinical pilot study testing moderate intensity exercise as an adjunct to nicotine replacement therapy.

**METHODS:** Sixty previously sedentary, healthy, adult female smokers (70% non-Hispanic White, mean (SD) age = 42.4 (11.5)) were randomly assigned to an 8-week program consisting of brief baseline counseling and the nicotine patch plus either 150 min/week of moderate intensity exercise or a wellness contact control. A previously validated questionnaire was used to assess smoking cessation self-efficacy immediately prior to randomization. Smoking cessation outcomes included carbon-monoxide confirmed 7-day point prevalence abstinence at post-treatment and at one-month follow-up.

**RESULTS:** Smoking cessation self-efficacy moderated treatment outcomes at post-treatment ( $p = .039$ ) and one-month follow-up ( $p = .051$ ). Specifically, participants with higher smoking cessation self-efficacy at baseline had a 122% increase in odds of being quit at post-treatment ( $OR = 2.23$ ,  $p = .076$ ), and a 288% increase in odds of being quit at one-month follow-up ( $OR = 3.88$ ,  $p = .029$ ) if they were in the exercise treatment condition; however, higher baseline self-efficacy did not result in increased odds of being quit at post-treatment ( $OR = 0.545$ ,  $p = .235$ ) or one-month follow-up ( $OR = 0.731$ ,  $p = .594$ ) among participants in the wellness condition.

**CONCLUSION:** Moderate intensity exercise may be a more effective adjunct to nicotine replacement therapy among previously sedentary women with initially high smoking cessation self-efficacy.

**Improving Physical Activity And Nutrition Assessment And Counseling In Community Health Centers**

Janet M. Shaw, FACSM, Caren J. Frost, Elise Sigüenza, Crystal Fuller. *University of Utah, Salt Lake City, UT.*  
Email: [Janet.Shaw@health.utah.edu](mailto:Janet.Shaw@health.utah.edu)  
(No relationships reported)

Community Health Centers (CHC) provide comprehensive care for medically underserved patients. Methods to provide quick and culturally relevant physical activity (PA) and nutrition assessment along with counseling to CHC patients are lacking.

**PURPOSE:** Using the PACE (Physician Assisted Counseling for Exercise) Program, we aimed to gain the insight of CHC providers and medical assistants (MAs) to improve PACE for clinic use with a target population of lower-income and primarily Spanish-speaking women.

**METHODS:** Site licenses for PACE were purchased. Four providers (3 MD, 1 PA-C) and eight MAs participated in two focus groups after providing written, informed consent. All participants were bilingual in English and Spanish. Focus groups were conducted at two clinics in urban Utah and each consisted of two providers and four MAs. The Spanish language PACE materials were provided to participants in advance of focus groups. Questions regarding perceived patient understanding of PACE materials, cultural meaningfulness of PACE and practical implementation of PACE in the clinic were asked. Each focus group lasted 60 minutes.

**RESULTS:** Three themes emerged from the focus groups. 1. Participants felt that PA and nutrition are important aspects of health that should be addressed in the context of primary care offered by their respective clinics. Participants noted that patients often request information on PA and nutrition, particularly with regard to weight loss. 2. The researchers felt that a successful PA and/or nutrition program should relate to the cultural background and consider financial constraints of the patient population. Participants suggested changes to the Spanish PACE text for greater patient appeal. 3. The PACE Program must be shortened and use more basic language for practical implementation in clinics. Providers have ~15-minute patient visits and patients are not accustomed to completing complex forms. Therefore, participating clinics cannot implement PACE in its current structure.

**CONCLUSION:** There is support for PA and nutrition assessment and counseling using PACE in urban Utah CHC clinics, yet changes must be applied to improve feasibility and cultural relevance to the patient population.

**Misunderstanding Of SPF Sunscreen Rating Among Varying Sport And Physical Activity Participants**

Susan K. Ailor, Kari L. Martin, LeAnna R. Lane. *University of Missouri, Columbia, MO.*  
Email: [ailors@health.missouri.edu](mailto:ailors@health.missouri.edu)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to evaluate knowledge of the skin protection factor (SPF) rating among various physical activity groups. The SPF factor is commonly used in labeling for sunscreens and, now, for clothing.

**METHODS:** A total of 1208 submitted answers to a demographic and 10 question T/F survey. Each participant listed activities in which they participate. Surveys were distributed during regional health fairs, skin cancer screenings, medical school classes, and dermatology and surgical oncology patient visits. Knowledge of SPF was measured by the true/false survey statement: "SPF (sun protection factor) represents the number of minutes a person can be out in the sun with sunscreen on and be getting the same amount of UV rays as if they were out in the sun with no sunscreen on for one minute."

**RESULTS:** In the groups listed, the above true statement was the most or 2<sup>nd</sup> to most incorrectly answered. In this survey, all ten statements are true for the purpose of being an educational tool. Participants may have been able to discern the answer pattern. Because of this, the percentage of correct answers to the SPF question is probably skewed high. In a future study, we plan to administer a revised survey instrument with a mix of true and false statements to specific sports teams.

SPF Knowledge by Activity
---------------------------

ACTIVITY	NUMBER	% CORRECT
Running, jogging	338	68
Swimming	320	63
Hiking	272	69
Bicycling	181	71
Tennis	120	68
Baseball	105	66
Soccer	99	65
Softball	94	64
Walking	78	67
Track/cross country	60	63

**CONCLUSION:** Even though “SPF” is a commonly used acronym indicating the level of sun protection offered in sunscreen and clothing, many people do not understand what SPF actually means. With ACSM and AHA guidelines and their support of the US Dept of Health and Human Services (DHHS) physical activity guidelines, we recommend that the ACSM address skin cancer prevention education, and, in particular, the promotion of accurate understanding of SPF nomenclature.

**1767 Board #117 May 27 2:00 PM - 3:30 PM**  
**Development And Feasibility Study Of A Chair-based Bladder Health Program For Senior Women**

Ihm Jeni, Sheila Ann Dugan, FACSM, Missy Lavender, Jennifer Hebert-Beirne, Jacqueline de la Cruz, Cody McSellers-McCray, Carol McPherson, Christine Cornell, Mary Susan Chen. *Rush University Medical Center, Chicago, IL.*  
*(No relationships reported)*

**PURPOSE:** To successfully adapt an evidenced-based pelvic fitness and educational program for women to a female senior population reporting bladder symptoms.

**METHODS:** Feasibility study with convenience sampling of women in independent living at The Altenheim, a senior community in Forest Park, Illinois who engaged in a six week fitness and educational class modeled after WHF’s medically-based Total Control™ pelvic exercise program designed for women in the general population. The class met once (1) a week for six (6) weeks for 60 minute pelvic fitness (45 min) and educational program (15 min). Excel and SPSS for demographics; SF-12; UDI-6; TUG; IIQ-7; symptom severity and bothersomeness of symptoms; perception of feasibility of fitness class; and overall health change at B/L & F/U.

**RESULTS:** Participants were eight white women, average age of 81. One subject did not attend the final class and with no follow up. SF 12: 7/8 with symptoms moderate to as bad as they can be at B/L. 3/7 nonexistent to moderate symptoms at F/U. 5/8 rated their health as “good” or “fair” at B/L 6/7 “excellent” or “very good” at F/U. 5/8 at B/L and 2/7 at F/U reported that because of their physical health, they accomplished less than they would like and were limited in the kind of activities in which they engaged. Timed Up and Go (TUG): 12.5 sec (SD 3.38) B/L, 10.8 sec (SD 2.19) F/U.

Urinary Distress Inventory (UDI): 6/8 moderately or greatly bothered by frequent urination at B/L. 3/7 with reduction in bothersomeness with one participant reporting none at F/U. 3/7 moderately or greatly bothered by urine leakage at B/L. 7/7 only slightly bothered or bothered not at all by urine leakage at F/U. Incontinence Impact Questionnaire (IIQ-7): 3/7 with ↓ extent to which urine leakage affected household chores. 2/7 with ↓ in how urine leakage affected social activities Satisfaction: 100% satisfied with the program. 75% definitely understood exercises; 25% somewhat. 5 definitely noticed changes in your bladder control/pelvic floor function at F/U; 2 somewhat

**CONCLUSIONS:** Senior women in independent living were able to engage in a pelvic floor fitness program in sitting. They were able to perform pre- and post-tests. The majority felt they understood the exercises and had positive changes in bladder symptoms. We are ready to use the program and assessments for a multi-site trial.

**1768 Board #118 May 27 2:00 PM - 3:30 PM**  
**Activity, Diet, And Compliance Trends In A University-based Exercise Prescription Study**

Jeff Angermann, Catherine McCarthy, Thomas Taber, Andrew Pasternak, Carol Scott. *University of Nevada, Reno, NV.*  
Email: jangermann@medicine.nevada.edu  
*(No relationships reported)*

Some of the challenges that primary care providers (PCPs) face in developing effective clinic-initiated exercise intervention programs include management of PCP time commitment, design of appropriately flexible yet specific exercise prescriptions, and streamlined patient referral to exercise professionals. In an increasingly challenging financial climate for providers and patients alike, there remains a need for model intervention programs that address these challenges at minimal expense.

**PURPOSE:** To design and validate components of an exercise prescription program suitable for adoption by primary care clinics, and to assess the value of specific exercise prescription relative to either (a) no advice or (b) standard advice as recommended by the American Association of Family Physicians (AAFP).

**METHODS:** 78 subjects (BMI 25≤x≤40) were recruited (by clinical or self referral), screened, and enrolled into the UNEPS exercise study at the University of Nevada, Reno. Subjects were randomized to one of three treatments (no advice, standard advice, and specific prescription) in order to assess the effect of fitness testing and prescription specificity on intervention compliance, resting metabolic rate (RMR) progression, VO<sub>2</sub>max progression, and activity levels during the 6-month exercise intervention.

**RESULTS:** Subjects receiving specific exercise prescription demonstrated significantly enhanced RMR and moderate activity levels (by accelerometry) relative to subjects receiving either no advice or standard advice.

**CONCLUSION:** Specificity in primary care-based exercise intervention programs contributes to beneficial increases in general activity.

*Supported by Nevada State Health Division Trust Fund for Public Health.*

**1769 Board #119 May 27 2:00 PM - 3:30 PM**  
**Healthcare Provider Counseling For Physical Activity, Diet, And Weight Management**

Elizabeth A. Fallon, Lindsay Ahalt, Sarah Corn, Melissa Bopp. *Kansas State University, Manhattan, KS.* (Sponsor: Timothy Musch, FACSM)  
*(No relationships reported)*

Healthcare provider (HCP) counseling for improving physical activity, diet, and weight management has proven efficacious yet the majority of HCPs do not counsel their patients for these behaviors.

**PURPOSE:** To understand HCP counseling rates and attitudes toward counseling for physical activity, diet, and weight management.

**METHODS:** A survey was mailed to randomly selected physicians (N = 1000), nurses (N = 1000), and all 697 physician assistants. HCPs indicated the percent of their patients

they counsel for physical activity, diet, and weight management. For each of these health behaviors, seven attitudes toward counseling were assessed using a 5-point Likert scale. Multiple regressions were conducted separately for physical activity, diet, and weight management counseling rates. Independent variables were HCP type (physician, nurse, physician assistant), HCP sex, HCP body mass index and health behaviors and HCP attitudes toward counseling.

**RESULTS:** Mean counseling rates for physical activity, diet, and weight management were 52.4%, 51.2%, and 41.1%, respectively (response rate = 16.4%;  $n = 443$ ). For physical activity, two factors explained 17.6% of variance in counseling rate. Nurses were significantly less likely to counsel for physical activity than physicians and physician assistants ( $p = 0.05$ ) and perception that patients are interested in receiving counseling was positively related to counseling rate ( $p < 0.001$ ). For diet, two factors explained 16.3% of variance in counseling rate. Perception that patients are interested in receiving counseling ( $p < 0.001$ ) and perception their patients would benefit from a healthier diet were positively related to counseling rate ( $p = 0.003$ ). For weight management, three factors explained 26.0% of variance in counseling rate. Nurses reported lower rates of counseling than physician assistants and physicians ( $p = 0.002$ ). Additionally, perception that patients are interested in receiving counseling ( $p < 0.001$ ) and perception their patients were overweight ( $p = 0.03$ ) were positively associated with counseling rate.

**CONCLUSION:** These data indicate all HCPs, especially nurses, should increase counseling. Furthermore, increasing HCP perception of patient interest in receiving counseling may increase counseling rates and, ultimately, reduce chronic disease.

**Healthcare Provider Physical Activity Prescription Intervention Pilot**

Roseann M. Lyle, FACSM, Lakshmi Josyula. *Purdue University, West Lafayette, IN.*  
Email: rlyle@purdue.edu  
(No relationships reported)

**PURPOSE:** To examine the feasibility and short-term impact of healthcare providers' recommendations of physical activity on the physical activity levels of patients on preventive care visits.

**METHODS:** Consenting adult patients completed questionnaires on their general health and physical activity (Short Form 36, Aerobic Center Longitudinal Study (ACLS) habitual physical activity, Patient-centered Assessment and Counseling for Exercise (PACE) readiness for physical activity, and Cancer Prevention Research Center exercise self-efficacy), and were assigned to 1 of 3 experimental groups, based on chronological order of entry into the study. At the office visit, the healthcare provider prescribed physical activity using a written prescription only (WP), a WP plus a toolkit containing an elastic band and instructions (WPT), or a WP plus a guide to local physical activity resources (WPG). 1 month post, participants completed the PACE survey, with possible scores from 1 to 8 (higher scores indicate more physical activity). 3 months post, baseline questionnaires were repeated.

**RESULTS:** 24 patients completed data-collection at baseline and 3 months; 22 completed baseline, 1 and 3 months. There were no baseline differences among the groups or between those who completed or did not complete the study. Within the overall group of 24 patients (mean age 57 years  $\pm$  10.01; mean BMI 33.4  $\pm$  7.6; 14 women/10 men; 9 WP, 6 WPT, 9 WPG) who returned questionnaires at baseline and 3 months, physical activity level, assessed by the PACE survey, increased ( $p=0.04$ ) from baseline (3.5  $\pm$  2.0) to 3 months (4.3  $\pm$  1.7). Within group analyses revealed that WPT improved ( $p=0.01$ ) from baseline (3.0  $\pm$  1.1) to 3 months (4.8  $\pm$  0.4), whereas WP and WPG did not. Among the 22 participants (all groups combined) who returned questionnaires at baseline, 1 and 3 months, physical activity level increased ( $p=0.01$ ) from 1 month (3.7  $\pm$  1.3) to 3 months (4.4  $\pm$  1.6) and approached a significant increase ( $p=0.06$ ) between baseline and 3 months.

**CONCLUSION:** Preliminary support is provided for the feasibility, and positive impact of, a healthcare provider's written prescription, in conjunction with a physical activity resource, e.g. an exercise toolkit, to enhance patients' physical activity levels over 3 months. Toolkits donated by the Hygenic Corporation.

**I'm Stressed! I Must/can't Exercise Today! Effects Of Stage On Physical Activity And Stress.**

Rafer S. Lutz<sup>1</sup>, Matthew A. Stults-Kolehmainen<sup>2</sup>, John B. Bartholomew, FACSM<sup>2</sup>. <sup>1</sup>Baylor University, Waco, TX. <sup>2</sup>University of Texas, Austin, TX.  
Email: Rafer\_Lutz@baylor.edu  
(No relationships reported)

While only a handful of prospective studies have been conducted in this area, there is evidence that people engage in less physical activity upon encountering higher levels of psychological stress. Despite this, physical activity is often reported to be an effective coping mechanism to relieve stress. In addition, motivational differences exist between frequent and infrequent exercisers. As a result, it might be that the impact of stress on freely chosen physical activity would differ based on exercise stage of change.

**PURPOSE:** Using a prospective design, we examined the relationship between stress and physical activity, while testing for a moderating effect of stages of change derived from the Transtheoretical Model.

**METHODS:** 95 college-aged females (19.34  $\pm$  2.08 yrs; 64.23  $\pm$  2.03 in; 138.27  $\pm$  29.92 lbs; 23.64  $\pm$  4.91 BMI) were recruited from undergraduate classes and the local community. Participants completed a battery of questionnaires before a 6-week evaluation period. During this period, participants were asked to return a leisure-time physical activity log daily and to return a stress events scale weekly (Weekly Stress Inventory; Brantley, et al., 1997).

**RESULTS:** Results of HLM analyses demonstrated that there was no effect of stress events frequency or intensity on physical activity. However, it was found that this effect was suppressed by exercise stage of change as stages of change interacted with stress (both event frequency and intensity) to effect the amount of total physical activity minutes reported per week (stress frequency,  $G = -2.61$ ,  $SE = 0.95$ ,  $t\text{-ratio} = -2.75$ ,  $df = 76$ ,  $p = 0.008$ ; stress intensity,  $G = -0.69$ ,  $SE = 0.25$ ,  $t\text{-ratio} = -2.74$ ,  $df = 76$ ,  $p = 0.008$ ). The stress - physical activity relationship was negative for those in the contemplation stage, positive for those in the maintenance stage, and non-existent for those in preparation and action phases.

**CONCLUSION:** Results are indicative of stress - physical activity relationships that vary by exercise stage of change. Physical activity participation for those at an early stage of change (i.e., contemplation) appears to be negatively influenced by stressful experience, whereas those at the highest stage of change (i.e., maintenance) may exercise more under stress.

**The Relationship Between Health Knowledge And Measures Of Health-related Physical Fitness**

Marc D. Faktor<sup>1</sup>, Darren E.R. Warburton<sup>1</sup>, Ryan E. Rhodes<sup>2</sup>, Shannon S.D. Bredin<sup>1</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada.  
<sup>2</sup>University of Victoria, Victoria, BC, Canada. (Sponsor: Keith George, FACSM)  
Email: marc.faktor@gmail.com  
(No relationships reported)

Research suggests that individuals who have increased fitness knowledge via health education are more likely to be physically active and fit. However, literature delineating the relationship between health knowledge base and the components of health-related physical fitness is scarce and inconsistent.

**PURPOSE:** To determine the relationship between health-related physical fitness knowledge (HRPFK) and objective measures of health-related physical fitness in adulthood.

**METHODS:** Health knowledge was assessed in 18 F and 16 M adults (19-49 yr) via the FitSmart, a 50 question standardized multiple choice examination of HRPFK, which incorporates: concepts of fitness, scientific principles of exercise, components of physical fitness, effects of exercise on chronic disease risk factors, exercise prescription, as well as nutrition, injury prevention, and consumer issues. Health-related physical fitness was assessed using the Canadian Physical Activity Fitness and Lifestyle Approach (CPAFLA), which objectively measures: physical activity participation (PAP), body composition (BMI, Waist Circumference (WC), Sum Of 5 Skinfolds), aerobic fitness (mCAFT), composite musculoskeletal fitness (grip strength, push-ups, flexibility, partial curl-ups, vertical jump, leg power, back extension (BE)), and composite back fitness (PAP, WC, flexibility, curl-ups, BE ). All measures were completed by a Canadian Society for Exercise Physiology-Certified Exercise Physiologist (CSEP-CEP).

**RESULTS:** HRPFK was significantly correlated to composite musculoskeletal fitness ( $r=0.40$ ). When controlling for socio-demographic variables (age, gender, income, & education), regression analyses showed that HRPFK was the strongest unique contributor to musculoskeletal fitness (standardized  $B=0.59$ ,  $p<0.05$ ). Within composite musculoskeletal fitness, there was a positive and significant correlation between HRPFK and push-ups ( $r=0.37$ ), as well as HRPFK and partial curl-ups ( $r=0.41$ ).

**CONCLUSION:** HRPFK is a significant contributor to and correlate of health-related physical fitness in adulthood. Clearly, the concept of HRPFK warrants further investigation as it holds important implications for the development of future health promotion initiatives.

**1773 Board #123 May 27 2:00 PM - 3:30 PM**

### Differences In Psychosocial Factors According To Physical Activity Levels In Males And Females

David J. Rice, Jeanette M. Garcia, Robert J. Robertson, FACSM, Elizabeth F. Nagle, FACSM, Deborah J. Aaron, FACSM. *University of Pittsburgh, Pittsburgh, PA.*

Email: djr45@pitt.edu

(No relationships reported)

**PURPOSE:** To examine differences in psychosocial factors according to physical activity (PA) levels in males and females.

**METHODS:** Subjects were 552 young adults (mean age  $29.4 \pm 1.1$  yrs). The sample was approximately 82% Caucasian, 15% African-American, with females comprising 57% of the sample. A Mann-Whitney U-test of independent samples was used to determine differences in 8 psychosocial variables (perceived barriers to PA, perceived benefits of PA, self efficacy, social support, perceived stress, decisional balance, depression, and PA enjoyment) between groups differing in total weekly PA. Participants were grouped based on weekly reported PA, with the cut-point set at 150 min/week of reported PA. Separate analyses were done for male and female PA groups.

**RESULTS:** The results showed that both male and female higher PA groups reported less perceived stress, lower depression, greater PA enjoyment, greater PA benefits, and greater self-efficacy than the lower PA groups ( $p<0.05$  for all variables). The results further showed that social support differed significantly ( $p = 0.04$ ) between PA groups for males but not for females, and that decisional balance ( $p = 0.011$ ) and perceived barriers ( $p < 0.001$ ) differed significantly between PA groups for females but not for males. See table for median scores  $\pm$  SD and  $p$ -value for the differences between PA groups, for males and females separately.

	Males				Females			
	Lower PA group Score	Higher PA group Score	p-value	U-score	Lower PA group Score	Higher PA group Score	p-value	U-score
Social Support	35.0 $\pm$ 9.5	40.0 $\pm$ 11.1	0.014	1454.0	37.0 $\pm$ 10.6	40.5 $\pm$ 11.6	0.197	8515.5
Perceived Barriers	31.0 $\pm$ 11.2	28.0 $\pm$ 9.2	0.072	2086.0	37.0 $\pm$ 10.3	30.0 $\pm$ 10.8	0.001	6528.5
Decisional Balance	1.1 $\pm$ 0.7	1.3 $\pm$ 1.2	0.313	1682.5	1.1 $\pm$ 1.0	1.5 $\pm$ 1.1	0.011	7602.5

**CONCLUSION:** Males and females differed by PA group for social support, perceived barriers and decisional balance. These results suggest that PA interventions should consider gender-specific strategies to increase compliance with PA programs.

### Psychosocial Variables Influencing Long-term Physical Activity Levels In Overweight Men And Women

Jessica L. Unick, John M. Jakicic, FACSM, Amy D. Otto, Christine A. Dutton, Krista L. Rompolski, David O. Garcia, Blake D. Justice. *University of Pittsburgh, Pittsburgh, PA.*

Email: jessunick@yahoo.com

(No relationships reported)

Physical activity (PA) is a primary predictor of weight maintenance. However, rates of long-term exercise adherence are less than optimal.

**PURPOSE:** To identify characteristics of individuals who have sustained high levels of PA at the end of an 18-month intervention.

**METHODS:** 173 overweight (BMI =  $27.0 \pm 1.7$  kg/m<sup>2</sup>; age =  $45.4 \pm 8.4$  years) subjects participated in an 18-month PA intervention and were instructed to exercise between 150-300 minutes/week. Questionnaires were administered at baseline, 6 and 18 months to assess PA, barriers, expected outcomes, and behavioral processes. Subjects were grouped according to PA energy expenditure at 6 and 18 months (MAINTAIN: expending  $\geq 1500$  kcal/wk at 6 & 18 months, NON-MAINTAIN:  $\geq 1500$  kcal/wk at 6 months &  $<1500$  kcal/wk at 18 months, NON-ADOPT:  $<1500$  kcal/wk at 6 & 18 months, LATE ADOPT:  $<1500$  kcal/wk at 6 months and  $\geq 1500$  kcal/wk at 18 months).

**RESULTS:** Weight loss at 18-months was  $-0.95 \pm 4.2$  kg and was significantly greater in the MAINTAIN group ( $-2.04 \pm 4.2$  kg) compared to the NON-ADOPT group ( $0.13 \pm 3.7$  kg) ( $p<0.05$ ). Physical activity levels at 18 months were significantly higher in the MAINTAIN ( $2493 \pm 1024$  kcals) and LATE ADOPT ( $2326 \pm 648$  kcals) groups compared to the NON-MAINTAIN ( $963 \pm 359$  kcals) and NON-ADOPT ( $802 \pm 442$  kcals) groups ( $p<0.05$ ). At 18 months, the MAINTAIN group perceived there to be greater health and overall benefits of PA and reported effort as being less of a barrier to PA compared to the NON-ADOPT group ( $p<0.05$ ). Several PA behavioral processes (reminding oneself, substituting alternatives, rewarding oneself) were greater in the MAINTAIN group compared to the NON-ADOPT group at 18 months ( $p<0.05$ ). The LATE ADOPT scored higher on the subscale, caring about the consequences of others, compared to the MAINTAIN group ( $p<0.05$ ).

**CONCLUSIONS:** Individuals adopting and sustaining high levels of PA perceive greater health benefits and report fewer barriers compared to individuals with low levels of PA. Moreover, individuals sustaining higher levels of PA report the use of more behavioral strategies than individuals with lower levels of PA long-term. Thus these differences should be considered when tailoring PA interventions to meet individual needs.

**A Role Of Social Cognitive Motivational Cues In Psychosocial And Muscular Endurance Training Responses**

Michael Nordvall, Susanne Goodwin, Janet Hinson. *Marymount University, Arlington, VA.*  
(No relationships reported)

Barriers to maintaining an exercise program have been well established; however many studies have stressed self-efficacy in social cognitive models rather than outcome expectancy to prolonged exercise participation. Social cognitive motivational cues have been established as a viable method to improve attendance, self-efficacy, and outcome expectations. The extent to which motivational cues influence psychosocial outcomes as well as regular exercise participation, particularly in an adult female population, remains unclear.

**PURPOSE:** To determine whether social cognitive motivational cues improve psychosocial and muscular endurance responses during a nine-week strength training program.

**METHODS:** Healthy adult female participants (42.1±6.9 yrs) were randomly assigned to an experimental group (N=6; those receiving social cognitive motivational cues) and control group (N=6). Self-efficacy, confidence to overcome barriers to physical activity, exercise outcome expectations, attendance, and muscular endurance were assessed in all subjects at baseline, 3, 6, and 9 weeks into the study. Supervised muscular endurance training and assessments consisted of modified push-ups according to ACSM guidelines. Within and between group comparisons were made using a 2 (group) x 4 (week) ANOVA with repeated measures.

**RESULTS:** Within group comparisons revealed improvements over time for several measures; however between group comparisons revealed that those subjects receiving motivational cues had higher mean (±SD) self-efficacy scores at 9 weeks, more confidence to overcome perceived barriers to physical activity at 3, 6, and 9 weeks, higher expected physical and psychological outcomes for the exercise program at 6 and 9 weeks compared to the control group ( $p \leq 0.05$ ). No differences between groups were noted for muscular endurance or attendance.

**CONCLUSIONS:** While there were no differences in muscular endurance training response and attendance between groups, social cognitive motivational cues had a greater impact on improving self-efficacy, confidence, and expected outcomes as well as reducing perceived barriers associated with maintaining an exercise program.

**Path Analysis Of Feelings Of Energy, Exercise-related Self-efficacy, And Voluntary Exercise Participation**

Seok Yoon<sup>1</sup>, Janet Buckworth, FACSM<sup>2</sup>, Brian Focht<sup>3</sup>. <sup>1</sup>*Chowan University, Murfreesboro, NC.* <sup>2</sup>*Ohio State University, Columbus, OH.* <sup>3</sup>*University of Delaware, Newark, DE.*  
Email: yoons@chowam.edu  
(No relationships reported)

**PURPOSE:** This study utilized a path analysis approach to examine the relationship between feelings of physical and mental energy, task and scheduling self-efficacy beliefs, and exercise participation among college students. Additionally, the mediating effect of task and scheduling self-efficacy beliefs on the relationship between the feeling of energy and exercise participation was also examined.

**METHODS:** A cross-sectional mailing survey design was used to measure feelings of physical and mental energy, task and scheduling self-efficacy beliefs, and voluntary exercise participation in 1,000 healthy undergraduate students (21+2yrs). A total of 399 participants completed the self-report survey questionnaire.

**RESULTS:** The result indicated that univariate relationships between feelings of physical and mental energy, task and scheduling self-efficacy beliefs, and exercise behaviors were significant ( $p < 0.05$ ). The path analysis revealed that the hypothesized path model had a strong fit to the study data (Chi-square=3.36,  $df=4$ ,  $p=0.496$ ; GFI=0.998, AGFI=0.979; RMSEA=0.00; NFI=0.998; CFI=0.90). The path model showed that feelings of physical energy had significant direct effects on task and scheduling self-efficacy beliefs as well as exercise behaviors. In addition, scheduling self-efficacy beliefs had direct effects on moderate and vigorous exercise behaviors. However, there was no significant direct relationship between task self-efficacy beliefs and exercise behaviors. The path model also revealed that scheduling self-efficacy beliefs partially mediated the relationship between feelings of physical energy and exercise behaviors.

**CONCLUSIONS:** Participants who have more positive feeling of physical energy tend to be more efficacious in exercise involvement. Participants who have high feelings of energy also seem to engage in more exercise behaviors, and their relationship would become stronger when they are efficacious in coping barriers for effectively scheduling regular exercises. This result is an important consideration in future intervention studies.

**Psychosocial Factors Influencing Physical Activity In Older Adults**

Aubrienne E. Rote, Ann M. Swartz, Susan E. Cashin, Scott J. Strath, Nora E. Miller, Elizabeth K. Grimm, Keith P. Gennuso, Chris J. Dondzila, Karlee M. Sweere. *University of Wisconsin-Milwaukee, Milwaukee, WI.*  
Email: arote@uwm.edu  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the theoretical model relating social support (SS), self-efficacy (SE), decisional balance (DB), and stages of change (SOC) to objectively measured physical activity (PA) level.

**METHODS:** One-hundred and thirty-eight older adults (107 females and 31 males; 63.7 ± 6.4 y; 30.7 ± 5.9 kg/m<sup>2</sup>), completed this cross-sectional study. Demographic information was collected. Anthropometrics, including height and mass, were measured using a stadiometer and balance beam scale, respectively. Surveys focusing on PA relating to SOC, SE, DB, and SS both from family and friends were completed. Finally, participants wore a New Lifestyles NL-800 pedometer during all waking hours for seven consecutive days and recorded the total number of steps accumulated each day. Average steps/d were calculated. Structural equation modeling was used to test the theoretical model relating measures of SOC, SE, DB, and SS to PA level as determined by steps/d.

**RESULTS:** Participants accumulated an average of 5,429 ± 2,022 steps/d. The majority of participants were of white race (91.2%), 53.7% were married, 61.6% lived alone, 53% were currently employed, and 68.2% had an annual income of less than or equal to \$50,000. Results showed a good fit between the model and the data ( $\chi^2(8) = 13.18$ ,  $p = 0.11$ , GFI = 0.97, RMSEA = 0.07). DB ( $b = 0.3$ ,  $p = 0.016$ ) and SS ( $b = 0.4$ ,  $p < 0.001$ ) were found to be significant predictors of pedometer-determined PA level in this older adult population while SE ( $b = 0.004$ ) and SOC ( $b = 0.006$ ) were not.

**CONCLUSION:** In agreement with current literature consensus, among the sociological factors measured in this study, older adults whose perceived benefits of physical activity more significantly outweighed barriers and who had more support from family and friends were more likely to be physically active. Contrary to published literature, the confidence this group of older adults had in their ability to be physically active and their motivational readiness for change were not important predictors of PA.

**Examination Of Preference For And Tolerance Of The Intensity Of Exercise Questionnaire In Older Adults**

Walter R. Bixby, FACSM<sup>1</sup>, Eric E. Hall, FACSM<sup>1</sup>, Katherine S. Morris Hall<sup>2</sup>, Paul C. Miller<sup>1</sup>. <sup>1</sup>*Elon University, Elon, NC.* <sup>2</sup>*University of Illinois, Champagne, IL.*  
Email: wbixby@elon.edu  
(No relationships reported)

The preference for and tolerance of the intensity of exercise questionnaire (PRETIE-Q; Ekkekakis et al., 2005) has been proposed as an individual difference measure of the intensity of exercise that one can tolerate and the intensity at which one prefers to exercise. Research suggests that the PRETIE-Q is able to determine who will persist beyond ventilatory threshold and who engages in more strenuous activity on a regular basis. Thus, this measure may be useful in prescribing exercise intensity based on an individual's preference for, and ability to tolerate, exercise intensity. The majority of research on this measure has been done in college-aged subjects.

**PURPOSE:** To examine the factor structure of the PRETIE-Q in an older adult population.

**METHODS:** 74 males (age = 78.5 +/- 7.1) and 110 females (age = 77.7 +/- 6.6) completed the PRETIE-Q and returned it in a self-addressed and stamped envelope. All participants were living independently in a senior community.

**RESULTS:** An initial confirmatory factor analysis on the 2-factor structure of the PRETIE-Q revealed poor fit (Chi square = 656.7 (105), CFI = .76, RMSEA = .09 (.07 - .10), SRMR = .07). An exploratory factor analysis was then conducted to identify a more parsimonious structure; however, no theoretically viable structures were generated. Finally, an alternative 2-factor model was specified omitting items that cross-loaded on the 2 factors, resulting in a 6-item measure. This model provided a better fit to the data (Chi square = 74.5 (15), CFI = .93, RMSEA = .05 (.00 - .11), SRMR = .04).

**CONCLUSION:** While the PRETIE-Q has been shown to have a stable 2 factor structure in college-aged subjects, this structure does not appear viable in an elderly adult population. This is perhaps, not surprising. The PRETIE-Q was developed in a much younger population than that used here and thus, the items in the PRETIE-Q may have little to no relevance to elderly adults. An attempt was made to determine if a different structure would be better suited to an elderly population and while a good statistical fit was found for one of these alternative structures, there exists numerous methodological issues which make the results difficult to interpret. Considerations for future research are discussed.

(No relationships reported)

The major goal of physical education (PE) is to facilitate students to develop physically active lifestyles. An important research area is to identify motivational strategies to maximize student motivation and engagement in PE and examine its trans-contextual effect on leisure-time physical activity. One important strategy synthesized from achievement goals research is the creation of a task-involved motivational climate in PE. Under this climate, students' goal orientations can be reinforced or altered to focus on mastery learning and self-improvements, rather than social comparisons. A task-involved goal is linked to adaptive motivational and behavioral patterns regardless of PSC. However, PSC mediates the relation between an ego-involved goal and motivational and behavioral responses. It is expected that such motivational effect in PE may affect leisure time physical activity via perceived sports competence (PSC). Evidence shows that PSC is distinguished from perceived behavioral control and strongly related to intentions. Little is known of the mediating relations among achievement goals, PSC, and exercise intentions.

**PURPOSE:** To examine the mediating relation among the perceived motivational climate and goal orientations in PE, PSC, and exercise intentions.

**METHODS:** 248 middle school students completed the questionnaires assessing the perceived motivational climate, goal orientations, PSC, and exercise intentions.

**RESULTS:** The SEM analysis with manifest variables indicated that PSC completely mediated the effect of ego goal orientations on intentions to exercise, and partially mediated the effects of task goal orientations. PSC and task goal orientations accounted for 11% of the variance in exercise intentions, and task and ego goal orientations accounted for 11% of the variance in PSC. The perceived motivational climate significantly predicted goal orientations in physical education.

**CONCLUSION:** A task-involved motivational climate not only can motivate students to learn in physical education, but also may go beyond the boundary of school physical education to facilitate them to develop physically active lifestyles. An important teaching implication is that physical education teachers should create task-involved and competence-focused motivational climates.

**Exercise Motivation In Older Adults**

Bridget M. Miller, Weston S. Kensinger. Oklahoma State University, Stillwater, OK. (Sponsor: Steve Edwards, FACSM)

Email: bridget.miller@okstate.edu

(No relationships reported)

Exercise is beneficial both physiologically and psychologically, and individuals are motivated to exercise for a number of different reasons. General recommendations suggest that internal motivation will likely improve exercise adherence and prolong the behavior change.

**PURPOSE:** To determine whether the motivation for exercise differs in a physically active elderly population compared to a younger, college-aged population.

**METHODS:** Participants were either physically active, healthy college-aged females (age 20.5 years) or physically active, healthy older (age 65.5 years) adults. Each participant completed the Exercise Motivation Scale as part of a larger study on exercise and mood. The Exercise Motivation Scale is a valid measure based on Deci & Ryan's self-determination theory and is comprised of 8 motivation subscales (amotivation, external regulation, introjected regulation, identified regulation, integrated regulation, internal motivation to learn, internal motivation to accomplish, and internal motivation to experience).

**RESULTS:** Overall, there was no difference between groups for any of the subscales for motivation for exercise. In addition, the highest subscale for both groups was identified regulation, a form of external motivation.

**CONCLUSION:** While it was hypothesized that individuals who had been successful at maintaining a physically active lifestyle for much of their lives would have a more internally motivated profile, that was not the case in this sample. It is possible that there is benefit for motivation of any kind in maintaining a health promoting behavior like exercise. This sample was comprised of individuals who had been consistently active, but it would be interesting to investigate whether the motivation profile of a new exerciser was different. Thus, future studies should look at the motivational differences for those older adults who became physically active later in adulthood.

**Effect Of Palm Cooling On Muscle Fatigue During High Intensity Bench Press Exercise**

Young Sub Kwon, Robert A. Robergs, Len Kravitz, Burke Gurney, Suzanne M. Schneider. University of New Mexico, Albuquerque, NM.

Email: youngsubkwon@hotmail.com

(No relationships reported)

Local cooling, or cryotherapy, can induce an ergogenic effect during short term intense exercise. Cryotherapy can be accomplished using either limb or whole body cold water submersion, cold water baths, or localized icing. However, these alternatives are not practical when concerned with weight training. One proposed method of personal cooling involves heat extraction from the palm using a device called the Rapid Thermal Exchange (RTX).

**PURPOSE:** The present study investigated the effect of local palm cooling during rest intervals between 4 sets of 85% 1RM bench press on total repetitions and exercise volume in highly resistance trained subjects in a thermo-neutral environment.

**METHODS:** Sixteen male subjects (mean±SD, age = 26.3±5.8 yr, height = 178.4±7.1 cm, body mass = 81.5±11.3kg, 1RM = 123.5± 12.6kg, %body fat = 10.3±5.4%, weight training experience = 10.2±5.8yr) performed 4 sets of bench press exercise to failure, with 3 min rest intervals. Exercise trials were performed in counterbalanced order on three days, separated by at least 3 days; No Cooling (NC), Palm Heating (PH), and Palm Cooling (PC). Heating and cooling occurred using the RTX set to 45 °C and 10 °C, respectively. Data was analyzed using 2-way repeated measures ANOVA and the Tukey's post hoc test.

**RESULTS:**

Table 1. Results for repetitions completed by set.				
	1	2	3	4
NC	6.69±1.89	5.13±1.75	3.56±1.79	3.38±1.41
PH	6.69±1.89	6±2*	4.19±1.72	3.69±1.3
PC	6.69±1.89	7.5±2.07*	5.06±1.39*	4.38±1.31*

\* $p < 0.05$

PC, 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> set repetitions were significantly higher than NC and PH. Total exercise volume for PC (2480±636) was significantly higher than NC (1972±632) and PH (2156±668) ( $p < 0.001$ ).

**CONCLUSIONS:** Palm cooling with RTX during rest periods between high intensity bench press sets is associated with increased exercise repetitions and exercise volumes. These results suggest that palm cooling provides enhancement of progressive resistive exercise.

Marques<sup>1</sup>. <sup>1</sup>University of Beira Interior/CIDESD, Covilhã, Portugal. <sup>2</sup>CIDESD, Vila Real, Portugal. <sup>3</sup>University of Trás-os-Montes and Alto Douro/CIDESD, Vila Real, Portugal. <sup>4</sup>University Pablo de Olavide, Seville, Spain.  
Email: ricardo\_ferraz@hotmail.com

(No relationships reported)

The bench press (BP) is a widely used movement to develop strength and power in the upper-body. Although BP has been extensively used, data about kinematics factors in light free weights is limited.

**PURPOSE:** The aim of this study was to examine if any differences exist in rate of force development (RFDmax), peak force (PF) and simultaneously common parameters for both variables in each force-time curve against three different light free weights.

**METHODS:** 14 subjects were measured during a concentric only bench press test with 25, 35, and 45kg. (40, 55%, and 70% of the group mean 1RM). A linear transducer attached to the barbell was used to sample displacement-time during the attempts.

**RESULTS:** The results of this study clearly indicated significant differences (Table 1) between different loads. The \* represents significant difference between 25 kg and other loads ( $p < .05$ ), † represents significant difference between all loads ( $p < .05$ ), and ‡ represents significant difference between 45 kg and the other loads ( $p < .05$ ).

Table 1. Mean and standard deviation of the different parameters at different loads.			
Parameters	25 kg	35 kg	45 kg
RFDmax (n/s)	15197(8194)	13908(4579)	15166(4668)
Time at RFDmax (msec)	13.29(1.07)*	14.79(.89)	15.14(.95)
Force at RFDmax (N)	356(55) †	445(39)	563(36)
Power at RFDmax (W)	39(20)	39(15)	44(18)
Velocity at RFDmax (m/s)	0.15(.17)	0.08(.03)	0.14(.17)
Peak Force (N)	536(112) †	624(67)	722(88)
Time peak force (msec)	41(12)	49(24)	35(6)
Power at peak force (W)	209(101)	206(115)	141(69) ‡
Velocity at peak force (m/s)	0.37(.14)	0.36(.18)	0.18(.06) ‡

**CONCLUSIONS:** The RFDmax is not dependent on the load during concentric bench press indicating that this parameter does not influence performance with light free weights. However, kinematics at PF only changes significantly when using the highest load (45kg) indicating that increasing load will enhance the differences in bench press performance.

**1783 Board #133 May 27 3:30 PM - 5:00 PM**  
**Effect Of Single Vs Multiple Sets Of Resistance Exercise On Muscle Strength**

Martim Bottaro, João Veloso, Tiago Riera, Saulo Martorelli, André Martorelli. University of Brasilia, Brasilia, Brazil.  
Email: martim@unb.br

(No relationships reported)

Most studies reported that performing resistance training with multiple sets per training session is more effective for increasing strength as training with a single set. However, only few studies compared the effects of single vs. multiple sets on strength between small vs. large muscle groups, and upper-body vs. lower-body muscle groups.

**PURPOSE:** The purpose of this study was to determine the effect of single sets vs. multiple sets, during the early phase of adaptation, on different muscle group strength in untrained subjects.

**METHODS:** Twenty six apparently healthy, untrained male participated in the study protocol. The volunteers were randomly assigned into one of two groups: 1) elbow flexion single set and knee extension three sets (E1-K3; n=13; 22.5 yrs), or 2) elbow flexion three sets and knee extension single set (E3-K1; n=13; 23.4 yrs). Subjects trained 2 days per week for 6 weeks and each workout consisted of 1 close chain knee extension exercise and 1 elbow flexion exercise. Training intensity varied between 8 repetition maximum (RM) and 12RM. Unilateral knee extension and elbow flexion strength were tested for both groups at 60°/s on a Biodex System 3 isokinetic dynamometer. Strength was expressed as peak torque (PT). Statistical evaluation of the data was measured using a 2 x 2 analysis of variance [group (E1-K3 and E3-K1) x time (pre and post)]. The probability level of statistical significance was set at  $p < 0.05$  in all comparisons.

**RESULTS:** The increase in PT of the knee extensors muscles from week 0 to 6 was significantly higher in the E1-K3 group (10.29%) than in the E3-K1 (3.78%) group, while no difference existed in PT gains between E1-K3 (7.75%) and E3-K1 (7.44%) of the elbow flexors muscles.

**CONCLUSIONS:** It was concluded that performing three sets of strength training is superior to one set for increasing strength of the knee extensors muscles. It was also concluded that single-set training protocols for the elbow flexors muscles might be sufficient for untrained individuals in the early phases of a strength-training program.

**1784 Board #134 May 27 3:30 PM - 5:00 PM**  
**Cardiovascular Responses To Unstable Surface Training In Healthy Adults**

Audrey L. Castlen, Mark M. Misic. *Northern Illinois University, DeKalb, IL.*  
(No relationships reported)

Unstable surface training has been shown to improve neuromuscular functioning and develop muscle strength in stabilizing muscles, but its effect on cardiovascular responses is unclear. Many practitioners state that unstable surface training demands a greater amount of energy which reduces or eliminates the need for additional exercise aimed at improving body composition or cardiovascular fitness. These benefits have not been scientifically studied, so these claims are untested.

**PURPOSE:** To investigate the impact of unstable surface training on cardiovascular responses in healthy adults.

**METHODS:** Twenty-one, college-aged students with previous weight training experience completed two, 30-min resistance workouts following a group exercise format. One workout was performed on a stable surface (STA) and the other on unstable surfaces (UNST). Order was randomly determined and workouts were identical outside of training surface. Workouts included four, 1-minute sets of crunches, squats, pushups, and lunges. During STA, exercises were completed on the floor; during UNST exercises were performed on a stability ball, ½ foam roller, inverted BOSU dome, and dynadisk, respectively. Heart rate was measured every five seconds using Polar Vantage XL heart rate monitors. Comparisons of mean heart rate were made between STA and UNST during the third and fourth sets of exercise using a dependent t-test.

**RESULTS:** Overall, UNST was shown to elicit a significantly greater cardiovascular response compared to STA (UNST=147 ± 18.1; STA=140 ± 16.7 bpm,  $p=.021$ ). A significant difference in cardiovascular response between training surfaces was found for crunches and pushups (UNST=137 ± 21.3; STA=124 ± 19.1 bpm,  $p<.001$ ; UNST=156 ± 17.8; STA=149 ± 16.7 bpm,  $p=.037$  respectively). No significant difference was found for squats or lunges (UNST=139 ± 18.9; STA=135 ± 18.4 bpm,  $p=.205$ ; UNST=157 ± 15.4; STA=154 ± 14.9 bpm,  $p=.175$  respectively).

**CONCLUSIONS:** UNST results in a greater cardiovascular response during a total body bout of exercise. Lower body exercises performed on unstable surfaces do not elicit a greater cardiovascular response individually. This may be due to the increased distance of an individual's center of gravity to the unstable surface during lower body exercises, causing greater instability.

---

**1785 Board #135 May 27 3:30 PM - 5:00 PM**  
**Influence Of The Ipsilateral Eccentric Contraction Training On Force Fluctuation In The Untrained Contralateral Limb**

Azusa Uematsu, Hirofumi Kobayashi, Tetsuya Ogawa, Koh Inoue, Shuji Suzuki. *Waseda University, Tokorozawa, Saitama, Japan.*  
Email: azusa-gold@toki.waseda.jp  
(No relationships reported)

Unilateral muscle training has effects on the untrained contralateral homologous muscle ("cross-education"). Greater "cross-education" has been evaluated by the change of maximal strength in untrained limb following eccentric contraction training than concentric contraction training. Possible causes of "cross-education" are neural adaptations. If so, it is expectable that not only the increase of maximal strength but also the improvement of submaximal muscle performance enhance, but the latter has not been evaluated following eccentric contraction training than concentric contraction training.

**PURPOSE:** To examine the effect of eccentric contraction training (ECCT) and concentric contraction training (CONT) on the force fluctuations (FF) during submaximal isometric contraction in elbow flexors.

**METHODS:** Ten participants were randomly assigned to ECCT (n = 5) and CONT (n = 5) group. Forces were recorded by using the load cell (LUR-A-2kNSA1, KYOWA) during maximal voluntary isometric contraction (MVC) and submaximal isometric contractions at 10, 30, 50 and 80 %MVC force level of before and after training in right and left elbow flexors. ECCT and CONT were performed to extend/flex the right cubital joint from maximal flexion/extension to extension/flexion using the dumbbell where the weight corresponding about 45-60 %MVC force of pre-training. Trainings were consisted of 6 sets of 10 repetitions in a day, 3 times per wk for 3wk. FF was calculated as follows; SD/mean force × 100. Comparisons of FF between pre- and post-training at each contraction level in both arms were made using paired-t test. Statistical significance level was set at  $p < 0.05$ .

**RESULTS:** MVC force of left arm was increased in CONT group, but not significantly. Left arm MVC force was significantly increased in ECCT group (109.2 ± 4.8% pre-training,  $p < 0.05$ ). FF of left arm at 50 %MVC force level in ECCT group was significantly decreased (pre-training; 1.9 ± 0.2%, post-training; 1.5 ± 0.1%,  $p < 0.05$ ). FF at the other force levels in left arm and all force levels in right arm did not change significantly.

**CONCLUSION:** ECCT induced significant increase of MVC force and decrease of FF during submaximal isometric contraction in left arm. Decrease of FF in the untrained arm may occur selectively depending on the load used in the trained arm.

---

**1786 Board #136 May 27 3:30 PM - 5:00 PM**  
**Effect Of Rest-interval On Muscle Fatigue In Young Men And Women.**

Rodrigo Celes<sup>1</sup>, Martim Bottaro<sup>1</sup>, João Veloso<sup>1</sup>, Diego Gonçalves<sup>1</sup>, Lee E. Brown<sup>2</sup>. <sup>1</sup>University of Brasília, Brasília, Brazil. <sup>2</sup>California State University, Fullerton, CA.  
Email: rodrigoces@terra.com.br  
(No relationships reported)

The Rest-Interval (RI) between sets is an important variable to be considered when prescribing effective resistance training. The adequate RI should prevent excessive muscle fatigue and allow complete muscle recovery between sets. Despite this positive effect on muscle fatigue and recovery, RI has not been well documented in young women. Also, studies reported that healthy young males have been shown to exhibit a faster rate of knee extensor torque fatigue than females, which is highly correlated to their peak voluntary work.

**PURPOSE:** To compare the effect of two different RI's between sets of isokinetic knee extension exercise on Peak Torque (PT), and Total Work (TW) between young men and women.

**METHODS:** 18 men (24.22 ± 2.58 yrs) and 11 women (27.0 ± 4.16 yrs) performed 3 sets of 10 unilateral isokinetic knee extension repetitions at 60°/s. The rest intervals between sets were 1 and 2 minutes and were counterbalanced across 2 testing days, separated by a minimum of 72 hours. The work-to-rest ratio was 1:3 and 1:6. Subjects were not involved in exercise programs that included resistance exercise within the last 6 months.

**RESULTS:** The results were as follows:

		men (n = 18)			women (n = 11)		
	SET	1st	2nd	3rd	1st	2nd	3rd
PT (N.m)	1min	263.32	230.98 *	200.38 * <sup>‡</sup>	162.13	149.55 *	136.74* <sup>‡</sup>
	2min	260.44	241.59 * <sup>†</sup>	222.72 * <sup>‡†</sup>	165.41	154.21* <sup>†</sup>	144.85* <sup>‡†</sup>
TW (J)	1min	2,698.24	2,273.91 *	1,865.97 * <sup>‡</sup>	1,492.92	1,327.81*	1,205.83* <sup>‡</sup>
	2min	2,610.51	2,384.96 * <sup>†</sup>	2,124.75 * <sup>‡†</sup>	1,532.45	1,425.93* <sup>†</sup>	1,306.64* <sup>‡†</sup>
* p < 0.05 less than 1st set.							
<sup>‡</sup> p < 0.05 less than 2nd set.							
† p < 0.05 greater than 1min.							

**CONCLUSION:** These results suggest that during maximal-effort muscle isokinetic contractions at 60°/s, males and females exhibit a similar susceptibility to muscle fatigue during isokinetic knee extension exercise. Also, it appears that a 1:6 work-to-rest ratio is not sufficient to promote full muscle strength recovery, for this specific fatiguing protocol, in non-resistance trained young men and women.

**1787 Board #137 May 27 3:30 PM - 5:00 PM**

**The Impact Of An Integrated Functional Resistance Training Program On Chronic Low-back Pain Patients**

Juan M. Cortell-Tormo<sup>1</sup>, José A. Pérez-Turpin<sup>1</sup>, Pablo Tercedor-Sánchez<sup>2</sup>, Alfonso Jiménez<sup>3</sup>, Roberto Cejuela-Anta<sup>1</sup>. <sup>1</sup>University of Alicante, Alicante, Spain. <sup>2</sup>University of Granada, Granada, Spain. <sup>3</sup>European University of Madrid, Madrid, Spain.  
Email: jm.cortell@ua.es

(No relationships reported)

Therapies involving physical exercise have a prominent role from different approaches for the treatment of low back pain. Furthermore, at the moment, new trends are being incorporated into the prescription of physical activity and exercise to improve health and quality of life in chronic low-back patients, but there are a lot of unknown effects.

**PURPOSE:** To evaluate the effects of functional resistance training, integrated in a general physical activity program, in functional disabilities and intensity of pain on a group of women with chronic low-back pain.

**METHODS:** Patients with chronic low back pain for more than 8 weeks but less than 6 months were included in the sample. A total of 19 (35,63±8,44 years old) women were randomized to either exercise group (n = 11) or control group (n = 8). 36 exercise sessions were developed in 3 months of intervention (1<sup>st</sup> month: postural and motor control; 2<sup>nd</sup> month: analytic resistance training exercises; 3<sup>rd</sup> month: analytic and functional resistance training exercises). Pain intensity (Visual Analogue Scale 0-10), and functional disability (Oswestry Disability Index) were recorded before and immediately after the treatment period.

**RESULTS:** The exercise group showed significantly higher improvements than control group in all outcome variables throughout the entire intervention period. Immediately after 3-months of exercise treatment 61,1% and 61,25% of the exercise group and 3,4% and 2,6% in the control group had reduced their functional disability and intensity of pain respectively (p<0,001). Clinically important differences between-group on function and pain were identified.

**CONCLUSIONS:** Functional progressive resistance training program, personalized and integrated after a stage of motor learning and analytic resistance training exercises has produced significant reductions in functional disability and pain intensity in women with chronic low-back pain.

**1788 Board #138 May 27 3:30 PM - 5:00 PM**

**Physical Activity Levels After Functional Resistance Training Program In Subjects With Low-back Pain**

José A. Pérez-Turpin<sup>1</sup>, Juan M. Cortell-Tormo<sup>1</sup>, Pablo Tercedor-Sánchez<sup>2</sup>, Alfonso Jiménez<sup>3</sup>, Juan J. Chinchilla-Mira<sup>1</sup>. <sup>1</sup>University of Alicante, Alicante, Spain. <sup>2</sup>University of Granada, Granada, Spain. <sup>3</sup>European University of Madrid, Madrid, Spain.  
Email: jose.perez@ua.es

(No relationships reported)

People with chronic low-back pain usually have functional disability due to pain. This conditions and facts could negatively affect the levels of physical activity and energy expenditure from daily life.

**PURPOSE:** To identify changes in levels of physical activity and energy expenditure in daily life produced by a physical activity therapy which integrates functional resistance training.

**METHODS:** Patients with chronic low back pain for more than 8 weeks but less than 6 months were included in the sample. A total of 19 (35,63±8,44 years old) women were randomized to either exercise group (n = 11) or control group (n = 8). 36 exercise sessions were developed in 3 months of intervention. Pain intensity (visual analogue scale 0-10), level of physical activity and energy expenditure (International Physical Activity Questionnaire (IPAQ)) were recorded before and immediately after the treatment period.

**RESULTS:** The control group showed no significant changes after the exercise intervention. In the experimental group the pain intensity had been reduced significantly (p<0,001), increased (p<0,05) 1,36 d·wk<sup>-1</sup> the frequency, 149,1 min·wk<sup>-1</sup> the duration and 2218,18 METs·min·wk<sup>-1</sup> energy expenditure from vigorous physical activities (8 METs). In moderate activities (4 METs) increased (p<0,05) the duration in 59,09 min·wk<sup>-1</sup> and weekly reduced the time that remained seated 166,36 min (p<0,05). The total weekly energy expenditure increased 2218,85 METs·min·wk<sup>-1</sup> (p<0,05).

**CONCLUSIONS:** Physical activity therapy, including functional resistance training, has produced significant increases in the frequency, duration and energy expenditure from daily life activities and has reduced the daily time that these patients remained seated.

**Improved Muscle Activation In Performing A Functional Lunge Versus A Traditional Squat**

Priscilla M. Dwelly<sup>1</sup>, Gretchen D. Oliver<sup>1</sup>, Heather R. Adams-Blair<sup>2</sup>. <sup>1</sup>University of Arkansas, Fayetteville, AR. <sup>2</sup>Eastern Kentucky University, Richmond, KY. (Sponsor: Charles Riggs, FACSM)  
Email: goliver@uark.edu

(No relationships reported)

The back squat is a common exercise for performance strength training and rehabilitation. Contrary to common clinical practice, variation in stance width during the squat has not shown to affect the isolation of quadriceps musculature. In addition to the stance width, squat depth has also been a focus of debate in muscle activation. Today, many practitioners are focusing on more functional activities and it is often questioned if the squat, especially to greater depths is truly a functional exercise.

**PURPOSE:** The purpose was to examine the muscle activation at three different squat depths and the body weight walking lunge.

**METHODS:** Eight healthy, female intercollegiate athletes (mean age 20.8 ± 3.9 y; mean height, 177.8 ± 10.9 cm; mean mass, 67.3 ± 9.9 kg) participated. Electromyographic (EMG) data were collected on the following muscles: medial hamstring (semimembranosus and semitendinosus), biceps femoris, gluteus medius, and gluteus maximus while participants performed the three different squat depths and a body weight walking lunge.

**RESULTS:** Kruskal-Wallis test revealed a significant main effect for exercise type on the rectus femoris ( $\chi^2=15.706$ ,  $p=0.001$ ); vastus medialis oblique ( $\chi^2=8.767$ ,  $p=0.03$ ); vastus lateralis ( $\chi^2=15.169$ ,  $p=0.002$ ); medial hamstrings ( $\chi^2=8.775$ ,  $p=0.03$ ); biceps femoris ( $\chi^2=14.258$ ,  $p=0.003$ ); and gluteus medius ( $\chi^2=10.387$ ,  $p=0.02$ ). Exercise type did not have a main effect on gluteus maximus muscle activity ( $p=0.05$ ). The results demonstrated that the total muscle activation of the squat depths were not greater than that of the walking lunge. It was revealed that the walking lunge did indeed produce more activation in the majority of all muscles analyzed, except rectus femoris, when compared to the three squat depths.

**CONCLUSIONS:** By training athletes in the walking lunge they can obtain the same results of that of squat to 90 training. Furthermore, the lunge allows athlete to be in a more functional position. From the basic lunge position of the knees flexed to 90 degrees we can begin to train explosive recovery moves which would transfer over to competition. Ideally, athletes should be training their kinetic chain fluidly and dynamically, the more dynamic the activity the more fluid the athlete's movement and posture will be in competition.

**Short-term Adaptations In Strength, Power And Body Mass Following Three Different Modes Of Resistance Training**

Christopher MacDonald, Hugh Lamont, John Garner. *University of Mississippi, University, MS.* (Sponsor: Mark Loftin, FACSM)

Email: cjmacdon@olemiss.edu

(No relationships reported)

Recently there has been an increase in focus looking at integrating differing modes of training such as resistance and plyometric training into periodized strength and conditioning programs. More specifically, optimal training techniques designed to maximize dynamic power and rates of force production (RFD) are receiving considerable interest because of the desire to produce high performance training environments. One area receiving increased attention is complex training which alternates between heavy and lighter load resistance exercises with similar movement patterns in a single exercise session. Such "complex pairings" may bring about a state of Post Activation Potentiation (PAP) resulting in increased dynamic power and RFD during the lighter load exercise. This may be a more effective strategy for developing sport specific power than resistance or plyometric training alone.

**PURPOSE:** The purpose of this research was to determine if complex training is more effective than resistance training or plyometric training at improving measures of power and strength in the lower limbs of college aged males after 3 weeks of training.

**METHODS:** Thirty four recreationally trained males trained in 1 of 3 methods; resistance (RT) ( $n = 13$ ; height: 180.14 ± 4.75 cm; body mass: 83.85 ± 20.54 kg), plyometric (PT) ( $n = 11$ ; 181.41 ± 7.97 cm; 81.25 ± 10.43 kg), or complex (CT) ( $n = 10$ ; 185.17 ± 5.56 cm; 87.54 ± 9.04 kg) twice a week for 3 weeks. Participants were tested pre and post training to assess body mass (kg), vertical jump height (cm), squat strength (kg), power (watts) and power per kg of body mass.

**RESULTS:** Repeated measures ANOVA (Group (3) x Time (2)) revealed no significant changes for body mass, vertical jump, power, or power/body mass ( $p > .05$ ). A significant increase was found for squat strength for all groups ( $F_{2, 31} = 53.22$ ,  $p < 0.00$ ) from pre to post with no significant differences between groups.

**CONCLUSIONS:** The incorporation of different modes of resistance training, over a 3 week microcycle, resulted in increases in squat strength for all 3 groups. This can be attributed to a learning effect of the training and/or testing exercise or to the neural adaptations that would be expected after this training cycle. The reported research is a mid point of a 6 week training study.

**Hormonal Responses Of Untrained Males And Females After An Acute Bout Of Resistance Training**

Jason Sawyer, Mary Pieklo, Sean Collins, Tracey Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*

Email: jason\_sawyer32@yahoo.com

(No relationships reported)

Males and females have an increase in muscular strength and hypertrophy following a resistance training program. The increase in strength and hypertrophy are heavily dependent upon the hormonal response that occurs acutely after exercise. The difference between untrained males and females in response to an acute bout of resistance training has not been established.

**PURPOSE:** To examine the effects of an acute resistance training protocol on the hormonal profile of untrained males and females.

**METHODS:** The males ( $n = 3$ ) and females ( $n = 3$ ) voluntarily participated in the study. Each subject performed a predicted 1 RM approximately 1 week before the second testing session. During the second testing session, each subject completed four sets of bench presses and leg presses at 60-70% of his or her predicted 1 RM. Testosterone, IGF-I, hGH, and cortisol were measured pre-exercise, immediately post-exercise, and 30 min post-exercise.

**RESULTS:** There was a significant interaction ( $p < .05$ ) for testosterone and IGF-I. Testosterone levels for males were higher compared to females. IGF-I levels were elevated immediately post-exercise compared to baseline values for males. No significant differences occurred for hGH or cortisol between males and females.

**CONCLUSIONS:** The hormonal responses that occur due to an acute bout of resistance training are gender specific. The elevations in testosterone and IGF-I for males may have occurred due to mechanical stress placed on the exercising muscles. The untrained status of the subjects may account for the lack of change of hGH and cortisol for males and females

**Reliability Of Maximal Strength Testing In Novice Weightlifters**

James A. Loehr<sup>1</sup>, Stuart M.C. Lee<sup>1</sup>, Alan H. Feiveson<sup>2</sup>, Lori L. Ploutz-Snyder, FACSM<sup>3</sup>. <sup>1</sup>Wyle, *Integrated Science and Engineering Group, Houston, TX.* <sup>2</sup>Johnson Space Center, *National Aeronautics and Space Administration, Houston, TX.* <sup>3</sup>Universities Space Research Association, *Houston, TX.*

Email: james.a.loehr@nasa.gov

(No relationships reported)

The one repetition maximum (1RM) is a criterion measure of muscle strength. However, the reliability of 1RM testing in novice subjects has received little attention. Understanding this information is crucial to accurately interpret changes in muscle strength.

**PURPOSE:** To evaluate the test-retest reliability of a squat (SQ), heel raise (HR), and deadlift (DL) 1RM in novice subjects.

**METHODS:** Twenty healthy males (31.5 ± 5 y, 179.1 ± 6.1 cm, 81.4 ± 10.6 kg) with no weight training experience in the previous six months participated in four 1RM testing sessions, with each session separated by 5-7 days. SQ and HR 1RM were conducted using a smith machine; DL 1RM was assessed using free weights. Session 1 was considered a familiarization and was not included in the statistical analyses. Repeated measures analysis of variance with Tukey's *post-hoc* tests were used to detect between-session differences in 1RM ( $p \leq 0.05$ ). Test-retest reliability was evaluated by intraclass correlation coefficients (ICC).

**RESULTS:** During Session 2, the SQ and DL 1RM (SQ: 90.2 ± 4.3, DL: 75.9 ± 3.3 kg) were less than Session 3 (SQ: 95.3 ± 4.1, DL: 81.5 ± 3.5 kg) and Session 4 (SQ: 96.6 ± 4.0, DL: 82.4 ± 3.9 kg), but there were no differences between Session 3 and Session 4. HR 1RM measured during Session 2 (150.1 ± 3.7 kg) and Session 3 (152.5 ± 3.9 kg) were not

different from one another, but both were less than Session 4 (157.5±3.8 kg). The reliability (ICC) of 1RM measures for Sessions 2-4 were 0.88, 0.83, and 0.87, for SQ, HR, and DL, respectively. When considering only Sessions 3 and 4, the reliability was 0.93, 0.91, and 0.86 for SQ, HR, and DL, respectively.

**CONCLUSIONS:** One familiarization session and 2 test sessions (for SQ and DL) were required to obtain excellent reliability ( $ICC \geq 0.90$ ) in 1RM values with novice subjects. We were unable to attain this level of reliability following 3 HR testing sessions; additional sessions are required to obtain an ICC of  $\geq 0.90$ . Resistive exercise training studies should consider the reliability of specific measures to ensure that reported strength changes are attributable to training and not to learning effects associated with 1RM testing.

**1793 Board #143 May 27 3:30 PM - 5:00 PM**  
**Development Of Muscular Strength Using Open And Closed Kinetic Chain Exercises**

Mark A. Sloniger, FACSM, Matthew P. Standridge. *Indiana University of Pennsylvania, Indiana, PA.*

(No relationships reported)

**PURPOSE:** To compare the effects of open versus closed kinetic chain training on the development of muscular (quadriceps) strength in adults, and to determine if muscular strength development associated with open kinetic chain training translates to improved performance of closed kinetic chain movements, and vice versa.

**METHODS:** A total of 25 sedentary and apparently healthy male and female subjects ranging from 25-55 years of age were divided into open (7 males, 6 females) or closed (7 males, 5 females) kinetic chain training groups. All subjects participated in either an open or closed kinetic chain strength training program for 12 weeks, and completed pre and post-training one repetition maximum (1RM) leg press and leg extension strength tests.

**RESULTS:** Mean Percent Change (MPC) in muscular strength following the training period was not significantly different ( $p > .05$ ) between open ( $32.0 \pm 14.2\%$ ) and closed ( $30.1 \pm 11.3\%$ ) kinetic chain training when assessed using an open kinetic chain strength test (1 RM leg extension). Absolute strength improvement ( $15.2 \pm 6.7$  kg) assessed by closed kinetic chain strength testing (1RM leg press) increased significantly ( $p < .05$ ) following open kinetic chain training. MPC in muscular strength was significantly greater ( $p < .05$ ) following closed ( $28.5 \pm 11.2\%$ ) compared to open ( $14.7 \pm 9.3\%$ ) kinetic chain training when assessed using a closed kinetic chain strength test (1RM leg press).

**CONCLUSION:** These data suggest that strength gains resulting from open and closed kinetic chain training enhance performance of an open kinetic chain movement to the same extent. Open kinetic chain training, however, did not enhance performance of a closed kinetic chain movement to the same extent as the closed kinetic chain training. The discrepancy between the two types of training with regard to performance of a closed kinetic chain movement may have resulted from development of muscle groups engaged during closed but not open kinetic chain training.

**The Current State Of Resistance Training Among Endurance Athletes**

John W. Wygand, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.*

Email: wygand@adelphi.edu

(No relationships reported)

Although numerous publications tout the value of resistance training for all populations, including endurance athletes, there is a paucity of information concerning the actual resistance training habits (RTH) of endurance athletes. For the purpose of this study, an endurance athlete is defined as one who performs a minimum of 30 minutes, three days each week of continuous high level aerobic activity.

**PURPOSE:** To ascertain the current resistance training habits of endurance athletes.

**METHODS:** A 37 question internet survey was cross validated and distributed in the Spring of 2008 by email to over 50,000 targeted email addresses (obtained from running and triathlon associations).

**RESULTS:** 1314 internet responses (2.6%) were obtained, which represented 85.8% runners and 9.5% triathletes, with the majority (57%) of responses from males. RTH differed slightly from in-season (I) to out-of-season (O). 63% report RTH  $> 1$  hr/wk during O, while  $< 55\%$  during I. Intensity was similar for O and I, with 64% terminating at a predetermined number of repetitions, thus intensity can not be quantified, but 15% achieve MMF.  $\sim 50\%$  perform  $\leq 2$  exercises, 3 sets,  $\leq 6$  min and 8-12 reps per muscle group for all muscle groups, except the abdominal muscles, in which 42% perform  $> 3$  exercises, 21% perform  $> 4$  sets, 32% spend  $> 10$  min and 38% perform  $> 20$  reps.

**CONCLUSION:** 88% of endurance athletes recognize the benefit of RT as either moderately or very important, and most perform some type of resistance training, with less than 9 % abstaining completely during either I or O.

**Effects Of Variable Velocity Eccentric Muscle Actions On Caloric Expenditure And Delayed Onset Muscle Soreness**

Benjamin L. Brock, Kathleen M. Knutzen, FACSM, L.R. Brilla, FACSM, Brandi S. Row. *Western Washington University, Bellingham, WA.*

Email: brockb83@gmail.com

(No relationships reported)

Eccentric training protocols require a decrease in metabolic demand and elicit greater muscle strain resulting in delayed onset muscle soreness (DOMS) when compared with concentric training program, using a similar load. However, it is not understood how altering the velocity of an eccentric training protocol will affect metabolic demand and muscle strain.

**PURPOSE:** To determine if velocity during eccentric exercise alters the amount of metabolic demand during exercise and muscle soreness after exercise.

**METHODS:** Thirty college-aged subjects who were enrolled in a beginning weight training class, were recruited for the study, with 15 subjects randomly assigned to either the high (40 cycles per minute) or low (18 cycles per minute) velocity groups. The testing session consisted of a five minute unilateral eccentric hip and knee extensor exercise at a constant workload of 65% of peak eccentric torque. To assess the effects of metabolic demand, energy expenditure and RER were taken for one minute after steady state was attained. To assess the effects of muscle soreness, the subjects completed an electronic muscle soreness questionnaire 12, 24, 36, 48, 60 and 72 hours post exercise. The statistical significance was determined by a t-test for caloric expenditure and RER values, while a repeated measure ANOVA was used to evaluate the effect of velocity on muscle soreness. The alpha level was set at 0.05.

**RESULTS:** Caloric expenditure and RER were statistically higher in the fast group when compare to the slow group. The fast and slow group had a mean caloric expenditure of  $10.79 \pm 2.00$  Kcal/min and  $6.40 \pm 1.75$  Kcal/min, respectively. The fast and slow group had a mean respiratory exchange ratio of  $1.08 \pm 0.19$  and  $0.91 \pm 0.12$ , respectively. No statistical difference in the degree and timeline of muscle soreness was seen between groups.

**CONCLUSION:** Altering the velocity of an eccentric muscle action increases the metabolic demand without increasing muscle soreness in college-aged subjects involved in a beginning weight training class. While the mechanism for eccentric muscle actions is still unclear, an increase in metabolic demand does not affect the amount of muscle strain associated with this type of muscle action.

**Effects Of Warm-up On Peak Torque, Rate Of Torque Development, And Electromyographic And Mechanomyographic Signals**

Kristianna M. Altamirano, Jared W. Coburn, Lee E. Brown, FACSM, Dan A. Judelson. *Cal State Fullerton, Fullerton, CA.*

Email: kristiannao@gmail.com

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if an active warm-up affects peak torque (PT), rate of torque development (RTD), and the electromyographic (EMG) and mechanomyographic (MMG) signals.

**METHODS:** Twenty-one men (mean age  $\pm$  SD = 23.9  $\pm$  2.6 y) visited the exercise physiology lab on two occasions. During the first visit they either performed an active warm-up (10 minutes of stationary cycling at 70% of predicted max heart rate) or sat quietly (no warm-up). Participants were then tested for isometric and isokinetic PT (60, 180, and 300 deg/s), and RTD (measured as S-gradient) on an isokinetic dynamometer. EMG and MMG sensors were placed over the vastus lateralis muscle of the right limb to monitor the electrical and mechanical aspects of muscle contractions, respectively. The testing protocol used for the first visit was repeated for the second visit, but the pre-exercise treatment (warm-up, no warm-up) not given during the first visit was administered.

**RESULTS:** The results indicated that an active warm-up did not affect PT, RTD, EMG amplitude, EMG frequency, or MMG frequency ( $p > 0.05$ ). However, MMG amplitude at 180 deg/s was significantly greater ( $p < 0.05$ ) in the warm-up condition compared to the no warm-up condition.

**CONCLUSIONS:** The results indicated that warm-up did not affect PT, RTD, EMG amplitude, EMG frequency, or MMG frequency. The increase in MMG amplitude, however, suggests that warm-up may have affected the mechanical properties of muscle by reducing muscular stiffness and/or decreasing intramuscular fluid pressure.

**1797 Board #147 May 27 3:30 PM - 5:00 PM**  
**The Effects Of Exercise Order On Power Output And Mechanical Work During Power Cleans**

Gavin L. Moir, Dan Ochnich, Chad A. Witmer, Shala E. Davis, FACSM. *East Stroudsburg University of Pennsylvania, East Stroudsburg, PA.*

Email: gmoir@po-box.esu.edu

(No relationships reported)

**PURPOSE:** This study aimed to investigate the effects of exercise order on mechanical work and power output during a series of power cleans (PC).

**METHODS:** Nine subjects performed five repetitions of PC with a load equivalent to 80% one repetition maximum for four sets during two separate sessions: 1) PC performed at the end of a series of resistance exercises designed to develop power, 2) only PC performed. The order of the two sessions was counterbalanced and both were separated by one week. The vertical position of the center of the bar was recorded during each PC repetition by a motion analysis system. Net power output during each repetition was then calculated using the work-energy relationship. The greatest value achieved during each set was recorded as peak power output (PP). Mechanical work (W) performed on the bar during each set of PC was calculated by integrating net power output. W was also totaled across the sets of each session to provide total work (TW). Fatigue values were calculated for PP (PP<sub>FATIGUE</sub>) during each set and TW (TW<sub>FATIGUE</sub>) during each session. Differences in PP, W and PP<sub>FATIGUE</sub> were analyzed using an ANOVA model with repeated measures on two factors (session [2 levels]; set [4 levels]), with t-tests used to analyze differences in TW and TW<sub>FATIGUE</sub>.

**RESULTS:** There were no significant main effects or interactions reported for PP, PP<sub>FATIGUE</sub>, or W ( $p > 0.05$ ). Similarly, there were no significant differences in TW or TW<sub>FATIGUE</sub> between the testing sessions ( $p > 0.05$ ). Despite the lack of significant group findings there were some notable individual responses, particularly for the fatigue scores.

**CONCLUSIONS:** When group responses are assessed the order in which resistance training exercises are performed does not affect work done or power output during PC. However, some individuals appear to produce more consistent PP values between sets when PC are performed after other resistance exercises, although the magnitude of PP may be reduced.

---

**1798 Board #148 May 27 3:30 PM - 5:00 PM**  
**Acute Effects Of Manipulating Volume And Load Of Back Squats On Countermovement Vertical Jump Performance**

Chad A. Witmer, David Mergy, Gavin Moir, Shala Davis, FACSM. *East Stroudsburg University, East Stroudsburg, PA.*

(No relationships reported)

**PURPOSE:** The acute effects of manipulating the volume and load of back squats on subsequent countermovement vertical jump performance were investigated in the present study.

**METHODS:** Eleven NCAA Division II female volleyball players performed 10 countermovement jumps (CMJ) on a force platform two minutes after the last squat repetition of a high load (HL) or high volume (HV) squat protocol for a total of 20 minutes. Two minutes of rest was provided between each CMJ. The HL protocol culminated in the subjects having to perform three repetitions with a load equivalent to 90% one-repetition maximum (1-RM) back squat, while 12 repetitions with a load equivalent to 37% 1-RM were performed in the HV protocol. Jump height (JH) and vertical stiffness (VStiff) were calculated during each CMJ and the changes in these variables following the two squat protocols was assessed using an ANOVA model with repeated measures on two factors (Protocol [2-levels]; Time [2-levels]).

**RESULTS:** There was no significant difference in JH following the HL and HV protocols ( $p > 0.050$ ). A significant Protocol x Time interaction for VStiff resulted from the increase following the HL protocol being greater than that following the HL protocol ( $p = 0.034$ ).

**CONCLUSION:** Neither squat protocol provided any benefit in improving JH. However, the heavy squat protocol produced greater increases in VStiff during the CMJ. Because of the increased VStiff caused by the HL protocol, volleyball coaches may consider using such protocols with their players to improve performance in jumps performed from a run such as the spike.

**1799 Board #149 May 27 3:30 PM - 5:00 PM**  
**Prediction Of The Total Energy Cost Of An Acute Bout Of Resistance Exercise In Young Men And Women**

Brad S. Lambert, Steven E. Martin, John S. Green, FACSM, Aaron F. Carbuhn, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.*

Email: bradlambert@hlkn.tamu.edu

(No relationships reported)

ACSM currently recommends resistance training (RT) for each major muscle group at least 2 times per week with a traditional repetition range of 8-12 per set. Because many investigators/fitness professionals consider kcal expenditure when creating training protocols, energy costs during both RT and aerobic training must be considered.

**PURPOSE:** To develop a regression equation to predict kcal expenditure for a RT bout involving each major muscle group using VO<sub>2max</sub>, height, weight, lean body mass, fat mass, and total exercise volume (TV=sets\*reps\*wt) as independent variables.

**METHODS:** Twelve subjects (7 men, 5 women, age 21-25 yrs) were tested using the standard Bruce treadmill protocol for VO<sub>2max</sub>, and strength tested to determine their 3-5 repetition max (RM) on Kaiser® RT equipment 1 week prior to their experimental RT bout. Body composition was assessed using DEXA. For their experimental RT bout, a warm-up set followed by 2-3 sets of 8-12 reps at 60-70% predicted 1RM were performed for each exercise. Each set was started every two minutes. Exercises progressed in the following order: leg press, chest press, leg curl, lat pull, leg ext., triceps ext., biceps curl. Oxygen consumption was measured continuously throughout the RT bout using an automated metabolic cart. Multiple Linear Regression was used to determine the best model for prediction of kcal consumption.

**RESULTS:** Mean kcal expenditure for the entire RT bout was 221.8 $\pm$ 20.65 kcal (men = 272 $\pm$ 36 & women = 150 $\pm$ 16) with a mean kcal cost of 26.32-38.94 per exercise. Large muscle group/multi-joint exercises had the highest total kcal expenditures as expected. Collinearity diagnostics from the regression revealed that VO<sub>2max</sub> (L/min) and the square root of TV (TV<sup>0.5</sup>) were the only predictors needed in the model with all other variables being highly intercorrelated with VO<sub>2max</sub> (L/min), thus not adding significant improvement to the model. The prediction equation was ( $p < 0.05$ , R<sup>2</sup>=0.86):

Total kcal = (37.264\*VO<sub>2max</sub> L/min) + (1.087\*TV<sup>0.5</sup>) - 132.488

**CONCLUSIONS:**  $\text{VO}_{2\text{max}}$  (L/min) and  $\text{TV}^{0.5}$  were found to be significant predictors of the energy cost of a RT bout involving each major muscle group. In regards to fitness, performance, and weight management, this equation may aid practitioners and young exercising adults in documenting kcal expenditure from resistance training.

**1800 Board #150 May 27 3:30 PM - 5:00 PM**  
**Effectiveness Of A 4-week Core Strengthening Program In Lactate And Running Speed**

Suleima Rivera-Vélez<sup>1</sup>, Nimar Pérez-Guerrero<sup>1</sup>, Carmen Capo-Lugo<sup>1</sup>, Cynthia Cruz<sup>1</sup>, Lucia Martinez<sup>2</sup>, Farah Ramirez, FACSM<sup>2</sup>, Heidi Venegas<sup>1</sup>, Alexis Ortiz<sup>1</sup>. <sup>1</sup>University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico. <sup>2</sup>University of Puerto Rico Rio Piedras Campus, San Juan, Puerto Rico.

Email: suleima.rivera@upr.edu

(No relationships reported)

Core strengthening is advocated as beneficial for the stabilization and control of the trunk. Greater core stability may influence sports performance producing more efficient movements that affect running speed and blood lactate concentration.

**PURPOSE:** To evaluate the effectiveness of a 4-week core strengthening program on running speed and blood lactate in young healthy adults.

**METHODS:** Ten young healthy adults from both sexes (age:  $25.4 \pm 2.27$  yrs, height:  $66.85 \pm 11.79$  cm, BMI:  $24 \pm 2.63$ ) were randomly assigned to a control or core strengthening intervention group. Both groups performed the testing protocol at baseline and after 4-weeks. A warm-up session (5 min walking at 4 mph) was performed followed by 4 sets of running at 5, 6, 7 and 8 mph, 4 min per set in order to determine running speed and lactate concentration. Blood lactate was obtained at the end of each set. A lactate level of  $\geq 4$  mmol/L was the criteria used to establish the speed at which the subjects reached their anaerobic threshold. The core strengthening program consisted of a warm-up, seven strengthening exercises and a cool-down. The exercise program consisted of one set of 15 repetitions for each exercise three times a week (1 set/15 reps/3 times/week). The control group was encouraged to continue with their daily routine and not to engage in additional exercises. Independent samples T-test were used to compare variables at baseline. Univariate Analysis of Variance (ANOVA) was used to compare post running speed at which the cut-off lactate level was reached and post lactate levels at the faster speed reached by the subject at baseline.

**RESULTS:** There were no differences between groups at baseline. Although the intervention group improved after the intervention (speed: 6.0 to 6.4; lactate: 5.6 to 4.0) the ANOVA showed no statistically significant differences for running speed ( $p=0.789$ ) and lactate levels ( $p=0.419$ ).

**CONCLUSIONS:** Four weeks of core strengthening seems not to be enough to improve running speed at which anaerobic threshold is reached and reduce lactate levels when running at a constant speed. Nevertheless, a larger sample size and a longer intervention time is needed for core strengthening to have an effect on running speed and anaerobic threshold. NIH Grants G12RR03051 and 1P20 RR11126, and NSCA Foundation supported this project.

**1801 Board #151 May 27 3:30 PM - 5:00 PM**  
**Sex Differences In Hamstring Relative Torque**

Brandon P. Uribe, Andy V. Khamoui, Tai Tran, Diamond Nguyen, Lee E. Brown, FACSM, Jared W. Coburn, Daniel A. Judelson. *California State University, Fullerton, Fullerton, CA.*

(No relationships reported)

Males often produce greater torque than females by virtue of a greater quantity of muscle mass. Although muscle quality between sexes may not be different, it remains questionable whether males and females produce similar relative torque when controlling for cross-sectional area (CSA) and body mass.

**PURPOSE:** To determine if sex differences exist in lower body peak torque relative to 1) muscle CSA ( $\text{Nm}\cdot\text{cm}^{-2}$ ) and 2) body mass ( $\text{Nm}\cdot\text{kg}^{-1}$ ).

**METHODS:** Fifty-seven male (age  $23.67 \pm 2.17$  years; height  $178.39 \pm 7.58$  cm; mass  $80.49 \pm 15.33$  kg) and 61 female (age  $22.93 \pm 2.08$  years; height  $164.20 \pm 7.30$  cm; mass  $62.84 \pm 11.85$  kg) subjects performed three maximal concentric knee flexion repetitions of their dominant leg on an isokinetic dynamometer at 14 randomized speeds ( $0-400^\circ\cdot\text{s}^{-1}$ ). Muscle cross sectional area (CSA) of the hamstrings was calculated via the Housh equation (1995) using skinfold of the anterior thigh and mid-thigh circumference. Two separate ANOVAs were used to determine any differences in relative torque by sex.

**RESULTS:** Males were significantly heavier (males  $80.49 \pm 15.33$  kg, females  $62.84 \pm 11.85$  kg) and had significantly greater hamstring CSA than females (male  $25.84 \pm 4.74$   $\text{cm}^2$ , females  $17.80 \pm 4.87$   $\text{cm}^2$ ). When controlling for body mass, males produced significantly ( $P<0.05$ ) greater peak torque than females ( $0^\circ\cdot\text{s}^{-1}$ : males =  $1.71 \pm 0.24$   $\text{Nm}\cdot\text{kg}^{-1}$ ; females =  $1.44 \pm 0.28$   $\text{Nm}\cdot\text{kg}^{-1}$ ;  $210^\circ\cdot\text{s}^{-1}$ : males =  $1.33 \pm 0.21$   $\text{Nm}\cdot\text{kg}^{-1}$ ; females =  $1.13 \pm 0.25$   $\text{Nm}\cdot\text{kg}^{-1}$ ;  $400^\circ\cdot\text{s}^{-1}$ : males =  $1.07 \pm 0.20$   $\text{Nm}\cdot\text{kg}^{-1}$ ; females =  $0.92 \pm 0.21$   $\text{Nm}\cdot\text{kg}^{-1}$ ). Other speeds showed similar results. However, when controlling for CSA, peak torque was not significantly different between sexes ( $0^\circ\cdot\text{s}^{-1}$ : males =  $5.35 \pm 0.99$   $\text{Nm}\cdot\text{cm}^{-2}$ ; females =  $5.26 \pm 1.33$   $\text{Nm}\cdot\text{cm}^{-2}$ ;  $210^\circ\cdot\text{s}^{-1}$ : males =  $4.15 \pm 0.59$   $\text{Nm}\cdot\text{cm}^{-2}$ ; females =  $4.14 \pm 1.49$   $\text{Nm}\cdot\text{cm}^{-2}$ ;  $400^\circ\cdot\text{s}^{-1}$ : males =  $3.29 \pm 0.64$   $\text{Nm}\cdot\text{cm}^{-2}$ ; females =  $3.23 \pm 0.68$   $\text{Nm}\cdot\text{cm}^{-2}$ ). Other speeds showed similar results.

**CONCLUSIONS:** These results suggest that males produce greater torque per kilogram of body mass in knee flexion exercise than females. However, there appears to be no difference in relative hamstring peak torque produced between sexes when controlling for CSA.

**Effects Of Strength And Endurance Training On Quadriceps And Hamstrings Using An Elliptical Device**

Barney LeVeau, Ph D, PT, FACSM, Rita Anderson, SPT, Courtney Barrett, SPT, Meridith McKenzie, SPT. *Alabama State University, Montgomery, AL.*

Email: bleveau@alasu.edu

(No relationships reported)

Background: The elliptical device is claimed to provide a low impact workout for cardiovascular training. Few studies, however, have focused on any strength and endurance gained by using the elliptical device.

**PURPOSE:** The purpose of this study was to determine if an elliptical device can elicit strength and endurance gains in the quadriceps and hamstrings muscles while subjects perform in a forward motion.

**METHODS:** Fourteen healthy female subjects, between the ages of 19-64 years participated in this study. Each performed on the Nautilus NE 3000 elliptical machine for fifteen minutes, two-three times per week for eight consecutive weeks. Strength of the quadriceps and hamstring muscles was measured using a 1RM on the Nautilus VR2 seated leg extension and flexion machines. Endurance gains in the quadriceps and hamstrings were assessed by calculating 70% of the initial 1RM for each, and completing as many as possible consecutive repetitions of bilateral knee extension and knee flexion on the VR2 machines.

**RESULTS:** The ANOVA showed a significant difference for strength gains in the quadriceps ( $F=68.29$ ,  $P<0.0001$ ) and hamstrings ( $F=55.08$ ,  $P<0.0001$ ) for the initial, four week, and eight week testing periods. The average increase in quadriceps strength for the eight weeks was  $40\pm18\%$ . The average increase in hamstrings strength for the eight weeks was  $25\pm12\%$ . The ANOVA showed a significant difference in endurance gains in the quadriceps ( $F=29.65$ ,  $P<0.0001$ ) and the hamstrings ( $F=14.26$ ,  $P<0.0001$ ) for the initial, four week, and eight week testing periods. The average increase in quadriceps endurance for the eight weeks was  $70\pm49\%$ . The average increase in hamstrings endurance for the eight weeks was  $120\pm101\%$ . The hamstring/quadriceps (H/Q) ratio also displayed a significant difference ( $F=8.39$ ) and had an average increase of  $7.87\pm9.77\%$  ( $P<0.05$ ) for the eight weeks.

**CONCLUSIONS:** The elliptical device can provide strength and endurance gains in both the quadriceps and hamstrings. The strengthening effect is greater for the quadriceps

than that of the hamstrings; however, the endurance gains were greater in the hamstrings than the quadriceps. The exercise specialist should be aware that these unequal strengthening effects lead to a decrease in the H/Q ratio.

**The Effects Of Maximum Voluntary Isometric Contraction On 1rm Performance In The Bench Press**

Tiffany J. Patrick<sup>1</sup>, David Bellar<sup>2</sup>, Matt Muller<sup>2</sup>, Meagan Williamson<sup>2</sup>, Ellen L. Glickman, FACSM<sup>2</sup>. <sup>1</sup>*Notre Dame College, South Euclid, OH.* <sup>2</sup>*Kent State University, Kent, OH.*

(No relationships reported)

In previous studies, isometric lifting has produced varied results. These studies have examined both the acute and training effects of isometric contraction on the bench press. To date no studies have examined the acute, selective fatigue of the primer movers at 90 degrees of elbow flexion on the bench press exercise.

**PURPOSE:** The purpose of this study was to determine if Maximum Voluntary Isometric Contraction (MVIC) at 90 degrees of elbow flexion would affect performance in the bench press exercise.

**METHODS:** The participants involved in this study were eight female college track and field athletes (Height 1.72m±0.9, BMI 32.1±9.2) who compete in the throwing event (Hammer, Shot Put, Discus, Javelin). The average 1RM bench press for the participants was 59.5±19.8 kilograms. A counterbalanced, within subjects design was chosen for this study. Participants were asked to report to the weight room on two separate occasions. Both days began with a standard warm-up of the bench press exercise consisting of 70% 1RM for a set of five repetitions and 80% 1RM for 3 repetitions. After the warm-up both trial days consisted of three separate, single maximal attempts to set a new 1RM in the bench press. The two treatments that were counterbalanced were Standard (STAND) and MVIC. The STAND treatment consisted only of the three maximal lifts in the bench press exercise. The MVIC treatment consisted of a 30 second maximal voluntary isometric contraction against a stationary bar at 90 degrees of elbow flexion immediately prior to each single maximal bench press lift to induce fatigue. A 72 hour washout period was incorporated between treatments.

**RESULTS:** A significant difference ( $p=0.020$ ) was found between treatments by paired sample t-test analysis. The standard group (60.95kg±18.83) significantly out performed the isometric group (53.0kg±11.48).

**CONCLUSION:** It is apparent from the findings of this study that preferential fatigue of the prime movers at 90 degrees of elbow flexion acutely reduces performance in the bench press exercise. This suggests that strengthening the muscles at this joint angle through training may have the potential to increase strength in the bench press exercise.

**Effect Of Resistance Training Frequency On Body Composition In Middle-aged Women**

Melissa J. Benton, PhD<sup>1</sup>, Pamela D. Swan, PhD, FACSM, FACSM<sup>2</sup>, Scot Raab, PhD<sup>1</sup>, Green T. Waggenger, PhD<sup>1</sup>. <sup>1</sup>*Valdosta State University, Valdosta, GA.* <sup>2</sup>*Arizona State University, Mesa, AZ.*

Email: mjbenton@valdosta.edu

(No relationships reported)

The effect of resistance training (RT) frequency on body composition has not been well studied in women, although they are at high risk for loss of lean mass with age.

**PURPOSE:** This study evaluated short-term effects of a 3- versus 4-day a week RT program on changes in absolute (kg) and relative (%) lean and fat mass.

**METHODS:** Nineteen untrained women (age 48 ± 1.2 years; BMI 28.8 ± 1.2) completed 8 weeks of RT. To promote adherence they self-selected assignment to either Group 3, which trained 3 nonconsecutive days of the week using a traditional total body protocol, or Group 4, which trained 4 consecutive days of the week using an alternating split training (upper-lower body) protocol. Group 4 completed 3 sets of 6 upper body exercises (chest press, latissimus pulldown, shoulder press, machine row, triceps pushdown, biceps curl) or 6 sets of 3 lower body exercises (leg press, leg extension, leg curl). Group 3 completed 3 sets of the same 8 exercises (excluding machine row) used for split training. Both groups completed 72 sets of 8-12 repetitions at 50-80% 1RM per week. Body composition was measured using air displacement plethysmography prior to and after completion of the RT program. To control for diet, participants were instructed not to change their intake or restrict calories during the study.

**RESULTS:** Both RT protocols were well-tolerated, had 98% adherence, and resulted in significant increases in upper and lower body strength ( $p < 0.01$ ). At baseline and after 8 weeks of RT there were no significant between-group differences in age, body mass, BMI, lean or fat mass. However, when both groups were combined there was a significant increase in absolute lean mass (1.1 ± 0.3 kg;  $p = 0.002$ ) accompanied by increases in body mass (1.04 ± 0.4 kg;  $p = 0.009$ ) and BMI (0.38 ± 0.1;  $p = 0.01$ ). A small, non-significant decrease in % body fat (-0.4 ± 0.3 %) was observed.

**CONCLUSIONS:** In untrained, middle-aged women initial, short-term gains in lean mass are not influenced by a training frequency of either 3 or 4 days a week. Consecutive-day split training is as well tolerated as traditional every-other-day total body training, even by novices. Therefore, for convenience and to promote adherence, women beginning a RT program should be taught both training protocols so they may schedule training sessions to fit their normal, weekly routine as closely as possible.

**Muscle Activation Pattern Is Similar Between The Pull-up And Lat-pull Exercise**

Travis M. Harvey, Zack F. Wagner, Robert W. Gregory, William F. Brechue, FACSM. *USMA, West Point, NY.*

Email: Travis.Harvey@usma.edu

(No relationships reported)

The lat pull-down (LP) exercise is commonly viewed as a corollary exercise to the pull-up (PU) and used to develop PU work capacity. Interestingly, neither 1-repetition maximum (1-RM) nor repetitions-to-failure (RTF; 60% of 1-RM) LP performance correlates with pull-up performance (Chandler et al., 2001).

**PURPOSE:** To determine the relationship between and muscle activation pattern of LP and PU performance.

**METHODS:** On two separate days, male subjects ( $n=9$ ; age: 20.3 ± 0.7 yrs; height: 177.7 ± 6.7 cm; mass: 78.3 ± 7.3 kg) performed a PU RTF test, a LP 1-RM test, and a LP RTF test at 60% of the LP 1-RM; pronated grip with controlled hand spacing. Surface EMG was collected during the first repetition of each exercise from the latissimus dorsi (LD), pectoralis major (PM), biceps brachii (BB), triceps brachii (TB), anterior deltoid (AD), and posterior deltoid (PD) muscle groups. The concentric phases of the EMG signals were integrated (iEMG) and normalized to EMG activity during a maximal voluntary isometric contraction (iEMG<sub>MVC</sub>) performed at the mid-range of each exercise.

**RESULTS:** The range of motion (ROM) was similar between LP (144±15°) and PU (132±20°). There was a weak, negative relationship between 1-RM LP (81.1±14.3 kg) and LP RTF ( $r=-0.44$ ). PU performance (14.8±5.6 reps; body mass 96% of 1-RM LP) was negatively correlated with 1-RM LP (81.1±14.3 kg;  $r=-0.53$ ) but not LP RTF (27.1±6.4 reps;  $r=-0.06$ ). However, work capacity (reps × load) was similar between PU RTF (1135±360 kg reps) and LP RTF (1297±6.4 kg reps). There was a progressive increase in iEMG/EMG<sub>MVC</sub> in PM, TB, LD, and PD throughout the concentric ROM in both PU and LP. iEMG/EMG<sub>MVC</sub> of PM, TB, AD, and PD was greater during PU than LP reflecting the greater load associated with PU (96% of 1-RM LP) as opposed to 60% of 1-RM. Interestingly LD muscle activity was not different between exercises.

**CONCLUSION:** Muscle activation pattern is similar in PU and LP; however the magnitude of the activation is greater during PU reflecting differences in load. Differences in performance of the PU and LP appear unrelated to the initial pattern of muscle activation.

### Elastic Band Bench Press Training Does Not Increase Power in Untrained Males

Matthew V. Bliss<sup>1</sup>, David M. Bellar<sup>1</sup>, Matthew D. Muller<sup>1</sup>, Edward J. Ryan<sup>1</sup>, Chul-Ho Kim<sup>1</sup>, Keisuke Ida<sup>1</sup>, Sarah M. Muller<sup>2</sup>, Jacob E. Barkley<sup>1</sup>, Ellen L. Glickman, FACSM<sup>1</sup>. <sup>1</sup>Kent State University, Kent, OH, <sup>2</sup>Vanderbilt University, Nashville, TN.  
Email: mbliss2@kent.edu

(No relationships reported)

It has been suggested that training with elastic bands in combination with free weights can potentially increase strength and power more so than free weights alone due to overstressing the concentric phase beyond the sticking point.

**PURPOSE:** The purpose of the study was to determine if using elastic bands during the bench press will increase power better than free weights alone.

**METHODS:** Eleven apparently healthy, untrained males (age 23±3 years) volunteered to participate in the 13 week study. During the first week all participants reported to the exercise physiology lab for a familiarization session whereby an instruction on how to perform the bench press was provided. This was followed by a one repetition maximum (1RM) to assess baseline strength. Following a 1RM power was assessed via a potentiometer using 50% of their 1RM. The training protocol consisted of five sets of five repetitions using 85% of the previous 1RM. Weeks two through four were used as a neural adaptation phase followed by a 1RM on week five. The subjects were then randomly assigned into one of two groups for the following weeks: groups that benched using 85% free weight tension with 15% elastic tension (BAND) or 100% free weight tension (STAND). The subjects were retested for strength and power during week nine and in weeks 10 through 12 the treatments were reversed.

**RESULTS:** Subjects' power was significantly increased throughout the 13 weeks ( $p = 0.00$ ). When covaried for order ANCOVA revealed that there was no main or interaction effect ( $p \geq 0.6$ ). Strength and power were also found to be strongly correlated in both treatments ( $p = 0.001$  for BAND &  $p = 0.003$  for STAND).

**CONCLUSIONS:** Based on these data the use of elastic bands with the bench press did not produce significantly greater gains in power vs. standard bench press, and that power and strength are strongly correlated regardless of the treatment.

#### Effects Of Resistance Exercise Of Different Intensity But Equal Work On Excess Post-exercise Oxygen Consumption

Milos Galecic, Christopher C. Cheatham, Michael G. Miller, Timothy J. Michael, FACSM, Jennifer Query. *Western Michigan University, Kalamazoo, MI.*

(No relationships reported)

Excess post-exercise oxygen consumption (EPOC) is defined as an increase in oxygen consumption ( $\text{VO}_2$ ) following the completion of exercise. Previous research has primarily focused on the influence of endurance-type exercise on EPOC.

**PURPOSE:** The purpose of this study was to compare the effect of a light versus heavy resistance exercise protocol of equal work on EPOC.

**METHODS:** Ten male subjects performed two days of one-repetition maximum (1-RM) testing and two experimental trials (Light: 3 sets of 15 repetitions at 40% 1-RM; Heavy: 4 sets of 4 to 8 repetitions at 80 to 87.5% 1-RM).  $\text{VO}_2$ , caloric expenditure, blood lactate concentration, heart rate, and blood pressure were measured at baseline, 5, 15, 30, 60, 90 and 120 minutes post-exercise, and 24 hours post-exercise.

**RESULTS:** For both exercise protocols,  $\text{VO}_2$  and caloric expenditure were significantly greater at 5 min post-exercise compared to baseline. In addition, at 5 min post-exercise,  $\text{VO}_2$  and caloric expenditure were greater during the light protocol compared to the heavy protocol. During the 120 minutes post exercise, there was no significant difference in EPOC ( $44.0 \pm 43$  and  $39.1 \pm 44.3 \text{ mL} \cdot \text{kg}^{-1}$ ;  $P = 0.786$ ) or total caloric expenditure ( $15.1 \pm 13.8$  and  $12.9 \pm 16.9 \text{ kcal}$ ;  $P = 0.742$ ) between the light and heavy protocols. For the light protocol, blood lactate concentration was significantly greater at 5 min post-exercise compared to BASE but there were no statistical differences in blood lactate concentration between BASE and any other time points. For the heavy protocol, blood lactate concentration was significantly greater at 5, 15 and 30 min post-exercise compared to BASE but there were no statistical differences in blood lactate concentration between BASE and any other time points. When comparing the two protocols, blood lactate concentration was significantly greater at 5 and 30 min post-exercise during the light protocol compared to the heavy protocol.

**CONCLUSIONS:** The data suggests that for resistance exercise protocols with an equal work volume, there is no difference in the magnitude and duration of EPOC.

### 1808 Board #158 May 27 3:30 PM - 5:00 PM

#### Muscle Activation Patterns And Repetitions-to-failure Performance In The Bench Press Exercise

Zack F. Wagner, Travis M. Harvey, Robert W. Gregory, William F. Brechue, FACSM. *United States Military Academy, West Point, NY.*

Email: zack.wagner@usma.edu

(No relationships reported)

The bench press (BP) exercise is used to determine and develop upper-body muscular strength and work capacity.

**PURPOSE:** To examine the muscle activation pattern during performance of a bench press repetitions-to-failure (RTF) test.

**METHODS:** Subjects ( $n=16$ ; Age:  $21 \pm 2$  yr; ht:  $179 \pm 6$  cm; wt:  $78 \pm 7$  kg) performed BP one-repetition maximum (1-RM) and RTF (60% 1-RM) test. Surface EMG was collected during each repetition of both tests from the pectoralis major (PM), triceps brachii (TB), anterior (AD) and posterior (PD) deltoid, latissimus dorsi (LD), and biceps brachii (BB) muscle groups. The concentric phase EMG signals were integrated (iEMG) and normalized to muscle group specific EMG activity collected during a maximal voluntary isometric contraction ( $\text{EMG}_{\text{MVC}}$ ) performed at the mid-range of the BP exercise and prior to initiating testing. Mean power frequency (MPF) was also determined for the concentric phase.

**RESULTS:** 1-RM BP ( $92.2 \pm 24.3$  kg) was moderately correlated with body mass ( $r=0.74$ ), fat-free mass ( $r=0.64$ ) and fat mass ( $r=0.71$ ). Subjects performed  $23.4 \pm 2.5$  reps during RTF. Although 1-RM was highly correlated with work capacity (load reps;  $1388 \pm 330 \text{ kg} \cdot \text{reps}$ ;  $r=0.89$ ) the relationship with RTF was negative and low ( $r=-0.22$ ). During RTF concentric contraction time increased ( $0.69 \pm 0.21$  to  $1.81 \pm 0.83$  sec), while range of motion ( $242 \pm 8^\circ$  to  $254 \pm 19^\circ$ ) and excentric contraction time ( $0.640$ - $0.900$  sec) did not change from the first to the last repetition. iEMG/  $\text{EMG}_{\text{MVC}}$  increased progressively from the beginning ( $-0.16$ - $0.30$ ) to the end ( $-0.21$ - $0.51$ ) of each concentric contraction in PM, TB, AD and LD during RTF. At failure iEMG/  $\text{EMG}_{\text{MVC}}$  increased at the beginning ( $-0.21$ - $0.46$ ) and end ( $-0.39$ - $0.83$ ) of the concentric contraction; the latter activity was equal to iEMG/  $\text{EMG}_{\text{MVC}}$  activity observed during 1-RM. MPF decreased in PM ( $55.2 \pm 8.1$  to  $47.1 \pm 5.6$  Hz) and TB ( $55.7 \pm 5.3$  to  $49.4 \pm 6.8$  Hz), while AD ( $54.2 \pm 4.4$  to  $53.5 \pm 3.5$  Hz) and LD ( $50.8 \pm 8.1$  to  $47.4 \pm 6.8$  Hz) remained unchanged.

**CONCLUSION:** There was a progressive increase in concentric contraction time and EMG activity and a decrease in MPF associated with muscle failure during RTF testing. The pattern and magnitude of EMG activity relative to  $\text{EMG}_{\text{MVC}}$  was similar in PM, TB, AD and LD muscle groups.

#### Medial And Lateral Gastrocnemius Activation Differences During Heel Raise Exercise With Three Different Foot Positions

Robert G. LeFavi, G. Ken Limbaugh, Jayme D. Eitner, Bryan L. Riemann. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)

Email: Robert.LeFavi@armstrong.edu

(No relationships reported)

Instructional guidelines from some national exercise certification organizations recommend performing heel raise exercise with varying initial foot positions to alter the involvement of the gastrocnemius' medial (MG) or lateral (LG) head.

**PURPOSE:** To compare MG and LG activation during the concentric (CP) and eccentric (EP) phases of heel raise exercise using neutral (N), internally-rotated (IR) and externally-rotated (ER) foot positions. The term "foot position" was maintained for consistency with instructional texts, though the initial foot position reflects hip rotation.

**METHODS:** Twelve healthy subjects (9 male, 3 female;  $24.0 \pm 3.8$  yrs) with resistance training experience performed free-weight (bar loaded to 30% body mass) heel raise exercise on a 3.8 cm block. Surface electromyographic (EMG) activity was recorded during five repetitions under each of the N, IR and ER foot positions, divided into CP and EP phases, and ensemble averaged within phase. Mean EMG amplitude, normalized to maximum voluntary contraction, was calculated. Separate two-factor (position by head) repeated measures analysis of variance were used for each phase. Simple main effects post hoc analyses of the significant ( $P < .05$ ) interactions were conducted.

**RESULTS:** During EP, significantly greater MG activity compared to LG activity was revealed for both N and ER. During CP, significantly greater LG activity compared to the MG occurred for IR. Further, post hoc analyses on the EP revealed that MG activity using ER was significantly greater than MG activity using IR or N. Likewise, analysis of CP revealed that LG activity using IR was significantly greater than LG activity using ER or N.

**CONCLUSION:** Altering foot positions during the heel raise exercise does alter relative muscle activation as measured by surface EMG. The MG is activated to a significantly greater extent than the LG during EP using N and ER, while the LG displays significantly greater muscle activity than the MG during CP using IR. Further research is recommended to elucidate the role of the contraction phases in these differences.

### Effects Of Gender And Different Temperature Modalities On Contraction Force Following A Resistance Exercise Program

Ronald Otterstetter<sup>1</sup>, Lucas C. Smith<sup>2</sup>, Stefan A. Mroczkowski<sup>2</sup>, Leigh Murray<sup>2</sup>, Stacey Buser<sup>1</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>Walsh University, North Canton, OH. (Sponsor: Gary Kamimori, FACSMM)

Email: ro5@uakron.edu

(No relationships reported)

**INTRODUCTION:** Different types of modalities that are applied post-therapy have been known to have an effect on muscle contraction force. Gender has also been shown to have an effect on maximal muscle contraction force.

**PURPOSE:** To examine the effects of gender, thermotherapy (THERM), and cryotherapy (CRYO) on skeletal muscle contraction force of the biceps muscle following a high volume and medium intensity resistance exercise program.

**METHODS:** Thirty one (31) subjects (16 males, 15 females) were randomly assigned to THERM, CRYO, and control (CON) groups. A 1-RM test was performed prior to any resistance training, and at 2, 4, and 6 weeks during training.

**RESULTS:** Significant ( $p = 0.008$ ) gender differences were observed on skeletal muscle contraction force (Females:  $22.4 \pm 2.3\%$  vs Males:  $10.1 \pm 2.1\%$ ) with females demonstrating a greater percentage increase. A significant treatment by gender difference was also observed [(CRYO: (Females:  $27.1 \pm 4.9.0\%$  vs Males:  $5.5 \pm 3.5\%$ ) CON: (Females:  $24.6 \pm 3.5\%$  vs Males:  $7.0 \pm 3.8\%$ )] with females demonstrating a greater percent increase compared to males following six weeks of resistance exercise program. A significant ( $p < 0.011$ ) increase in skeletal muscle contraction force over time was observed in all groups.

**CONCLUSION:** Gender, along with modality, demonstrated a significant difference in muscle contraction force following resistance exercise. In the group tested, females showed a higher potential for increase in skeletal muscle contraction force.

### Metabolic Demand Of A Kettlebell Workout Routine

Janna Castellano, St. Cloud State University, St. Cloud, MN. (Sponsor: David Bacharach, FACSMM)

(No relationships reported)

Kettlebell routines work to train the body as a whole by improving function, stabilizing joints, and rehabbing athletes after injury. However, the metabolic demand of a single kettlebell routine as it compares to other modes of exercise has not been determined. The purpose of this study was to measure oxygen consumption while completing a kettlebell routine in an effort to accurately determine oxygen consumption and thereby caloric expenditure during the routine. Ten subjects (5 male, 5 female) completed multiple cycles of nine different kettlebell exercises in succession, with each cycle lasting approximately 5-7 minutes. Subjects went about the routine at a self selected pace using either a 10 lb kettlebell (females) or a 20 lb kettlebell (males). Throughout the routine, oxygen consumption (VO<sub>2</sub>) and heart rate (HR) were measured continuously (Oxycon Mobile, Cardinal Health, Inc.). Total test time ranged from 14-22 minutes. Mean values were determined for HR and VO<sub>2</sub> for each exercise, as well as for the entire routine. An overall average for HR and VO<sub>2</sub> was calculated for males and females. The Weir equation was used to calculate per minute caloric expenditure for each subject and to generate a mean caloric requirement for the kettlebell exercises and overall routine (See Fig. 1). Results indicate

this kettlebell routine provided a metabolic demand equal to that of typical exercises such as treadmill walking on an incline, stationary cycling, elliptical exercise, stairmaster or running. These data also demonstrate kettlebell activity could be used as a viable form of cross training to maintain health and improve overall fitness.

The study was funded by a grant from cfit2/believe/it, LLC. Mpls, MN, a distributors of kettlebells.

(No relationships reported)

Resistance training (RT) increases muscle mass and basal metabolic rate, and thus positively affects body composition. However, there is considerable debate over which RT protocol is most effective. Identifying RT protocols that acutely maximize caloric output may provide insight when addressing health concerns such as metabolic syndrome and sarcopenic obesity. Most studies that have measured caloric output during RT have compared protocols such as circuit to hypertrophy training using varying loads, volumes, and repetitions.

**PURPOSE:** To compare oxygen consumption ( $\text{VO}_2$ ), heart rate (HR), and lactate (La) responses to circuit (CIR) and hypertrophy (HYP) patterns under high-speed (HS) and controlled-speed (CS) conditions while holding volume, intensity, and lifting technique constant during a whole-body RT workout.

**METHODS:** Five resistance-trained male subjects ( $27.4 \pm 5.6$  yrs,  $84.8 \pm 13.3$  kg,  $178.8 \pm 10.9$  cm) participated in 5 testing and a 1RM day. Conditions were: control (CON), controlled speed hypertrophy (CSHYP) and circuit (CSCIR), and high-speed hypertrophy (HSYYP) and (HSCIR). Testing days consisted of a 30 min supine baseline measure, 39.5 min workout protocol, and 90 min supine EPOC measure, except CON, when the subject rested for the entire duration. Workouts consisted of 3 sets of 10 repetitions for 9 exercises at 50% 1RM, either as fast as possible or at a rate of 1.5s concentric/1.5s eccentric. HR and  $\text{VO}_2$  were measured continuously; 9 lactate samples were taken over the 2.7 hr protocol.

**RESULTS:** No significant differences were seen across baseline measures. During exercise all training conditions produced higher  $\text{VO}_2$ , HR, and La than CON. CSHYP increased HR and La more than either HS condition. Over the 90 min EPOC, HYP showed greater  $\text{VO}_2$  than CON; all conditions showed increased HR. CSHYP produced higher HR and La than HS. CIR showed greater La than HYP, while CS showed increased HR and La over HS; all were increased over CON.

**CONCLUSION:** Our pilot data show that under conditions where load, volume, and repetitions are held constant, CIR and HYP training appear to have equal capacity to elevate oxygen consumption regardless of training speed; however, HYP training produces slightly higher EPOC levels. Additionally, higher La levels and subject feedback indicate a greater effort during CS versus HS training.

**Blood Lipid Profile Response To An Acute Bout of Resistance Training**

William W. Edwards<sup>1</sup>, Shyam S. Mali<sup>1</sup>, Ellen L. Glickman, FACSM<sup>2</sup>, Arnold G. Nelson, FACSM<sup>3</sup>, Thomas C. Palfrey<sup>4</sup>. <sup>1</sup>Texas A & M University - Kingsville, Kingsville, TX. <sup>2</sup>Kent State University, Kent, OH. <sup>3</sup>Louisiana State University, Baton Rouge, LA. <sup>4</sup>Xavier University, New Orleans, LA.  
Email: kfwwe00@tamuk.edu

(No relationships reported)

Obesity, a risk factor for diabetes mellitus, is a growing epidemic. It is well known that the blood lipid profile improves with endurance training and resistance training. Whether improvements occur in the lipid profile in response to one session of resistance training are unclear.

**PURPOSE:** To determine the effect of an acute bout of resistance training on the blood lipid profile response in young adults.

**METHODS:** Twenty healthy recreationally trained college students (13M, 7F;  $20.1 \pm 1.3$  yr;  $82.0 \pm 24.4$  kg; BMI  $27.4 \pm 6.7$ , respectively) enrolled in a resistance training activity class volunteered for participation in this study. All participants were free of any illness or medication that might affect lipid profile. Workout modalities included resistance training machines and free weights. Fasting seated blood samples were taken immediately before (pre) and after (post) the class session and measured for total cholesterol (TC), high-density lipoproteins (HDL), low-density lipoproteins (LDL), triglycerides (TG) and TC/HDL ratio. Paired t-tests were used to compare the responses in the individual components of the pre-exercise and post-exercise lipid profile.

**RESULTS:** Data are reported as mean  $\pm$  SD. TC was reduced post-exercise vs. pre-exercise ( $139.2 \pm 34.8$  vs.  $145.2 \pm 39.4$  mg-dl<sup>-1</sup>,  $p=0.02$ ), as was LDL ( $88.0 \pm 29.0$  vs.  $96.7 \pm 42.2$  mg-dl<sup>-1</sup>,  $p=0.04$ ). There were no significant differences ( $p>0.05$ ) between pre- and post- HDL, TG, and TC/HDL.

**CONCLUSION:** From these data, participation in an acute bout of resistance training that was one hour in duration improved the TC and LDL components of the blood lipid profile. To better understand the longitudinal lipid profile response with resistance training across age, gender, and ethnicity, future research may involve measuring the lipid profile on a more frequent basis.

**Effect Of Concurrent Training On Blood Lipid Profile In Untrained Men**

Ehsan Ghahramanloo<sup>1</sup>, Adrian Midgley<sup>2</sup>, Lars R. McNaughton, FACSM<sup>3</sup>, David J. Bentley<sup>1</sup>. <sup>1</sup>University of NSW, Sydney, Australia. <sup>2</sup>University of Hull, UK, United Kingdom. <sup>3</sup>University of Hull, UK, United Kingdom.

(No relationships reported)

Cardiovascular disease (CVD) is predicted to be the main cause of death in developed countries by 2020. Regular physical activity is believed to decrease the risk of CVD by increasing the turnover of lipid substrates, with effects on transport and cell availability. Previous investigations have shown that endurance training results in beneficial changes in the serum lipid profile. Available results concerning the effects of strength training on the serum lipid profile are more conflicting. There is little information regarding the effects of concurrent training (endurance and resistance training performed in the same overall regime) on blood lipid profile in sedentary male subjects.

**PURPOSE:** This study compared the effects of three different 8-wk training programs [endurance training (ET), strength training (ST) and concurrent training (CT)] on blood lipid profile and body composition in untrained young men.

**METHODS:** A total of 27 subjects were randomly allocated to an ET, ST or CT group which performed either progressive treadmill (ET), free weight (ST) or both the endurance and strength training requirements for 8 weeks. The endurance (E) training program involved running at 65% of HRmax for thirty minutes per session and three sessions per week where the HR reached 80% towards the end of the program. The strength (S) training program involved performing three sets of bench press, squat, pull down and legs curl with 50% of 1RM, 10 repetitions per set and three sessions per week where the intensity reached 80% of 1RM and where the repetition decreased to 6 towards the end of the program. The Concurrent (C) training program included both E and S training requirements.

**RESULTS:** High-density lipoprotein and low-density lipoprotein profiles significantly improved in the ET and CT groups ( $p < 0.01$ ) but not in the ST group. Triglyceride and total cholesterol profiles significantly improved in all three training groups. Total fat mass significantly decreased in the ET and CT groups ( $p < 0.001$ ) but not in the ST group, whereas fat free mass significantly increased in the ST and CT groups ( $p < 0.01$ ) but not in the ET group.

**CONCLUSION:** These results indicate that CT can be used to simultaneously improve both the serum lipid profile and body composition of previously untrained, apparently health young men.

**Yoga And Functional Resistance Training Improves Body Composition,  $\text{VO}_{2\text{peak}}$  And Mood State In Women**

Paul J. Arciero, FACSM, Tyson McKechnie, Nicole DiMarzio, Gilbert Rodriguez, Pamela Brewer, Amanda Mercep. Skidmore College, Saratoga Springs, NY.

Email: parciro@skidmore.edu

(No relationships reported)

Yoga and functional resistance exercise are common modes of physical activity. However, there are limited numbers of randomized, controlled studies using objective quantitative measures comparing the relative effectiveness of each form of activity.

**PURPOSE:** To compare the effects of a 10-wk yoga vs. functional resistance training intervention on total and regional body fat distribution, blood lipids, aerobic capacity, and mood state.

**METHODS:** Thirty-three, healthy women ( $43.2 \pm 4.6$  yrs) were randomly assigned to 10-wks of Pulse Yoga (PY;  $n=8$ ), functional resistance training (FCT;  $n=9$ ), or wait-list control (C;  $n=8$ ). Experimental groups (PY, FCT) participated in three 60-75 min exercise sessions/wk, whereas controls maintained their pre-existing level of physical activity

(<60min physical activity/wk). All subjects followed an energy-balanced healthy eating plan throughout the 10-wks. Outcome assessments performed at baseline and after the 10-wk intervention included total and regional body composition analysis (DXA), blood lipid profile, Profile of Mood States (POMS), and aerobic fitness.

**RESULTS:** Twenty-five of the 33 women recruited and randomized were included in the analysis (three drop-outs, five non-compliant). Total %body fat and abdominal %body fat declined significantly ( $P<0.05$ ) in PY (-5.9%; -6.4%) and FCT (-5.8%; 8.8%) but remained unchanged in C. Total cholesterol levels decreased significantly ( $P<0.05$ ) in all three groups PY (12.5%), FCT (11.5%) and C (11.5%), whereas triglyceride levels decreased significantly in PY (32%) and C (23%) and remained unchanged in FCT. Tension decreased in FCT (7.5 vs. 4,  $P<0.05$ ) and vigor increased in PY (15 vs. 20.5,  $P<0.05$ ) following the intervention. Estimated  $\text{VO}_{2\text{peak}}$  increased significantly ( $P<0.05$ ) in both treatment groups following the training (PY; 30 vs. 35 ml/kg/min, 16.6%; FCT; 31 vs. 36 ml/kg/min, 16.8%).

**CONCLUSION:** Both yoga and functional resistance exercise training elicit favorable changes in total and regional body fat distribution and aerobic fitness which coincides with enhanced psychological mood state. These findings support the use of yoga and functional resistance exercise for improved body composition, cardiovascular and psychological health in middle aged women.

Email: mbranders@ifi.ku.dk

*(No relationships reported)*

**INTRODUCTION:** A recent study has shown that regular soccer training has significant health beneficial effects for untrained males with elevated risk of lifestyle diseases. It elevated maximal oxygen uptake, lowered blood pressure (BP) and LDL cholesterol (Krstrup et al., 2008). Soccer is an intermittent activity with periods at near maximal heart rates and multiple strength related specific soccer movements.

**PURPOSE:** To study the effect of 12wks intense interval running or strength training on selected health variables.

**METHODS:** 16 untrained males (36.7 $\pm$ 5.7 yrs, 182 $\pm$ 6 cm, 93.7 $\pm$ 13.9 kg, 36.5 $\pm$ 6.4 ml  $\text{O}_2$ /kg/min) were randomly separated in two matched groups, i.e. one group performing intense interval running (IR) for 5x2 min with heart rates  $>90\%$ HR<sub>max</sub>, interspersed by 1-min recovery periods, and one group performing heavy-resistance strength training (ST) with multiple strength exercises for the legs (week 0-4: 12-16RM, week: 4-12: 6-10RM). Both groups trained 2.0 $\pm$ 0.3 times per week for 12 weeks. Blood pressure and blood glucose were determined after an overnight fast. On a separate day an exhaustive incremental treadmill test was completed.

**RESULTS:** After the training period, fasting blood glucose was reduced ( $P<0.05$ ) in IR (5.7 $\pm$ 0.2 vs. 5.2 $\pm$ 0.1mM). For IR, systolic blood pressure was 8mmHg lower ( $P<0.05$ ) after the training period, whereas no significant changes occurred for ST. After the training period, LDL-cholesterol was unaltered in IR (3.4 $\pm$ 0.2 vs. 3.3 $\pm$ 0.2mM;  $P>0.05$ ) and tended to be higher in ST (3.1 $\pm$ 0.3 vs. 3.5 $\pm$ 0.3mM;  $P=0.052$ ). After the training period, the maximal oxygen uptake increased by 14 $\pm$ 4% in IR, which was significantly more ( $P<0.05$ ) than in ST (4 $\pm$ 3%).

**CONCLUSION:** Short-duration intense intermittent training (~20 min per week) is more effective than high-resistance-training for short-term changes in aerobic power, fasting blood glucose and blood pressure in untrained males.

**Effect Of Weight Training On Power Performance And Heart Rate Variability During A 72-hour Recovery**

Chia-Hua Kuo, Kun-Ning Chen, Zuei-Lien Chen, Yi-Ming Tsai. *Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: John L Ivy, FACSM)

Email: kch@tpcc.edu.tw

*(No relationships reported)*

**PURPOSE:** This study determined the effect of strength training on heart rate variability (HRV) during a 72-h recovery for elite weight lifters, and its links to muscle strength, pain feeling and plasma creatine kinase level.

**METHODS:** Following a 10-d detraining period, seven weight lifters performed a 2-h strength training program including back squat, seated shoulder press, dead lifts, and front squat. Strength performance was evaluated at baseline (before training) and 3, 24, 48, 72 h following training. HRV (HF and LF/HF), pain index, plasma creatine kinase were measured.

**RESULTS:** Strength performance was recovered to baseline in approximately 24 h following training. Dead lifts and front squat were maximally increased above baseline in 48 h, whereas back squat and seated shoulder press were maximally increased above baseline in 72 h. Plasma creatine kinase level was peaked at 3 h following training and gradually decline for 72 h. Although the pain feeling was not completely cleared, vagal activity (mirrored by natural log HF) was maximal at 72 h after training.

**CONCLUSIONS:** Similar to most of previous finding, improvement in power performance occurred 48-72 h following strength training. The present study found an association between strength performance and vagal activity during a 72-h recovery period.

**Effect Of A 12-week Exercise Intervention On Body Composition Variables In African American Women**

Lyndsey Hombuckle, Pei-Yang Liu, Emily Simonavice, Jasminka Z. Ilich, Jeong-su Kim, Lynn B. Pantan, FACSM. *Florida State University, Tallahassee, FL.*

*(No relationships reported)*

**PURPOSE:** This study evaluated body composition changes in middle-aged, obese, African-American women after a 12-week exercise intervention.

**METHODS:** Height, weight, waist and hip circumferences, and body composition variables via dual-energy X-ray absorptiometry were measured in 20 African-American females (age: 49 $\pm$ 4 yr; BMI: 34.2 $\pm$ 4.9 kg/m<sup>2</sup>). Subjects were randomly placed into one of two exercise training groups. One group was instructed to increase their daily walking to  $\geq 10,000$  steps/day (W; n=10) and the other group was given the same walking prescription, but additionally strength trained 2 days/wk (WS; n=10). Subjects performed 3 sets of 8-12 repetitions of 10 exercises focusing on the major muscle groups. Strength was evaluated for the upper and lower body by performing 1-repetition maximum tests for the chest press and leg extension. A two-way repeated measures ANOVA was performed to examine changes between the two groups. Significance was accepted at  $p<0.05$ .

**RESULTS:** WS significantly increased daily walking (5344 $\pm$ 1944 to 8037 $\pm$ 1137 steps/day;  $p<0.01$ ), while W showed a non-significant increase in daily walking (6203 $\pm$ 2840 to 7924 $\pm$ 1862 steps/day;  $p=0.08$ ). WS significantly increased upper (106 $\pm$ 12 to 125 $\pm$ 10 kg) and lower body (104 $\pm$ 22 to 125 $\pm$ 24 kg) strength ( $p<0.01$ ) and W showed no change for either measure. There was also a significant decrease in waist circumference for only WS (91.5 $\pm$ 7.9 to 89.6 $\pm$ 7.1 cm;  $p=0.025$ ). Values for body weight, BMI, % body fat, lean body mass, and bone density did not significantly change in either group after the 12-week intervention compared to baseline.

**CONCLUSIONS:** Strength training combined with a pedometer-based walking program increased walking volume and muscular strength, and decreased waist circumferences in obese, middle-aged, African-American women. This reduction in waist circumference may have significant health implications for risk factors of cardiovascular disease.

**1819 Board #169 May 27 2:00 PM - 3:30 PM****Eccentric Exercise Training-induced Skeletal Muscle Hypertrophy Is Augmented By Concomitant Blood Flow Restriction**Mizuki Sudo, Yutaka Kano. *Univ. of Electro-communications Dept. of Appl. Physics & Chemistry, Chofu, Tokyo, Japan.*

Email: sudo@ecc.pc.uec.ac.jp

(No relationships reported)

Eccentric contractions (ECC) induce skeletal muscle damage as well as stimulating muscle hypertrophy and hyperplasia. However, our previous study (Med. Sci. Sports Exer. 40: S196, 2008) demonstrated that ECC-induced skeletal muscle damage is suppressed by performing ECC whilst blood flow is restricted (BFR). It has been recently reported that restriction of muscle blood flow during low intensity concentric muscle contractions potentiate muscle hypertrophy (Fujita et al. J. Appl. Physiol. 103: 903-10, 2007).

**PURPOSE:** To test the hypothesis that ECC training-induced skeletal muscle hypertrophy is augmented by concomitant BFR.

**METHOD:** Wistar rats (male, 12 week-old) were divided into four groups: normal control group (CONT, n=6), blood flow restriction group (BFR, n=6), ECC without BFR group (ECC, n=6) and ECC with BFR group (BFR+ECC, n=4). In anesthetized rats, the right tibialis anterior muscle (TA) was subjected to 40 times-repeated ECC with/without occlusion pressure (~200 mmHg, by thigh cuff occlusion). ECC was evoked by surface electric stimulation (100 Hz, ~5 V) while the muscle was being simultaneously stretched by a synchronized electromotor. Training was conducted 2 days/wk, for 6 wks. TA muscles were removed 24 hours after the last exercise training bout and muscle fiber cross-sectional areas (CSA) were evaluated morphometrically from hematoxylin-eosin stained thick sections.

**RESULTS:** The muscle-to-body weight ratio (mg/g) increased significantly ( $P<0.05$ ) after training in both ECC ( $1.87 \pm 0.1$ ) and BFR+ECC ( $1.95 \pm 0.1$ ) compared with CONT ( $1.56 \pm 0.1$ ). The range of CSA was larger in both ECC ( $21\text{--}5936\mu\text{m}^2$ ) and BFR+ECC ( $156\text{--}5295\mu\text{m}^2$ ) compared with CONT ( $78\text{--}4423\mu\text{m}^2$ ). Mean CSA was significantly increased in BFR+ECC ( $1658 \pm 32\mu\text{m}^2$ ) compared with both CONT ( $1199 \pm 97\mu\text{m}^2$ ) and ECC ( $1316 \pm 109\mu\text{m}^2$ ). There was no statistical difference in mean CSA between ECC and CONT, in part because a large number of small regenerating fibers were observed in ECC but interestingly not in ECC+BFR.

**CONCLUSION:** ECC training-induced skeletal muscle hypertrophy is augmented by concomitant BFR which also appears to decrease the presence of small regenerating fibers.

---

**1820 Board #170 May 27 2:00 PM - 3:30 PM****Kinetics of Intramuscular Inorganic Phosphate During Low Intensity Exercise With Blood Flow Restriction**Masato Sugaya<sup>1</sup>, Satoshi Fujita<sup>1</sup>, Riki Ogasawara<sup>1</sup>, Hayao Ozaki<sup>1</sup>, Mikako Sakamaki<sup>1</sup>, Tadashi Suga<sup>2</sup>, Masashi Omokawa<sup>2</sup>, Shingo Takada<sup>2</sup>, Yoshiaki Sato<sup>1</sup>, Koichi Okita<sup>2</sup>, Takashi Abe<sup>1</sup>. <sup>1</sup>University of Tokyo, kashiwa, Japan. <sup>2</sup>Hokusho University, ebetsu, Japan.

(No relationships reported)

Under the same loading condition, dynamic exercise combined with blood flow restriction (BFR) causes more rapid reduction in muscle power (muscle fatigue) than without blood flow restriction. Furthermore, low-intensity resistance exercise combined with BFR causes as much muscle fatigue as that of high-intensity exercise. However, the mechanisms of such exercise induced muscle fatigue with BFR are unknown. Recent studies have suggested that the accumulation of inorganic phosphate (Pi), which accelerates under ischemic exercise, may also contribute to muscle fatigue.

**PURPOSE:** To investigate the kinetics of intramuscular Pi concentration during resistance exercise with blood flow restriction.

**METHODS:** Ten healthy young men ( $24.9 \pm 5.4$  yrs,  $174.4 \pm 7.1$  cm,  $71.1 \pm 10.0$  kg) performed unilateral planter flexion exercise (30 reps  $\dot{A}f_{-1}$  set followed by 15 reps  $\dot{A}f_{-3}$  sets with 30-seconds rest between sets) in a supine position in phosphorus magnetic resonance spectroscopy (MRS system). Each subject underwent three exercise conditions; at low-intensity (20%1-RM) either with (L-BFR) or without (L-CON) blood flow restriction, and high-intensity exercise (HIGH; 70%1RM, 15 reps  $\dot{A}f_{-3}$  sets with 3 min rest between sets) without blood flow restriction. For L-BFR, proximal part of thigh in the exercising leg was pressurized at 220 mmHg with inflexible cuff (5cm wide). Change in intramuscular Pi was monitored continuously during the entire protocol.

**RESULTS:** During exercise, Pi increased progressively and similarly for L-BFR and L-CON group. However, during the rest interval, the rate of decline (recovery rate) was slower in L-BFR such that the % change in Pi was significantly higher in L-BFR than L-CON before the initiation of following set. As a result, the % change in Pi at the end of 4<sup>th</sup> set was significantly higher in L-BFR than L-CON (L-BFR;  $94.0 \pm 30.3$  %, L-CON;  $64.0 \pm 20.2$  %). However, % change in Pi for HIGH was still significantly higher than L-BFR and L-CON.

**CONCLUSIONS:** Low-intensity resistance exercise combined with blood flow restriction induced accumulation of Pi faster than control exercise mainly due to the delayed recovery during the rest periods.

(No relationships reported)

**PURPOSE:** To determine whether low-intensity (LI) blood flow restricted exercise (BFRE) induces delayed-onset muscle soreness (DOMS), and evaluate the contribution of the BFRE concentric (CON) versus eccentric (ECC) actions on DOMS.

**METHODS:** We performed two experiments. In experiment 1, nine subjects ( $25 \pm 5$  yrs) performed 3-sets of unilateral knee extension BFRE (CON and ECC) at 35% of maximal voluntary contraction (MVC) to failure with a proximally located thigh cuff inflated 30% above systolic blood pressure. Subjects repeated the protocol with the contralateral limb without flow restriction. In experiment 2, nine different subjects ( $22 \pm 6$  yrs) performed the aforementioned BFRE protocol with one limb performing only the CON action and the contralateral performing the ECC actions. The following indices of DOMS were assessed before exercise and 24, 48, and 96-hours post: soreness (0-10 scale), algometry (pain-pressure threshold; PPT), MVC and vastus lateralis cross-sectional area (CSA) measured with ultrasound imaging to assess muscle swelling.

**RESULTS:** Experiment 1: BFRE resulted in a 24% reduction in the PPT, an 8-14% reduction in strength and a 4-5% increase in CSA 24-48 hours post-exercise ( $p<0.05$ ). No changes were observed following LI exercise without restriction. Experiment 2: CON BFRE resulted in a 20% reduction in the PPT, and a 3-6% increase in CSA 24-48 hours post-exercise ( $p<0.05$ ). No changes were observed following ECC BFRE.

**CONCLUSIONS:** BFRE induces DOMS, with the CON action contributing more than the ECC. Further investigation into the feasibility of BFRE is warranted, and additional work is needed to determine the mechanism behind BFRE-induced DOMS.

**The Effects Of Differing Thigh Composition On Tissue Oxygenation Of The Quadriceps Following Vascular Restriction**

Jacqueline Escobar<sup>1</sup>, Murat Karabulut<sup>1</sup>, Takashi Abe<sup>2</sup>, Yoshiaki Sato<sup>3</sup>, Michael G. Bembien, FACSM<sup>4</sup>. <sup>1</sup>University of Texas at Brownsville, Brownsville, TX. <sup>2</sup>University of Tokyo, Chiba, Japan. <sup>3</sup>University of Tokyo, Tokyo, Japan. <sup>4</sup>University of Oklahoma, Norman, OK.

(No relationships reported)

KAATSU is a new training technique which can utilize different initial pressures (ranging between 30 and 70 mmHg) prior to an incremental increase in pressure to restrict blood flow during exercise, however it has not been investigated if tissue oxygenation would be affected by the composition of the restricted limb.

**PURPOSE:** To examine the effects of subcutaneous fat and lean muscle mass on tissue oxygenation of the quadriceps muscles while using three different initial restriction pressures.

**METHODS:** Six healthy males (30.0±4.6 years) had their thigh size measured by circumferences, skinfolds, ultrasound, and dual energy x-ray absorptiometry (DXA) to determine volume and thickness of subcutaneous fat and regional bone free muscle mass. Following skin preparation, Near-Infrared Spectroscopy was placed over the mid-thigh to measure tissue oxygenation. The KAATSU belt was placed on the upper most portion of the thigh, and participants then experienced initial pressures of 30, 50, and 70 mmHg in random order on three separate days. Tissue oxygenation was recorded at rest (lying down) once initial pressure was set, then following six pressures (120, 140, 160, 180, 200, and 220 mmHg) were sequentially applied to restrict blood flow for 4-min with 2-min rest periods between trials without pressure. Pearson correlations explored relationships between variables with the level of significance set at 0.05.

**RESULTS:** Correlations between leg LBM and tissue oxygenation were significant and strong ( $r = 0.87$  to  $0.97$ ) when initial pressure was set at 70 mmHg, however, there was only minimal association with subcutaneous fat. A significant positive correlation was detected between tissue oxygenation and thigh circumference at 70 mmHg ( $r = 0.85$ ), however when the restriction pressure was increased, correlations became non-significant and moderate in nature ( $r = 0.58$  to  $0.78$ ). Tissue oxygenation was generally inversely or weakly related to thigh circumference ( $r = -0.62$  to  $0.32$ ), subcutaneous fat ( $r = -0.53$  to  $0.41$ ), and leg LBM ( $r = -0.45$  to  $0.34$ ) when initial pressures were set at 30 and 50 mmHg.

**CONCLUSIONS:** The findings indicated that when using the highest initial restrictive pressure of 70 mmHg, tissue oxygenation was positively correlated with leg muscle mass due to greater blood pooling.

**The Effect Of 4-week Low-intensity Ischemic Training On Quadriceps Size, Performance And Oxygen Availability**

Alan Kacin<sup>1</sup>, Klemen Strazar<sup>2</sup>, Gasper Podobnik<sup>3</sup>. <sup>1</sup>University of Ljubljana, College of Health Studies, Ljubljana, Slovenia. <sup>2</sup>University Clinical Center, Orthopaedic Clinic, Ljubljana, Slovenia. <sup>3</sup>Institute of Oncology, Ljubljana, Slovenia.

Email: alan.kacin@vsz.uni-lj.si

(No relationships reported)

Low-intensity/high-repetition exercise combined with restricted blood flow has been reported effective for increasing muscle mass and muscle strength. In contrast, ischemic exercise has been also shown to have an opposite effect: enhanced muscle aerobic metabolism and endurance capacity.

**PURPOSE:** To evaluate the effect of ischemic training on quadriceps performance, cross-sectional area (CSA) and O<sub>2</sub> availability.

**METHODS:** Ten healthy males trained on a leg-extension machine at loads equal to 15% of maximal voluntary contraction (MVC) force for 16 training sessions. One leg (I-leg) was trained with vascular occlusion induced by cuffs ( $\geq 230$  mmHg), whereas the other leg (C-leg) completed the same training volume without blood flow restrictions. Peak muscle strength was assessed with isometric MVC force, while endurance capacity was evaluated with one control and one ischemic test of repetitive load lifting to volitional failure. Oxygen availability in v. lateralis and activation of rectus f. and v. medialis during the endurance trials were measured with near-infrared spectroscopy and surface EMG. Muscle CSA was measured with a series of slices acquired by MRI. All tests and measurements were performed prior to and after training. Differences in means were tested using factorial ANOVA.

**RESULTS:** After training, a 9±2%, 5±1% and 7±1% increase ( $P < 0.05$ ) in CSA of rectus f., v. lateralis and v. medialis was observed in the I-leg, respectively. There was no change in MVC force in either I-leg or C-leg. Number of repetitions during control endurance test with I-leg and C-leg increased ( $P < 0.01$ ) by 63±9% and 36±8%, respectively. Root mean square EMG amplitudes of all muscles remained similar in both legs. The attained plateau of relative decrease in oxy-haemoglobin was reduced ( $P < 0.01$ ) by 15.7±0.4 µmol in I-leg and 6.7±0.4 µmol in C-leg. In contrast, the mean relative increase in total haemoglobin was higher ( $P < 0.01$ ) by 9.3±0.2 µmol in I-leg and 5.4±0.2 µmol in C-leg. The slope of change in both oxy- and deoxy-haemoglobin at the onset of exercise increased ( $P < 0.05$ ) in both legs, but more in I-leg.

**CONCLUSION:** Ischemic training substantially augments endurance capacity of m. quadriceps, which can be attributed mainly to enhanced muscle blood supply and O<sub>2</sub> availability. Increased muscle CSA may be an index of ischemia-induced capillarisation.

**Influence Of Endurance Training Connected With Intermittent Hypoxia On Muscle Tissue Adaptations**

Bronislav L. Gavenauskas, Iryna N. Mankovska, Valentyna I. Nosar. Bogomoletz Institute of Physiology, Kiev, Ukraine.

Email: btr@biph.kiev.ua

(No relationships reported)

Mechanisms of muscle tissue adaptation to endurance training (ET) under influence of intermittent hypoxic training (IHT) are poorly understood.

**PURPOSE:** To compare muscle tissue adaptations induced by ET combined with IHT to those occurring with ET only at the same relative workload.

**METHODS:** Sixty Wistar rats were divided into 4 groups, defined as follows: 1 - control; 2 - ET: rats were swimming with a load which corresponded to 70-75% VO<sub>2</sub> max for 4 weeks with duration 30 min/day; 3 - IHT: rats were breathing with hypoxic mixture containing 12 % O<sub>2</sub> for 15 min with 15-min rest intervals, 5 times daily; 4 - ET+IHT: rats underwent the IHT sessions, as in III, combined with exercise sessions, as in II, for the last 2 weeks of ET. Physical endurance, maximal oxygen uptake VO<sub>2</sub> max, muscle PO<sub>2</sub> (P<sub>m</sub>O<sub>2</sub>), blood and muscle pH were determined. It was also investigated the muscle metabolic parameters (lactate and pyruvate concentration, lactate/pyruvate and NAD/NADH ratios, succinate dehydrogenase activity, ADP-stimulated mitochondrial respiration).

**RESULTS:** Endurance, VO<sub>2</sub> max, and P<sub>m</sub>O<sub>2</sub> maximally increased (5 times, 16 and 60%, respectively, compared to control) in those animals that simultaneously underwent ET and IHT. After using of the testing intensive physical workload, there was registered in group 1 a significant decrease in P<sub>m</sub>O<sub>2</sub> (from 23.5 ± 2.1 to 16.4 ± 1.9 mm Hg), blood pH (from 7.36 ± 0.012 to 6.88 ± 0.022), and muscle pH (from 6.88 ± 0.031 to 6.23 ± 0.024). The animals in group 4 demonstrated after the testing workload a non-significant decrease in P<sub>m</sub>O<sub>2</sub> (from 39.5 ± 3.3 to 34.8 ± 3.1 mm Hg), blood pH (from 7.32 ± 0.030 to 7.11 ± 0.028), and muscle pH (from 6.86 ± 0.024 to 6.48 ± 0.024). Such testing workload led to the lesser shifts of metabolic parameters witnessing for the tissue hypoxia development in muscle of rats adapted both to IHT and ET than in rats adapted to ET only. ET + IHT led to a mostly expressed increase in the mitochondrial respiration control (V<sub>3</sub>/V<sub>4</sub>) and ADP/O ratio under α-ketoglutarate oxidation compared to those values under succinate oxidation.

**CONCLUSIONS:** Combination IHT with ET is found to be the most productive model for improving oxygen transport to and within muscle cells and increasing the NADH-dependent oxidation pathway role in mitochondrial energy production.

(No relationships reported)

Previous research has demonstrated that blood flow restriction during low intensity resistance exercise (BFR-Low) results in a potent muscle growth response in humans. However, it is unclear whether this stimulus is similar to that provoked with free-flow high intensity resistance exercise (FF-HI).

**PURPOSE:** To determine the acute growth hormone (GH) and insulin-like growth factor (IGF-1) responses to BFR-Low and FF-HI in young adults. Additionally, because BFR may induce adverse reactions we evaluated cardiovascular, endothelial inflammation with vascular cell adhesion molecule (VCAM) and blood coagulation (D-dimer) responses.

**METHODS:** Ten healthy subjects aged 20-39 years reported to the laboratory between 7 and 9 AM on two separate occasions in a fasted condition. Knee extension exercise was performed at 20% of maximal strength for the BFR-Low condition in comparison to a FF-HI performed at 80% of maximal strength. Both conditions were performed for 5 sets until task failure. During BFR-Low exercise, a 10 cm wide tourniquet cuff was placed around the upper thigh at 1.5 systolic blood pressure immediately before exercise and remained inflated (~15 minutes). Blood was sampled every 10 minutes for 150 minutes to assess GH responses and IGF-1 was measured at baseline and 90 minutes post-exercise.

**RESULTS:** Subjects demonstrated a greater mean increase in GH levels with BFR-Low exercise ( $2.1 \pm 2.1$  ng/ml) when compared to FF-HI ( $1.5 \pm 2.6$  ng/ml), but this difference was not statistically different ( $p = 0.61$ ). IGF-1 levels demonstrated no change regardless of the exercise condition. Peak heart rate (HR) and systolic blood pressure (BP) showed similar responses to both conditions (HR: BFR-Low:  $83.8 \pm 12.4$ ; FF-HI:  $84.8 \pm 6.7$  bpm) (SBP: BFR-Low:  $148.8 \pm .9$  vs. FF-HI:  $139.0 \pm 15.6$  mmHg). Peak diastolic blood pressure was elevated to a greater extent during BFR-Low exercise (BFR-Low:  $103 \pm 9.7$ ; FF-HI:  $92.6 \pm 12.4$ ,  $p=0.05$ ). D-dimer, a degradation product of crosslinked fibrin and VCAM levels showed no change 30 min post exercise for either condition.

**CONCLUSIONS:** Resistance exercise performed at low intensity with BFR has a similar systemic acute growth, blood coagulation and endothelial inflammatory response, but greater cardiovascular demand when compared to resistance exercise performed at a high intensity.

**1826 Board #176 May 27 2:00 PM - 3:30 PM****Changes In Tissue Oxygenation And Muscular Function In Response To Vascular Restriction**

Murat Karabulut<sup>1</sup>, David Wittenburg<sup>1</sup>, Yoshiaki Sato<sup>2</sup>, Takashi Abe<sup>3</sup>, Michael G. Bembien, FACS<sup>4</sup>. <sup>1</sup>University of Texas at Brownsville, Brownsville, TX. <sup>2</sup>University of Tokyo, Tokyo, Japan. <sup>3</sup>University of Tokyo, Chiba, Japan. <sup>4</sup>University of Oklahoma, Norman, OK.

Email: murat.karabulut@utb.edu

(No relationships reported)

A single bout of low-intensity resistance exercise (20% 1-RM) combined with vascular restriction (i.e., KAATSU training) takes about 3-5 min to elicit a fatigue response. It has been reported that vascular restriction alone has been used to prevent atrophy, therefore, it would be important to determine how different pressures of blood flow restriction, applied for similar durations, can alter the metabolic demands of skeletal muscle and change muscle function.

**PURPOSE:** To examine the effects of altering vascular restriction pressure of the leg on percent voluntary activation (PVA) of the medial gastrocnemius (MG), tissue oxygenation of the calf muscles, and the electromyographic (EMG) and mechanomyographic (MMG) responses of MG.

**METHODS:** Thirteen young healthy males (Mean  $\pm$  SD age =  $24.6 \pm 5.3$  years; height =  $175.7 \pm 5.3$  cm; weight =  $77.7 \pm 7.5$  kg) performed one maximal isometric voluntary contraction (MVC) of the right plantar flexors at baseline. Then, following 2-min rest, six different pressures (40, 120, 160, 180, 200, 250 mmHg) were sequentially applied to restrict blood flow for 4-min with 2-min rest periods between trials with no pressure. At the end of each pressure setting, a MVC was performed. PVA, EMG and MMG responses were assessed during the twitch interpolation technique and tissue oxygenation was measured by near infrared spectroscopy. A repeated measures ANOVA was used to determine the main effects for trial with the level of significance set at 0.05.

**RESULTS:** The results showed that tissue oxygenation significantly decreased with increasing pressures ( $p < 0.05$ , ranged from 81% to 46%). However, there were no significant changes in MVC torque, PVA, EMG amplitude, EMG mean power frequency (MPF), MMG amplitude, and MMG MPF.

**CONCLUSIONS:** Four minute periods of restricting blood flow to the lower limb with pressures up to 250 mmHg were not sufficient to induce a significant metabolic challenge that would cause changes in muscular function.

**1827 Board #177 May 27 2:00 PM - 3:30 PM****Improved Skeletal Muscle Mechanical Efficiency With Reduced Blood Flow Induced By Pharmacological Blockade**

Luke J. Haseler<sup>1</sup>, Lars Hansen<sup>2</sup>, Robert Boushel<sup>2</sup>, Ylva Hellsten<sup>2</sup>, Bengt Saltin<sup>2</sup>. <sup>1</sup>Griffith University, Queensland, Australia. <sup>2</sup>University of Copenhagen, Copenhagen, Denmark.

Email: L.Haseler@griffith.edu.au

(No relationships reported)

Recent studies have reported that during submaximal exercise under conditions of reduced blood flow, induced by pharmacological blockade of nitric oxide synthase (NOS) and prostaglandin (PG) synthesis, the  $\dot{V}O_2$  of the muscle is reduced for a given power output (Mortensen et al. *J Physiol.* 581: 853-861, 2007).

**PURPOSE:** To test the hypothesis that reduced nitric oxide (NO) and PG availability alters mitochondrial function, resulting in improved mechanical efficiency.

**METHODS:** Seven healthy subjects ( $24 \pm 0.8$  yrs) had catheters placed in the femoral artery of their exercising leg and performed 3 bouts of single leg knee-extension exercise ( $19.5 \pm 1$  W) under the following conditions: (1) Control, (2) L-NMMA (single block), and (3) L-NMMA + Indomethacin (double block). Using <sup>31</sup>P magnetic resonance spectroscopy (MRS), we monitored the levels of phosphocreatine (PCr) breakdown and PCr recovery kinetics of the quadriceps muscles during and after 4 min of dynamic exercise. In the single and double block conditions, L-NMMA (1.0 mg/min/kg leg mass) was infused alone or in combination with Indomethacin (50  $\mu$ g/min/kg leg mass) for 4 min, prior to and during exercise, and for 2 min of the recovery period.

**RESULTS:** There was a reduction in the amount of PCr breakdown in the double block condition compared to the control condition ( $41.2 \pm 3$  vs  $55.8 \pm 4$  % of resting level,  $p < 0.05$ ). No difference was observed in PCr levels between the control and single block condition. PCr recovery kinetics were not different across the 3 conditions.

**CONCLUSION:** Given the relationship between PCr breakdown and muscle  $\dot{V}O_2$ , the data reveal that mechanical efficiency is improved when NO and PG synthesis are reduced by pharmacological blockade. The reduced PCr breakdown and lack of impairment in PCr recovery kinetics in the face of likely reduced muscle blood flow suggests that reduced NO and PG availability improve mitochondrial efficiency.

**Five Week Assessment Of In-water Power Output In Competitive Swimmers**

Brian V. Wright, Chris L. Brammer, Joel M. Stager, FACSM. *Indiana University, Bloomington, IN.*  
Email: bvwright@indiana.edu  
(No relationships reported)

The use of commercially available semi-tethered resistive swim training devices as a means of introducing in-water "overload" during training in competitive swimming is common place. However, only limited research has been completed analyzing the efficacy of such devices as a means to improve performance during a competitive swim season.

**PURPOSE:** To characterize potential differences in power output in competitive swimmers following a 5 week in-water resistive training program.

**METHODS:** 18 competitive swimmers (8 female, 10 male) took part in a 5-week 'in-water' resistive training program utilizing a power rack (i.e. system of pulleys and weights that allows a swimmer to be tethered via waist belt to the resistive load while swimming). Each swimmer completed a pre and post-assessment. The assessment consisted of a series of 10 meter maximal freestyle swimming bouts with an increasing resistive load on each consecutive bout. From there, 80% of peak power was calculated and the corresponding load was utilized for the 5-week training period. Each swimmer completed two training sessions per week (total of 9 sessions). The first session began with 8 repetitions with approximately one minute of rest between each repetition. In each successive week the repetitions were increased by two bouts with the final training session consisting of 16 repetitions. Speed, stroke count and resistance were recorded for each bout.

**RESULTS:** Paired samples t-tests displayed significant ( $p < 0.001$ ) increases in power output (61.4 W vs. 66.1 W) and distance per swim stroke (0.62 m/stroke vs. 0.67 m/stroke) from pre to post assessments. There was no significant difference in swim stroke rate (strokes/second) from pre to post assessment and thus increases in velocity were a function of DPS and not stroke rate.

**CONCLUSION:** The results of this project suggest that in-water resistive training has the ability to increase swimming power output. While improvements in power are important, it is the relationship between the increases in power and swim velocity that interest coaches. The project suggests that training of this nature is capable of improving swim velocity (at least in a tethered condition) via increases in DPS and not swimming stroke rate.

**1829 Board #179 May 27 2:00 PM - 3:30 PM**  
**Unique Aspects Of The Pacing Pattern In 800m Running And 200m Swimming**

Steven J. Vesbach, Jos J. deKoning, FACSM, Alejandro Lucia, John P. Porcari, FACSM, Carl Foster, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*  
Email: foster.carl@uwlax.edu  
(No relationships reported)

The pattern of energy distribution, reflected by movement velocity is thought to be negatively accelerated in 800m running and relatively even in 200m swimming. However, official split times may lack the temporal resolution to fully appreciate the pacing pattern.

**PURPOSE:** This study was designed to make high temporal resolution observations of the pacing pattern in WR performances for 800m running and 200m swimming (time base ~2 min).

**METHODS:** Archival video records of WR performances were reviewed and hand timed, using natural markers in the environment (with official race splits as a correlating factor) to allow measurement of mean velocity at ~12% distance increments (100m and 25m for running and swimming, respectively). Velocity curves were fitted using a best fit polynomial (3<sup>rd</sup> order) and with a simple linear model.

**RESULTS:** The mean (with official split) performances were: 102.28±0.99s (49.72±1.03, 52.49±0.37) for 800m and 104.31±1.04s (25.74±0.98, 25.97±1.03, 26.19±1.14, 26.34±1.32) for 200m. With velocities expressed relative to the mean velocity of the race, using a linear model, both the 800m ( $R^2=0.22$ ) and 200m ( $R^2=0.25$ ) were negatively accelerated, with the negative acceleration more pronounced in the 800m. This pattern persisted even when the opening segment (100m or 25m) was removed. When a best fit model was applied, the 800m ( $R^2=0.42$ ) was described by an overall negatively accelerated biphasic curve, with evidence of an end spurt during the last 100m. For the 200m ( $R^2=0.46$ ), there was evidence of large velocity differences during the first and last 25m of each length of the pool, associated with an increase in speed from the push off and progressively slower free swimming velocities during the last 25m of successive pool lengths.

**CONCLUSIONS:** The results support the concept that the pacing strategy during 800m running and 200m swimming is more complex than reflected by official race splits, and that velocity data with higher temporal resolution may be of considerable value relative to understanding the energy distribution of competition.

**Effects Of 2min Active Recovery On A "Booster" VO<sub>2</sub>Max Test Using Male Cross Country Runners**

Andy Bosak, Daniel Cataldo, Jeremy Yearwood. *Brock University, St. Catharines, ON, Canada.* (Sponsor: David Gabriel, FACSM)  
Email: abosak@brocku.ca  
(No relationships reported)

Maximal aerobic capacity (VO<sub>2</sub>max) tests typically end at the point of volitional exhaustion. However, previous research with averagely fit individuals and highly fit female athletes suggest that concluding a maximal treadmill test with 2min active recovery and allowing subjects to exercise a second time at the workload eliciting volitional exhaustion results in significantly greater VO<sub>2</sub> max values (1.4% and 4.2% mean increase, respectively). The potential effects of this testing sequence (2min recovery) on VO<sub>2</sub>max treadmill tests has not been evaluated utilizing highly fit NCAA male distance runners.

**PURPOSE:** To examine changes in VO<sub>2</sub>max values following 2min of active recovery at the conclusion of a treadmill GXT to volitional exhaustion.

**METHODS:** Ten NCAA Division II male X-country runners completed a max treadmill GXT until reaching volitional exhaustion (MAX1). Immediately following 2min active recovery (at 0% grade & 2.5 mph), each subject exercised to volitional exhaustion a second time (MAX2). MAX1 and MAX2 were compared using a paired T-test. Differences were considered significant at  $p < 0.05$ .

**RESULTS:** No significant differences ( $p = 0.38$ ) occurred between MAX1 ( $64.7 \pm 3.8$  ml/kg/min) and MAX2 ( $64.2 \pm 4.8$  ml/kg/min). The mean change from MAX1 to MAX2 following 2min active recovery was -0.8% with individual values ranging from -7.7% to +2.6%. However, 50% of the subjects benefited (+1.4% mean increase) from the booster test with individual increases of +0.2% up to +2.6%.

**CONCLUSION:** Mean results suggest that 2min active recovery may not allow significantly greater VO<sub>2</sub> max values to be achieved by highly fit male runners during treadmill testing, yet 50% of the subjects increased their VO<sub>2</sub>max during the "booster max" treadmill protocol. Further research is needed to determine if fitness level, running experience, age, sport specificity, or other variables might affect this exercise testing protocol.

**1831 Board #181 May 27 2:00 PM - 3:30 PM**  
**Comparison Of Coach Vs Athlete Ratings Of Training: Effect Of Sex And Performance Ability**

Carl Foster, FACSM, Lisa Wedekind, Rebecca A. Battista, Richard Pein, Carrie Needham, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*  
Email: foster.carl@uwla.edu  
(No relationships reported)

Previous studies demonstrate a disparity between coaches training plans and athletes training, with athletes often working hard on coach intended easy days, and unable to work hard on coach intended heavy days.

**PURPOSE:** We compared training duration, intensity and cumulative training load between coach and swimmers, and whether differences were related to sex or performance ability.

**METHODS:** NCAA Division III swimmers (13males, 15females), trained by the same coach, recorded training over 6 weeks during the middle of the season. For each practice the coach rated the intended training duration, intensity and Load using the Session RPE method. The athletes rated each training session independently, as well as reported any non-coach prescribed exercise. Athlete performance was ranked by national qualifiers (NQ) (n=6), conference point scorers (CPS) (n=12), conference participants (CP) (n=10).

**RESULTS:** Although, for coach vs all swimmer comparisons, there was no significant difference in the mean training Load (442+314 vs 416+4-6,  $R^2=0.38$ ), duration (79+49 vs 77+66 min,  $R^2=0.44$ ) or RPE (4.1+2.8 vs 3.4+3.0,  $R^2=0.44$ ), the  $R^2$  values were rather low. There were no differences in the coach vs athlete matching of training patterns attributable to gender or swimming ability. Differences in the execution of training were attributable to missing training sessions secondary to illness or study, but were not different in relation to sex (males=17.2%, females=15.6%) or swimming ability (NQ=17.2%, CPS=15.6%, CP=17.7%) or to performing unscheduled recreational exercise not accounted for in the coaches plan, in relation to sex (males=13.6%, females=15.6%) or swimming ability (NQ=15.2%, CPS=16.5%, CP=12.5%).

**CONCLUSIONS:** Despite a successful competitive season (36%NQ + 43% CPS), the execution of the coaches training plan was generally unsatisfactory. These results suggest that strategies to better correlate athlete execution of the coaches training plan might augment performance.

**1832 Board #182 May 27 2:00 PM - 3:30 PM**  
**Age-related Performance Decrements In Elite Age-group Triathletes**

Vince Nethery, David Derkacs, Robert Pritchett, Leo D'Acquisto. *Central Washington Univ., Ellensburg, WA.* (Sponsor: Peter A Harmer, FACSM)  
Email: netheryv@cwu.edu  
(No relationships reported)

Highly trained age-group triathletes vie for the few coveted slots for World Championships by competing at selected qualifying events around the world. However, little is known about age-related performance decrements in elite multi-discipline endurance sports such as triathlons.

**PURPOSE:** To determine the magnitude and rate of decline in overall and sub-discipline triathlon performance across an 18-70yr age-span in males and females (n=70 per age group).

**METHODS:** Completion time, along with swim, bike, and run performances of the top five finishers in each age category at world-championship "Ironman 70.3" qualifying events (n=14) were retrospectively assessed. Age-group completion time and split times for swim (1.9km), cycle (90.1km), and run (21.1 km) components were compared (ANOVA-Bonferroni post-hoc). Absolute and relative differences among age groups were calculated and comparisons made between males and females at each age level.

**RESULTS:** Age impacted triathlon performance ( $p=0.0001$ ), however decrements were not evident until age 45yrs for either completion time or for any sub-component performance, for either gender. Performance decrements (per half-decade) for the 45yr and older age groups were smaller for cycling (4-7%) than for either running (7-13%) or swimming (7-24%), with an ordinal relationship noted between age and percent decrement per half-decade. For each age group, males were consistently faster than females in both overall and in sub-components (12% to 20%) with greater differences in the older age categories.

**CONCLUSIONS:** Highly trained males and females maintained endurance performance into the fifth decade of life. Overall performance declined nonlinearly after age 45yrs, with the more complex motor skill swim and the weight-bearing impact-oriented run showing greater declines than the mechanically constrained and low-impact cycling component. Performance-based analysis of world-class age group athletes offers a unique opportunity to investigate the relationship between aging and exercise capacity.

**1833 Board #183 May 27 2:00 PM - 3:30 PM**  
**Upper Extremity Power Characteristics In Men's National Team Gymnasts**

Jeni McNeal<sup>1</sup>, William A. Sands, FACSM<sup>2</sup>, Michael H. Stone<sup>3</sup>. <sup>1</sup>Eastern Washington University, Cheney, WA. <sup>2</sup>United States Olympic Committee, Colorado Springs, CO. <sup>3</sup>East Tennessee State University, Johnson City, TN.  
(No relationships reported)

Men's gymnastics is a highly upper-body strength and power dominant sport. However there is a paucity of information about the upper-body power characteristics of this population. This information is necessary for developing monitoring and talent identification programs for this sport.

**PURPOSE:** The purpose of this study was to compare the upper-body power characteristics of men's national team gymnasts in three explosive push-up tasks, mimicking the static, countermovement, and drop jumps typically used for assessing lower extremity power.

**METHODS:** U.S. Men's Gymnastics Junior and Senior National Teams (n = 16) performed two trials each of single maximal-effort push-up tests on a force platform (1000Hz). The push-up tests included a static push-up (SP) performed with the gymnasts starting in the fully flexed down position of a pushup and then propelling themselves upward and away from the force platform. For the counter-movement push-up test (CMP) the gymnasts started in the extended push-up position, and then performed a counter-movement to push away from the force platform. Finally, the drop push-up (DP) involved the athletes dropping from raised surfaces (36.5 cm), one under each hand, onto the force platform. They then propelled themselves upward as quickly as possible after hand contact. Repeated measures ANOVAs were performed on 4 power variables derived from the force-time record.

**RESULTS:** Lower values for vertical velocity, push height of flight, and peak power were observed for the CMP (1.44±0.88 m/s, 0.14±0.12 m, 1066.8±438.1 W) and SP (1.61±0.64 m/s, 0.15±0.11 m, 1181.7±397.9 W) compared to DP (3.35±1.17 m/s, 0.64±0.54 m, 2752.4±869.1 W), ( $p < 0.001$ ), but did not differ from each other. Peak force was similar between the CMP and DP, but greater when compared to the SP.

**CONCLUSION:** The comparisons showed the importance of a rapid stretch-shortening cycle in upper body power performance in men's national team gymnasts.

**Imposing A Theoretical Optimal Pacing Strategy Compared To Self-paced Competition In 1500-m Speed Skating**

Florentina J. Hettinga<sup>1</sup>, Jos J. De Koning, FACSM<sup>1</sup>, Leanne Schmidt<sup>1</sup>, Nienke Wind<sup>1</sup>, Brian R. MacIntosh, FACSM<sup>2</sup>, Carl Foster, FACSM<sup>3</sup>. <sup>1</sup>Research Institute Move, Faculty of Human Movement Sciences, VU University, Amsterdam, Amsterdam, Netherlands. <sup>2</sup>University of Calgary, Calgary, AB, Canada. <sup>3</sup>University of Wisconsin-LaCrosse, LaCrosse, WI.  
Email: floor.hettinga@tno.nl  
(No relationships reported)

**PURPOSE:** Humans are well equipped to adequately choose the right pace on a specific effort, such as a 1500-m speed skating. The purpose of the present study was to investigate if a theoretically optimal pacing profile, overriding self-paced strategy, yielded better performance.

**METHODS:** 7 national level speed-skaters performed a self-paced 1500 m and a 1500 m with an imposed pacing strategy. The races were analyzed by obtaining velocity (every 100 m) and body position (every 200 m) to calculate total mechanical power output. Together with gross efficiency and aerobic power output, obtained in separate trials, data were used to calculate anaerobic power output profiles. An energy flow model was applied to the 1500-m self-paced trial and a range of pacing strategies was simulated for each individual by varying the distribution of anaerobic energy ( $P_{an}$ ) over time ( $t$ ). Athletes were instructed to skate more like the theoretically optimal pacing profile and resulting performance was compared to self-paced performance.

**RESULTS:** Confirming previous results, the energy flow model predicted a faster start strategy to be optimal. However, final times of the imposed strategy trials were about 2 s slower than self-paced performance ( $115.39 \pm 4.45$  s vs  $117.29 \pm 3.53$  s). Total power distribution per lap differed, with a higher value over the first 300 m for the imposed strategy ( $637.0 \pm 49.4$  W vs.  $612.5 \pm 50.0$  W). All parameters of anaerobic power distribution over time, described by a mono-exponential equation, did not differ (self-paced:  $P_{an} = 102.2 + 673.0 * e^{(-0.056 * t)}$  vs. imposed:  $P_{an} = 91.6 + 710.9 * e^{(-0.054 * t)}$ ). The effort of a faster first lap resulted in a changed skating position. The summation of increased knee- and trunk-angles resulted in a higher aerodynamic drag coefficient throughout the race.

**CONCLUSION:** Without appropriate training, imposing a theoretically optimal pacing profile does not lead to better performance. An imposed fast start has relatively large consequences on speed skating technique, affecting work per stroke and aerodynamics negatively. Since the ability to maintain body position is an important performance determining factor in skating, a predefined movement where body weight has to be carried continuously, it might be beneficial to train this aspect of performance combined with pacing strategy.

---

**1835 Board #185 May 27 2:00 PM - 3:30 PM**  
**Performance Comparison Of The Cartwheel Vs Glide Shot Put Techniques**

Nate Lawton<sup>1</sup>, Jeni McNeal<sup>1</sup>, William Sands, FACSM<sup>2</sup>. <sup>1</sup>Eastern Washington University, Cheney, WA. <sup>2</sup>US Olympic Training Center, Colorado Springs, CO.

(No relationships reported)

An emerging technique in the shot put is the use of a cartwheel prior to release, such as a gymnast would use to generate horizontal velocity in tumbling. It is hypothesized that the position of the body at landing may result in a large muscular stretch-shortening response in the trunk, which combined with the horizontal velocity generated by the cartwheel may lead to greater velocity of the shot at release thus increasing horizontal distance.

**PURPOSE:** The purpose of this study was to compare the kinematics of the cartwheel (CW) and glide (G) techniques in the shot put in three female heptathletes.

**METHODS:** Three individual case studies were performed. Subjects put a 4 kg women's indoor shot for all trials. Each subject received extensive training in the CW technique and all were deemed proficient in this technique prior to data collection. Ten trials of each technique were completed on separate days. All trials were videotaped (60 Hz), and the horizontal distance of each trial were recorded. Performances were digitized (Peak Motus) and release variables calculated. Descriptive statistics of mean, standard deviation, and coefficient of variation for each subject were used to compare the variables of release height, angle, and velocity, and horizontal distance of all 60 trials.

**RESULTS:** All subjects experienced their single best throw using CW (6.49, 6.04, 8.77 m) compared to G (5.35, 5.89, 8.63 m). Subject 2 showed decreased variation of performance suggesting increased performance stability with CW compared to G. Across the 10 trials, average release height in the CW (2.14, 2.6, 2.44 m) was greater than the G (1.86, 1.84, 2.23 m), as was release angle (CW 17.9°, 14.4°, 33.6° vs G 14.1°, 12.5°, 30.3°) for all subjects.

**CONCLUSION:** The cartwheel technique shows promise as a beneficial technique for heptathletes. Further research is needed to determine performer characteristics and applicability of this technique.

**Relationship Between Laboratory Testing And On-ice Skating Performance In Division I Men'S Hockey Athletes**

Jeffrey A. Potteiger, FACSM, Dean L. Smith, Mark Maier, Tim Foster. *Miami University, Oxford, OH.*

Email: potteija@muohio.edu

(No relationships reported)

**PURPOSE:** Few data exist examining the ability of laboratory testing of strength and anaerobic power to predict on-ice skating ability. We examined the relationship between off-ice laboratory testing and on-ice skating performance in Division I men's hockey athletes.

**METHODS:** 21 males ( $20.7 \pm 0.35$  years) participated in the assessment of body composition, isokinetic quadriceps and hamstring strength, and anaerobic muscle power via Wingate 30 s cycle ergometer test. Air displacement plethysmography was used to determine % body fat (%FAT), fat-free mass (FFM), and fat mass (FM). Peak torque and total work during 10 maximal effort repetitions at  $120^\circ \text{s}^{-1}$  was measured during concentric muscle actions using a Cybex isokinetic dynamometer. Muscle power was measured using a computerized Monark cycle ergometer with flywheel resistance set at 7.5% of body mass. On-ice skating performance was measured during six timed 87.78 m sprints with subjects wearing full hockey equipment. On-ice linear momentum was calculated from the skating test. Correlation coefficients were used to determine relationships between laboratory testing performance and on-ice performance.

**RESULTS:** Subjects weighed  $88.4 \text{ kg} \pm 1.75 \text{ kg}$  and were  $11.6 \pm 1.02$  %FAT. A significant correlation was found between Wingate peak anaerobic power ( $1302.8 \pm 185.1$  W) and on-ice linear momentum ( $1077.2 \pm 104.4 \text{ kgm s}^{-1}$ ),  $r(19) = .73$ ,  $p = .0002$ . Other significant correlations were observed between Wingate average anaerobic power per kilogram body mass ( $11.7 \pm 0.9$  W) over the first 10 seconds and the average on-ice sprint time ( $7.97 \pm 0.22$  s),  $r(19) = -.51$ ,  $p = .019$  and peak anaerobic power per kilogram body mass ( $14.8 \pm 1.5$  W) and average on-ice sprint time ( $7.97 \pm 0.22$  s),  $r(19) = -.43$ ,  $p = .049$ . The first five seconds of average power on the Wingate test per kilogram body mass ( $12.8 \pm 1.1$ ) and average on-ice sprint time ( $7.97 \pm 0.22$  s) was also significant,  $r(19) = -.55$ ,  $p = .01$ .

**CONCLUSIONS:** Several measures of anaerobic power were significantly correlated to on-ice skating performance. It is possible to predict on-ice skating performance from common laboratory measures of anaerobic muscle power.

**Age-related Performance Declines In Men's Freestyle Swimming Events**

James M. McKenzie, Earl W. Scofield, Joel M. Stager, FACSM. *Indiana University, Bloomington, IN.*

Email: mckenzmj@indiana.edu

(No relationships reported)

Routine, daily exercise has been shown to decrease mortality and morbidity risk in older adults (Pateron, Jones, and Rice, 2007), however the role of continued exercise on athletic performance is less clear. Athletic performance is expected to decrease dramatically during the sixth decade of life (Tanaka and Seals, 2003), but more research is needed to determine how long athletic performance can be maintained.

**PURPOSE:** This analysis was designed to determine the relationship between age and freestyle swim performance in men.

**METHODS:** Data was collected from the 'Top Ten' times for 2006 and 2007, as reported on the United States Masters Swimming website (usms.org). Times from 6 freestyle events (short course yards) were collected for 13 age groups, from 25-29 years old, and in 5 year increments up to 85-89 years old. Data were analyzed using a two-way ANOVA with SPSS.

**RESULTS:** Statistical analysis found swim times of 25 year olds up to 54 year olds in the 50 yd and 200 yd freestyle were the same. The 100 yd freestyle showed equivalent swim times for age 25 to 64. The 500, 1000 and 1650 yd freestyle events had equivalent swim times for ages 25 to 59. Swimmers older than these ranges showed increasing

rates of decline in performance. The individual events showed significant differences in the age\*distance interaction. Regression analysis found an increasing rate of decline as race distance increased (range of 0.0607 to 2.0064 s · yr<sup>-1</sup>).

**CONCLUSIONS:** Swimmers are able to maintain athletic performance into their 50s, and into the 60s for the 100 yd freestyle. This data supports maintenance of athletic performance well into middle age with consistent exercise. A previous study of Masters Track Athletes found significant differences for each decade of age after 30 (Baker, Tang, and Turner, 2003). In contrast, these results show no significant differences until at least 55 years old. The age range with equivalent performances was shared by the longer distance events (500 - 1650 yd), however there was no consistent pattern for age-related changes as indicated by the significant age\*distance interaction. Performance appears to be better preserved in the shorter distance events based on the regression analysis of each event.

**A Method To Obtain Instantaneous Power Output Data Of Athletes During Competition**

Jos J. de Koning, FACSM<sup>1</sup>, Carl Foster, FACSM<sup>2</sup>. <sup>1</sup>VU-University, Amsterdam, Netherlands. <sup>2</sup>University of Wisconsin-La Crosse, La Crosse, WI.

Email: j.dekoning@fbw.vu.nl

(No relationships reported)

**BACKGROUND:** During high level competition humans are approaching their power output (PO) limits. Performance depends not only on the produced amount of energy but also on how the energy is distributed, the pacing strategy. There is limited data available on how energy is distributed during competition. To understand how humans use their energetic resources it would be useful to combine velocity data with data on technique so that instantaneous PO can be approximated.

**PURPOSE:** To develop a method to approximate the instantaneous PO of athletes during competition.

**METHODS:** During the 2002 Winter Olympics from all male speed skaters (n=47) in the 1500m competition high resolution velocity data with optical tracking technology (Sportvision, USA) and video data in the sagittal plane (collected 2 x per lap) were collected. Trunk and knee position from the video data together with mass and height were used in existing models to obtain aerodynamic characteristics of the skaters. An Energy Flow Model was constructed for each skater and optimization techniques were used to approximate PO parameters in order to fit the high resolution velocity data.

**RESULTS:** On average the 1500m was skated in 107.77s (SD±2.0). We were able to reproduce the observed velocity profiles of the skaters with our optimized Energy Flow Model. The calculated instantaneous PO (in Watt) of the skaters at the 1500m can be described with the first order expression:  $PO = 376 + 648 * e^{(-0.063 * t)}$ , with  $t$  is time. When the best 10 skaters were compared to the performers ranked 20<sup>th</sup> to 30<sup>th</sup> ( $PO_{best10} = 393 + 710 * e^{(-0.058 * t)}$  vs.  $PO_{20-30} = 386 + 631 * e^{(-0.069 * t)}$ ) it became clear that best performances on the 1500m were reached with a pacing strategy, in which a higher PO was generated in the beginning of the race. The difference in time between both groups (105.33s ±0.63 vs. 108.37s ±1.61) was mainly caused by a higher velocity of the faster group in the first half of the race.

**CONCLUSION:** It was possible to approximate instantaneous power output by means of an Energy Flow Model, with high resolution velocity data and aerodynamic characteristics of the skaters as input variables.

**Comparison Of Monitoring Tools For Training Intensity In Swimmers**

Julie K. Johnson, Rebecca A. Battista, Richard Pein, Chris Dodge, Carl Foster, FACSM. University of Wisconsin - Lacrosse, La Crosse, WI.

(No relationships reported)

Blood lactate concentration [BL] and respiratory gas exchange are widely used to prescribe athletic training intensity. However, whether intensity thresholds defined from these measurements are interchangeable is relatively unknown.

**PURPOSE:** The purpose of this study was to determine the relationship between the [BL] threshold and the ventilatory threshold (VT) in swimmers.

**METHODS:** Division III collegiate swimmers (8 male, 7 female, aged 19.7 ± 1.5 years) performed an incremental tethered VO<sub>2</sub> test and an incremental 6 x 200-m swim to measure [BL]. The VT and respiratory compensation threshold (RCT) were detected using the v-slope method and confirmed by ventilatory equivalents. [BL] threshold was determined as the first inflection in the [BLa]-velocity curve as well as the interpolated speed at [BL]=4mmol\*l<sup>-1</sup>. Heart rate (HR) threshold was defined as a percentage of maximum HR. Velocity and power output were calculated for each of the 200m swims.

**RESULTS:** Comparing the individual HR corresponding to VT, RCT, and LT, there was no significant relationship between HR at LT and VT ( $r = 0.21$ ) or between LT and RCT ( $r = 0.17$ ). There was a moderate correlation ( $r = 0.60$ ) between the percent of maximum velocity at LT (92% ± 4.0) and VT (84% ± 5.0). The percent of maximum power at LT (77% ± 9.0) was significantly correlated with both percent maximum power at VT (57% ± 9.0,  $r = 0.72$ ) and RCT (66% ± 7.0,  $r = 0.64$ ). In contrast, no significant correlation was found between any of the thresholds in terms of percent of maximum HR.

**CONCLUSION:** These results suggest that LT, VT, and RCT represent individually separate swimming training intensities and are not broadly interchangeable. However, the significant relationship between LT and VT, represented as a percent maximum swimming velocity or swimming power, suggests that further exploration be performed on the topic of monitoring training intensity with physiological thresholds.

**1840 Board #190 May 27 2:00 PM - 3:30 PM**  
**Comparisons Of Relationships To Bone Mineral Density In Division III Female Collegiate Athletes.**

Rebecca A. Battista, Larissa Dreyer, Chris Dodge, Carl Foster, FACSM. University of Wisconsin - Lacrosse, La Crosse, WI.

Email: battista.rebe@uwla.edu

(No relationships reported)

While participation in sport and activity has positive influences on bone other factors are hypothesized to affect bone mineral density including dietary influences and menstrual cycle changes.

**PURPOSE:** The purpose of this study was to determine the association between dietary intake and menstrual cycle fluctuations to bone mineral density (BMD) in Division III collegiate female athletes.

**METHODS:** Fifty-three female collegiate athletes (aged 20.1 ± 1.1 years) from three different sports (swimming, gymnastics, basketball) were measured once during their respective pre-season training. Measures included dual energy X-ray absorptiometry to determine total BMD and bone mineral content (BMC). Height (cm), weight (kg), and age of menarche were also measured. All athletes completed a 24 hour dietary recall with prompting questions and food models and data was analyzed using ESHA Food Processor for total calories and calcium intake. Finally, use of oral contraceptives and menstrual cycle regularity over the course of one year was recorded. Pearson correlations were calculated and a step wise regression was performed to determine potential predictors of BMD. Additional comparisons were made between outcome variables and sport, use of oral contraceptives, and menstrual cycle regularity.

**RESULTS:** Significant relationships were found between BMD and weight, calcium, and BMC. Step wise regression analysis revealed the only significant predictor of BMD was weight ( $r=0.40$ ,  $r^2=0.16$ ). BMC was the only significant relationship that was maintained when separated by sport. ANOVA ( $P < 0.05$ ) determined that BMD, BMC, height, and weight were significantly different between sports with basketball players having the highest BMD, BMC, and being the tallest and heaviest. Comparisons by use of oral contraceptives and regularity of menstrual cycle revealed no significant differences.

**CONCLUSIONS:** These observations are similar to others suggesting a relationship between high loading sports and bone mineral density. However, while other studies suggest a relationship between dietary intake and menstrual cycle regularity to BMD, none was found in this study. Nonetheless, further information regarding the influence of these variables to

Email: dfergu14@unc.edu

(No relationships reported)

With the growing popularity of the National Association for Stock Car Auto Racing (NASCAR) there is a demand for skilled pit crew athletes that will aid in the success of NASCAR teams. There is limited information regarding the physiological demands and subsequent effect on the performance of pit crew athletes.

**PURPOSE:** The goal of this study was to determine the heart rate (HR) and core temperature (CT) response to race situations in pit crew athletes.

**METHODS:** HR and CT of pit crew athletes (n=6) were measured during six NASCAR Sprint Cup races using ingestible sensors (HQ Inc.). The HR and CT measurements were made before the race began, every 15 mins after the start of the race, and immediately after each pit stop.

**RESULTS:** The data showed that during the race, as compared to baseline, CT increased  $0.78 \pm 0.26^\circ\text{C}$  and HR increased  $23 \pm 16$  bpm as compared to baseline (both  $p < 0.001$ ).

Discussion: The increase in CT and HR in pit crew athletes during a Sprint Cup race could have a negative effect on performance.

**What Dictates The Self Selection Of Recovery Time In Multiple Repeat Sprint Training?**

Gregory B. Dwyer, FACSM<sup>1</sup>, Gavin Moir<sup>1</sup>, Mark Glaister<sup>2</sup>. <sup>1</sup>East Stroudsburg University, East Stroudsburg, PA. <sup>2</sup>St Marys College, Twickenham, United Kingdom.

Email: gdwyer@po-box.esu.edu

(No relationships reported)

Recent research has investigated the dynamics of multiple repeat sprint training (MSRT). There are many applications of this modality to coaching and performance (e.g., Work:Rest intervals). The impact of self-selection of the recovery interval time on various physiological indices has yet to be explored.

**PURPOSE:** To explore the effect of self selection of recovery times on various intensity indices during repeat sprint running.

**METHODS:** Twenty physically active males (age=21.3±2.3) performed four separate bouts of 12 repeated 30 yard sprints (spt) with a self-selected recovery time (SSREC) between each sprint. Only data from bout four is presented in this abstract. Each SPT and REC was timed using photocells. In addition, the subject wore a downloadable heart rate monitor and was asked their rating of perceived exertion (RPE; 6-20 scale) after sprints 3, 6, 9 and 12. A maximal treadmill exercise test was administered within one week of the MRST for the determination of various aerobic capacity measures (e.g.,  $\text{VO}_{2\text{max}}$ ).

**RESULTS:** Three distinct groups emerged based upon the recovery (REC) data collected; specifically the pattern and coefficient of variation (CV) of the REC times. Those three groups were: I steady SSREC (n=3), II increasing SSREC (n=12) and III variable SSREC (n=5). The data table follows:

Group	Ave SPT time (sec)	Ave REC time (sec)	delta RPE (spt 3 to 12)	HR Rec % (delta HR REC / REC time)	$\text{VO}_{2\text{max}}$ (ml/kg/min)	REC CV (sec)
I	4.31±.07	73.49±12.59	1.06±.24	0.31±.11	51.07±5.54	6.37±2.62
II	4.40±.16	76.21±13.95	0.50±.26	0.32±.12	56.22±6.54	15.45±2.10
III	4.52±.31	83.09±13.97	0.27±.18	0.30±.07	45.15±1.80	24.54±4.56

\* delta RPE significantly different ( $\alpha < .05$ ) by groups using Kruskal-Wallis statistical test.

**CONCLUSION:** The RPE appeared to influence the self-selection of recovery time more so than did other measured indices. It was the change in RPE over time that seemed to influence SSREC. However, RPE did not appear to correlate well with the intensity of the MSRT. Metabolic data (e.g., Blood Lactates) may further elucidate this relationship.

**1843 Board #193 May 27 2:00 PM - 3:30 PM**

**Identification Of Bias In The Natural Progression Of Swim Performance**

Christopher L. Brammer, David A. Tanner, Joel M. Stager, FACSM. Indiana University, Bloomington, IN.

Email: brammerc@indiana.edu

(No relationships reported)

The longitudinal progression of athletic records has been described by best fit curves which can be used to extrapolate future athletic performances. Any subsequent significant deviations from these curves would suggest compelling evidence of cataclysmic changes introduced into the sport.

**PURPOSE:** We evaluated elite swim performances to determine if bias can be identified within competitive swimming.

**METHODS:** The fastest eight men and women performances of Olympic swimming events from 1972 through 2004 were analyzed. Using the mean time across all years, a best-fit power curve [ $\text{time} = a \cdot \text{year}^b$ ] was calculated for each swim event. These equations were used to predict the finish time of the 2008 Olympics. A 95% confidence interval was established about the mean to determine if actual times were faster or slower than predicted. A binomial test of statistical significance was used to test whether or not the year as a whole was above or below the prediction line ( $p < 0.05$ ). These procedures were repeated for each of the previous five Olympic Games.

**RESULTS:** In 2008, 26/26 (100%) events were below the prediction line and 17/26 (65%) events were faster than predicted. However, for the previous five Olympics combined, only 11/122 (9%) events were faster and 10/122 (8%) events were slower than predicted. In 2000, 20/26 events were below the predicted values. In contrast, 20/24 events in 1996 were above the predicted values.

**CONCLUSIONS:** It is expected that swim performances improve over time and we have shown that they do so in a predictable manner. These results indicate a bias has been identified for the 2000 and 2008 Olympic Games such that these performances were faster than predicted. Conversely, the 1996 Games were slower than predicted.

**1844 Board #194 May 27 2:00 PM - 3:30 PM**  
**Age Classification In Usa Swimming Are Current Competitive Age Groups Appropriate?**

Kosuke Kojima, Christopher L. Brammer, Joel M. Stager, FACSM. *Indiana University, Bloomington, IN.*  
 Email: [kokojima@indiana.edu](mailto:kokojima@indiana.edu)  
 (No relationships reported)

Age classification in youth sports is an attempt to equalize competition, to enhance the chances of success, and to reduce the risk of injury associated with size and strength mismatches for all participants. USA Swimming has established 4 unisex age-groups according to chronological age (CA). The groups are composed of plural CAs; 10 yrs & under, 11-12, 13-14, and 15 yrs & over. However, due to considerable differences in growth and maturational status among adolescents within any given CA, by combining swimmers of different CA into a group the opportunity to compete equally may simply not be so.

**PURPOSE:** The aims of the study were to evaluate the current age classifications enforced by USA Swimming and to potentially provide a statistical rationale for proposing alternative age classifications.

**METHODS:** Performances were acquired through the website of USA Swimming for the top U.S. 100 men and women swimmers for each age (5 yrs to 20 yrs and >21 yrs) over the last 3 years. Data for each age were pooled and averaged for 3 separate distances (50-, 100-, and 200-yard freestyle). A  $17 \times 2 \times 3$  (age  $\times$  sex  $\times$  distance) ANOVA with Tukey's post-hoc test was used to analyze differences in performance between swimmers of different CA and to provide potential age classifications.

**RESULTS:** Significant differences ( $p < 0.01$ ) in mean times between all ages were revealed up to 13, 13, and 14 yrs in women in the 50-, 100-, and 200-yard freestyle, respectively. When collapsing distance, differences were found up to 14 yrs, and 3 homogeneous subsets were identified between the ages of 15 and 20 yrs (15-16, 16-18, and 17-20 yrs) in women swimmers. For the men, differences were found up to 15, 16, and 16 yrs old for three distances, respectively. As collapsing distances, there were differences up to 16 yrs old. Three subsets (17-18, 18-19, and 19-20 yrs) were also demonstrated in men swimmers.

**CONCLUSIONS:** Because differences in performance exist among swimmers within the current defined age groups (11 year-old vs. 12 year-old for example), stratifying swimmers using a single CA may be a better method for insuring fairness and equality in competition. The significant differences in swim time disappear at a younger age in women when compared to men, which may be due to sex differences in growth and maturational timing.

**1845 Board #195 May 27 2:00 PM - 3:30 PM**  
**Comparing Practice And Game Heart Rate Response In Women's College Ice Hockey Players**

Julianne M. Vasichek, John R. Keener, FACSM, Kenneth J. Harkins, Duane Millsagle. *University of Minnesota Duluth, Duluth, MN.*  
 Email: [jvasiche@d.umn.edu](mailto:jvasiche@d.umn.edu)  
 (No relationships reported)

Ice hockey competition requires players to use all energy systems within intermittent work and rest periods. Collegiate coaches try to mimic energy use during practice while addressing tactical aspects of team play. These coaches must consider 2-4 practices and 2-3 games per competition week, for a seven-month period, with 3-5 weeks of no competition. Coaches must also avoid under or over-training athletes.

**PURPOSE:** Compare cardiovascular demands of ice hockey practices to games in collegiate women's ice hockey athletes.

**METHODS:** During a 5-day competition week, twelve elite Division I women's ice hockey players were monitored in 3 on-ice practice sessions, 1 off-ice anaerobic bike session, and 2 competitions. Athletes wore Suunto heart rate monitors. The participants were forwards (n=6), defensemen (n=5), and goaltender (n=1). Not all players participated in all sessions, though (n=90%) in each session. Maximum heart rate (HR max) was determined as the highest on-ice heart rate achieved.

**RESULTS:** All analysis was performed with Suunto Team Manager Software. Mean percentages were based on individual total session times. During practice, these times varied due to extra tactical work and with games remained the same for everyone. The mean percentage of time spent at percent of HR max are listed as follows:

	>90%	90-80%	80-70%	70-60%	<60%
Practice 1	1	18	23	23	26
Bike Sprints	1	31	40	20	1
Practice 2	0	10	20	21	41
Practice 3	1	15	20	23	41
Game 1	10	28	29	26	8
Game 2	7	25	23	33	14

**CONCLUSION:** A significant percentage of time was spent in >90% HR max and 90-80% HR max in games then practices. The bicycle sprints achieved a greater percentage of time at 90-80% and 80-70% then practices and games. Continued research is needed to determine results over a greater amount of sessions and to avoid possible detraining effects occurring in-season.

**1846 Board #196 May 27 2:00 PM - 3:30 PM**  
**Vo<sub>2peak</sub> Validation Using A Scifit™ Arm Ergometer And Relationship To Performance In Trained Swimmers.**

Tim A. Muth, Ian K. Ratz, Mike A. Busa, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.*  
Email: tmuth@emich.edu  
(No relationships reported)

Upper body exercise is an important factor in training and exercise prescription in various populations, therefore it is important that we can properly quantify performance as well as provide a means for accurate, consistent testing. Arm ergometry provides professionals the ability to measure metabolic changes in populations who have partial or complete loss of function in the lower extremities (e.g. paraplegics). Arm ergometry may also be a useful testing/training approach for athletes that primarily utilize upper body musculature (e.g. swimmers).

**PURPOSE:** Using trained swimmers, to determine if the Upper Body Ergometer (Pro II Arm Ergometer; SciFit, OK) is i) an accurate and reliable device for the determination of  $VO_{2peak}$ , ii) to determine if there was a training effect in an incremental  $VO_{2peak}$  protocol and iii) to determine the relationship between  $VO_{2peak}$  obtained using this device and swimming performance

**METHODS:** Ph 1: To determine validity and reliability, trained male swimmers ( $n = 8$ ;  $28.5 \pm 9.5$  yrs) performed two incremental protocols ( $VO_{2peak}$ ) consisting of a four min warm-up at 15W followed by two min at 50W and progressing 10W every two min until volitional exhaustion. Ph 2: Inter-collegiate Division I swimmers ( $n=8$ ), also performed a 400 m swim trial following a  $VO_{2peak}$  to determine the relationship between  $VO_{2peak}$  using this ergometer and swim performance. Pearson's product correlations, ANOVA and reliability were calculated using SPSS 15.0 (SPSS Inc., IL;  $\alpha=0.05$ ).

**RESULTS:** There was a linear relationship between workload and  $VO_2$  in all trials ( $R = .96$ ;  $p \leq .01$ ) while Cronbach's alpha for test-retest reliability for  $VO_2$  was .98. There were no significant differences in performance by trial in WL ( $p = .272$ ) or  $VO_2$  ( $p = .151$ ). Swimming performance times showed moderately strong negative correlation with  $VO_{2peak}$  ( $R = -.692$ ;  $P = .039$ ).

**CONCLUSIONS:** SciFit Pro II Arm Ergometer is an accurate and reliable device for determination of  $VO_{2peak}$  in trained swimmers and there was no training effect when using this device. The relationship between performance time and  $VO_{2peak}$  determined on this ergometer indicated it may be of value as a dry land training device for collegiate swimmers.

**1847 Board #197 May 27 2:00 PM - 3:30 PM**  
**Comparison Of A Monark Cycle Ergometer And A Velotron In Measuring Physiologic Responses In Trained Cyclists.**

Laura Vedeen, Kristen M. Lagally, FACSM, Dale D. Brown, FACSM, David Q. Thomas, FACSM. *Illinois State University, Normal, IL.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the power output and physiological responses of trained cyclists to maximal oxygen uptake testing ( $VO_{2max}$ ) on a standard laboratory cycle ergometer (i.e. Monark) and cyclist-specific designed ergometer (i.e. Velotron).

**METHODS:** Thirty trained cyclists performed a  $VO_{2max}$  test on both cycle ergometers. Test order was counterbalanced between the Monark and Velotron. Initial power output for both tests was 100 Watts and power output increased by 20 Watts every minute until volitional fatigue. Oxygen uptake, ventilation, heart rate, and ratings of perceived exertion (RPE) were monitored throughout the tests. Paired t-tests were used to examine differences in  $VO_{2max}$ , maximum heart rate (HRmax), peak power output (PPO), ventilatory threshold (VT), heart rate at VT (HRvt), power output at VT (POvt), and RPE between the two maximal tests.

**RESULTS:** Results indicated that PPO ( $p = 0.001$ ) and POvt ( $p = 0.013$ ) were significantly higher when cyclists were tested on the Velotron (PPO =  $326 + 65$  W, POvt =  $243 + 54$  W) compared to the Monark (PPO =  $310 + 59$  W, POvt =  $234 + 46$  W). There were no significant differences in  $VO_{2max}$ , HRmax, HRvt, VT or RPE between the two ergometers.

**CONCLUSIONS:** The primary finding was that cyclists achieved a higher power output at maximal and threshold intensities when tested on the Velotron. When using PO to determine changes in performance or establish training intensities, cyclists should be tested on an ergometer that most closely resembles their personal riding mechanics.

**Does Acute Stretching Modify A Surfer's Ability To Keep A Teetering Board Horizontal?**

Joke Kokkonen<sup>1</sup>, Arnold G. Nelson, FACSM<sup>2</sup>. <sup>1</sup>BYU Hawaii, Laie, HI. <sup>2</sup>Louisiana State University, Baton Rouge, LA.  
(No relationships reported)

**PURPOSE:** Since the sensitivity of the stretch reflex is influenced by acute stretching activities, it was questioned whether an acute stretch would influence a surfer's ability to maintain a teetering board at the horizontal position.

**METHODS:** Ten male surfers with more than two years of experience did three trials of four 30 s tests on a stabilometer on four separate days. The test criterion was the average time during the three 30 s trials that each subject could keep the stabilometer at 180°. Each subject balanced with their feet either parallel (PR) or perpendicular (PD) to the stabilometer's axis of rotation. PR and PD were both done following either 30 minutes of quiet sitting (non-stretched, NS) or 30 minutes of stretching activities (stretched, S). Stretching exercises consisted of various assisted and unassisted static stretches of the hamstring, quadriceps and calf muscle groups.

**RESULTS:** Improved flexibility following the stretching exercises was demonstrated by significant ( $p < 0.05$ ) increases in each subject's sit-and-reach for both PR-S ( $6.5 \text{ cm} \pm 1.6$ ) and PD-S ( $6.4 \text{ cm} \pm 2.0$ ). Balance time was not significantly different following the stretching regimen for either the PR-NS vs. PR-S ( $27.5 \text{ s} \pm 3.5$  vs.  $27.3 \text{ s} \pm 4.2$ ), or the PD-NS vs. PD-S ( $20.1 \text{ s} \pm 6.2$  vs.  $23.2 \text{ s} \pm 5.8$ ).

**CONCLUSIONS:** Even though acute stretching reduces the stretch reflex, this reduction was insufficient to alter the surfer's ability to maintain a teetering board at the horizontal position. Apparently, experience in maintaining balance on an unsteady surface can overcome any loss in peripheral proprioception.

**1849 Board #199 May 27 2:00 PM - 3:30 PM**  
**Comparison Of Single And Multi-sport Athletes' Performance On The Y Balance Test**

Joni T. McFelea<sup>1</sup>, Phillip J. Plisky<sup>1</sup>, Kyle Kiesel<sup>1</sup>, Paul Gorman<sup>2</sup>, Mitchell J. Rauh<sup>3</sup>. <sup>1</sup>University of Evansville, Evansville, IN. <sup>2</sup>ProRehab-PC, Evansville, IN. <sup>3</sup>Rocky Mountain University of Health Professions, Provo, UT.  
Email: jm476@evansville.edu  
(No relationships reported)

**PURPOSE:** To compare Y Balance Test scores in high school athletes that compete in one sport compared to a similar group of high school athletes who compete in multiple sports.

**METHODS:** These data are part of a larger scale study that is examining Y Balance Test scores in athletes in various sports and competition levels. Ninety-two high school athletes that participated in only one sport were matched, by gender and sport played, to athletes who participated in multiple sports. All athletes completed informed consent and were free from injury at the time of testing. Each athlete performed the Y Balance Test protocol that examines lower extremity reach distance during unilateral stance in the anterior, posteromedial, and posterolateral reach directions. The greatest reach distance of three trials in each reach direction was used for analysis. All reach distances were normalized to limb length. One-way ANOVAs were performed to examine differences between the single sport and multiple sport athletes.

**RESULTS:** While no significant differences existed for height and weight between the two groups ( $p > 0.05$ ), single sport athletes were older than multiple sport athletes by 6 months on average ( $p < 0.05$ ). For the Y Balance Test scores, no significant differences were observed for any of the reach distances when normalized to limb length ( $p > 0.05$ ). In addition, no significant differences were found when making bilateral comparisons for the specific reach directions ( $p > 0.05$ ).

**CONCLUSIONS:** Participating in multiple sports does not appear to improve performance on distance reach score for any of the three reach directions on the Y Balance Test.

**1850 Board #200 May 27 2:00 PM - 3:30 PM**  
**No Change In Muscular Endurance, Flexibility, Anaerobic Power, And Recovery After Ingesting Oxygen Enhanced Water**

Scott N. Drum, Christina A. Buchanan. *Western State College of Colorado, Gunnison, CO.*

Email: sdrum@western.edu

(No relationships reported)

Adequate oxygen utilization is necessary to properly recover from an exhaustive anaerobic exercise bout, enhance performance related to muscular endurance and flexibility, or to aid in recovery. On this premise, additional oxygen uptake may augment overall performance and recovery and is a major claim of Perfect Empowered Drinking Water™ (PH<sub>2</sub>O) (London, UT).

**PURPOSE:** To investigate the purported claims of PH<sub>2</sub>O, including enhanced performance and recovery during strength, flexibility, and anaerobic power exercise.

**METHODS:** This was a randomized, double-blind, placebo controlled trial in which eight moderately trained, male cyclists performed push-ups to fatigue (PU) set to a metronome (25 reps/minute), sit and reach (S&R), total body rotation on right and left sides (TBRR and TBRL, respectively), arm pull on right and left sides (APR and APL, respectively), and two, 30-second Wingate tests (W1 and W2) separated by a 90-second active and 90-second passive recovery on three separate occasions under the following conditions: control (C), tap water (TW), and PH<sub>2</sub>O. Four ounces of water (either TW or PH<sub>2</sub>O) were ingested prior to the strength and flexibility tests, then again prior to and within 60-seconds after W1. Comparisons between conditions were conducted using a one-way ANOVA with significance set at  $p < 0.05$ .

**RESULTS:** Subject characteristics (mean  $\pm$  SD) included age ( $28.0 \pm 6.0$  years), height ( $178.0 \pm 5.4$  cm), and body weight (BW) ( $73.0 \pm 6.7$  kg). No significant differences between conditions were observed. TBRR ( $18.3 \pm 6.6$  inches), average power W1 ( $655.3 \pm 55.5$  Watts (W) and  $9.0 \pm 0.8$  W/kg BW), and average power W2 ( $520.1 \pm 112.0$  W) were greatest with C. PU ( $37.3 \pm 9.1$  reps), TBRL ( $17.9 \pm 5.4$  inches), APR ( $11.6 \pm .7$  rating of perceived exertion (RPE)), APL ( $11.8 \pm .7$  RPE), peak power W2 ( $1324.0 \pm 141.7$  W and  $18.4 \pm 2.9$  W/kg BW), and average power W2 ( $7.6 \pm 0.5$  W/kg BW) were greatest with TW. S&R ( $13.9 \pm 4.4$  inches), and peak power W1 ( $1490.3 \pm 145.1$  W and  $20.8 \pm 3.6$  W/kg BW), were greatest with PH<sub>2</sub>O.

**CONCLUSION:** Results indicated that ingestion of oxygen rich water before and after specific types of exercise did not significantly improve performance, including enhanced recovery between two Wingate cycle tests separated by 3-minutes of active/passive recovery. However, on several parameters, PH<sub>2</sub>O seemed to induce a greater mean score.

**1851 Board #201 May 27 2:00 PM - 3:30 PM**  
**Cardiac Autonomic Responses To Repeated Shuttle Sprints**

Fábio Y. Nakamura<sup>1</sup>, Lúcio F. Soares-Caldeira<sup>1</sup>, Paul B. Laursen<sup>2</sup>, Marcos D. Polito<sup>1</sup>, Lucas C. Leme<sup>3</sup>, Martin Buchheit<sup>4</sup>. <sup>1</sup>Universidade Estadual de Londrina, Londrina, Brazil. <sup>2</sup>Edith Cowan University, Joondalup, Australia. <sup>3</sup>Unopar/Sercomtel Handball Team, Londrina, Brazil. <sup>4</sup>Picardie Jules Verne University, Amiens, France.

Email: fabioy\_nakamura@yahoo.com.br

(No relationships reported)

Team sport match play requires athletes to perform a number of repeated shuttle sprints. However, the acute effects of these repeated sprint sequences on lactic acidosis and resulting autonomic state perturbation are not known.

**PURPOSE:** To observe and compare the blood lactate and post-exercise cardiac autonomic responses of a repeated shuttle-sprint ability test (RSSA test) with the 30-15 Intermittent Fitness Test (30-15<sub>IFT</sub>); the latter test representing a standard for exhaustive supramaximal effort.

**METHODS:** Thirteen adult team sport players performed the RSSA test and 30-15<sub>IFT</sub> on separate days in a counter-balanced order. The RSSA test consisted of six repetitions of maximal 2 x 15 m shuttle sprints (~5 s) departing every 20 s, while 30-15<sub>IFT</sub> involved progressive 30 s shuttle runs interspersed with 15 s of passive recovery until exhaustion. Blood lactate was measured before and after the tests, while autonomic responses were assessed using immediate heart rate (HR) recovery (e.g., HRR<sub>60s</sub>) and heart rate variability (HRV) indices.

**RESULTS:** Peak blood lactate ( $10.6 \pm 2.1$  vs.  $10.2 \pm 2.8$  mM) and HRR<sub>60s</sub> ( $36.4 \pm 7.8$  vs.  $39.3 \pm 7.9$  bpm) were similar after both the RSSA test and 30-15<sub>IFT</sub>. With the exception of the vagal-related time-varying root mean square of successive R-R interval differences at each 30 s, which recovered earlier after the RSSA test compared with 30-15<sub>IFT</sub>, all HRV indices decreased similarly after both tests in comparison to baseline values.

**CONCLUSIONS:** the RSSA test was shown to induce comparable levels of lactic acidosis and post-exercise autonomic state as the 30-15<sub>IFT</sub>. These levels of metabolic and autonomic states are likely to occur during team sport match play.

---

**Influence Of Recovery Duration Following A Potentiating Stimulus On Muscular Power In Recreationally Trained Individuals**

Eddie Jo, Daniel A. Judelson, Lee E. Brown, FACSM, Jared W. Coburn, Nicole C. Dabbs, Brandon P. Uribe. *California State University, Fullerton, Fullerton, CA.*

Email: eddyjo22@gmail.com

(No relationships reported)

**PURPOSE:** Athletes competing in explosive sports often experience temporarily increased muscular power following a heavy load exercise called postactivation potentiation (PAP). Previous research examining recreationally trained individuals (RTI), however, shows mixed results under similar conditions. As the balance between PAP and fatigue mechanisms following a heavy load exercise influences the overall outcome, the recovery duration following the stimulus might explain the inconsistent results noted in RTI. Therefore, the purpose of this study was to investigate the effect of recovery duration following a potentiating stimulus on muscular power in RTI.

**METHODS:** Seven male RTI (age =  $24 \pm 4$  y, height =  $173.8 \pm 10.7$  cm, mass =  $90.1 \pm 28.2$  kg, 1RM to body mass ratio =  $1.4 \pm 0.3$ ) with at least one year of back squat experience completed six experimental trials. The first session assessed subjects' height, mass, and 1RM on the parallel back squat. The second session (control) assessed subjects' baseline power measures on a 30 s Wingate Test using 7.5% of baseline body mass as resistance. For sessions 3-6, subjects performed a potentiating exercise (1 set of 5 repetitions at 85% 1RM), rested for 5, 10, 15, or 20 min, and performed an identical Wingate Test. Subjects experienced rest durations in randomized order on separate days.

**RESULTS:** No significant differences ( $p > 0.05$ ) existed among control and experimental trials in absolute peak power, absolute average power, relative peak power, relative average power, and fatigue index.

**CONCLUSIONS:** These results indicate that a heavy load squat protocol known to stimulate PAP in competitive athletes failed to induce PAP in RTI regardless of rest duration. This suggests that discrepancies in previous literature describing RTI cannot be explained by differences in recovery period among studies. RTI might display these inconsistencies because "recreational training" encompasses a wide spectrum of training intensities, i.e. better trained RTI might demonstrate PAP similar to athletes while less advanced RTI fail to experience similar benefits. In conclusion, heavy load squats did not improve subsequent performance following any rest periods, suggesting that the effectiveness of potentiating stimuli does not vary as a function of fatigue in recreationally trained individuals.

**1853 Board #203 May 27 2:00 PM - 3:30 PM****Trimp Methodological Issues. A New Accurate Methodology**

Carlos González-Haro<sup>1</sup>, Iñigo San Millán<sup>2</sup>, José Manuel González-de-Suso<sup>3</sup>, Piero Galilea<sup>4</sup>. <sup>1</sup>*School of Medicine (University of Zaragoza), Zaragoza, Spain.* <sup>2</sup>*University of Colorado Sports Medicine Center and University of Colorado Hospital, Denver, CO.* <sup>3</sup>*Real Sociedad de Fútbol SAD, San Sebastián, Spain.* <sup>4</sup>*Sant Cugat del Vallés Olympic Training Center (CAR), Sant Cugat del Vallés, Spain.*

Email: ghcarlos@gmail.com

(No relationships reported)

Training impulse concept (TRIMP) uses a fixed exponential function to quantify aerobic training load, and modified TRIMP (TRIMP<sub>mod</sub>) uses an individual exponential function to quantify more accurately.

**PURPOSE:** To compare workload quantification between TRIMP, TRIMP<sub>mod</sub> and a new proposed methodology.

**METHODS:** 20 amateur road cyclists (AC), 20 Pro Tour cyclists (PC), 19 young soccer players (YS), and 19 elite rowers (ER), performed a maximal progressive test until exhaustion. Heart rate (HR), and blood lactate concentration ([La<sup>-</sup>]) were measured throughout the tests. TRIMP and TRIMP<sub>mod</sub> were calculated. A polynomial equation which fit the best to the relation [La<sup>-</sup>]-%HR<sub>max</sub> was used as a new methodology to calculate TRIMP<sub>fit</sub>. A theoretical exercise duration of 60 min was used in all cases. Three methodologies were compared at 2 specific points (LT, OBLA). Coefficient of determination (R<sup>2</sup>) was calculated in order to establish the equation that fit the best. All variables were analyzed by one-way ANOVA.

**RESULTS:** The R<sup>2</sup> of polynomial equations (3<sup>rd</sup> to 5<sup>th</sup> degree) to calculate TRIMP<sub>fit</sub> was significantly higher than the R<sup>2</sup> of the exponential equations to calculate TRIMP<sub>mod</sub> (R<sup>2</sup> = 0.8285 ± 0.1189 vs. 0.9835 ± 0.0270, respectively) (p<0.01). TRIMP has a tendency to underestimate TRIMP<sub>mod</sub> and TRIMP<sub>fit</sub>. Furthermore, TRIMP<sub>mod</sub> has a tendency to overestimate TRIMP<sub>fit</sub> at lactate threshold (LT) exercise intensities. At higher intensities (OBLA), TRIMP<sub>fit</sub> is overestimated or underestimated depending of athletes' adaptation of athletes to maximal exercise.

	TRIMP		TRIMP <sub>mod</sub>		TRIMP <sub>fit</sub>	
	LT	OBLA	LT	OBLA	LT	OBLA
AC	73 ± 19 <sup>a</sup>	203 ± 40 <sup>c, e</sup>	101 ± 21 <sup>a, b</sup>	240 ± 0 <sup>c, d</sup>	82 ± 25 <sup>b</sup>	345 ± 178 <sup>d, e</sup>
PC	113 ± 25	194 ± 30 <sup>g, h</sup>	117 ± 34 <sup>f</sup>	240 ± 0 <sup>g</sup>	97 ± 40 <sup>f</sup>	249 ± 80 <sup>h</sup>
YS	114 ± 18 <sup>i</sup>	188 ± 22 <sup>k, m</sup>	133 ± 28 <sup>i, j</sup>	240 ± 0 <sup>k, l</sup>	115 ± 32 <sup>j</sup>	217 ± 46 <sup>l, m</sup>
ER	115 ± 19 <sup>n, p</sup>	151 ± 25 <sup>q, s</sup>	162 ± 31 <sup>n, o</sup>	240 ± 0 <sup>q, r</sup>	136 ± 32 <sup>n, p</sup>	194 ± 34 <sup>r, s</sup>

a, b, g, i, k, n, q, r, s p<0.001; c, e, f, h, j, m, o p<0.01; d, l, p p<0.05.

**CONCLUSION:** The polynomial equation that fits the best to the [La<sup>-</sup>]-%HR<sub>max</sub> relation is the most accurate way to calculate TRIMP<sub>fit</sub>.

---

**1854 Board #204 May 27 2:00 PM - 3:30 PM****Warm-up And Physical Performance: What Is The Relationship? A Systematic Review With Meta Analysis**

Andrea Fradkin<sup>1</sup>, Tshami Zazryn<sup>2</sup>, James Smoliga<sup>3</sup>. <sup>1</sup>*Bloomsburg University, Bloomsburg, PA.* <sup>2</sup>*Monash University, Frankston, Australia.* <sup>3</sup>*Marywood University, Scranton, PA.* (Sponsor: Eric Rawson, FACSM)

Email: afradkin@bloomu.edu

(No relationships reported)

Although the practice of warm-up is widely used, the value of completing one is a worthy research question. At present, it is not known whether warming-up is benefiting, harming, or having no effect on individuals.

**PURPOSE:** To review the existing scientific evidence relating performance to warm-up.

**METHODS:** A systematic review and meta analysis was undertaken. Relevant studies were identified by searching Medline, SPORTDiscus, and PubMed (1966 - April 2007). This review included studies that investigated the effects of warming-up on performance improvement in physical activities. Studies were included only if the participants were human, and only if the warm-up included activities other than just stretching. Studies reported in languages other than English were not included. The quality of included studies was assessed independently by two assessors using the PEDro scale.

**RESULTS:** 32 studies, all of high quality (6.5 - 9 (mean = 7.6) out of 10 on the PEDro rating scale) reported sufficient data (quality score >6) on the effects of warming-up on improving performance in humans. Warm-up was shown to improve performance in 79% of the criterions examined.

**CONCLUSION:** This analysis has demonstrated that performance improvements can be demonstrated following completion of adequate warm-up activities. This review has also shown that there is little evidence to suggest that warming-up is detrimental to sports participants. Further well-conducted randomised controlled trials are needed to determine the role of warming-up prior to exercise in relation to performance improvement.

**B-37 Free Communication/Poster - Worksite Interventions**

MAY 27, 2009 1:00 PM - 6:00 PM

ROOM: Hall 4F

---

**1855 Board #205 May 27 3:30 PM - 5:00 PM****The Effects Of A Multi-level Physical Activity And Health Promotion Intervention On A Group Of Females In The Worksite Setting**

Cameron L. Troxell, Jeanne D. Johnston, Whitney Hornsby, Abigail Laymon, Anne P. Massey. *Indiana University Bloomington, Bloomington, IN.*

(Sponsor: Georgia C. Frey, FACSM)

(No relationships reported)

Worksite health programs may be an effective manner to reach the general population in an effort to promote increased physical activity and improve health. Furthermore, multilevel interventions targeting multiple behaviors have been shown to be more effective than a single approach.

**PURPOSE:** To analyze the impact of a multilevel physical activity intervention on physical activity and cardiovascular risk factors in the worksite population.

**METHODS:** Subjects included 16 female university employees aged 43.5 years  $\pm$  16.1 who participated in a weekly class tailored to increase physical activity (Active Living Every Day) while utilizing a wireless accelerometer device and a web-based tracking program. Height, weight, body mass index (BMI), percent body fat (%BF) and blood pressure were determined via standard procedures at baseline and at the end of the program. Physical activity was quantified through the use of a wireless accelerometer. A repeated measures ANOVA was utilized to examine differences between baseline and post intervention.

**RESULTS:** The mean pre-intervention BMI was 34.3  $\pm$  9.5 placing 88% of subjects into either the overweight or obese category. A significant decrease in diastolic blood pressure (79.4 $\pm$ 10.2 to 75.8 $\pm$ 8.8), weight (90.0 $\pm$ 24.6 to 87.5 $\pm$ 23.7) and BMI (34.3  $\pm$  9.5 pre to 33.4 $\pm$ 9.3) were noted from baseline to post-intervention. Values for %BF and systolic blood pressure decreased and physical activity increased; however, these changes were not significant.

**CONCLUSION:** Our results indicate that the multilevel physical activity intervention was successful at reducing cardiovascular risk factors such as body weight, diastolic blood pressure, and BMI; however, considering the limited number of participants, further research is needed to determine if this approach will be consistent within the general worksite population.

**A Hospital-based Wellness Program: Effects On Employees' Sickness-related Absenteeism**

Gianfranco Stupar<sup>1</sup>, Auro Gombacci<sup>1</sup>, Cesarina Listuzzi<sup>2</sup>, Natalia Rosignoli<sup>3</sup>, Kyriakos Tsapralis<sup>1</sup>, Riccardo Zero<sup>1</sup>. <sup>1</sup>Trieste Sports Medicine Center, Trieste, Italy. <sup>2</sup>Azienda Ospedaliero-Universitaria "Ospedali Riuniti" Trieste, Trieste, Italy. <sup>3</sup>Azienda Ospedaliero-Universitaria "Ospedali Riuniti" Trieste, Trieste, Italy.

Email: stupar@alice.it

(No relationships reported)

"Ospedali Riuniti", an Italian public hospital with 1400 beds and 3000 employees, has implemented a health promotion program ("Wellness Program"), which aims to improve employees' Wellness.

The program, medically led by a Sports Medicine specialist, is multitasking-structured and organized into five so-called Activities, strongly linked together: Fitness, Nutrition and Metabolism, Smoke-Out, Mind&Body and Kids' Wellness.

**PURPOSE:** To assess a possible reduction in sickness-related absences (SRA) between employees enrolled in the program.

**METHODS:** a sample of 200 employees, enrolled in the program and participating to the programs' activities for a two years period, were monitored for their sickness-related absences from work for a period of four months before ( $t_0$ ) and after ( $t_1$ ) their program participation. SRA were divided into two categories: short length (SL; 0-3 days) and long length (LL; 4 days or more).

**RESULTS:** we observed a decrease in SRA of employees involved in the activities of the program. In  $t_1$ , employees with no SRA raised from 50 to 55% of the sample; employees with SL decreased from 25% to 12%. Days of SL-SRA were reduced by 42.9%; days of LL-SRA were reduced by 12.7%.

**CONCLUSION:** our data support previous scientific evidence of a valuable reduction of SRA following the implementation of multifactorial, wellness-oriented, health promotion programs in the workplace; we remark the importance of a well designed evaluation process as a part of the core strategy of any workplace health promotion program.

**Women Health Care Workers' Response To Coaching Intervention To Reduce Chd And Stroke Risk Factors**

Tomas Green<sup>1</sup>, Cresendo Eldridge<sup>1</sup>, Michele Hunnicutt<sup>1</sup>, Jaya Paraniham<sup>1</sup>, Leif Peterson<sup>1</sup>, Tinker Murray, FACSM<sup>2</sup>. <sup>1</sup>The Methodist Hospital, Houston, TX. <sup>2</sup>Texas State University, San Marcos, TX.

(No relationships reported)

**PURPOSE:** To determine the efficacy of a free onsite employee wellness coaching program as an intervention for promoting healthy lifestyle changes in women to lower their targeted health risks associated with the onset of CHD and stroke.

**METHODS:** Employees (N=63, age = 43 $\pm$ 10.8) were selectively evaluated for this study after their participation in the 2006 and 2007 annual employee health fairs. The inclusion criterion for participation was subjects have a BMI  $\geq$  25 and at least one more CHD health risk factor. They also had to be willing to participate for 26 weeks in the Healthy Lifestyle Coaching program. During the health fair, each employee completed a health risk appraisal, finger prick blood draw, and biometric assessments. The 6 month intervention required each participant to attend a 30 minute weekly coaching session with an ACSM Certified Wellness Coach. Data were analyzed for baseline and post assessments for BMI, weight, waist girth, total cholesterol, HDL cholesterol, LDL cholesterol, triglycerides, glucose, and blood pressure.

**RESULTS:** A Bonferroni-corrected t-test analysis revealed significant differences ( $p < 0.005$ ) in BMI (34.3  $\pm$  6.0 to 32.4  $\pm$  5.5), weight (202.3  $\pm$  42.8 to 189.8  $\pm$  36.9), waist girth (40.8  $\pm$  6.2 to 38.0  $\pm$  5.2), total cholesterol (201.8  $\pm$  38.5 to 189.2  $\pm$  34.6), systolic blood pressure (126.8 $\pm$ 10.5 to 120.7 $\pm$ 12.3), and diastolic blood pressure (81.6  $\pm$  8.3 to 77.1  $\pm$  9.8). Although there was no statistical significant change in, HDL cholesterol, LDL cholesterol, and triglycerides, each of these variables improved.

**CONCLUSIONS:** Study results demonstrate that a work-site coaching intervention is an effective resource to help women modify lifestyle behaviors directly related to CVD. Further research is needed to determine work-site coaching effectiveness in alternative working environments, and the sustainability of positive lifestyle changes.

Email: fstoler@att.net

(No relationships reported)

**PURPOSE:** To measure the effect of a university based worksite wellness program on clinical outcomes in female participants from baseline to 12 weeks, and at follow-up; and to examine differences in week 12 outcomes between those who did and did not return for follow-up

**METHODS:** Female subjects (N=78; age = 47.96  $\pm$  8.75) participated in a 12-week, university-based wellness program that consisted of 12 weekly group sessions and three individual sessions on topics related to nutrition, physical activity, and behavior modification. Body weight, BMI, waist (WC) and hip (HC) circumferences, systolic and diastolic blood pressures (SBP, DBP), percent body fat, total cholesterol (TC) and non-fasting glucose were measured at baseline, week 12 and follow-up. Follow-up was done at one point in time which represented six, nine, or 12 months after intervention; 54 subjects returned compared with 24 who did not return. Univariate analyses were used for each of the clinical outcome measures.

**RESULTS:** All subjects improved at the end of the 12-week intervention with reductions in: body weight (1.70  $\pm$  2.44 kg,  $p < 0.001$ ), BMI (0.63  $\pm$  0.90,  $p = 0.000$ ), SBP (2.33  $\pm$  8.80 mm/Hg,  $p = 0.005$ ), DBP (1.70  $\pm$  7.76 mm/Hg,  $p = 0.016$ ), WC (2.87  $\pm$  3.15 cm,  $p < 0.001$ ), HC (2.20  $\pm$  2.68 cm,  $p < 0.001$ ) and percent body fat 0.55  $\pm$  2.02,  $p = 0.006$ ). Weight reduction at week 12 was positively correlated with BMI ( $r = 0.997$ ,  $p = 0.01$ ), WC ( $r = 0.388$ ,  $p = 0.01$ ), and HC ( $r = 0.522$ ,  $p = 0.01$ ). Those that returned for follow-up had a lower mean body weight at baseline (190.8 lbs  $\pm$  44.7) and week-12 (187.7 lbs  $\pm$  44.6). There was a significant interaction for HC in those that returned for follow-up compared to those who did not return ( $p = 0.002$ ). Those that returned for follow-up ( $n = 57$ ) had a decrease in HC from week 1 to 12 of 1.61 cm ( $\pm 2.25$  cm) compared to a greater decrease of 3.58cm ( $\pm 3.11$  cm) for those who did not return.

**CONCLUSIONS:** The worksite wellness program had a positive impact on improving clinical outcome measures in females after the 12-week intervention. For those who returned for post-intervention follow-up, there was maintenance of the improvements from the end of the program. For those who did not return for follow-up, they may have experienced recidivism.

**Impact Of Worksite Health Promotion On Corporate Environmental Health, Culture And Individual Employee Health Risks**

Gabrielle Foley, Cassandra Hoeibel, Mya Swanson, Jonathan Crossley, Joan M. Dorn. *University at Buffalo, Buffalo, NY.*

Email: gsfoley@buffalo.edu

(No relationships reported)

**PURPOSE:** Western New York Wellness Works (WNYWW) is a community-based research initiative designed to examine the individual, cultural, and environmental outcomes of self-directed programming in diverse, small- to medium-sized organizations.

**METHODS:** An RFP was released and applicants responded with proposals for two year worksite wellness interventions that demonstrated evidence of employee need and interest, proof of organizational commitment, and 1-to-1 matched funding of up to \$25k/year. Individual, cultural, and environmental outcomes were measured by individual health risk appraisals (HRA), individual health culture assessments (HCA), and organizational Heart Check Plus (HCP), respectively. Pre-post comparisons of HCP were examined for all organizations that completed the initiative and for individuals who completed HRAs and HCAs (n pre = 1472; n post = 1721).

**RESULTS:** 10 organizations, representing 6895 employees completed the initiative. Aggregate analyses revealed overall organizational environmental improvements (37.6% to 66.3%,  $p < 0.001$ ) as well as significant improvements in HCP environmental components including smoking, nutrition and physical activity (all  $p < 0.01$ ). Positive cultural changes included significant increases in % of employees who reported their co-workers expect each other to exercise regularly (pre=37.2%, post=44.6%,  $p < 0.001$ ), maintain a healthy weight (pre=44.7%, post=50.2%,  $p < 0.01$ ), eat nutritious foods (pre=41.8, post=47.1,  $p < 0.01$ ) and eat foods low in fat/sugar (pre=39.9%, post=44.8%,  $p < 0.05$ ). As measured through the HRA, a higher percentage of employees were aware of their blood pressure (pre=57.1%; post=61.8%,  $p < 0.05$ ) and cholesterol (pre= 45.4%; post=50.0%) ( $p < 0.05$ ) and were non-smokers (pre=81.0%, post=86.0%,  $p < 0.01$ ) but no significant changes were noted for BMI, physical activity or dietary intake of fat or fiber.

**CONCLUSIONS:** Our findings indicate that the WNYWW self-directed health promotion programs were effective in changing worksite environments, corporate culture and employees' risk factor knowledge, but that significant changes in individual health behaviors may require more intense intervention than those undertaken by the participating companies.

**Comparison Of Accelerometer And Physical Activity Questionnaire Data In Middle-aged Women**

Kelley K. Pettee<sup>1</sup>, James J. McClain<sup>2</sup>, Kristi L. Storti<sup>3</sup>, Chong D. Lee<sup>4</sup>, Barbara E. Ainsworth, FACSM<sup>1</sup>. <sup>1</sup>University of Nebraska Medical Center, Omaha, NE. <sup>2</sup>National Cancer Institute, Bethesda, MD. <sup>3</sup>University of Pittsburgh, Pittsburgh, PA. <sup>4</sup>Arizona State University, Mesa, AZ.

Email: kpettee@unmc.edu

(No relationships reported)

**PURPOSE:** To compare physical activity (PA) estimates from two accelerometer-based prediction equations with PA questionnaires (PAQ) designed for use in middle-aged women.

**METHODS:** Data were obtained from the Evaluation of Physical Activity Measures in Middle-Aged Women study. Participants included 66 women [(mean  $\pm$  SD), aged 52.6  $\pm$  5.4 years] who wore an ActiGraph accelerometer daily, for 35 consecutive days and completed four PAQs: 1) past week (PW) and 2) past month (PM) modifiable activity questionnaire (MAQ), 3) Nurses' Health Study (NHS) and 4) Women's Health Initiative (WHI) PAQs. Volume of PA, in MET-h/wk, was estimated from accelerometer data using the Freedson et al. and Swartz et al. prediction equations. PAQ summary scores are in MET-h/wk. Spearman rank order correlation coefficients ( $\rho$ ) were used to compare accelerometer and PAQ derived MET-h/wk. Percent (%) error of the PAQs was calculated as  $[(\text{PAQ} - \text{accelerometer}) / \text{accelerometer}] * 100$ . All summary data are presented as median (25<sup>th</sup>, 75<sup>th</sup> percentiles).

**RESULTS:** MET-h/wk for the accelerometer data using the Freedson and Swartz equations were 11.4 (8.9, 12.7) and 17.3 (13.9, 19.0), respectively. MET-h/wk scores for the PMMAQ, PWMAQ, NHS and WHI PAQs were 24.8 (10.7, 38.0), 21.9 (9.3, 35.8), 23.5 (12.0, 44.3), and 19.3 (10.5, 33.4), respectively. All PAQs were related to the Freedson derived MET-h/wk estimates [ $\rho = 0.28$  to  $0.49$  (all  $p < 0.03$ )], with the strongest associations observed with both MAQ versions. All PAQs, except the WHI, were associated with the Swartz derived MET-h/wk estimates [ $\rho = 0.27$  to  $0.44$  (all  $p < 0.03$ )], with the strongest association observed with the PWMAQ. All PAQs overestimated the Freedson derived MET-h/wk, with median % error ranging from 60.6 to 101.4%, with the WHI having the lowest and NHS having highest % error. For the Swartz equation, the median % error of the PAQ MET-h/wk was lower, with values ranging from 5.8 to 35.0%. Similarly, the WHI and NHS had the lowest and highest % error, respectively.

**CONCLUSIONS:** Data describe the difference between accelerometer and PAQ predicted MET-h/wk and support prior observations that PA levels are typically overestimated when measured with PAQs.

**Evaluating Accelerometer Cut-points To Classify Physical Activity Levels In Overweight/obese Middle-age-to-older Women**

Stephen Herrmann<sup>1</sup>, Teresa Abraham<sup>1</sup>, Barbara Ainsworth, FACSM<sup>1</sup>, Muriel Gilman<sup>2</sup>. <sup>1</sup>Arizona State University, Mesa, AZ. <sup>2</sup>Bemidji State University, Bemidji, MN.

Email: stephen.herrmann@asu.edu

(No relationships reported)

Physical activity (PA) patterns of middle-age and older adults differ by type and intensity from younger adults. Due to age-related changes in fitness, older adults may spend more time in lower absolute intensity PA and perceive it as moderate or vigorous PA. Similar situations may exist for overweight/obese adults who may have weight-related increases in the energy cost of movement. Differences in movement patterns may lead to misclassification of PA if measurement standards are based on younger, leaner populations. Advances in ActiGraph accelerometer scoring protocols permit classification of a wider range of PA than previously identified allowing studies of inactivity and lifestyle PA on health outcomes.

**PURPOSE:** To compare differences in min/day spent in levels of PA using Freedson's three-category and Matthews' modified five-category accelerometer cut-points.

**METHODS:** Cross-sectional study with 44 women (age, 50.4  $\pm$  10.2 yr; BMI, 32.3  $\pm$  5.7) wearing an ActiGraph (previously CSA) accelerometer for 8.1  $\pm$  3.6 days, averaging

888.3 ± 68.6 min/d. Movement counts (cts) were collected under free-living conditions and categorized by intensity using Freedson cut-points [light (<1951 cts), moderate (1952-5724 cts), vigorous (>5725 cts)] and the three additional Matthews' modified cut-points [inactive (0 - 99 cts), light lifestyle (100 - 759 cts), moderate lifestyle (760 - 1951 cts). Since data were skewed, they were normalized using log transformations with data presented as the geometric mean.

**RESULTS:** Using Freedson's cut-points, most of the time was spent in light PA (873.9 min/d) as compared to moderate (10.4 min/d) and vigorous-intensity PA (1.24 min/d). With Matthews' modified cut-points, light and moderate-intensity time was redistributed as inactivity (588.4 min/d), light lifestyle (198.4 min/d), moderate lifestyle (52.2 min/d). Moderate walking and vigorous PA remained the same.

**CONCLUSIONS:** These data show the impact of establishing accelerometer cut-points that reflect time spent in varying PA at the lower intensity movement spectrum. Data are needed to compare the cut-points levels with health outcomes in varying populations to determine their sensitivity for health promotion research and to establish their utility in surveillance systems to characterize population PA levels.

**Accelerometer-determined Steps/day In U.S. Adults**

Catrine Tudor-Locke, FACSM, William D. Johnson, Peter T. Katzmarzyk, FACSM. *Pennington Biomedical Research Center, Baton Rouge, LA.*  
(No relationships reported)

The 2005-2006 National Health and Nutrition Examination Survey (NHANES) released, for the first time, ActiGraph AM-7164 accelerometer-defined step data in addition to time in intensity (defined by activity counts). This accelerometer is known to have a lower sensitivity threshold than accepted pedometers, leading to relatively higher step estimates. **PURPOSED:** To provide the population- and sex-specific epidemiology of accelerometer-determined steps/day with and without censoring steps detected at the lowest end of the activity spectrum (i.e., inactivity).

**METHODS:** Step data were recorded minute-by-minute. Steps/minute were summed over the 1,440-minute day to produce a cumulative daily record. Daily steps were summed and divided by the number of days the accelerometer was worn to derive average steps/day. The analysis sample represents 3,744 participants ≥20 years of age who had at least one valid day (i.e., at least 10 hours) of monitoring. Means (SEM) for steps/day were computed using all steps (i.e., uncensored) and again after censoring those steps taken at an intensity <500 activity counts/minute (indicative of inactivity).

**RESULTS:** The sample took 9,676 ± 107 uncensored steps/day or 6,540 ± 106 censored steps/day, representing an approximate difference of 3,000 steps/day. Extrapolating from this nationally representative sample, 64 % of U.S. adults take ≥ 7,500 steps/day (i.e., they are considered to be somewhat active to highly active), if uncensored steps are considered, and only 31% if censored steps are considered.

**CONCLUSIONS:** The results indicate that adults take approximately 10,000 uncensored accelerometer-determined steps/day, which is improbable considering other studies of free-living physical activity in the U.S. Further, it suggests a level of steps/day that is used to identify active individuals and therefore insinuates that physical activity intervention is unwarranted in this country. In reality however, evidence continues to accumulate that the American obesity epidemic persists and is actually growing in magnitude unthwarted. Until a valid conversion factor is ascertained for translating accelerometer- and pedometer-determined steps, our use of the <500 activity count/minute threshold has considerable merit.

**Effects Of Varied Accelerometer Wear Time Requirements On Physical Activity Data In African American Women**

Barbara E. Ainsworth, FACSM<sup>1</sup>, Teresa L. Abraham<sup>1</sup>, Deborah Parra-Medina<sup>2</sup>, Elizabeth Fore<sup>3</sup>, Sara Wilcox, FACSM<sup>3</sup>. <sup>1</sup>Arizona State University, Mesa, AZ. <sup>2</sup>University of Texas Health Sciences Center at San Antonio, San Antonio, TX. <sup>3</sup>University of South Carolina, Columbia, SC.  
Email: Barbara.Ainsworth@asu.edu  
(No relationships reported)

**PURPOSE:** Accelerometers are often used to objectively assess physical activity (PA) in intervention studies. Most studies have subjects wear the accelerometer for 7 d/wk, and utilize at least 3 days of movement data to reflect a usual week's PA pattern. The standard practice requires days with accelerometer recordings < 10 hr/day to be deleted. To minimize deleting data and to potentially increase the number of d/wk accelerometer data are used for analyses, we hypothesized that reducing the minimum hr/day wear time will have little or no difference in the minutes spent in varying intensity levels while increasing the days/wk and subjects with data eligible for analyses. We examined what impact varying the criteria for accelerometer wear time had on min/day (varied intensities), d/wk, and number of subjects with eligible data.

**METHODS:** 237 African American women (age 51.7 ± 10.5; BMI 34.9 ± 10.1) wore an ActiGraph accelerometer for 7 days. Data were summed separately across 10, 9, 8, 7, and 6 hrs/day to reflect minimal daily wear times. Based on Matthews' modified cut-point counts (cts), minutes in inactivity (0-100 cts), light (101-759 cts), moderate lifestyle (760-5724 cts), moderate walking (1952-5724 cts), and vigorous PA (≥ 5725 cts) were computed for each wear time. SAS 9.2 repeated measures analyses were used to determine differences in number of subjects, days/wk, and mean min/day at each PA intensity level for each wear time. Alpha was set at p < .01.

**RESULTS:** Significant differences were observed in min/day and days/wk between 6, 7, 8, 9, and 10 hrs/day wear times for all PA levels, except vigorous intensity, which was not significantly different for min/d or d/wk across wear times. For moderate lifestyle PA, a wear time of 8 hr/d (vs. 10 hr/d) increased the number of subjects with acceptable data by 13, increased the d/wk from 3.9 to 4.5, and reduced the min/day of activity from 115.6 to 109.9 minutes. Lowering the threshold from 8 to 6 hrs /d added 0.4 days, 7 subjects, and decreased activity to 105.2 minutes.

**CONCLUSIONS:** For this sample, a decrease in the accelerometer wear time from 10 to 8 hr/d was more inclusive of subject data with little loss in the minutes accumulated at each intensity level. Additional decreases in hours yielded little added value.

**Accelerometer Assessment Of Physical Activity Vs. Inactivity In Hispanic Adults Living With Hiv**

José R. Quiñones-González, Norberto Quiles, Moraima Feliciano, Farah A. Ramírez-Marrero, FACSM. *University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico.*  
Email: joselo28@gmail.com  
(No relationships reported)

Physical activity (PA) and physical inactivity (PI) are two ends of a behavioral continuum that greatly impacts health. However, the objective assessment of PI has not been well characterized.

**PURPOSE:** To test the hypotheses that 1) light physical activity (LPA), and moderate to vigorous PA (MVPA) will be inversely associated with PI when objectively assessed with accelerometer, and 2) the proportion of participants classified as active and not-inactive will be opposed to the proportion classified as not-active and inactive.

**METHODS:** A group of 56 Hispanic adults (males 34, females 22, age 46.5±8.8 yrs, BMI 26.8±5.3) living with HIV wore the accelerometer ActiGraph for 7-days. Min/week of no-activity, light, moderate, and vigorous activity was determined using <100, 100-1951, 1952-5724, and >5724 activity counts, respectively. Classification of PA (active vs. not-active) was based on the achievement of ≥150 min/week of MVPA, and classification of PI (inactive vs. not-inactive) was based on the average number of min/day of no-activity.

**RESULTS:** Mean min/day of no-activity, light, moderate and vigorous activity was 1090.2±121.9, 320.1±119.4, 31.3±17.1, and 3.9±9.7, respectively. Using both methods of classification, 62.5% were active-not-inactive, and 65.5% were inactive-not-active ( $\chi^2$  test for independence P=0.04). MVPA was inversely associated with PI (r = -0.35, P= 0.02), but the strongest inverse association was between LPA and inactivity (r = -0.96, P<0.001). PA and PI were not associated with health parameters such as BMI, waist circumference, and life satisfaction.

**CONCLUSION:** Although PA and PI are inversely associated, they appear to measure different behavioral constructs, suggesting that activity is not the opposite end of inactivity.

**Differences In Accelerometer Output Across Site Placement And Body Mass Index Category.**

Nora E. Miller, Scott J. Strath, Ann M. Swartz. *University of Wisconsin - Milwaukee, Milwaukee, WI.*

Email: nem2@uwm.edu

*(No relationships reported)*

**PURPOSE:** The primary purpose of this study was to explore the effect of accelerometer (ACC) placement at the hip versus low back (LB) on monitor output (counts·min<sup>-1</sup>) during treadmill walking. The secondary purpose was to examine differences in ACC counts·min<sup>-1</sup> measured in normal compared to overweight and obese adults at the hip and LB.

**METHODS:** Sixty adults (mean age 54.5 ± 10.3 yrs) completed a five-stage treadmill walking test (2.0-4.0 mph; increasing in 0.5 mph increments every five minutes) while wearing two Actigraph 7164 ACC (Actigraph LLC, Pensacola, FL) affixed to an elastic belt and worn around the waist. Specifically, one ACC was placed vertically at the right anterior axillary line at waist level and a second ACC mounted vertically at the center of gravity on the LB (lumbar vertebrae 4-5). Paired samples *t*-tests were run to compare ACC counts·min<sup>-1</sup> measured at the hip versus the LB at each speed for the group as well as by body mass index (BMI) category (normal vs. overweight /obese). Independent samples *t*-tests were conducted to explore differences in BMI category for ACC counts·min<sup>-1</sup> measured at both the hip and LB for each speed.

**RESULTS:** There were significant differences between hip and LB ACC counts·min<sup>-1</sup> measured at all treadmill speeds (*p*<0.001). When splitting the sample by BMI category (normal [mean BMI: 22.6 kg·m<sup>-2</sup>] vs. overweight/obese [mean BMI: 28.3 kg·m<sup>-2</sup>], hip and LB ACC counts·min<sup>-1</sup> were significantly different for both BMI categories at each speed (*p*<0.001). There were no significant differences in ACC counts·min<sup>-1</sup> measured independently at the hip or LB when comparing normal to overweight /obese at any of the treadmill walking speeds.

**CONCLUSIONS:** Data from this study suggest there are significant differences in ACC output between hip and LB placement. As a result, it becomes difficult to compare ACC outcomes across studies where researchers favor either placement to determine the time spent in various intensities of physical activity. Additionally, erroneous results are likely if hip generated cut points are applied to LB placement studies. Data from this study supports no differences in ACC output when comparing across BMI category.

---

**1866 Board #7 May 28 8:00 AM - 9:30 AM**

**Comparison Of Output From Four Different Actigraph Accelerometers**

Dinesh John, David R. Bassett, FACSM, Brian M. Tyo. *University of Tennessee, Knoxville, TN.*

Email: djohn1@utk.edu

*(No relationships reported)*

Motion sensors from Actigraph are the most commonly used accelerometers in physical activity research. Currently, researchers can use the 7164 or one of three different versions of the GT1M to objectively measure physical activity. However, it is not clear if there is a difference between outputs obtained from each of these four accelerometers.

**PURPOSE:** To examine if differences exist between outputs from the 7164 and the three versions of the GT1M at a given walking or running speed.

**METHODS:** Ten male participants (23.6 ± 2.9 yrs) completed two sessions of walking and running for three minutes on a treadmill at ten different speeds while wearing either the 7164 and the latest GT1M or version one (V1) and version two (V2) of the GT1M. Participants walked at 1.9, 3.1, and 4.4 mph followed by running at 5.0, 6.2, 7.5, 8.7, 10.0, 11.2, and 12.4 mph. The accelerometers were worn on the left and right anterior axillary lines at the waist. Testing was performed on two different days and a counterbalanced within subjects design was used to account for potential differences attributable to accelerometer placement.

**RESULTS:** Repeated measures ANOVA followed by post-hoc pairwise comparisons with bonferroni corrections were used to examine outputs from the accelerometers (*p*<0.008). There were no significant differences at any given walking or running speed between the accelerometers. At all running speeds, outputs from the 7164 and V2 displayed the lowest and highest counts/min (cpm) values, respectively. Between these two accelerometers, there was a steady increase in the mean difference scores ranging between 200 + 340 cpm at 5 mph and 612 + 372 cpm at 12.4 mph. Output from all accelerometers peaked at 8.7 mph (mean range: 8974 + 677 to 9412 + 982 cpm) and then gradually declined with increasing speed. The mean difference score at peak output was greatest between the 7164 and V2 at 439 + 565 cpm.

**CONCLUSIONS:** Although there were no statistically significant differences between outputs from all the accelerometers, the large standard deviations observed at various speeds indicate that there is a high level of variability in the 7164 and V2 response for different people.

**Validity Of An Armband Physical Activity Monitor In Measuring Energy Expenditure During Eighteen Different Activities**

Paige Dudley, David R. Bassett, FACSM, Dinesh John, Scott E. Crouter, FACSM. *University of Tennessee, Knoxville, TN.*

*(No relationships reported)*

**PURPOSE:** To examine the validity of an armband physical activity monitor in estimating energy expenditure (EE) over a wide range of physical activities.

**METHODS:** 68 participants (mean age = 39.5 ± 13.0 yrs.) performed one of three routines consisting of six activities (approximately 10 min. each) while wearing the armband and the Cosmed K4b<sup>2</sup> portable metabolic unit. A break of 3 to 5 minutes was given between activities. Routine 1 (n=25) (Indoor Home-based Activities) included TV watching, reading, doing laundry, ironing, light cleaning, and aerobics. Routine 2 (n=22) (Miscellaneous Activities) included driving, Frisbee golf, grass trimming, gardening, moving dirt with a wheelbarrow, and loading and unloading boxes (6.8kg). Routine 3 (n=21) (Outdoor Aerobic Activities) included road walking, track walking, walking with a bag (6.8 kg), singles tennis, track running, and road running.

**RESULTS:** Mean differences between the EE values in METS (criterion minus estimated) for all routines are as follows. Routine 1: watching TV (-0.1), reading (-0.1), laundry (0.1), ironing (-1.3), light cleaning (-0.4), and aerobics (0.4). Routine 2: driving (-0.6), Frisbee golf (-0.9), grass trimming (-0.5), gardening (-1.5), moving dirt with a wheelbarrow (-0.1), loading and unloading boxes (0.1). The mean MET value differences for Routine 3 were as follows: road walking (-1.0), track walking (-0.8), walking with a bag (-0.6), tennis (1.6), track running (2.2), and road running (2.1). Repeated measures ANOVA followed by post-hoc pairwise comparisons with bonferroni corrections were used to compare criterion versus estimated measures (*p*<0.008). Results showed that the armband significantly overestimated EE during low intensity activities like ironing (by 70%), light cleaning (by 15%), driving (by 74%), Frisbee Golf (by 24%), gardening (by 55%), and road walking (by 26%) and also significantly underestimated higher intensity activities like tennis (by 20%) and both kinds of running (by 20%).

**CONCLUSION:** Although the armband estimates for nine out of the 18 activities were within 16% of the criterion, the armband showed a statistical difference from the criterion for several activities. Algorithms need to be refined to increase the accuracy of EE estimations.

**1868 Board #9 May 28 8:00 AM - 9:30 AM**

**A Comprehensive Evaluation Of Accelerometer Energy Expenditure And Met Prediction Equations**

Kate Lyden, Sarah L. Kozey, Cheryl A. Howe, John W. Staudenmayer, Patty S. Freedson, FACSM. *University of Massachusetts, Amherst, MA.*  
(Sponsor: Patty S. Freedson, FACSM)  
(No relationships reported)

Numerous accelerometers and prediction methods are used to estimate energy expenditure (EE). Validation studies have been limited to small sample sizes in which participants complete a narrow range of activities.

**PURPOSE:** To evaluate the ability of one proprietary and ten published prediction equations to estimate EE from three commercially available activity monitors (AM).

**METHODS:** 252 participants completed an average of 6 treadmill (TRD) (1.34, 1.56, 2.23 m.sec-1 each at 0% and 3% grade) and 5 self-paced activities of daily living (ADLs). ADLs were randomly selected from a menu of 17 activities. AMs were worn while EE was measured using a portable metabolic unit.

**RESULTS:** An average of 2438 samples were used to assess the validity of eleven prediction equations, including the Freedson MET (F), Swartz MET (S), two Crouter MET equations (C1) and (C2), Heil 1R (H1) and 2R (HH1) MET, Heil 1R (H2) and 2R (HH2) kcal, Freedson kcal (F2), Chen kcal (CH) and one proprietary kcal (P). When TRD and ADL activities were evaluated together, each equation, except F2, significantly underestimated EE. When evaluated separately, each equation significantly underestimated ADLs, while TRD activities were significantly underestimated by 8 equations, significantly overestimated by 2 equations and accurately predicted by S and H2. Percent bias and precision were determined for all activities combined, ADLs, and TRDs.

% Bias (Precision) METs							% Bias (Precision) kcals-min-1					
	F	S	C1	C2	H1	HH1	H2	HH2	F2	CH	P	
All	-24.6 (1.92)	-10.4 (1.91)	-18.6 (2.13)	-9.7 (2.49)	-21.0 (2.20)	-20.5 (2.14)	-21.3 (2.61)	-21.1 (2.52)	-2.0 (2.71)	-34.5 (2.55)	-7.8 (2.79)	
ADL	-39.8 (2.30)	-21.7 (2.33)	-12.1 (2.46)	-15.6 (2.62)	-40.7 (2.48)	-37.0 (2.50)	-48.3 (3.00)	-43.4 (3.02)	-17.8 (3.24)	-42.0 (3.11)	-30.9 (3.41)	
TRD	-13.4 (1.25)	-2.0 (1.28)	-23.8 (1.71)	-5.3 (2.35)	-6.2 (1.44)	-8.1 (1.42)	-1.8 (1.53)	-4.8 (1.49)	9.7 (1.9)	-29.3 (1.94)	8.7 (1.56)	

On average, ADLs were underestimated by 31.8% and TRDs were underestimated by 6.9%.

**CONCLUSION:** The AM prediction equations did not yield accurate point estimates of METs or EE across a broad range of activities. Future research should focus on developing more precise methods to estimate EE from AMs.

Supported by NIH CA121005

# 1869 Board #10 May 28 8:00 AM - 9:30 AM Body Mass Index Affects Accelerometer Counts During Walking

Yuri Feito, David Bassett, Jr, FACSM, Dixie Thompson, FACSM, Brian Tyo. *University of Tennessee, Knoxville, TN.*  
(No relationships reported)

Accelerometers have been used to provide objective measures of physical activity and energy expenditure in free-living individuals. However, to our knowledge, output from these devices has not been compared between normal, overweight and obese individuals.

**PURPOSE:** To determine the effects of body mass index (BMI) on accelerometer counts during treadmill walking.

**METHODS:** Fifty-six adults (M= 28; F= 28) took part in the study. They wore an omnidirectional accelerometer (ActiCal™, (AC)) and a uniaxial accelerometer (ActiGraph™ GT1M (AG)) on the right and left hip, respectively, while walking at 40, 67, and 90 m·min<sup>-1</sup>.

**RESULTS:** Results are shown in Table 1 as Mean ± SE.

Table 1: Activity Counts-min-1				
Device	BMI Category (kg/m <sup>2</sup> )	40 m · min-1	67 m · min-1	90 m · min-1
AC	≤ 24.9	382 ± 36	1418 ± 73	2890 ± 94
	25.0 - 29.9	400 ± 60	1496 ± 122	3075 ± 158
	≥ 30.0†	615 ± 59	1684 ± 120	3397 ± 156
AG	≤ 24.9	512 ± 51	2152 ± 99	3904 ± 142
	25.0 - 29.9	679 ± 84	2340 ± 162	4217 ± 234
	≥ 30.0	930 ± 102	2457 ± 198	4318 ± 286

† Significant difference between obese group and other two groups (p< 0.05)

**CONCLUSION:** Our data suggest that BMI does not have a statistical significant effect on the activity counts recorded by the AG. However, BMI does affect the AC with the obese group recording 13% and 17% higher activity counts than the overweight and normal weight groups, respectively (p< 0.05). Researchers should be aware of these effects and further research should be conducted to explain these differences.

# 1870 Board #11 May 28 8:00 AM - 9:30 AM Validation Of Accelerometers During Walking At Three Step Frequency On Various Walking Speeds

Jonghoon Park, Kazuko Ishikawa-Takata, Shigeo Tanaka, Yuko Mekata, Izumi Tabata, FACSM. *National Institute of Health and Nutrition, Tokyo, Japan.* (Sponsor: Tabata, Izumi, FACSM)  
Email: jonghoonp@hotmail.com  
(No relationships reported)

The influences of walking speeds on the validation of uni- and tri-axial accelerometers have been clearly demonstrated, but it is unclear whether the alterations of step frequency during walking would affect the accurate estimation of the accelerometers.

**PURPOSE:** To test the validation of uni- (Lifecorder (LC), Suzuken Inc., Japan) and tri-axial accelerometers (Activity monitor (AM), Matsushita Electronic Works, Ltd., Japan; Active style pro (ASP), Omron Health Care Co., Ltd., Japan) under various walking conditions altered by three different step frequency.

**METHODS:** Healthy men and women (n=18, age=29.6 yrs) volunteered as subjects. Three trials (55, 75, and 95 m/min) were designed to manipulate three step frequency - low (- 15% of normal step frequency), normal, and high (+ 15%) - on each walking speed. Subjects were attached to a facemask connected to the Douglas bag, to the LC on the left side of the waist at midline of left thigh, to the AM on the left side of the waist, and to the ASP on the right side of the waist. The subjects walked for 5 minutes matching each step frequency, and respiratory measurements were also made during the last 2 minutes.

**RESULTS:** When examining the percent error between measured METs (Douglas bag) and predicted METs (accelerometers), the LC at the low step frequency became greater as walking speed increases (significantly underestimated by 25 %, 34 %, and 42 % at the 55, 75, and 95m/min, respectively). There was a significant correlation between the percent error and step frequency in pooled all trials (controlling for speed,  $r=0.75$ ,  $p<0.0001$ ). A multiple regression analysis of predictors of the percent error (including step frequency, speed, and sex) showed that step frequency was the strongest predictor ( $b = 0.895$ ). In contrast, the AM and ASP well performed in the speed of 55 or 75 m/min whereas slightly underestimated at the low step frequency in the speed of 95 m/min. There were no statistical differences between in the percent of error and step frequency in the AM, but a weak correlation in the ASP ( $r=0.23$ ,  $p < 0.01$ ) was observed.

**CONCLUSIONS:** The accuracy of the Lifecorder, a uniaxial accelerometer, is affected by the alterations of step frequency during walking, however, those of Activity monitor and Active style pro, a triaxial accelerometer, are less affected by them.

**1871 Board #12 May 28 8:00 AM - 9:30 AM**

**Validation Of The 1r And 2r Regression Models To Predict Energy Expenditure Using The Actical Accelerometer**

TaShauna U. Goldsby, Cheryl A. Howe, Sarah Kozey, John W. Staudenmayer, Patty S. Freedson, FACSM. *University of Massachusetts, Amherst, MA.*  
Email: tugoldsb@kin.umass.edu

(No relationships reported)

Accelerometers are used to objectively measure activity energy expenditure (AEE). A new approach for estimating AEE employs either a single (1R) or double (2R) regression equation. The 1R was developed on treadmill (TM) activities and activities of daily living (ADLs) of various intensities. The 2R consists two non-overlapping linear regression equations, one for light to moderate and another for vigorous activity.

**PURPOSE:** To validate the 1R and 2R models for predicting AEE from activity counts.

**METHODS:** 102 subjects (64 female and 37 male) ( $X \pm SD$  age =  $34.9 \pm 12.4$  y) completed 6 TM activities and 17 ADL's. Activities were performed for 7 min with subjects wearing a portable metabolic measurement system. Resting metabolic rate (RMR) was measured prior to the activity protocol to determine AEE (total energy expenditure - RMR). Pearson correlation coefficients were computed to examine the relationship between predicted and measured AEE. A repeated measures ANOVA was used to examine the difference between measured AEE (AEE<sub>meas</sub>) and Actical estimated AEE (AEE<sub>est</sub>) from the 1R and 2R equations.

**RESULTS:** AEE<sub>meas</sub> and AEE<sub>est</sub> were highly correlated for 7 out of 15 activities for 1R ( $R^2 = 0.71 - 0.92$ ) and for 5 out of 15 activities for the 2R equation ( $R^2 = 0.70 - 0.91$ ). AEE<sub>meas</sub> and AEE<sub>est</sub> were significantly different for all intensity levels for both the 1R and 2R equations ( $p < 0.0001$ ).

	Light Activities	Moderate Activities	Vigorous Activities
1R (kcal·kg <sup>-1</sup> ·min <sup>-1</sup> )	0.002 (±0.003)	0.048 (±0.019)	0.096 (±0.043)
2R (kcal·kg <sup>-1</sup> ·min <sup>-1</sup> )	0.002 (±0.003)	0.047 (±0.019)	0.098 (±0.046)

**CONCLUSION:** AEE<sub>meas</sub> and AEE<sub>est</sub> for 1R and 2R equations were correlated for a limited number of activities. Neither equation accurately estimated AEE when MET intensity values were assigned to the activities. Point estimates of AEE from the activity monitor yielded differences that over time would lead to an underestimation of AEE.

**Effect Of Monitor Placement On 3dNX™ Accelerometer Output During Treadmill Exercise**

Fleur E. Horner, Mark P. Rayson, Victoria L. Richmond, James M. Carter. *Optimal Performance Ltd, Bristol, United Kingdom.*

Email: fleur@optimalperformance.co.uk

(No relationships reported)

Accelerometers are commonly used to provide estimates of energy expenditure and quantify physical activity patterns during a wide range of free-living activities.

**PURPOSE:** To assess the effect of monitor placement on triaxial accelerometer count magnitude during incremental treadmill exercise. **METHOD:** Five male and 6 female, recreationally-active subjects (age  $22 \pm 3$  yr; height  $173 \pm 9$  cm; mass  $71 \pm 11$  kg) completed two incremental treadmill protocols separated by no more than five days. The protocol consisted of three 5-minute walking stages (4, 5 and 6 km·h<sup>-1</sup>), three 5-minute jogging stages (8, 10 and 12 km·h<sup>-1</sup>) and four 30-second sprints (14, 16, 18 and 20 km·h<sup>-1</sup>). Each subject wore four 3dNX™ units on an elastic belt; two positioned in the small of the back (lumbar 4-5) and one positioned on each hip (midaxillary line). The sum of the counts from all 3 axes were stored every 5 s. Five-second epoch accelerometer counts were averaged over each stage. The effects of placement (hip and back) and speed, which were considered fixed, and the interaction effects (placement x speed) on count magnitude were tested by ANOVA.

**RESULTS:** Overall there were no significant differences in count magnitude between hip and back placement ( $p = 0.738$ ). A borderline interaction effect was observed between placement and speed ( $p = 0.059$ ). Paired t-tests showed significant differences at 4, 5, 8, 10 and 12 km·h<sup>-1</sup>. Hip placement resulted in higher count magnitude than back placement at 4 and 5 km·h<sup>-1</sup>, on average 10 % and 6 % higher respectively. Back placement yielded higher count magnitude than hip placement at 8, 10 and 12 km·h<sup>-1</sup>, on average 8 %, 7 % and 3 % higher respectively.

**CONCLUSION:** There were small differences in count magnitude when the monitor was worn on the hip and the back. The direction and magnitude of the differences depend on the speed of the treadmill exercise.

**Exploring Validity And Reliability Of Physical Activity Questionnaire For Children (PAQ-C) And Modifications Using**

## Accelerometry

David J. Stockton<sup>1</sup>, K. Ashlee McGuire<sup>2</sup>, Lindsay Nettlefold<sup>2</sup>, Dona Tomlin<sup>1</sup>, Heather McKay<sup>2</sup>, PJ Naylor<sup>1</sup>. <sup>1</sup>University of Victoria, Victoria, BC, Canada. <sup>2</sup>University of British Columbia, Vancouver, BC, Canada.

Email: djstockton@telus.net

(No relationships reported)

**BACKGROUND:** Self-report physical activity (PA) tools are problematic in children and yet remain important, as they are inexpensive and easy to administer. The PAQ-C is a self-report instrument for children aged 8-14 years that has been validated previously using accelerometry (1 minute epochs). The Action Schools! BC (AS! BC) study used the PAQ-C and accelerometry to assess PA but modified the first question of the PAQ-C to generate a continuous variable (minutes of PA/day).

**PURPOSE:** The purpose of this study was to explore, 1) concurrent validity for both the PAQ-C summary score and the modified question, using accelerometry data collected every 15 seconds and 2) the psycho-metric properties of the PAQ-C.

**METHODS:** Data were collected during the baseline phase of the AS! BC Dissemination Trial (October 2005 - January 2006). Six hundred and forty-four children consented to both the questionnaire and accelerometry assessment. Complete data were available for 313 children (aged  $9.9 \pm 0.6$  yr). Students with a minimum of 3 days of accelerometry data collected in the same 7-day period as the PAQ-C were included in the sub-analysis (n=44). Physical activity was measured with an ActiGraph GT1M monitor and analyzed as 15-second epochs for 3-5 days (minimum 10 hr/d).

**RESULTS:** The PAQ-C PA score was significantly associated with accelerometry variables; minutes of MVPA/day ( $r=.482$ ,  $p<.001$ ), counts/day ( $r=.431$ ,  $p<.004$ ) and counts/min ( $r=.462$ ,  $p<.002$ ). Minutes of MVPA calculated from the modified Question 1 were significantly associated with MVPA/day by accelerometry ( $r=.316$ ,  $p<.0001$ ). Internal consistency of the PAQ-C (n=644) was acceptable (Chronbach's alpha .755).

**CONCLUSION:** Our analysis confirmed the validity of the PAQ-C and the modified question 1 as a stand-alone 7-day recall measure when compared to accelerometry. Thus, we suggest that the PAQ-C or its modified question 1 are viable alternatives to objective physical activity measurement.

(No relationships reported)

**PURPOSE:** To study differences in patterns of objectively measured physical activity between weekdays and weekend days and between different time blocks during the day in relation to age and gender. This knowledge is of great importance when planning preventive initiatives aimed at increasing levels of physical activity in children.

**METHODS:** A total of 653 girls and 640 boys provided valid weekly accelerometer measurements of physical activity. Twenty randomly selected children from 10 schools were measured every week (2002-2005). Time periods were divided into school time (8am-1.30pm), after school care time (1.30pm-4pm) and evening time (4pm-9pm).

**RESULTS:** Physical activity levels were significantly lower during weekends compared to weekdays in all age groups and this pattern was similar across low, medium and high active children. Physical activity levels were highest during school time and after school care time on weekdays compared to all other time periods. The difference in activity levels between boys and girls was highest during school time and after school care time. Furthermore, the results show an age related decline in physical activity between ages 6-10 years for both girls and boys.

**CONCLUSIONS:** It is important to counterbalance the age related decline in physical activity in children as early as from the age of six years. It is significant to target girls to become more active in the school setting when the difference in physical activity levels between girls and boys is most pronounced. However, it appears difficult to compensate the low levels of activity during weekends and evenings by increased physical activity at school. Increased family involvement seems to be a prerequisite for a successful physical activity intervention in this age group.

### 1875 Board #16 May 28 9:00 AM - 10:30 AM Predicting Energy Expenditure From Accelerometer Counts At 12 And 16 Years In The Same Individuals

Alex Griffiths<sup>1</sup>, Sam D. Leary<sup>1</sup>, Calum Mattocks<sup>2</sup>, Andy R. Ness<sup>1</sup>, Chris J. Riddoch<sup>2</sup>, Kate Tilling<sup>1</sup>, Steven N. Blair, FACSM<sup>3</sup>. <sup>1</sup>University of Bristol, Bristol, United Kingdom. <sup>2</sup>University of Bath, Bath, United Kingdom. <sup>3</sup>University of South Carolina, Columbia, SC.

Email: alex.griffiths@bristol.ac.uk

(No relationships reported)

Accelerometry is an objective method of assessing levels and patterns of physical activity and is relatively precise. To be able to further explore the association between accelerometer counts and health outcomes, it is important to know how such measures of movement relate to energy expenditure.

**PURPOSE:** To determine how accurately an equation developed in 12 year old children predicts energy expenditure from accelerometer counts during free-living activities in the same children aged 16.

**METHODS:** Children aged 12 were recruited from a large birth cohort, the Avon Longitudinal Study of Parents and Children (ALSPAC). Accelerometer counts, oxygen uptake ( $\text{VO}_2$ ) and carbon dioxide output ( $\text{VCO}_2$ ) were recorded during four activities (slow walking, fast walking, hopscotch and jogging) at age 12 and again at age 16. Energy expenditure per kg was calculated from  $\text{VO}_2$  and  $\text{VCO}_2$ . Random intercepts modelling (to allow for multiple measurements on each child) was used to construct a prediction equation for the 12 year olds, with gender as a possible confounder. Limits of agreement were used to assess the adequacy of the equation in the same children at age 16.

**RESULTS:** Valid data were obtained for 22 children at both age 12 (mean age 12.4 years, SD 0.2 years) and at age 16 (mean age 15.9 years, SD 0.2 years). The prediction equation obtained at age 12 was: Energy expenditure ( $\text{kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) =  $0.0695 + 0.000105 \times \text{counts per minute} + 0.0546 \times \text{gender}$  (0=female, 1=male). When applied to the same children at age 16, this equation tended to over-estimate energy expenditure (mean difference between predicted and actual values  $0.15 \text{ kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ). The 95% limits of agreement were -0.17, 0.46.

**CONCLUSION:** An equation predicting energy expenditure from accelerometer counts at age 12 does not accurately describe the relationship between the two measurements in the same children at age 16. In longitudinal studies such as ALSPAC, it will be necessary to derive new equations at each age. Further data are being collected (approximately 60 subjects in total) and this analysis will be repeated using all available data.

---

### 1876 Board #17 May 28 9:00 AM - 10:30 AM Youth Accelerometer Cutoffs For Moderate-to-vigorous Physical Activity: A Sensitivity Analysis

John R. Sirard, Carrie D. Heitzler, Leslie A. Lytle. University of Minnesota, Minneapolis, MN.

Email: sirar001@umn.edu

(No relationships reported)

The various accelerometer count cutoffs available for youth and adult populations may not be compatible with each other; an important issue due to an increasing interest in

tracking health behaviors as adolescents transition into young adulthood.

**PURPOSE:** To 1) determine the effect of various cutoffs for determining adolescent moderate-to-vigorous physical activity (MVPA) and 2) identify the congruence between youth and adult cutoffs.

**METHODS:** Baseline data from a longitudinal observational study were used (N=288, 49% male, mean age=15+1.8 years, age range 11-17, 97% White). ActiGraph (Pensacola, FL) data were collected in 30-second intervals for one week and categorized as MVPA if the data point was above the count cutoff used. The Freedson/Trost (FT) equation was applied to the data entering either 3 METS, 4 METS or an age-adjusted MET value to theoretically adjust for children's higher resting metabolic rates.

**RESULTS:** The table contains the results of the repeated measures analysis.

Variable	Cutoffpoint				
	FT-3	FT-4	FT-METadj	Puyau	TAAG
MVPA min.day-1	55+29.4a	30+19.2b	31+19.0b	20+15.0c	23+16.7c
> 60 min.day-1 of MVPA (%)	37.0	4.9	6.4	3.5	3.8
Values with different letters are significantly different from each other (p<0.0001)					
FT-3 = FT equation with age and 3 METS					
FT-4 = FT equation with age and 4 METS					
FT-METadj = FT equation with age and age-adjusted METS					

For a 17-year old the MVPA cutoffs using the FT-4, Puyau, and TAAG equations are 3239, 3200, and 3000 cnts·min<sup>-1</sup>, respectively. The FT-3 and FT-MET<sub>adj</sub> 17-year old cutoffs (2069, 2349 cnts·min<sup>-1</sup>, respectively) provide the most congruence with the adult NHANES MVPA cutoff (2020 cnts·min<sup>-1</sup>).

**CONCLUSION:** The cutoff used to categorize intensity of activity can significantly affect physical activity outcome variables. The FT-3 and FT-MET<sub>adj</sub> were the most congruent with the adult cutoff. The FT-MET<sub>adj</sub> cutoff may be more appropriate for those studying a wide age range of youth and those with both adolescents and young adults in their datasets. Funding source: NCI's Transdisciplinary Research in Energetics & Cancer Initiative (NCI Grant 1 U54 CA116849-01)

#### 1877 Board #18 May 28 9:00 AM - 10:30 AM

##### Intra-individual Variation Of Physical Activity At Ages 12-14 As Assessed By Accelerometry

Andy R. Ness<sup>1</sup>, Sam D. Leary<sup>1</sup>, Louise Glynn<sup>1</sup>, Alex Griffiths<sup>1</sup>, Calum Mattocks<sup>2</sup>, Chris J. Riddoch<sup>2</sup>, Kate Tilling<sup>1</sup>, Steven N. Blair, FACSM<sup>3</sup>.

<sup>1</sup>University of Bristol, Bristol, United Kingdom. <sup>2</sup>University of Bath, Bath, United Kingdom. <sup>3</sup>University of South Carolina, Columbia, SC.

Email: andy.ness@bristol.ac.uk

(No relationships reported)

Accurate estimates of habitual physical activity (PA) are essential when examining the associations between PA and health outcomes. Intra-individual variation throughout the year may lead to inaccurate assessment, and few studies have examined intra-individual variation over a year in children.

**PURPOSE:** To use accelerometry to estimate and compare intra-individual variation of children's PA (over the course of a year) at two timepoints during adolescence, and to compare estimates at age 14 with previously reported estimates at age 12 years.

**METHODS:** As part of the Avon Longitudinal Study of Parents and Children (ALSPAC), all children attending clinics at 12 and 14 years were asked to wear accelerometers for 7 days to obtain counts per minute (cpm) data to quantify total activity. At age 12 years, 349 children were also asked to wear the accelerometer for 7 days on 3 further occasions throughout the year. At age 14 years, 104 children were also asked to wear the accelerometer for 3 days on 3 further occasions throughout the year. Random intercepts models were used to estimate the inter- and intra-individual components of PA at each of the 2 timepoints.

**RESULTS:** Data were considered valid if the accelerometer was worn for at least 10 hours for at least 3 days. A total of 315 children had valid data for at least 2 measurement occasions at the 1<sup>st</sup> timepoint, and 61 children had valid data for at least 2 measurement occasions at the 2<sup>nd</sup> timepoint. The unadjusted intraclass correlation coefficient (ICC) for cpm was 0.54 at the 1<sup>st</sup> timepoint and 0.50 at the 2<sup>nd</sup> timepoint. After adjustment for gender, age and BMI, values were 0.49 and 0.53 respectively. After further adjustment for month of measurement, values were 0.53 and 0.55 respectively.

**CONCLUSION:** There is substantial intra-individual variation in objectively measured PA, which is of the same order of magnitude for different ages during adolescence. Any study using a single measurement occasion with PA as the exposure should take account of this by adjusting for regression dilution.

---

#### 1878 Board #19 May 28 9:00 AM - 10:30 AM

##### Predictive Validity Of A Triaxial Accelerometer Met Prediction Equation For Children And Adolescents

Paul D. Loprinzi<sup>1</sup>, Meghan M. Senso<sup>1</sup>, Karin Pfeiffer, FACSM<sup>2</sup>, Stewart G. Trost, FACSM<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>Michigan State University, East Lansing, MI.

(No relationships reported)

Accelerometers are a widely used objective measure of physical activity (PA) in studies involving youth. Youth specific cut-points for the estimation of time spent in sedentary (SED), light (LPA), moderate (MPA), and vigorous (VPA) PA have been developed, but these have not been evaluated for validity in an independent sample.

**PURPOSE:** This study evaluated the predictive validity of a previously published triaxial accelerometer MET prediction equation (Rowlands et al., 2004) for children.

**METHODS:** 100 (61 boys, 39 girls) children and adolescents (mean age: 11.2 ± 2.7 yr, ht: 149.1 ± 17.7 cm, wt: 44.1 ± 17.3 kg, BMI%: 58.2 ± 26.5) completed 12 standardized activity trials (AT's). AT's included 1 resting AT (supine lying), 2 sitting AT's (writing and computer game), 5 lifestyle AT's (sweeping, laundry, throw and catch, aerobics, and basketball), and 4 locomotive AT's (slow walking, fast walking, fast treadmill walking, and running). Each AT lasted 5 min with the exception of the resting trial (10 min). During each AT, participants wore a triaxial accelerometer on the left and right hip. VO2 was measured by a portable indirect calorimetry system. Differences between measured and predicted METs were assessed using dependent t-tests. Classification accuracy was assessed using percent agreement (%Ag), sensitivity (Se), and specificity (Sp).

**RESULTS:** The equation under-predicted the MET level of the resting, sitting, and lifestyle AT's (P<0.0001), and over-predicted the MET level of the locomotive AT's (P<0.05). The magnitude of underestimation ranged from 1.2 METs for resting to 2.2 METs for basketball. The magnitude of overestimation ranged from 0.9 METs for fast walking to 2.1 METs for running. The correlation between predicted and observed METs was 0.89 (P < 0.0001). For SED, %Ag, Se, and Sp were 67.3%, 100%, and 62.5%. For LPA, %Ag, Se, and Sp were 66.1%, 4.2%, and 87.8%. For MPA, %Ag, Se, and Sp were 69.9%, 44.3%, and 88.8%. For VPA, %Ag, Se, and Sp were 87.6%, 67.6%, and 92.3%. For MVPA, %Ag, Se, and Sp were 81.9%, 71.4%, and 98.6%.

**CONCLUSIONS:** These data show that the Rowlands triaxial accelerometer equation does not accurately predict METs but may be useful for classifying MVPA.

Supported by Grant R01HD055400 from the National Institute Of Child Health And Human Development.

1879 Board #20 May 28 9:00 AM - 10:30 AM

**Effect Of Epoch Length On Objectively-measured Physical Activity In Middle School Students**

Matthew T. Mahar<sup>1</sup>, Ashley M. Guerieri<sup>1</sup>, Michael A. Kanters<sup>2</sup>, Jason N. Bocarro<sup>2</sup>. <sup>1</sup>East Carolina University, Greenville, NC. <sup>2</sup>North Carolina State University, Raleigh, NC. (Sponsor: David A. Rowe, FACSM)

Email: maharm@ecu.edu

(No relationships reported)

Accelerometers are used to measure different intensities and durations of physical activity. It has been suggested that researchers use short sampling intervals, or epochs, to assess the intermittent patterns of physical activity indicative of children. Less is known about the appropriate epoch for assessing physical activity in middle school students. Because accelerometers sum activity counts over the selected epoch, short bursts of moderate or vigorous activity, which generate high activity counts, may not be detected when activity counts are summed over longer epochs (e.g., 1 minute).

**PURPOSE:** The purpose of this study was to investigate the effect of different epochs on the assessment of physical activity in middle school students using Actigraph accelerometers.

**METHODS:** Fifty-seven boys and girls (mean age =  $11.0 \pm 0.5$  years) wore an Actigraph GT1M accelerometer set to record in 15-second epochs on their right hips for seven consecutive days. Fifteen-second epochs were reintegrated into 60-second epochs for comparison. Previously published age-specific equations were used to establish cut-points for moderate (4 METs), moderate-to-vigorous, and vigorous (7 METs) intensity activity for each epoch setting. Paired samples t-tests were used to evaluate mean differences between estimated minutes of each outcome variable for each epoch setting.

**RESULTS:** A significant epoch effect was present for time spent at moderate, moderate-to-vigorous, and vigorous intensity activity ( $p < .01$ ). Minutes of moderate ( $43.5 \pm 14.6$  vs.  $34.8 \pm 16.1$  min), moderate-to-vigorous ( $49.2 \pm 17.8$  vs.  $36.9 \pm 17.9$  min), and vigorous ( $5.5 \pm 4.0$  vs.  $2.1 \pm 2.5$  min) activity were significantly higher for the 15-sec epoch setting than for the 60-sec epoch setting, with moderate to large effect sizes.

**CONCLUSION:** Statistically significant epoch effects are present when measuring middle school students physical activity of moderate intensity or greater. These findings indicate that use of a longer epoch produces fewer minutes of moderate, moderate-to-vigorous, and vigorous physical activity and the use of shorter epochs may be necessary in order to reliably capture physical activity of middle school students.

1880 Board #21 May 28 9:00 AM - 10:30 AM

**Tracking Children's Physical Activity: An 8 Year Longitudinal Follow-up Using Accelerometry And Dxa**

Kathleen F. Janz, FACSM, Elena M. Letuchy, Trudy L. Burns, Julie M. Eichenberger Gilmore, James C. Torner, Marcia C. Willing, Steven M. Levy. University of Iowa, Iowa City, IA.

Email: kathleen-janz@uiowa.edu

(No relationships reported)

**PURPOSE:** Physical activity (PA) tracking studies can determine when children settle into activity patterns and how attributes may influence the stability of activity. This study examined the tracking of physical activity over an 8-year period in relation to adiposity and maturity.

**METHODS:** Participants were children from the Iowa Bone Development Study. PA was measured at ages 5, 8, 11, and 13 via accelerometry (Actigraph). Children wore the accelerometer for 3 to 5 days and a summary variable of moderate through vigorous activity (MVPA) was constructed using the Freedson equation. % fat was measured using dual-energy x-ray absorptiometry (Hologic 2000 at ages 5, 8 and Hologic 4500 at ages 11, 13). Maturity offset was predicted using the Mirwald equations. 270 children (140 girls and 130 boys) with all data available at ages 5 and 13 were included in the data analysis.

**RESULTS:** Spearman rank-order correlation coefficients between baseline (age 5) and follow-up MVPA and % fat ranged from 0.20 to 0.42 ( $p < 0.05$  all associations). Generalized estimating equations (GEE) were used to examine the stability of MVPA across all years after controlling for the influence of % fat and maturity. The adjusted GEE estimate for MVPA was 0.32 for boys (95% CI = 0.22, 0.43) and 0.36 for girls (95% CI = 0.23, 0.49). % fat was significant in this model ( $p < 0.05$ ); maturity was not. Based on GEE, logistic regression analysis was used to examine if "at risk" children could be predicted. The least active quartile for MVPA was set as "at risk." The unadjusted odds ratios (OR) were 3.51 (95% CI = 1.87, 6.58) for boys and 3.69 (95% CI = 1.97, 6.90) for girls. After adjustment for % fat, the OR were 3.74 (95% CI = 2.00, 6.99) and 3.75 (95% CI = 2.01, 7.00) in boys and girls, respectively. The OR for boys with higher than average % fat at age 5 was 5.18 (95% CI = 2.28, 11.73).

**CONCLUSIONS:** MVPA is moderately stable throughout childhood and predictive of later MVPA regardless of changes in adiposity. Young overweight and inactive boys are more likely to remain inactive throughout childhood when compared to peers. Since habitual activity patterns in young children tend to continue to adolescence, early intervention strategies appear warranted.

(No relationships reported)

Systemic vascular nitric oxide (NO) bioavailability is known to play a key role in regulation of vascular tone at rest in Normoxic (N) and Hypoxic (H) conditions (Maher et al. Circulation 2008. 117 (5) 594-7). However, the effect of altered oxygen delivery as a function of exercise and inspiratory hypoxia and subsequent implications for NO metabolites remains unknown.

**PURPOSE:** The present study examined the effects of physical exercise and H on NO metabolites in the systemic circulation. Specifically, we hypothesized that exercise would result in a net loss of NO metabolites which would be compounded in hypoxia due to a) PO<sub>2</sub> mediated re-apportionment and/or b) oxidative inactivation.

**METHODS:** Fourteen healthy males aged 24 (mean)  $\pm$  5 (SD) years performed two incremental tests to volitional exhaustion in N (21%O<sub>2</sub>) and H (~12%O<sub>2</sub>). Maximal oxygen consumption (VO<sub>2max</sub>) was measured off line using the Douglas bag method and arterial haemoglobin oxygen saturation (SaO<sub>2</sub>) via pulse oximetry. Blood samples were taken from an antecubital vein before and immediately after exercise for determination of PO<sub>2</sub> and plasma concentrations of nitrite (NO<sub>2</sub>), nitrate (NO<sub>3</sub>) and S-nitrosothiols (RSNO) via ozone-based chemiluminescence using modified tri-iodide/vanadium reagents. Data were analyzed with a two-way repeated measures ANOVA and *post-hoc* Bonferroni-corrected paired samples *t*-tests and relationships between variables by a Pearson Product Moment correlation coefficient.

**RESULTS:** H decreased SaO<sub>2</sub> (N:  $96 \pm 1$  vs H:  $77 \pm 4\%$ ,  $P < 0.05$ ) and subsequently VO<sub>2max</sub> (N:  $3.92 \pm 0.30$  vs H:  $3.00 \pm 0.17$  L/min,  $P < 0.05$ ).

Total NO did not change as a result of exercise and hypoxia (N:  $-0.4 \pm 6.3$  vs H:  $-1.2 \pm 7.7 \mu\text{mol}$ ). The exercise-induced reduction in NO (N:  $-137 \pm 93$  norm vs. H:  $-78 \pm 99$  nmol) was mirrored by an exercise-induced increase in RSNO (N:  $+11 \pm 31$  vs. H:  $+21 \pm 16$  nmol ( $P < 0.05$ ). A more marked reduction in NO was observed during N exercise ( $P = 0.07$ ).

**CONCLUSION:** These findings demonstrate an exercise induced re-apportionment of NO across the metabolite pool (from nitrite to RSNO) that may help conserve vascular  $\text{O}_2$  delivery which is especially important in H. Alternatively the reduction in nitrite and tendency towards a decrease total NO may reflect oxidative inactivation.

**Acute Effects Of Whole Body Vibration During Passive Standing On Arterial Stiffness**

Masae Miyatani<sup>1</sup>, Kei Masani<sup>1</sup>, J Totosy de Zepetnek<sup>2</sup>, Milad Alizadeh-Meghrizi<sup>1</sup>, Milos R. Popovic<sup>1</sup>, C Catharine Craven<sup>1</sup>. <sup>1</sup>Toronto Rehabilitation Institute, Toronto, ON, Canada. <sup>2</sup>University of Waterloo, Waterloo, ON, Canada. (Sponsor: Izumi Tabata, FACSM)  
 Email: miyatani.masae@torontorehab.on.ca  
 (No relationships reported)

Patients with spinal cord injury (SCI) are prone to coronary artery disease (CAD) resulting in high CAD related morbidity and mortality. Increased arterial stiffness is a well-established CAD risk factor among able-bodied individuals. Whole body vibration (WBV) with static squat exercise acutely decreases arterial stiffness among able-bodied individuals. People with SCI can passively stand with the assistance a standing frame. WBV may be beneficial as an alternate to exercise for decreasing arterial stiffness among people with SCI.

**PURPOSE:** To investigate the acute effects of WBV during passive standing on arterial stiffness in able-bodied individuals.

**METHODS:** Seven healthy men (Age:  $27 \pm 7$  yrs; Height:  $177.8 \pm 8.9$  cm; Body weight:  $77.8 \pm 8.7$  kg) performed WBV during passive standing in the standing frame (Easystand 5000). The WBV session consisted of 10 sets of 60 s-vibration (frequency, 45Hz; amplitude, 1.2mm) with inter-set resting periods of 60 s each. Arterial stiffness (pulse wave velocity in cm/sec) was measured from the common carotid to the femoral artery (c-f PWV) and from the femoral to posterior tibial artery (f-a PWV). Blood pressure (BP) and heart rate (HR) were measured pre and 2min post WBV.

**RESULTS:** BP and HR did not change from baseline after WBV. f-a PWV significantly decreased after the WBV ( $940 \pm 88$  cm/sec vs.  $926 \pm 88$  cm/sec,  $p < 0.05$ ). The group mean of c-f PWV decreased ( $1067 \pm 973$  cm/sec vs.  $973 \pm 273$  cm/sec,  $p = 0.174$ ), although it was not statistically significant.

**CONCLUSIONS:** WBV during passive standing acutely decreased arterial stiffness, especially in the leg in able-bodied individuals. These results suggest that WBV with passive standing may be feasible as an alternate for exercise in people with SCI for decreasing arterial stiffness.

**A Cool Down Period After A Bout Of Dynamic Exercise Does Not Attenuate PEH In Treadmill Trained Rats**

Bart D. Worthington, D. Fred Peterson. A.T. Still University, Kirksville, MO. (Sponsor: William L. Sexton, FACSM)  
 Email: bworthington@atsu.edu  
 (No relationships reported)

Post-exercise hypotension (PEH) is a well established phenomenon that occurs in a variety of exercise settings in humans and animals. PEH is characterized by increased vascular conductance and decreased cardiac output, which does not appear to be due to sympathetic withdrawal. It has been proposed that elimination of the muscle pump may contribute to PEH.

**PURPOSE:** Our aim was to determine if the fall in blood pressure after a bout of treadmill exercise could be attenuated or eliminated by continued low intensity walking. Thus, the purpose of the study was to test the hypothesis that continued low intensity exercise, a "cool down period", following a bout of dynamic exercise would attenuate the magnitude of PEH.

**METHODS:** Eight male Sprague-Dawley rats ( $350 \pm 7$  g) were previously trained 5 days/wk, for 2-4 wks on a motor-driven treadmill. Under isoflurane anesthesia the right carotid artery was catheterized. After two days recovery, blood pressure and heart rate were measured before, during and after a 20 min bout of running on a rodent treadmill at 20 m/min, 20% incline. On consecutive days, at the conclusion of the exercise bout, each rat either stopped exercise completely (no cool down, NCD) or continued walking at 5 m/min for 10 min before stopping (cool down, CD), as determined by random assignment.

**RESULTS:** Similar to previous reports, during the NCD protocol, blood pressure fell below the initial resting baseline ( $112 \pm 3$  mmHg) in all animals reaching its nadir between 20 and 30 min post-exercise (20 min,  $104 \pm 2$  mmHg; 25 min,  $104 \pm 2$  mmHg; 30 min,  $104 \pm 3$  mmHg;  $p < 0.05$ ). PEH was not affected during the CD protocol, as blood pressure fell below baseline ( $109 \pm 2$  mmHg) to its nadir (30 min,  $102 \pm 3$  mmHg; 35 min,  $103 \pm 3$  mmHg; 40 min,  $103 \pm 3$  mmHg;  $p < 0.05$ ). The time to maximum fall in blood pressure was delayed by the duration of the cool down period (to 30 min). Blood pressure remained elevated 10 min post-run during CD ( $112 \pm 3$  mmHg), while falling precipitously during the NCD ( $105 \pm 3$  mmHg;  $p = 0.028$ ).

**CONCLUSIONS:** These results suggest that, although a cool down period delays the immediate fall in blood pressure post-exercise, it does not attenuate the ultimate magnitude of PEH. These data suggest that at the conclusion of a protracted exercise bout, a period of low intensity exercise may diminish the potential for post-exercise syncope.

**Does Advanced Cardiac Impedance Technology Accurately Measure Cardiac Output During Submaximal Steady State Exercise?**

Craig E. Broeder, FACSM, Jared Hickok, Amanda Burditt. Benedictine University, Lisle, IL.  
 Email: jazzercb@mac.com  
 ( C.E. Broeder, PhysioFlow Corporation, Contracted Research.)

**PURPOSE:** This study determined if advanced cardiac impedance technology (ACI) could accurately measure cardiac output during steady-state cycling exercise compared to values calculated using the direct Fick equation developed by Stringer et al (1997). **METHOD:**  $\text{VO}_2$  max was determined on both a treadmill (Mean =  $3.96 \pm 1.2$  liters/min) and cycle ergometer (Mean =  $3.42 \pm 1.2$  liters/min) in 15 subjects (Age:  $34.3 \pm 9.4$  yrs). Steady-state exercise wattage was set at 25%, 50%, and 75% of peak watts achieved. Subjects exercised 8 mins at each stage. The last 4 mins were used to determine the ACI values for cardiac output (Q), heart rate, stroke volume, EDV, SBP, DBP, and systemic vascular resistance. Both the submaximal and maximal exercise trials were performed in duplicate to assure accurate data collection. No significant differences were observed in test-retest trials. Thus, the mean of duplicate trials was used for all data analyses.

**RESULTS:** There was no significant difference between the cardiac output determined by the Stringer equation and the ACI measured Q value. The percent differences across exercise intensity's for Q were 4.2%, -1.5%, and -6.7% for the 25%, 50%, and 75% of max watts, respectively. Linear regression analyses indicated r-squared = 0.99, SEE = 0.20 liters,  $p = .001$ . For all trials combined, the mean percent difference between the stringer cardiac output and the ACI cardiac output was 0.5%.

STAGE INTENSITY	VO2	% OF VO2 MAX	A-V DO2	STRINGER Q	ACI Q	% DIFFERENCE
25% MAX WATTS	1.37	40.1	0.097258	14.1	13.5	4.2%

50% MAX WATTS	2.17	63.5	0.120650	18.0	18.3	-1.5%
75% MAX WATTS	3.02	88.3	0.145504	20.8	22.2	-6.7%
MEAN OF ALL TRIALS	2.19	63.9	0.121138	18.1	17.97	0.5%

**CONCLUSION:** In conclusion, these data indicate that the ACI system used in this study was highly accurate in determining a person's Q during steady state exercise ranging between 40.1% and 88.3% of VO<sub>2</sub> max. Future studies need to determine if similar accuracy can be achieved using other forms of exercise, i.e., treadmill.

##### Acute Exercise Reverses Dysfunction Of Endothelial Progenitor Cells In Chronic Heart Failure.

Emeline M. Van Craenenbroeck, Paul Beckers, Vicky Y. Hoymans, Nadine Possemiers, Kurt Wuyts, Johan Roeykens, Christiaan J. Vrints, Viviane M. Conraads. *Antwerp University Hospital, Edegem, Belgium.*

Email: Emeline.Vancraenenbroeck@ua.ac.be

A. Van Berendonck presenting

(No relationships reported)

**PURPOSE:** Exercise training partially restores endothelial function and exercise capacity in chronic heart failure (CHF) patients. Training-induced mobilization of endothelial progenitor cells (EPC) and their associated regenerative capacity might explain these observed benefits. We studied the number and function of EPC at baseline and after a cardio-pulmonary exercise test (CPET).

**METHODS:** Endothelial function was assessed by flow mediated dilation (FMD) of the brachial artery in 41 sedentary CHF patients (pts). Twenty two pts were classified as mild CHF (62 ± 3 yrs, NT-proBNP < 800 pg/ml, LVEF 32 ± 1%, FMD 5.3 ± 0.5%, mean ± SEM) and 19 as severe CHF (63 ± 3 yrs, NT-proBNP > 800 pg/ml, LVEF 23 ± 2%, FMD 6.4 ± 0.6%). Circulating CD34<sup>+</sup> and CD34<sup>+</sup>/KDR<sup>+</sup> cells (EPC) were determined by flow cytometry before and 10 minutes after CPET. Migration of UEA+/acLDL+ EPC towards VEGF and SDF-1α was assessed at day 7 of culture. Thirteen age-matched healthy subjects (56 ± 2 yrs, FMD 7.1 ± 0.4%) served as controls.

**RESULTS:** Numbers of CD34<sup>+</sup> cells were decreased in both mild (0.329 ± 0.07 of lymphocytes) and severe CHF pts (0.336 ± 0.05%) compared to healthy controls (0.599 ± 0.09%) and correlated positively with VO<sub>2</sub> peak and maximal workload (all p<0.05). Numbers of CD34<sup>+</sup>/KDR<sup>+</sup> cells were not significantly different between groups. Migratory capacity of EPC was significantly decreased in mild CHF pts (35.5 ± 3.1%) and severe CHF pts (33.1 ± 3.8%) compared to healthy subjects (63.7 ± 5.7%, p<0.05) and correlated with VO<sub>2</sub> peak (r=0.682, p=0.021). Following exercise, migratory capacity improved acutely in mild CHF pts (35.5 ± 3.1% vs. 46.2 ± 3.5%, p=0.005) and severe CHF pts (33.1 ± 3.8% vs. 50.1 ± 3.8%, p=0.003), whereas a significant improvement was absent in healthy subjects (63.7 ± 5.6% vs. 52.4 ± 4.9%, p>0.05). A single exercise bout had no effect on circulating EPC numbers.

**CONCLUSION:** CHF patients exhibit reduced EPC numbers and function which is correlated to disease severity and exercise capacity. Acute exercise improves migratory activity of EPC, whereas their number remains unaltered. The increase is larger in advanced disease stages. The latter suggests that the exercise-induced stimulus for endothelial restoration is larger in clinically more affected patients.

##### Sex Differences In Carotid Baroreflex Control Of Heart Rate At Rest And During Dynamic Exercise In Humans

Areum Kim<sup>1</sup>, Colin N. Young<sup>1</sup>, Shekhar H. Deo<sup>1</sup>, James P. Fisher<sup>2</sup>, Paul J. Fadel<sup>1</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>University of Birmingham, Birmingham, United Kingdom. (Sponsor: Peter B. Raven, FACSM)

Email: akcz2@mizzou.edu

(No relationships reported)

Previous studies in animals have demonstrated that the arterial baroreflex control of heart rate (HR) was greater in female compared to male rodents. In contrast, equivocal results have been reported in humans with several studies reporting that young women, in fact, exhibit a reduced cardiac baroreflex sensitivity compared to young men. In addition, to date, no studies have examined differences in the baroreflex control of HR during exercise in young men and women.

**PURPOSE:** To determine if the carotid baroreflex control of HR differs between young men and women at rest or during dynamic exercise.

**METHODS:** Beat-to-beat HR and blood pressure were measured in nine young women (22±1 yr) and men (22±1 yr) at rest and during steady-state leg cycling at 50% HR reserve. All women were studied during the early follicular phase of the menstrual cycle (days 2-5). Five second pulses of neck suction (NS, -60 Torr) and neck pressure (NP, +40 Torr) were applied to selectively load and unload the carotid baroreceptors, respectively. In addition, HR variability analyses were employed to investigate time and frequency domain indices of parasympathetic and sympathetic control of HR.

**RESULTS:** At rest and during exercise, HR responses to NS were significantly greater in women than men (rest, D -16±3 women vs. D -8±1 men bpm, P=0.002; exercise, D -17±3 women vs. D -6±1 men bpm, P=0.004), whereas responses to NP were similar between groups (rest, D +7±1 women vs. D +5±1 men bpm, P=0.222; exercise, D +4±1 women vs. D +2±1 men bpm, P=0.096). In addition, there were no differences in HR variability measurements between women and men both at rest and during exercise.

**CONCLUSION:** Carotid baroreflex mediated HR responses to a hypertensive challenge are greater in young women both at rest and during exercise. In contrast, the ability of the carotid-cardiac baroreflex to respond to a hypotensive challenge is similar between young women and men. Overall, these preliminary data suggest that sex differences in cardiac baroreflex responses are selective to hypertensive challenges both at rest and during exercise.

#### 1887 Board #28 May 28 8:00 AM - 9:30 AM

##### Carotid Baroreflex Control Of Arterial Blood Pressure At Rest And During Dynamic Exercise In Young And Older Men

James P. Fisher<sup>1</sup>, Colin N. Young<sup>2</sup>, Paul J. Fadel<sup>2</sup>. <sup>1</sup>University of Birmingham, Birmingham, United Kingdom. <sup>2</sup>University of Missouri, Columbia, MO. (Sponsor: Peter B. Raven, FACSM)

Email: j.p.fisher@bham.ac.uk

(No relationships reported)

The arterial baroreflex is of fundamental importance for evoking and maintaining the normal cardiovascular adjustments to exercise. Previous studies have reported that exercise-induced blood pressure responses are exaggerated in older individuals; however, whether alterations in arterial baroreflex function contribute to the greater pressor response during exercise in older subjects remains unclear.

**PURPOSE:** To begin to investigate how healthy aging influences the carotid baroreflex regulation of blood pressure during dynamic exercise.

**METHODS:** Mean arterial pressure (MAP) and heart rate (HR) were continuously recorded at rest and during leg cycling performed at 50% HR reserve in 8 young (23±1 yr) and 6 older middle-aged (61±1 yr) healthy men. Five second pulses of neck pressure (NP, +40 Torr) and neck suction (NS, -60 Torr) were applied to selectively unload and load

the carotid baroreceptors, respectively.

**RESULTS:** At rest, MAP responses to NP tended to be lower in older subjects ( $D+5\pm 1$  older vs.  $D+8\pm 1$  young mmHg;  $P=0.056$ ), whereas responses to NS were significantly greater compared to younger subjects ( $D-15\pm 2$  older vs.  $D-8\pm 2$  young mmHg). Group responses to NP were unchanged by exercise (rest vs. exercise;  $P=0.919$ ) such that the tendency for a reduced response in the older men persisted during leg cycling. In contrast, the MAP responses to NS were attenuated in the older group during exercise but not in the younger group. Thus, the age-group differences to a hypertensive challenge were eliminated during exercise.

**CONCLUSIONS:** These preliminary data suggest that healthy aging alters the carotid baroreflex control of blood pressure both at rest and during dynamic exercise. Further studies are needed to determine how these alterations in arterial baroreflex regulation may influence the pressor response to exercise.

**Effect Of 30-second All-out Exercise On Selected Haemorheological And Platelet Markers In Healthy Subjects**

Renate M. Leithauser, Ralph Beneke, FACSM. *Department of Biological Sciences, University of Essex, Colchester, United Kingdom.*

Email: rleith@essex.ac.uk

(No relationships reported)

Strenuous physical exercise promotes a prothrombotic state and may cause acute myocardial infarction. In a previous study we demonstrated that high-intensity all out exercise like the 30-second Wingate Anaerobic test (WAnT) can lead to activation of blood coagulation and fibrinolysis in healthy subjects. An effect on selected haemorheological markers like fibrinogen (Fib) and platelet count as well as the plasma level of the platelet activation marker soluble p-selectin (sP-sel) is less well investigated.

**PURPOSE:** To analyze the acute effect of a WAnT on indicators of metabolic stress, haemoconcentration and haemorheological and platelet markers.

**METHODS:** Thirteen healthy male leisure time athletes (mean  $\pm$  SD; age  $28.8 \pm 7.2$  yrs, height  $1.84 \pm 0.06$  m, body mass  $82.7 \pm 9.0$  kg) performed a 30-second WAnT. Before and immediately after the WAnT as well as 9 and 30 min into a passive recovery period venous blood was taken for the analysis of plasma lactate concentration (PLA) and pH, total protein (TP) and hematocrit (HCT), FIB, platelet count and sP-sel.

**RESULTS:** Pre-test values of all measures were well within the reference range for healthy subjects. Maxima of PLA ( $17.7 \pm 2.0$  mmol  $l^{-1}$ ), TP ( $6.84 \pm 0.27$  g  $dl^{-1}$ ) and HCT ( $49.0 \pm 2.0$  %) and the minimum of pH ( $7.17 \pm 0.04$ ) were found at 1 or 9 min post WAnT (all  $p < 0.0083$ ). Also Fib ( $278.8 \pm 45.8$  mg  $dl^{-1}$ ) and sP-sel ( $89.9 \pm 26.0$  ng  $ml^{-1}$ ) showed maxima at 1 or 9 min (all  $p < 0.0083$ ), whilst an increase in platelets ( $310 \pm 10 \cdot 10^9 l^{-1}$ ) was not found before 9 min ( $p < 0.0083$ ). Only sP-sel returned to pre-test levels at 30 min. Interrelationships between Fib and TP ( $r = 0.45$ ,  $p < 0.001$ ) and sP-sel and pH ( $r = -0.35$ ,  $p < 0.05$ ), respectively were found.

**CONCLUSION:** The results seem to indicate that the WAnT induced metabolic acidosis contributes to the increase in sP-sel whilst the metabolic osmotic effect attributes to the response of Fib.

Email: Viviane.Conraads@ua.ac.be

A. Van Berendoncks Presenting

(No relationships reported)

**PURPOSE:** Physical training has important peripheral vascular effects. Endothelial progenitor cells (EPC) play an regenerative role at the level of the endothelium. We determined a time-curve of circulating EPC before/after a maximal exercise test (ET) in healthy subjects (HS) and in patients (pts) with chronic heart failure (CHF). The influence of exercise on the diurnal variation of EPC, characterized by an evening peak, was assessed.

**METHODS:** Eight subjects (4 HS,  $20 \pm 0.9$  yrs, Watt max  $265 \pm 10$ ; 4 CHF pts,  $70 \pm 5$  yrs, left ventricular ejection fraction  $20 \pm 5$  %, Watt max  $53 \pm 10$ ) underwent ET. Venous blood was taken before, within 10 min, after cessation of ET, after 30', 60', 2 - 4 - 8 - 12 - 24hrs, 2 - 4 days. Circulating CD34<sup>+</sup>/KDR<sup>+</sup> EPC were quantified in whole blood by flow cytometry.

**RESULTS:** Results are shown in the figures (mean  $\pm$  SEM). ET acutely increased total leucocyte count in both groups (HS:  $p = 0.1$ ; CHF:  $p = 0.01$ ). A second, delayed leucocytosis, was documented in HS, but not in CHF pts. EPC increased acutely following ET in HS, stayed elevated for 1hr, whereas in CHF pts this increase was absent after 1hr. EPC remained elevated the next morning in both groups, although still lower in CHF pts. Normal diurnal variation was suppressed post-ET in both groups.

**CONCLUSION:** Acute exercise induces an increase in leucocyte and EPC numbers, which is smaller and less prolonged in CHF suggesting a general exhaustion of progenitor cells in the bone marrow. Moreover, the present results have consequences for the standardization of blood sampling in future EPC studies. In order to avoid intra-individual variability, recent physical exercise at the time of blood sampling should be taken into account.

(No relationships reported)

Post-exercise hypotension (PEH) has been well-documented and considered as a health promotion benefit of aerobic exercises; however, dramatic PEH and postural hypotension which caused falling and head injury have been reported after ultramarathon (UM) race.

**PURPOSE:** To investigate the relationships among exercise duration, PEH and postural hypotension in UM runners.

**METHODS:** Thirty two experienced UM runners were recruited, 19 subjects participating in 12 hours UM (12UM) and 13 subjects participating in 24 hours UM (24UM). The distance covered during 12 hours and 24 hours were also reported as the physical workload. The resting sitting and standing blood pressures measured before and immediate after the UM were recorded and the PEH was calculated afterward. The postural hypotension index (PHI), blood pressure difference between sitting and standing were also measured before and after the race.

**RESULTS:** The systolic blood pressure (SBP) and diastolic blood pressure (DBP) significantly decreased after both 12UM (DSBP:  $-30.63 \pm 16.37$  mmHg; DDBP:  $-17.79 \pm 11.74$  mmHg,  $p < 0.05$ ) and 24UM (DSBP:  $-25.85 \pm 8.51$  mmHg; DDBP:  $-11.85 \pm 10.46$  mmHg,  $p < 0.05$ ). The prevalence of SBP  $< 100$  mmHg which representing the person would be about to faint are 50% in both groups after the competition. Asymptomatic postural hypotension defined as a fall in SBP of greater than 20 mmHg from the sitting to the erect position without syncopal symptoms was present in 5 runners (15.6%) before the race and in 9 runners (28.1%) afterward. The degree of postural variation in SBP was unrelated to the changes in body weight or running distance.

**CONCLUSION:** Dramatic PEH and postural hypotension with individual differences after UM was noted, and the prevalence of PEH and postural hypotension after the 24UM

**Validation Of A Bioelectrical Impedance Analysis Equation Predicting Body Composition Using Conductor Length Instead Of Height.**

David L. Gee, Jessica D. Nye, Donna R. Parsons, Cen-Tsong Lin. *Central Washington University, Ellensburg, WA.*

Email: geed@cwu.edu

(No relationships reported)

Bioelectrical impedance analysis (BIA) is widely used in predicting body composition. Impedance of an electrical current that passes through the body is related to the composition of the body but also to the length of the conductor, conventionally estimated using height.

**PURPOSE:** To compare a BIA equation predicting fat-free mass (FFM) that utilized actual conductor length (Parsons) with a conventional BIA equation (NHANES), using hydrodensitometry as the reference method.

**METHODS:** Thirty-nine male and 53 female subjects were studied. BIA was performed using a four-terminal impedance plethysmograph. The Parsons equation, validated using an independent sample of 91 subjects, is  $FFM = 0.607 (CL2/R) + 0.265(BW) + 0.184(Xc) + 1.82(G) - 14.7$ , where: CL2 = Conductor Length Squared (cm), R = Resistance (ohms), BW = Body Weight (kg), Xc = Reactance (ohms), and G = Gender (Males = 1, Females = 0).

**RESULTS:** For both sexes, FFM predicted by both Parsons and NHANES equations were equally and highly correlated with FFM measured using hydrodensitometry ( $r = 0.88$  to  $0.91$ ). For males, both equations had equal precision in predicting FFM ( $R^2$  (Parsons) =  $0.711$ ,  $R^2$  (NHANES) =  $0.718$ ). However, for females, FFM predicted with the Parsons equation had a much higher precision than FFM predicted with the NHANES equation ( $R^2$  (Parsons) =  $0.771$  and  $R^2$  (NHANES) =  $0.578$ , respectively).

**CONCLUSION:** These results suggest that using conductor length in BIA equations may result in more precise predictions of FFM for females.

**PURPOSE:** To investigate the validity of single-frequency bioelectrical impedance method (BI; Muscle-alpha, Phision) to assess body composition changes during a 12-week aerobic exercise program in comparison with dual-energy X-ray absorptiometry (DXA; QDR 4500, Hologic).

**METHODS:** Eighteen obese men (age:  $49.1 \pm 11.3$  years, body mass index:  $28.7 \pm 1.8$  kg/m<sup>2</sup>) participated in this study. They enrolled in a 90-min supervised exercise program mainly consisting of aerobic exercise (60-80% of heart rate reserve) on a regular basis of 3 d/wk for 12 weeks. Percentage of fat mass (%fat), fat mass (FM) and fat-free mass (FFM) were measured before and after the program using BI and DXA.

**RESULTS:** With  $-2.7 \pm 2.4$  kg of weight reduction during the program, %fat and FM significantly decreased ( $P < 0.05$ ), but FFM remained unchanged when assessed by BI and DXA. Significant differences ( $P < 0.05$ ) were observed between BI and DXA at baseline for %fat (28.2% vs. 25.4%), FM (23.5 kg vs. 21.3 kg) and FFM (59.7 kg vs. 62.6 kg). Further, significant differences ( $P < 0.05$ ) were observed after the program for %fat (25.2% vs. 23.3%), FM (20.4 kg vs. 19.0 kg) and FFM (60.2 kg vs. 62.3 kg) and change in FM ( $-3.1$  kg vs.  $-2.3$  kg). At each time point, %fat, FM and FFM measured by BI were significantly lower ( $P < 0.05$ ) than those by DXA. The correlation coefficients between BI and DXA were similar at baseline and after the program, while rather low for the change in %fat ( $r = 0.63, 0.69$ , and  $0.33$ , respectively), FM ( $r = 0.81, 0.86$ , and  $0.59$ , respectively) and FFM ( $r = 0.98, 0.98$ , and  $0.15$ , respectively). A Bland-Altman analysis revealed no significant bias (change%fat:  $r = -0.21$ , standard error of estimate: SEE =  $1.36$ ,  $P = 0.40$ ; changeFM:  $r = -0.09$ , SEE =  $1.54$ ,  $P = 0.72$ ; changeFFM:  $r = -0.35$ , SEE =  $0.96$ ,  $P = 0.16$ ).

**CONCLUSIONS:** BI and DXA are able to track changes in %fat and FM similarly during an aerobic exercise program in obese men. Additionally, there are no significant differences in %fat and FM between the two methods, suggesting that BI can be used in a clinical setting.

**The Effect Of Submaximal Exercise And Hydration Status On Bioelectrical Impedance Analysis**

Kimberly A. Smith, Anne E. Hays, Jeff Lynn, Marty Prokop, Ciara Pomerico, Jeremy Miller, Whitney Nardoza, April Pinkney. *Slippery Rock University, Slippery Rock, PA.* (Sponsor: Patricia A. Pierce, FACSM)

Email: kimberly.smith@sru.edu

(No relationships reported)

**PURPOSE:** The purpose of this investigation was to determine the effect of moderate exercise with or without mild dehydration on BIA%FAT.

**METHODS:** Thirty-nine male ( $n=13$ ) and female ( $n=26$ ) subjects (age= $19.3 \pm 0.9$ yr, body fat= $19.1 \pm 8.5\%$ ) underwent testing on two days. On day one, the Dehydration Session (DS), subjects' weight and BIA%FAT were recorded. Subjects then ran 30 min on a treadmill at an intensity of 60-85% HR<sub>max</sub>. After the exercise session, weight and BIA%FAT were re-measured and the amount of weight lost in sweat was recorded in kilograms. A subset of the population ( $n=9$ ) remained in the lab at rest for one hour without eating, drinking, or urinating. Weight and BIA%FAT were recorded every 15 min to determine the lasting effect of exercise on BIA%FAT. On day two, the Euhydration Session (ES), subjects repeated the DS procedure with the exception that subjects drank water equal to the amount of sweat lost during the DS.

**RESULTS:** During the DS, subjects lost a significant amount of water weight ( $-1.25$ kg;  $p<0.01$ ) and BIA%FAT ( $-1.27\%$ ;  $p<0.01$ ). During the ES, subjects maintained body weight through hydration ( $-0.02$ kg;  $p>0.05$ ), but BIA%FAT significantly decreased ( $-0.86\%$ ;  $p<0.01$ ). From 15-60 min post exercise, BIA%FAT significantly increased for both the DS and ES as subjects remained at rest in the lab. After 60 min of seated rest, the DS BIA%FAT remained significantly lower than pre-exercise BIA%FAT ( $p<0.05$ ). Contrary to the DS, BIA%FAT returned to pre-exercise levels in the ES.

**CONCLUSIONS:** BIA%FAT decreased after a 30 min bout of submaximal treadmill exercise regardless of water consumption. This decrease in BIA%FAT is not solely hydration or weight dependent. There was a tendency for BIA%FAT to increase in the hour post exercise in both DS and ES trials even though no water was consumed during this time. The maintenance of hydration during the ES allowed BIA%FAT to return to baseline after 60 min of seated rest, contrary to the DS.

**Accuracy Of Bioelectrical Impedance Analysis Instruments For The Measurement Of Body Composition In Collegiate Baseball Players**

Jeremy T. Barnes, Craig L. Elder, Marcia N. Nelms, Thomas J. Pujol, FACSM, Monica L. Kearney, Jeremy P. Loenneke, Ron D. Williams, Jr..  
*Southeast Missouri State University, Cape Girardeau, MO.*  
(No relationships reported)

**PURPOSE:** Fitness assessments of athletes usually include a measure of body composition. The purpose of this study was to examine whether five different Bioelectrical Impedance Analysis (BIA) instruments varied in their estimates of body composition. The five instruments were the Tanita BF-350, Tanita BF-522, Omron HBF-500, Omron HBF-306, and Omron HBF-300.

**METHODS:** Criterion body composition was measured using DEXA (Lunar Prodigy Advance). In addition, body composition was estimated using skinfolds (SKF). Subjects of the study were 35 college baseball players. Mean (+ SD) subject characteristics were age 20.17 (+1.36) yrs, height 1.82 (+0.06) m, weight 88.45 (+9.50) kg, and body mass index (BMI) 26.69 (+2.20) Kg/m<sup>2</sup>.

**RESULTS:** The percent body fat results were as follows: the Tanita BF-350 = 14.67 + 3.77, the Tanita BF-522 = 14.92 + 3.85, the Omron HBF-500 = 22.47 + 4.51, the Omron HBF-306 = 14.84 + 3.23, the Omron HBF-300 = 15.70 + 4.27, SKF = 18.74 + 6.45, and the DEXA = 20.31 + 7.28. Data were analyzed using repeated measures analysis of variance (ANOVA) and post-hoc paired sample t-tests. A significant F (F = 567.485, p < .001) was found for the 7 different measures of body composition. Post-hoc tests showed statistically significant differences between the DEXA and all the other estimates of body composition.

**CONCLUSIONS:** Although the SKF underestimated body composition and the Omron HBF-500 overestimated body composition the results of this study suggest that for college baseball players the Omron HBF-500 and SKF may provide a valid assessment of body composition in non-laboratory settings. However, the other four BIA instruments all significantly underestimated percent body fat.

**The Ability Of Bioelectrical Impedance To Track Body Composition Changes During A Physical Activity Intervention**

Patrick L. Schneider<sup>1</sup>, Scott E. Crouter<sup>2</sup>, Dixie L. Thompson, FACSM<sup>3</sup>, David R. Bassett, Jr., FACSM<sup>3</sup>. <sup>1</sup>Belmont University, Nashville, TN. <sup>2</sup>University of Massachusetts Boston, Boston, MA. <sup>3</sup>University of Tennessee, Knoxville, TN.  
Email: schneiderp@mail.belmont.edu

(No relationships reported)

Body composition is an important component of an individual's health and fitness profile.

**PURPOSE:** The purpose of this study was to assess the ability of bioelectrical impedance (BIA) to accurately track body composition changes during a physical activity intervention in previously sedentary, overweight men and women.

**METHODS:** Fourteen men (46+7 y) (mean+SD) and 22 women (age, 47+5 y) with a body mass index >25 kg m<sup>-2</sup> participated in a 36-week walking intervention (with a goal of 10,000 steps per day). Body composition was measured by air displacement plethysmography (ADP) and BIA at baseline, after 20 weeks and after 36 weeks.

**RESULTS:** Over the 36-week intervention, the women lost 1.6+4.8 kg of body mass while the men lost 3.9+4.2 kg. Compared to ADP, the decline in percent body fat was significantly underestimated by BIA in women, but not in men.

Percent body fat and fat mass measured at baseline, 20 weeks, and 36 weeks			
Men	Baseline	20 Weeks	36 Weeks
ADP (% body fat)	34.5+6.5	32.6+6.7*	31.7+7.2*
BIA (% body fat)	33.1+6.3	31.6+6.3*	30.8+6.9*
ADP (fat mass, kg)	37.7+13.6	34.8+13.6*	33.8+13.9*
BIA (fat mass, kg)	36.3+13.6	33.7+12.8*	32.9+14.1*
Women			
ADP (% body fat)	48.1+5.3	46.2+5.7*	46.6+5.3
BIA (% body fat)	45.1+4.0	45.6+3.8	45.4+3.7
ADP (fat mass, kg)	46.1+12.2	43.6+11.1*	44.0+11.1
BIA (fat mass, kg)	43.3+11.4	43.1+10.7	42.8+10.3

\* Indicates a significant difference from baseline (P<0.05)

At each time point, BIA estimated % body fat to be significantly lower in both men and women when compared to ADP (P<0.05).

**CONCLUSION:** BIA appears to be a suitable method for detecting body composition changes in men. However, BIA did not accurately detect body composition changes in women and therefore, an alternative body composition assessment method should be considered for this population.

**1896 Board #37 May 28 9:00 AM - 10:30 AM**  
**The Effect Of Acute Fluid Consumption On Segmental Bioelectrical Impedance Analysis**

Curt B. Dixon<sup>1</sup>, Joseph L. Andreacci<sup>2</sup>, Fredric L. Goss, FACSM<sup>3</sup>. <sup>1</sup>Lock Haven University, Lock Haven, PA. <sup>2</sup>Bloomsburg University, Bloomsburg, PA. <sup>3</sup>University of Pittsburgh, Pittsburgh, PA.  
Email: cdixon@lhup.edu

(No relationships reported)

**PURPOSE:** To examine the effect of acute fluid consumption on impedance (IMP) and percent body fat (%BF) determined by segmental bioelectrical impedance analysis (SBIA).

**METHODS:** Seventy-six healthy, recreationally active adults (41 women; 35 men) volunteered to participate in this study (age = 21.0 ± 1.6 y; body mass index = 25.0 ± 3.2 kg/m<sup>2</sup>). Subjects had their body composition assessed by SBIA (Tanita model: BC-418) on three separate occasions. After an initial baseline body composition measurement, subjects consumed water (H<sub>2</sub>O: 20 oz.), a carbohydrate/electrolyte drink (CHOE: 20 oz., 35 grams of carbohydrate; 270 mg sodium; 75 mg potassium), or received nothing, which served as the control (CON). Subjects were reassessed 20, 40 and 60 min following (POST) the baseline measure in each treatment condition.

**RESULTS:** Following fluid consumption (H<sub>2</sub>O and CHOE), IMP, %BF and body mass were significantly different at 20 min (mean difference: H<sub>2</sub>O = 12.9W, 1.0%, 0.5 kg; CHOE = 13.6W, 1.2%, 0.6 kg), 40 min (H<sub>2</sub>O = 15.2W, 1.1%, 0.5 kg; CHOE = 12.2W, 1.1%, 0.5 kg) and 60 min (H<sub>2</sub>O = 14.0W, 1.0%, 0.3 kg; CHOE = 13.0W, 1.0%, 0.3 kg)

POST when compared to baseline values ( $P<0.001$ ). Fluid type had no effect on the magnitude of change POST. During the CON trial, IMP and %BF were significantly greater at 40 min (mean difference = 7.4W; 0.3%) and 60 min (10.9W; 0.5%) POST when compared to baseline ( $P<0.003$ ).

**CONCLUSION:** Fluid consumption significantly increased SBIA-determined IMP and body mass resulting in the overestimation of %BF (~1.0%). As such, when precision is critical, fluid restriction prior to SBIA assessment is recommended in order to avoid temporary alterations in hydration state that may influence body composition measures.

**Acute Fluid Ingestion Impacts Leg-to-leg Bioelectrical Impedance Analysis In Children**

Joseph L. Andreacci<sup>1</sup>, Curt B. Dixon<sup>2</sup>, Elise Fitzgerald<sup>1</sup>, Stephanie Rodgers<sup>1</sup>, Timothy R. McConnell, FACSM<sup>1</sup>. <sup>1</sup>Bloomsburg University, Bloomsburg, PA. <sup>2</sup>Lock Haven University, Lock Haven, PA.

Email: jandreac@bloomu.edu

(No relationships reported)

**PURPOSE:** To examine the effect of acute fluid consumption on body composition measures determined by leg-to-leg bioelectrical impedance analysis (LBIA) in children.

**METHODS:** Forty-five children (20 girls; 25 boys) between 7 and 16 years of age had their percent body fat (%BF) assessed by LBIA (Tanita model: TBA-300A) on two separate occasions: a control (CON) and fluid trial. During the fluid trial, subjects were randomly assigned into either a water (H<sub>2</sub>O; 11 girls; 13 boys) or Gatorade® (CHOE; 9 girls; 12 boys) group. After a baseline body composition measurement, subjects consumed either 12 oz. (355 ml) of H<sub>2</sub>O, CHOE, or received nothing, which served as the CON. Subjects were reassessed 20, 40 and 60 min following post fluid consumption in each treatment group and in the CON group.

**RESULTS:** Following fluid consumption (H<sub>2</sub>O and CHOE), impedance (IMP) was significantly greater ( $P<0.05$ ) at 20 min (H<sub>2</sub>O =  $544.1 \pm 70.2W$ ; CHOE =  $565.8 \pm 70.7W$ ) when compared to baseline values (H<sub>2</sub>O =  $538.5 \pm 67.2W$ ; CHOE =  $558.2 \pm 66.9W$ ). Body mass was significantly greater ( $P<0.05$ ) at 20 min ( $45.6 \pm 15.4kg$ ), 40 min ( $45.6 \pm 15.4kg$ ) and 60 min ( $45.4 \pm 15.4kg$ ) POST CHOE consumption, when compared to baseline values ( $45.2 \pm 15.3kg$ ). Following the consumption of H<sub>2</sub>O, %BF was significantly greater ( $P<0.05$ ) at 20 min, 40 min and 60 min POST (mean difference: 0.8%; 0.7%; 0.6%, respectively) when compared to baseline values. When subjects consumed CHOE, %BF was significantly greater ( $P<0.05$ ) at 20 min (mean difference: = 0.9%) and 60 min (mean difference = 0.4%) POST when compared to baseline values. During the CON trial there were no significant changes in %BF over time, whereas IMP was significantly greater ( $P<0.05$ ) at 40 min ( $555.5 \pm 68.6W$ ) and 60 min ( $556.4 \pm 67.4W$ ) POST when compared to baseline values ( $551.1 \pm 67.0W$ ). Body mass at 60 min (mean difference = 0.2kg) was significantly greater ( $P<0.05$ ) when compared to the baseline CON value.

**CONCLUSIONS:** The ingestion of 12 oz. of fluid significantly increased LBIA-determined %BF values in children. Therefore, when precision is critical, we recommend adhering to the fluid restriction guideline prior to the LBIA measurement to avoid fluid-induced alterations in the child's %BF estimate.

**Validation Of Bioelectrical Impedance Analyzers As A Measure Of Percent Body Fat.**

Anne E. Hays, Kimberly Smith, Jeff Lynn, Marianne Mentch, Megan Knechtges, Jeremy Gebhart, Taylor Swiedom, Andrea Campbell. *Slippery Rock University, Slippery Rock, PA.* (Sponsor: Patricia Pierce, FACSM)

Email: anne.hays@sru.edu

(No relationships reported)

**PURPOSE:** To determine the reliability and validity of the Tanita® and Omron® bioelectrical impedance analyzers (BIA) to estimate percent body fat. Each analyzer operated under two settings, standard and athletic, which were meant to be used for sedentary or active individuals respectively.

**METHODS:** Thirty-nine male (n=13) and female (n=26) subjects (age=19.3±0.9yr, body fat=19.1±8.5%) underwent testing on two separate occasions. Underwater weighing (UWW) was used as the criterion measure to determine percent body fat. Subjects' height and weight were measured and four BIA measurements were conducted (Tanita standard, Tanita athletic, Omron standard, and Omron athletic). Subjects then sat for 30 minutes and weight and BIA were re-analyzed to determine test-retest reliability.

**RESULTS:** Each of the four BIA measurements produced similar results before and after 30min of sitting ( $r = .997-.998$ ;  $p<0.01$ ) establishing excellent test-retest reliability. There was a significant difference between percent body fat derived by UWW and percent body fat estimated by the Tanita athletic mode ( $p<0.05$ ). There were no significant differences between the remaining BIA-estimated percent body fat measurements and UWW ( $p>0.05$ ).

**CONCLUSION:** Tanita and Omron bioelectrical impedance analyzers were reliable, and with a given standard error, can be used to estimate percent body fat when used prior to exercise and when all pre-test assumptions are met. However, the Tanita athletic mode significantly underestimated percent body fat in this sample of SRU students.

**Tracking Changes In Body Fat Using Commercially Available Bia Devices Compared To A Four-Compartment Model**

Jordan R. Moon, Abbie E. Smith, Sarah E. Tobkin, Christopher M. Lockwood, Kristina L. Kendall, Jennifer L. Graef, Michael D. Roberts, Vincent J. Dalbo, Chad M. Kerkisick, Joel T. Cramer, Travis W. Beck, Jeffrey R. Stout, FACSM. *The University of Oklahoma, Norman, OK.*

Email: jordanmoon@ou.edu

(No relationships reported)

Over the past few years the number of bioelectrical impedance analysis (BIA) devices has grown significantly. Several of these devices are designed for consumer purchase with price tags of less than \$100. Many of these BIA devices are designed for predicting percent body fat (%fat); however, the validity of these devices has not been established.

**PURPOSE:** Validate %fat values estimated using commercially available scales compared to a four-compartment (4C) model.

**METHODS:** Three foot-to-foot scales, one hand-to-hand device, and one foot-to-hand scale were evaluated before and after a ten-week exercise intervention in overfat and obese individuals compared to a 4C model. The 4C model included body volume, bone mineral content, and total body water measured by underwater weighing, dual-energy X-ray absorptiometry, and deuterium oxide, respectively. Sixty overfat and obese men and women ( $27 \pm 8yr$ ,  $33.41 \pm 3.81\%$ fat) participated in the study.

**RESULTS:** Only the foot-to-hand BIA scale produced non-significant pre and post %fat estimations compared to the 4C model [constant error (CE)<1.44%fat]; however, the post- total error (TE) value was unacceptable (4.07%fat). Delta %fat values were more accurate than the pre and post-intervention values compared to the 4C model. Of all devices, one foot-to-foot device produced a significant CE value (-1.23%fat) in the exercise group (n=32) while no device produced a significant CE (CE < 1.19%fat) value in the control group (n=28). However, delta TE values ranged from 1.76 to 3.41%fat indicating a large variation between devices.

**CONCLUSIONS:** Pre, post, and delta values indicated that the most accurate BIA for predicting %fat was the foot-to-hand device. However, the 95% limits of agreement for the exercise group indicated individual overestimations upwards of 4.14%fat and underestimations as large as 3.07%fat. Therefore, commercial scales are not valid for a single estimation of %fat and are more accurate for tracking changes with individual errors  $\pm 3.6\%$ fat.

**Caffeine Does Not Alter Heart Rate-Derived Estimates Of Oxygen Uptake During Heavy Exercise**

Robert Pettitt<sup>1</sup>, Klaus R. Marg<sup>2</sup>, Felicia Greer<sup>2</sup>, Brian E. Udermann, FACSM<sup>3</sup>, Mark G. Abel<sup>4</sup>. <sup>1</sup>Minnesota State University, Mankato, MN. <sup>2</sup>California State University, Fresno, CA. <sup>3</sup>University of Wisconsin-La Crosse, La Crosse, WI. <sup>4</sup>University of Kentucky, Lexington, KY.  
Email: robert.pettitt@mnsu.edu

(No relationships reported)

Heart rate (HR)-derived estimation of oxygen uptake ( $\text{VO}_2$ ) during exercise is more accurate when the differences in reserves above and below gas exchange threshold (GET) are adjusted for. Caffeine's accelerating effect on resting HR may translate to exercising HR and therefore may invalidate HR-derived estimates of  $\text{VO}_2$  during exercise; however, no direct research supports such a claim.

**PURPOSE:** To evaluate the efficacy of HR-derived estimates of  $\text{VO}_2$  during heavy exercise in control (CTRL) and 6 mg·kg<sup>-1</sup> caffeinated (CAF) states.

**METHODS:** Nine men ( $\text{VO}_{2\text{max}}$ :  $57 \pm 5$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, age:  $36 \pm 4$  y) completed a graded exercise test to determine power evoking the GET. Each subject returned on two separate occasions and in counterbalanced order and in double-blind fashion, ingested dextrose or CAF 1-hr prior to engaging a 20-min constant-load, pedaling bout. For each bout, subjects pedaled on their own bicycle mounted to a CompuTrainer at an intensity equivalent to the power evoking the GET. Actual and HR-estimated  $\text{VO}_2$  data were summed for the total 20-min exercise time (total  $\text{VO}_2$ ) then compared using Bland-Altman plots. Two-way ANOVA with repeated measures was used to compare actual-estimate and CTRL/CAF differences.

**RESULTS:** Total  $\text{VO}_2$  accumulated during CAF ( $70 \pm 8$  L) was higher than CTRL ( $67 \pm 8$  L) ( $F_{1,7} = 8.95$ ,  $p = 0.02$ ). There was no difference ( $F_{1,7} = 0.39$ ,  $p = 0.55$ ) in actual versus HR-derived total  $\text{VO}_2$  estimates in either CTRL or CAF states. Actual-estimate differences (Mean) and limits of agreement ( $\pm 2\text{SD}$ ) were low for CTRL ( $0.70 \pm 4.46$ ) and CAF ( $1.12 \pm 4.22$  L) states.

**CONCLUSION:** Moderate-dose CAF intake elevates  $\text{VO}_2$  but does not affect the accuracy of HR-derived estimates of  $\text{VO}_2$  during heavy exercise.

**Effects Of Caffeinated And Uncaffeinated Energy Drinks On Muscular Strength And Endurance**

Nora B. Burton, Michelle A. Hardy, Randal H. Glaser, Aaron H. Honeycutt, Michael B. Hubier, Chris M. Ready, Gordon L. Warren, FACSM. Georgia State University, Atlanta, GA.

(No relationships reported)

Caffeine ingestion has been found to increase muscle activation and as a result strength. However, it is not known if caffeine when combined with carbohydrate, such as that in a commercial energy drink, would have a similar effect.

**PURPOSE:** To compare a caffeinated energy drink's effect on muscle activation and strength with that of placebo and an uncaffeinated energy drink.

**METHODS:** A convenience sample of 15 college students was used in a double-blind, repeated measures experimental design. Each subject performed 3 trials, ingesting either a caffeinated energy drink (Full Throttle, The Coca-Cola Company), an uncaffeinated version of the energy drink, or a placebo drink. The interpolated twitch procedure was used to assess maximum voluntary isometric contraction (MVIC) strength, electrically-evoked strength, and muscle activation during MVIC of the knee extensors both before and after drink ingestion, and after a fatiguing bout of 50 concentric contractions.

**RESULTS:** The mean change in MVIC strength from before to after drink ingestion was greater for the caffeinated ( $+5.0\%$ ;  $\text{SE}=1.7\%$ ) and uncaffeinated ( $+4.7\%$ ;  $\text{SE}=1.1\%$ ) energy drinks compared to placebo ( $-0.5\%$ ;  $\text{SE}=1.5\%$ ) ( $p=0.017$ ); there was no significant difference between the two energy drinks. There was no effect of drink type on the changes in electrically-evoked strength or muscle activation from before to after drink ingestion. In addition, there was no effect of drink type on the changes in any variable from before to after the fatiguing bout of contractions. The similar increase in MVIC strength from before to after drink ingestion seen with the two energy drinks is not easily explained. The caffeinated energy drink significantly increased the plasma glucose level over that for placebo whereas the uncaffeinated drink did not. Furthermore, the serum caffeine level was 14-fold greater with the caffeinated energy drink compared to the uncaffeinated drink.

**CONCLUSION:** Both caffeinated and uncaffeinated energy drinks can increase MVIC strength in the unfatigued state but the mechanism for the ergogenic effect is unclear.

**Acute Effects Of A Caffeine-containing Thermogenic Supplement On Endurance Performance And Muscular Strength In Men**

Ashley A. Walter, Trent J. Herda, Eric D. Ryan, Pablo B. Costa, Katherine M. Hoge, Travis W. Beck, Jeffrey R. Stout, FACSM, Joel T. Cramer, FACSM. University of Oklahoma, Norman, OK.

Email: ashannwalter@ou.edu

(No relationships reported)

**PURPOSE:** To determine the effects of a thermogenic nutritional supplement on muscular strength, endurance performance, and rating of perceived exertion during cycle ergometry in college-aged men.

**METHODS:** Twenty recreationally-trained men (mean  $\pm$  SD age =  $21.5 \pm 1.4$  years; stature =  $178.2 \pm 6.3$  cm; mass =  $76.5 \pm 9.9$  kg;  $\text{VO}_{2\text{PEAK}} = 3.05 \pm 0.59$  L/min<sup>-1</sup>) volunteered to participate in this randomized, double-blinded, placebo-controlled, cross-over study. All testing took place over a three-week period, with each of the 3 laboratory visits separated by 7 days ( $\pm 2$  hours). During visit 1, a graded exercise test was performed on a Lode Corival cycle ergometer (Lode, Groningen, Netherlands) until exhaustion (increase of 25 W every 2 min) to determine the maximum cycle ergometry power output (W) at the  $\text{VO}_{2\text{PEAK}}$  (Parvo Medics TrueOne® 2400 Metabolic Measurement System, Sandy, Utah). In addition, one-repetition maximum (1-RM) strength was assessed using the bench press (BP) and leg press (LP) exercises. During visits 2 and 3, the subjects were asked to consume a capsule containing either the active supplement (200 mg caffeine, 33.34 mg capsaicin, 5 mg bioperine, and 20 mg niacin) or the placebo (175 mg of calcium carbonate, 160 mg of microcrystalline cellulose, 5 mg of stearic acid, and 5 mg of magnesium stearate in an identical capsule) 30 min prior to the testing. Testing included a time-to-exhaustion (TTE) ride on a cycle ergometer at 80% of the previously-determined power output at  $\text{VO}_{2\text{PEAK}}$  followed by 1-RM LP and BP tests. Rating of perceived exertion (RPE) was also assessed throughout the TTE tests.

**RESULTS:** There were no differences ( $p > 0.05$ ) between the active and placebo trials for BP, LP, TTE, or RPE. However, for the BP and LP scores, the baseline values (visit 1) were less than the values recorded during visits 2 and 3 ( $p \leq 0.05$ ).

**CONCLUSIONS:** Our findings indicated that the active supplement containing caffeine, capsaicin, bioperine, and niacin did not alter muscular strength, cycling endurance, or RPE during the TTE test in college-aged men when compared to a placebo trial.

**ACKNOWLEDGEMENTS:** This study was funded by a grant from the General Nutrition Corporation, Pittsburgh, PA.

**Influence Of A CYP1A2 Polymorphism On The Ergogenic Effects Of Caffeine During Sprint Cycling**

Michael J. Saunders, FACSM, Christopher J. Womack, FACSM, David J. Bolton, Marta K. Bechtel, Bridget A. Holroyd, Megan D. Garvey, Wade H.

Dunham, Lori B. Mattox. *James Madison University, Harrisonburg, VA.*

(No relationships reported)

**PURPOSE:** Cytochrome P450 is a liver enzyme which plays a key role in caffeine metabolism. A (C/A) single nucleotide polymorphism at intron 1 of the Cytochrome P450 gene influences caffeine metabolism, with individuals possessing the C variant having slower caffeine metabolism and subsequently higher plasma caffeine levels following caffeine ingestion. Thus, this genetic polymorphism could potentially explain variability in responses to caffeine supplementation. The purpose of this study was to determine if this specific CYP1A2 polymorphism influenced the ergogenic effect of caffeine supplementation during short-duration cycling.

**METHODS:** 24 male cyclists (24.9±7.5 yrs, 179.9±9.6 cm, 76.1±13.4 kg) performed two exercise tests to volitional exhaustion on an electrically braked cycle ergometer, at a workload corresponding to 150% of  $\dot{V}O_{2peak}$ . One hour prior to testing subjects ingested either 6 mg/kgBW of caffeine (CAF) or a placebo (PLA), administered in double-blind fashion. DNA was obtained from whole blood samples and genotyping was performed via polymerase chain reaction using allele-specific primers. Subjects were grouped as those homozygous for the A variant (n=11) and those possessing the C variant (n=13).

**RESULTS:** Caffeine significantly increased time to exhaustion ( $p<0.05$ ) in the overall group. There was a strong, but not significant ( $p=0.06$ ) tendency for subjects homozygous for the A variant to derive greater performance improvements from caffeine (33%; PLA=86.1±25.1 s, CAF=114.5±37.9 s) compared to subjects possessing the C variant (11%; PLA=86.9±31.0 s, CAF=96.6±25.4 s). Blood lactate levels were significantly increased by caffeine intake, both at rest (CAF=1.03±0.33 mmol/L; PLA=0.75±0.28 mmol/L) and post-exercise (CAF=7.59±1.04 mmol/L; PLA=7.13±1.02 mmol/L), independent of genotype. Peak HR was also significantly elevated in the caffeine trials (CAF=178±11 bpm; PLA=175±9 bpm), with no influence of genotype. Isometric MVC of the leg-extensors significantly decreased from pre-exercise (525.2±122.3 N) to post-exercise (490.8±116.2 N), with no influence of caffeine or genotype.

**CONCLUSIONS:** Subjects homozygous for the A variant may have a more pronounced ergogenic effect from caffeine during sprint cycling than individuals who possess the C variant.

Email: jmrosene@plymouth.edu

(No relationships reported)

**PURPOSE:** The purpose of this investigation was to determine the effects of 3-d of creatine supplementation on thermoregulation and muscle force output.

**METHODS:** 14 males participated in two exercise bouts (thermoregulation and muscle force), following 3-d of creatine supplementation (0.3 g/kg total body weight) or placebo. For the thermoregulation session subjects ran for 60 min at 60-65% of  $\dot{V}O_{2max}$  in the heat (32.58 ± 0.91°C; 18.52 ± 4.79%). Immediately following the thermoregulation session muscular force output was measured isokinetically at velocities of 60, 180, and 300°/s. Pre- and post-test thermoregulatory measures included nude body weight (NBW), urine specific gravity (USG), total body water (TBW), extracellular water (ECW), intracellular water (ICW), serum creatine levels (SCR), and urinary creatinine levels (UCR). During the 60 min run core temperature ( $T_{re}$ ) was assessed in 5 min intervals. Peak torque was used to assess isokinetic muscular force output. The velocities and repetitions included 60°/s x 10 reps; 180°/s x 15 reps; and 300°/s x 30 reps. **RESULTS:**  $T_{re}$  increased over the 60 min run for both conditions. For TBW and ECW there were significant ( $p < .05$ ) treatment and time effects. TBW was significantly greater following creatine supplementation versus placebo, and pre-test TBW values were greater than post-test TBW values. ECW was greater following creatine supplementation versus placebo, and pre-test ECW values were significantly less than post-test ECW values. No significant difference ( $p > .05$ ) was found between conditions for ICW, NBW, USG, UCR, and SCR. However, pre-test scores for ICW, USG, UCR, and SCR were significantly less ( $p < .05$ ) at pre-test versus post-test. There were no significant differences ( $p > .05$ ) in peak torque values between conditions for each velocity. A significant ( $p < .05$ ) overall velocity effect was found for both flexion and extension. As velocity increased, mean peak torque values decreased. **CONCLUSIONS:** 3-d of creatine supplementation does not effect thermoregulation during submaximal exercise in the heat. The lack of difference in peak torque values suggests that 3-d of creatine supplementation is not enough to elicit an ergogenic effect for muscle force output following endurance activity.

**The Effect Of Two Different Creatine Formulations On Skeletal Muscle Creatine Retention**

Joan M. Eckerson, FACSM<sup>1</sup>, Anthony J. Bull<sup>1</sup>, Geri A. Moore<sup>1</sup>, Jennifer C. Yee<sup>1</sup>, Brian D. Roy<sup>2</sup>. <sup>1</sup>*Creighton University, Omaha, NE.* <sup>2</sup>*Brock University, St. Catharines, ON, Canada.*

(No relationships reported)

Many creatine (CR) supplements contain dextrose, since early research suggested that a large insulin spike enhanced CR uptake into muscle. However, it has also been reported that CR uptake is primarily dependent upon sodium vs. insulin, which has led to the formulation of products that contain higher amounts of sodium and no dextrose; therefore, these products may also be Calorie free. Few studies have compared the efficacy of these 'sugar free' CR products to more traditional formulations that include dextrose.

**PURPOSE:** To compare the effects of two different CR formulations on total skeletal muscle CR retention (TCR) following loading and maintenance doses.

**METHODS:** 19 resistance trained men ( $X \text{ age} \pm \text{SEM} = 29 \pm 2 \text{ yr}$ ) randomly received one of two treatment conditions: (1) dextrose-free CR supplement containing 5g CR citrate and 250mg sodium (n=9; SOD) or (2) a CR supplement containing 5g CR monohydrate and 36g dextrose (n=10; DEX). Each treatment was dissolved in 16oz water and ingested 4 times per day for 5d (loading) followed by 5 g/d for 28d (maintenance). Body weight (BW) was measured using a calibrated physician's scale and muscle biopsies were obtained from the vastus lateralis using a fine needle aspiration technique at baseline (BL) and following the loading and maintenance doses for the determination of free CR (fCR) and phosphocreatine (PCR). The data were analyzed using 2x3 ANOVA ( $p<.05$ ).

**RESULTS:** All CR values are expressed as mmol/kg dw. There were no significant time x group interactions for BW, fCR, PCR, or TCR; however, there was a significant time effect for fCR ( $p = .003$ ). Scheffe' post hoc tests showed a significant increase in fCR at 5d (59.63 ± 5.8) and 28d (58.40 ± 5.23) when compared to BL (47.90 ± 5.23).

**CONCLUSION:** These findings suggest that SOD and DEX CR formulations are equally effective for increasing fCR in resistance trained men. The increase in fCR (25%) following 5d of loading is comparable to increases reported in previous studies, and remained elevated throughout the 28d maintenance period. Although 5d CR loading with DEX resulted in an extra 576 kcal/d, there were no significant differences between or within groups for BW. The mean increase in BW at 5d and 28d for all 19 subjects compared to BL was 1.34 kg and 2.11 kg, respectively.

**Influence Of Creatine Supplementation On The Parameters Of The All-out Critical Power Test**

Anni Vanhatalo, Andrew M. Jones, FACSM. *University of Exeter, Exeter, United Kingdom.*

Email: a.vanhatalo@exeter.ac.uk

(No relationships reported)

**PURPOSE:** We tested the hypotheses that a 5-day creatine loading intervention would result in no alteration in the power asymptote (the critical power, CP), but would significantly increase the curvature constant ( $W\dot{C}$ ; analogous to the total amount of work done above CP) using a novel all-out cycling test protocol to establish the parameters

of the power-duration relationship.

**METHODS:** Following institutional ethical approval, seven healthy males completed 3-min all-out critical power tests against fixed resistance on an electrically braked cycle ergometer after a 5-day dietary supplementation with 20 g per day of creatine monohydrate (CR) or the same dose of a glucose placebo (PL). The CP was estimated from the mean power output sustained over the final 30 s of the test and the W<sub>6</sub> was estimated as the power-time integral above the end-test power output. Differences between conditions were assessed by paired samples t-tests and statistical significance was accepted at  $P < 0.05$  level.

**RESULTS:** Creatine supplementation resulted in a significant increase in body mass (from  $80.4 \pm 9.2$  kg at baseline to  $81.5 \pm 9.5$  kg;  $P < 0.05$ ), whereas the body mass was not different after the placebo supplementation ( $80.3 \pm 9.3$  kg;  $P = 0.74$ ). There were no differences in the power profiles of the 3-min all-out tests following PL and CR supplementation (CP; PL:  $252 \pm 30$  vs. CR:  $255 \pm 28$  W,  $P = 0.14$ ; W<sub>6</sub>; PL:  $19.4 \pm 3.5$  vs. CR:  $19.2 \pm 3.4$  kJ,  $P = 0.77$ ; total work done; PL:  $64.8 \pm 4.9$  vs. CR:  $65.0 \pm 4.9$  kJ,  $P = 0.49$ ).

**CONCLUSIONS:** In contrast to earlier studies which established the parameters of the power-duration relationship using the conventional prediction trial protocol, the present study indicates that creatine loading does not alter either the CP or the W<sub>6</sub> as assessed using the novel 3-min all-out test and has no ergogenic effect on power output during prolonged all-out cycling.

**Three Weeks Creatine Monohydrate Supplementation Affects Testosterone And Dihydrotestosterone Conversion In Young Rugby Players**

Naomi E. Brooks, Johann van der Merwe, Kathryn H. Myburgh, FACSM. *Stellenbosch University, Stellenbosch, South Africa.*

Email: nbrooks@sun.ac.za

(No relationships reported)

Creatine supplementation influences muscle mass, however the mechanisms behind the ergogenic effects of creatine have not been elucidated. Testosterone can stimulate muscle growth by increasing protein synthesis and potentially re-utilizing amino acids from muscle protein breakdown. Testosterone can be converted into a more bioactive metabolite, Dihydrotestosterone (DHT) by 5- $\alpha$  reductase. DHT has recently been shown to be related to protein synthesis at the transcriptional level. Both T and DHT, as well as the conversion of T to DHT may be beneficial in muscle development and hypertrophy, and creatine supplementation may take effect through these androgens.

**PURPOSE:** To measure serum T and DHT and calculate the conversion rate after 21 days creatine supplementation administered in a double blind placebo controlled cross over study design with a 6 week washout period.

**METHODS:** 20 Caucasian males from a Rugby Institute situated near Stellenbosch University in South Africa took part in the study, (aged 18-19 yrs). Subjects were randomly assigned to two groups. Subjects underwent a 7 day loading period with creatine supplementation or placebo followed by 14 days maintenance dose (Cr or placebo). Creatine monohydrate was given with glucose (25g/day creatine and 25g/day of glucose) for loading dose and 5g/day creatine and 25g/day of glucose for maintenance dose. Placebo group received glucose only (50g/day glucose) for loading dose and 30g/day glucose for maintenance dose. Blood samples were taken at day 0, after 7 days supplementation and after the further 14 day maintenance period. T and DHT were measured using DSL Testosterone and Dihydrotestosterone radio immunoassay. Repeated measures ANOVA was used.

**RESULTS:** There was no difference in body mass prior to the experiment. Creatine supplementation appeared to significantly increase the rate of conversion of T to DHT after 7 days (36% increase;  $p < 0.0001$ ) and 21 days (22% increase;  $p < 0.01$ ) of creatine monohydrate supplementation. There was no change in % body fat in either group.

**CONCLUSIONS:** Creatine supplementation may act, at least in part, through the increased rate of conversion of T to DHT.

(No relationships reported)

Previous studies showed that ingestion of caffeine together with creatine may inhibit the effects of creatine on anaerobic exercise. Although some studies indicated that ingested caffeine after short-term creatine supplementation could increase maximal accumulated oxygen deficit, there was no evidence to prove whether this supplementary method could facilitate stop-and-go exercise performance.

**PURPOSE:** This study was to investigate the effects of caffeine ingestion after creatine supplementation on intermittent high-intensity cycling sprints performance.

**METHODS:** Twelve physically active men were administered in a double-blind, randomized, counterbalanced design to perform intermittent high-intensity sprints ( $6 \times 10$ -s; repeated at 60-s intervals, HIS) on a cycling ergometer with or without caffeine ingestion. After short-term creatine monohydrate supplementation ( $0.3 \text{ g} \cdot \text{kg}^{-1} \cdot \text{day}^{-1}$ , 5 days), subjects ingested  $6 \text{ mg} \cdot \text{kg}^{-1}$  caffeine or placebo (maltodextrin) 1 hour before HIS trials. Heart rate was monitored continuously throughout the tests, with rating of perceived exertion (RPE) recorded after each sprint. Earlobe blood samples were also drawn immediately after each sprint to evaluate lactate and glucose concentrations.

**RESULTS:** Compared with placebo, caffeine did not result in higher maximal power output ( $842.3 \pm 102.2$  vs.  $813.5 \pm 95.3$  watts,  $p > 0.05$ ). However, the relative peak power output in caffeine treatment was significantly higher than in placebo during the first sprint ( $11.7 \pm 0.7$  vs.  $11.3 \pm 0.7$  watts  $\cdot \text{kg}^{-1}$ ,  $p < 0.05$ ) and second sprint ( $11.5 \pm 0.7$  vs.  $10.8 \pm 0.7$  watts  $\cdot \text{kg}^{-1}$ ,  $p < 0.05$ ). Heart rates were significantly increased with caffeine treatment from the third sprint to the final sprint, and the blood lactate and glucose concentrations were also significantly elevated through the HIS trial. Furthermore, there were no significant effects of caffeine ingestion on the RPE scores.

**CONCLUSIONS:** The present study showed that caffeine ingestion after short-term creatine supplementation could improve intermittent high-intensity sprints performance, but might also induce higher metabolic stress.

**Overload Creatine Supplementation Effect On Volleyball Players Strength**

Paulo V. João<sup>1</sup>, Pedro A. Figueiredo<sup>2</sup>, José Monteiro<sup>1</sup>, Maria P. Moata<sup>1</sup>. <sup>1</sup>*UTAD, Vila Real, Portugal.* <sup>2</sup>*UP, Porto, Portugal.*

Email: pvicente@utad.pt

(No relationships reported)

**PURPOSE:** To determine the effects of overload oral creatine supplementation during 7 days, on strength gain and delayed muscle fatigue of Volleyball players.

**METHODS:** Twenty four male Volleyball players, with an average age of 21.4 yrs ( $\pm 2.4$ ) took part in this study: 12 constituted the placebo group (PG) and ingested 20 g of manitol per day, and the others ingested 20 g of creatine monohydrate (CG) per day, distributed by four doses of 5 g each (in the morning, after lunch and before and immediately after the training). To measure strength levels, all the athletes performed a Squat Jump (SJ) and a Counter Movement Jump (CMJ) in the Ergo Jump (Globus Ergo Tester) at the beginning and in the end of the training session, both before the supplementation program started (pretest) and after 7 days (posttest). The groups' strength levels comparisons between pretest and posttest and between the beginning and the end of each training session were made using two-way ANOVA with repeated measures.

**RESULTS:** There were no differences in SJ performance between pretest and posttest either in PG ( $0.64 \pm 0.04$  vs.  $0.66 \pm 0.07$  at beginning, and  $0.64 \pm 0.05$  vs.  $0.65 \pm 0.04$  at the end of training session) or in CG ( $0.60 \pm 0.07$  vs.  $0.59 \pm 0.09$  at beginning, and  $0.59 \pm 0.07$  vs.  $0.61 \pm 0.06$  at the end of training session). Similarly, there were no differences in CMJ performance between pretest and posttest either in PG ( $0.65 \pm 0.04$  vs.  $0.67 \pm 0.03$  at beginning, and  $0.66 \pm 0.03$  vs.  $0.66 \pm 0.03$  at the end of the training session) or in CG

(0.61±0.07 vs. 0.60±0.08 at beginning, and 0.60±0.07 vs. 0.61±0.07 at the end of the training session).

**CONCLUSIONS:** The overload creatine supplementation failed to induce an increase in strength gain and delayed muscle fatigue of Volleyball players.

**Creatine Supplementation: Effects On Leg Power During Repeat Sprint Running In Collegiate Football Players**

Glenn A. Wright, Michael DeLong, Kaitlin Sweeney, James White, Richard P. Mikat, FACSM. *UW LaCrosse, LaCrosse, WI.*

Email: wright.glen@uwla.edu

(No relationships reported)

American football is characterized by work:rest ratios of ~5 s of intense work with ~45 s recovery between plays. Although many research studies show that creatine loading is effective during repeat sprint activity on a cycle ergometer, the effectiveness of creatine loading has been less convincing during sprint running using sprint times as a performance measure. In studies that have shown no benefit during repeat sprint running tests, some have postulated that the increased body mass with creatine loading may compromise any metabolic benefit that may enhance sprint running performance.

**PURPOSE:** To determine the effects of creatine loading on repeat sprint running performance by measuring leg power on a loaded non-motorized treadmill during sprint running.

**METHODS:** On 2 occasions 7 d apart, 20 collegiate football players participating in an off season training program performed a repeat sprint test (RST) consisting of 2 sets of 5 maximal 5 s sprint runs on a non-motorized treadmill against a load equal to 15% body mass. Recovery between sprints was 45 s, while between sets of sprints was 10 min. Players were familiarized with the RST 2 times prior to the initial test. After the initial test, players were matched by average power produced during the RST and separated into 2 supplementation groups: creatine (Cr- 5 g x 4/d for 6 d) or placebo (PL- same dose of maltodextrin) in a double blind design. Percent body fat was determined before each test using 7 site skinfold method.

**RESULTS:** A significant increase in body mass following loading was observed in the Cr group (Pre, 90.8 ± 9.9 kg; Post 92.0 ± 9.8 kg, p=0.01), but not in PL (Pre, 93.4 ± 7.8 kg; Post 93.9 ± 7.7 kg, p=0.09). Body fat did not change Pre to Post for either group (Cr, p=0.64; PL, p=0.38). Neither group showed a significant pre vs. post difference in performance for peak power (Cr, p=0.67; PL, p=0.93), average power (Cr, p=0.89; PL, p=0.73), peak velocity (Cr, p=0.73; PL, p=0.52), average velocity (Cr, p=0.14; PL, p=0.45) or fatigue decrement for peak power (Cr, p=0.90; PL, p=0.25), average power (Cr, p=0.81; PL, p=0.26), peak velocity (Cr, p=0.49; PL, p=0.20) or average velocity (Cr, p=0.87; PL, p=0.86).

**CONCLUSIONS:** The results of this study indicate that sprint power and velocity during a RST similar to the work:rest ratios for football are not affected by 6 d of creatine loading.

**Wingate Performance And Surface Emg Frequency Variables Are Not Affected By Creatine Or Creatine+caffeine Ingestion**

Jacobo O. Morales<sup>1</sup>, Felicia Greer<sup>1</sup>, Darpan I. Patel<sup>2</sup>, Tim R. Anderson<sup>1</sup>, Wade Gilbert<sup>1</sup>, Amanda Stetler<sup>1</sup>, John Monroe<sup>1</sup>. <sup>1</sup>California State University, Fresno, Fresno, CA. <sup>2</sup>Cedra Clinical Research LLC, San Antonio, TX.

Email: jacobom@csufresno.edu

(No relationships reported)

The possible synergistic effects of creatine and caffeine on anaerobic exercise are controversial. It is unknown if these substances, when taken together, impact motor unit recruitment as determined from surface EMG.

**PURPOSE:** Examine if power output and EMG variables during high intensity cycling are affected following creatine and/or creatine+caffeine ingestion.

**METHODS:** 18 active college males (mean ±SD, age: 22.9 ± 2.4 yr; body mass: 87.03 ± 10.6 kg) performed the Wingate Test (WG) after 7 days of ingesting either placebo (cornstarch) or creatine (5 grams, 4x/d). On day 7, subjects ingested either placebo (dextrose) or caffeine (5 mg/kg body weight) 1 hr prior to testing. Treatments were: 1) Placebo (PL) - placebo loading + placebo; 2) Creatine (CR) - creatine loading + placebo; 3) Creatine + Caffeine (CRCaff) - creatine loading + caffeine. For all WG, peak power (PP), minimum power (MP) and the percent decline in power (Pd) were calculated. EMG records of the right vastus lateralis (VL) and gastrocnemius (GA) corresponding to the PP and MP periods were collected. The EMG signals' amplitude (IEMG), and their mean (MNPf) and median frequencies (MDPf) were calculated. A 2-Way Repeated Measures ANOVA (Treatment x Time) determined the effect of the treatments on all dependent measures across time.

**RESULTS:** There was a significant decline from PP to MP in all treatments (p<0.001). There was no treatment effect in the power output variables (PP: PL, 1101 ± 128W; CR, 1112 ± 155W; CRCaff, 1133 ± 133W) (MP: PL, 561 ± 70W; CR, 572 ± 61W; CRCaff, 546 ± 135W) (Pd: PL, 48 ± 6.2%; CR, 48 ± 6.3%; CRCaff, 51 ± 12%). For both muscles, MNPf and MDPf diminished significantly (p<0.001) across time and to a similar degree in all trials. The supplementation treatments had no effect on the corresponding IEMG scores of the VL and GA.

**CONCLUSIONS:** Creatine and/or creatine+caffeine supplementation do not affect power output during a WG test. These supplementation protocols do not impact neuromuscular drive as indicated by the similar IEMG scores between treatments. The frequency content of the EMG signal and thus, the nature of the recruited motor units before and after the expression of fatigue were not affected by the treatments. The lack of change in the muscles' IEMG along with the decline in power suggests a peripheral, as opposed to a neural mechanism of fatigue.

**Prediction Of Maximal Rates Of Water Excretion With Excessive Water Consumption During Exercise.**

Edward J. Zambraski, FACSM<sup>1</sup>, Jacques R. Poortmans, FACSM<sup>2</sup>. <sup>1</sup>US Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>Universite de Bruxelles, Brussels, Belgium.

(No relationships reported)

Excessive fluid consumption may expand plasma volume and lead to hyponatremia. Cases of water intoxication and hyponatremia have been reported during exercise. It has been suggested that the inability of the kidneys to excrete an excessive fluid load during exercise represents an abnormality of renal function. A fundamental principle is that the maximal urine volume is limited or determined by the amount of "free water" that reaches the collecting ducts. Changes in glomerular filtration or the filtered load and increases in renal tubular reabsorption of sodium and water will limit free water delivery to the collecting ducts.

**PURPOSE:** To use existing data to model renal function during moderate/heavy exercise to predict maximal rates of water excretion.

**METHODS:** Based upon human studies and micropuncture and renal denervation data in animals, rates of glomerular filtration, tubular reabsorption, as influenced during exercise, were used to calculate free water delivery to the collecting duct.

**RESULTS:** A glomerular filtration of 60 ml/min was used. Estimates of tubular reabsorption, driven by sympathetic neural activity, angiotensin II, and aldosterone, were predicted to return 90 % of the filtered water load back to the circulation. The resultant free water delivery to the collecting ducts was 6 ml/min. With a full suppression of ADH, 6 ml/min represents the maximal urine flow rate that can be achieved by normally functioning kidneys during exercise. If there is non-osmotic mediated release of ADH this maximal urine flow rate will be reduced below 6 ml/min.

**CONCLUSION:** In the absence of significant sweat losses, during heavy exercise the consumption of more than 6 ml/min of water will result in the dilution of plasma and possible hyponatremia.

**Modulation Of Renin, Angiotensin, Aldosterone And Arterial Distensibility Following Aerobic Exercise In Pre-hypertensive Individuals**

Scott R. Collier<sup>1</sup>, Vincent Frechette<sup>2</sup>, Hong Ji<sup>3</sup>, Kathryn Sandberg<sup>3</sup>. <sup>1</sup>*Appalachian State University, Boone, NC.* <sup>2</sup>*SUNY Upstate Medical University, Syracuse, NY.* <sup>3</sup>*Georgetown Medical University, Washington, DC.*  
(No relationships reported)

Hypertension is associated with increased arterial stiffness, which leads to ventricular remodeling and increased risk for cardiovascular disease. The renin-angiotensin-aldosterone system (RAAS) is a key regulator of blood pressure (BP) and plays a role in modulating vascular function. Yet, few studies have compared the hemodynamic and vascular effects of aerobic exercise (AE) with concomitant changes in the RAAS.

**PURPOSE:** The purpose of this study was to investigate the changes in resting hemodynamics (systolic and diastolic BP (SBP & DBP)), arterial distensibility (pulse wave velocity (PWV)) and modulations of the RAAS.

**METHODS:** Following 4 weeks of a control wait period we supervised 8 pre-to stage-1 unmedicated, obese hypertensives (5M and 3W, 54±2.8 yrs) for 4 weeks of moderate intensity (3x/week at 65%  $\dot{V}O_{2max}$ ) aerobic exercise training (AE). Fasted blood draws were taken at 0700 h at the start of the control, exercise and at the end of the exercise training periods. An ANOVA with repeated measures was used to make the pre-post comparisons with significance set at  $p < 0.05$ .

**RESULTS:** There were no significant changes during the 4 week control period in any variables, however AE significantly decreased SBP (pre vs post training: 137±1.6 vs 133.5±1.9 mmHg) and DBP (pre vs post training: 74.7 vs. 72.6 mmHg). AE decreased both central and peripheral PWV (pre vs post: 10.2±0.39 to 10±0.39m/s and 10.3±0.4 to 9.9±0.4m/s, respectively). While there were no significant changes in angiotensin and plasma renin activity, there were significant decreases in aldosterone (pre vs post training: 176±28 to 123±25 pg/mL).

**CONCLUSIONS:** These data suggest that the significant decrease in aldosterone following AE may lower BP by decreasing plasma volume in obese-hypertensive individuals, leading to decreases in pulse wave transit time.

Background: Atherosclerosis is an inflammatory disease. Atherogenic lipoproteins cause inflammatory responses to the vascular wall in the early stage of atherogenesis. (-)-Epigallocatechin-3-gallate (EGCG), the main catechin in green tea, has been well known about its benefits in cardiovascular system and anti-oxidant effects. However, its protective effects against oxidized low density lipoprotein (oxLDL)-induced endothelial inflammation still unclear.

**PURPOSE:** In this study, we examined whether EGCG prevents inflammatory responses in endothelial cells caused by oxLDL and to explore the possible mechanism.

**METHODS:** Primary human umbilical vein endothelial cell cultures (HUVECs) incubated with oxLDL were used to explore the anti-inflammatory effects of EGCG. The expression of NF- $\kappa$ Bp65, phosphorylated p38 and cyclooxygenase -2 (COX-2) was measured by Enzyme-Link Immunosorbent Assay (ELISA), Western blot and immunocytochemistry. Adhesion molecule expression of intercellular adhesion molecule (ICAM), E-selectin and monocyte chemoattractant protein-1 (MCP-1) as well as several pro-inflammatory cytokines including interleukin-8 (IL-8), interleukin-6 (IL-6) and Endothelin-1 (ET1) were investigated by real-time PCR, ELISA and flow cytometry.

**RESULTS:** Our results showed that oxLDL-induced inflammatory response including activation of NF- $\kappa$ Bp65, phosphorylation of P38, expression of COX-2, adhesion molecule (ICAM, E-selectin and MCP-1) and pro-inflammatory cytokines (IL-6, IL8 and ET1) both in mRNA and protein levels. All these parameters were significantly rescued by pretreatment with EGCG.

**CONCLUSIONS:** We demonstrated that EGCG prevent oxLDL-induced inflammatory responses, implying that EGCG has a potential role in the prevention of atherosclerotic vascular disease.

(No relationships reported)

Background: *Solanum lyratum Thunberg* (SL), well known as “*Herba Solani Lyrati*”, is one of the traditional medicines in China. It has been widely used for regulating body immune function and against allergic diseases for generations. However, little is known about whether SL has a protective effect on endothelial dysfunction caused by oxidized low density lipoprotein (oxLDL).

**PURPOSE:** To determine the protective effects of SL on endothelial dysfunction mediated by oxLDL and to explore the underlying mechanism.

**METHODS:** Primary human umbilical vein endothelial cell cultures (HUVECs) treated with oxLDL were used to explore the protective effect of SL. 1,1-diphenyl-2-picryl-hydrazyl (DPPH) radical scavenging activity, HUVECs mediated oxidative modification of LDL, superoxide dismutase (SOD) and reactive oxygen species (ROS) generation were determined to evaluate the antioxidant effects of SL. Expression of adhesion molecules (MCP-1, CXCR6) as well as inflammatory cytokines (endothelin-1, IL-6 and IL-8) were measured by real-time polymerase chain reaction (PCR), Enzyme-Linked Immunosorbent Assay (ELISA) and flow cytometry. In addition, several apoptotic features, such as the accumulation of intracellular calcium and mitochondrial destabilization and the activation of caspase 3 were also investigated.

**RESULTS:** SL at a dose as low as 2.5  $\mu$ g/ml scavenged approximately 93% DPPH radical and inhibited HUVECs mediated oxidative modification of LDL in a dose-dependent manner. SL ameliorated the oxLDL-attenuated SOD activity that, subsequently, resulting in a decreased ROS generation. SL pretreatment inhibited the upregulation of adhesion molecules expression and inflammatory cytokine release caused by oxLDL. Furthermore, SL reduced the accumulation of oxLDL-induced intracellular calcium, decreased the disturbance of Bcl-2 family protein balance and subsequent mitochondrial membrane potential collapse, decreased the level of cytochrome c released into the cytosol and decreased the activation of caspase 3.

**CONCLUSIONS:** Our results suggest a possible mechanisms linking to ROS generation, expressions of adhesion molecules, inflammatory cytokines release and induction of

**Improved Apoptotic Gene Profile Of The Survived Remodeled Myocardium By Exercise Conducted Prior To Acute Infarction**

Anat Dayan<sup>1</sup>, Metsada Pasmanik Chor<sup>1</sup>, Jasmine Jacob<sup>2</sup>, Mickey Scheinowitz, FACSM<sup>1</sup>. <sup>1</sup>Tel-Aviv University, Tel-Aviv, Israel. <sup>2</sup>Sheba Medical Center, Tel-Hashomer, Israel. (Sponsor: Prof. Mickey Scheinowitz, FACSM)

Email: anntt@bezeqint.net

(No relationships reported)

Long-term exercise training induces favorable morphological changes that play a major role in the prevention of Acute Myocardial Infarction (AMI). It is postulated that even short episodes of exercise bouts provide sufficient cardiac protection due to changes in the molecular and gene expression which may improve cardiac myocytes oxygen and energy supply, viability, and LV wall elasticity.

**PURPOSE:** To study the effect of short-term (3 weeks) exercise training, conducted prior to AMI on the molecular alterations related to cardiac healing during remodeling.

**METHODS:** SD male rats (n=188) underwent short-term (90 min, 5 days/wk, 3 weeks) of swimming exercise training, or remained sedentary (Ex/Sed). At the end of the training/ sedentary period, rats were subjected to AMI induced by surgical ligation of the left coronary artery and thereafter remained sedentary during the 4-week remodeling period (ExMI/SedMI), and thereafter sacrificed. At sacrifice, hearts were harvested, weighted, and the viable left ventricle underwent RNA extraction. Gene expression was obtained using gene-array (Affymetrix Rat 230 2.0®), scanned and analyzed by MAS5, which followed by Super-Paramagnetic Clustering (SPC), using Treeview and the Expander programs. Further verification of the selected mRNA gene expression was conducted using qRT-PCR.

**RESULTS:** Cluster analysis of 486 genes significantly changed ( $p < 0.05$ ) in ExMI vs. SedMI groups (Ex/Sed). Accordingly, viable myocardium of ExMI rats manifest gene expression to a lesser extent compared to SedMI animals during remodeling. This was accompanied with a reduced mRNA expression of pro-apoptotic (Gsk-3 $\beta$ ; Igfbp3; Ddit3;  $p \leq 0.05$ ) and increased anti-apoptotic related genes (Myc; Crebbp;  $p \leq 0.05$ ), reduced mRNA expression of fibrosis related genes (Timp; Bgn; Itga; Colla1; Colla2;  $p \leq 0.05$ ) and increase in the expression of oxidative metabolism related genes (Cpt1a; Cs; Fabp3; Had;  $p \leq 0.04$ ).

**CONCLUSION:** Short-term exercise training prior to acute myocardial infarction induces molecular alterations of the survived viable myocardium, resulting in myocyte preservation, and improved oxidative metabolism.

**The Effect Of Voluntary Exercise On Cardiac Remodeling In *Apc<sup>Min/+</sup>* Mice**

Raymond W. Thompson, Wayne Carver, Mark Davis, Larry Durstine, FACSM, James A. Carson, FACSM. *University of South Carolina, Columbia, SC.*

Email: rwthomps@gwm.sc.edu

(No relationships reported)

*ApcMin/+* mice experience intestinal adenomas and chronic inflammation that lead to cachexia and cardiac enlargement. Physical activity can maintain overall physical function, lower chronic inflammation and attenuate cardiac enlargement.

**PURPOSE:** To determine whether lifetime voluntary exercise attenuates cardiac enlargement and related changes in gene expression in *ApcMin/+* mice.

**METHODS:** C57BL/6 (*wt*) and *ApcMin/+* mice given access to running wheels or served as cage controls beginning at 4 wks of age and mice were sacrificed at 26 wks of age. Body weights, heart, gastrocnemius, mammary fat pads, and spleens wts were determined and hearts were frozen. Collagen 1a, TGF $\beta$ , myosin heavy chain (MHC)a, and MHCb were determined by RT-PCR. STAT3 activation was determined by western blot analysis.

**RESULTS:** Body wts were 10% lower in *ApcMin/+* than *wt* mice ( $21.5 \pm 5$  vs  $24.2 \pm 7$  g) ( $P \leq 0.05$ ) and were not altered by exercise. Gastrocnemius muscle wts were 37% lower in *ApcMin/+* than *wt* mice ( $68 \pm 5$  vs  $108 \pm 4$  mg) ( $P \leq 0.05$ ) but were not altered by exercise. Mammary fat pad wts were lower in *ApcMin/+* than *wt* mice ( $28 \pm 11$  vs  $262 \pm 49$  mg) ( $P \leq 0.05$ ), and were not altered by exercise. Heart wts were 25% heavier in *ApcMin/+* than *wt* mice ( $9.0 \pm 3$  vs  $7.6 \pm 3$  mg/mm) ( $P \leq 0.05$ ) but were not altered by exercise. Procollagen 1a gene expression was 300% greater in *ApcMin/+* than *wt* mice ( $3.6 \pm 9$  vs  $1 \pm 1$ ) ( $P \leq 0.05$ ), but exercise attenuated this expression by 48% in *ApcMin/+* mice ( $1.9 \pm 2$ ) ( $P \leq 0.05$ ). MHCa gene expression was not different between *ApcMin/+* and *wt* mice, nor was it altered by exercise. However, MHCb gene expression was attenuated by exercise in both *ApcMin/+* and *wt* mice ( $0.5 \pm 1$  vs  $1 \pm 1$ ) ( $P \leq 0.05$ ) but was not different between *ApcMin/+* and *wt* mice.

**CONCLUSIONS:** These results demonstrate that increased exercise altered cardiac extracellular matrix and myocyte gene expression. The exercise-induced changes altered the physiological function of the heart during cancer-cachexia that were independent of heart and body weight in *ApcMin/+* mice.

**Acute And Chronic Endurance Exercise Improve Endothelial Progenitor Cell Function And Reduce Expression Of Oxidative Stress-Related Genes.**

Nathan T. Jenkins, Sarah Witkowski, Espen E. Spangenburg, James M. Hagberg, FACSM. *University of Maryland, College Park, MD.*

Email: jenkins@umd.edu

(No relationships reported)

Endothelial progenitor cells (EPCs) are a recently-identified circulating cell type that participate in the maintenance and repair of the vascular endothelium. Oxidative stress impairs EPC function, but the effects of acute and chronic exercise on gene expression that regulates oxidative stress in EPCs have never been studied. The lectin-like oxidized LDL receptor 1 (LOX-1) and NADPH oxidase pathways contribute to oxidative stress and were investigated as target genes in this study.

**PURPOSE:** To test the hypothesis that chronic and acute endurance exercise increase EPC colony forming units (CFU-EC) and reduce the expression of genes involved in cellular oxidative stress.

**METHODS:** Young ( $26 \pm 2$  yr) active ( $n = 5$ ) and inactive ( $n = 3$ ) men were studied. CFU-EC were cultured from blood samples obtained before and after 30 min treadmill running at 75%  $\text{VO}_{2\text{max}}$ . LOX-1 and NADPH oxidase (subunits gp91<sup>phox</sup>, p47<sup>phox</sup>, and p67<sup>phox</sup>) mRNA levels were measured using semiquantitative RT-PCR after 5 days of culturing the EPCs.

**RESULTS:** CFU-EC did not differ between groups at baseline, but in active individuals CFU-EC increased after acute exercise by  $7.9 \pm 3.9$  colonies ( $p = 0.056$ ). CFU-EC in the inactive group did not change after acute exercise ( $-0.8 \pm 1.6$  colonies,  $p = 0.3$ ). gp91<sup>phox</sup> mRNA levels were lower in active than inactive participants at baseline (43% group difference,  $p = 0.02$ ) and decreased significantly after acute exercise in both groups (active:  $-34 \pm 11\%$ ,  $p = 0.02$ ; inactive,  $-32 \pm 7\%$ ,  $p = 0.04$ ). LOX-1 mRNA was not different between groups at baseline ( $p = 0.14$ ) but tended to decrease following acute exercise in the active group ( $-10 \pm 6\%$ ,  $p = 0.09$ ). There were no group or acute exercise-induced differences in p47<sup>phox</sup> or p67<sup>phox</sup> mRNA levels.

**CONCLUSION:** Endurance exercise training may enhance EPC function by reducing oxidative stress. An acute bout of exercise reduces expression of NADPH oxidase and possibly LOX-1. Importantly, these differences in gene expression were observed despite no group differences in CFU-EC at baseline and only the active group increased CFU-EC with acute exercise. Exercise may, therefore, have powerful effects on EPC function through mediating the intracellular environment.

(No relationships reported)

In experimental models of exercise and heart failure, aerobic performance is closely linked to cardiomyocyte contractility and to the function of sarco-endoplasmic reticulum  $\text{Ca}^{2+}$  ATPase (SERCA2). Cardiac specific disruption of the *Serca2* gene controlled by tamoxifen administration in vivo (KO) induces severe congestive heart failure within 7 weeks, while control mice with floxed *Serca2* alleles (FF) preserve cardiac function. Four weeks after tamoxifen treatment the level of *Serca2a* mRNA in cardiomyocytes is less than 5% in KO mice.

**PURPOSE:** Our working hypothesis was that *Serca* gene ablation reduces aerobic fitness and impairs adaptation to exercise training.

**METHODS:** To determine whether responses in KO mice differed from those in control, a four-week high intensity exercise training program started two weeks after gene excision. Training was done as interval running on a treadmill, 8 min at 85-90% of maximum oxygen uptake capacity ( $\text{VO}_{2\text{max}}$ ) interspersed with 2 min at 40-50%, 1 hour, 5 days per week. High-frequency echocardiography was performed, and  $\text{VO}_{2\text{max}}$  and maximum running speed (RS) were measured. Protein analyses were carried out on left ventricular myocardium (LV) and soleus muscle.

**RESULTS:**  $\text{VO}_{2\text{max}}$  and RS increased in SERCA2 FF mice during the training period. SERCA2 KO animals maintained their RS despite a 36% decrease in  $\text{VO}_{2\text{max}}$ . In sedentary KO mice, RS was reduced by 28% and  $\text{VO}_{2\text{max}}$  by 50%. Echocardiography showed a 32% left atrial dilation in both trained and sedentary KO groups, but no differences in LV dimensions. Change in stroke volume was nominally lower in trained compared to sedentary KO mice. Right ventricle and lung weights were increased and histology demonstrated pulmonary congestion and heart failure in SERCA2 KO mice, independent of training. LV citrate synthase activity, and NCX, phospholamban and *Serca2a* protein levels were unaffected by training. Capillary density in soleus muscle increased in both sedentary and trained KO mice compared to FF controls.

**CONCLUSIONS:** Running capacity is maintained by exercise training after cardiac *Serca2* gene excision despite a significant decrease in  $\text{VO}_{2\text{max}}$ . Maintained LV stroke volume and neovascularisation in skeletal muscle seem to partly explain the maintained running capacity.

**Exercise Training Corrects Control Of Diastolic Calcium In Hearts From Myocardial Infarction Heart Failure Rats**

Ole J. Kemi<sup>1</sup>, Niall MacQuaide<sup>1</sup>, Morten A. Hoydal<sup>2</sup>, Per M. Haram<sup>3</sup>, Øyvind Ellingsen<sup>2</sup>, Godfrey L. Smith<sup>1</sup>, Ulrik Wisloff<sup>2</sup>. <sup>1</sup>*University of Glasgow, Glasgow, United Kingdom.* <sup>2</sup>*Norwegian University of Science and Technology, Trondheim, Norway.* <sup>3</sup>*University of Tromsø, Tromsø, Norway.*

Email: o.kemi@bio.gla.ac.uk

(No relationships reported)

Arrhythmias cause ~50% of deaths in heart failure (HF), but no satisfactory treatment exists. An underlying scenario is the impaired control of cardiomyocyte intracellular diastolic  $\text{Ca}^{2+}$ . Exercise training corrects abnormal cyclic  $\text{Ca}^{2+}$  handling in HF, but control of diastolic  $\text{Ca}^{2+}$  remains unstudied.

**PURPOSE:** To study the effect of exercise training on the generation and propagation of spontaneous diastolic  $\text{Ca}^{2+}$  waves in failing left ventricle cardiomyocytes.

**METHODS:** We induced myocardial infarctions (MI) and HF by coronary artery ligation in Sprague-Dawley rats. MI was evidenced by echocardiography, indicating that 40±5% of the LV was infarcted, whereas HF was evidenced by increased LV end-diastolic pressures and decreased contraction-relaxation rates and exercise work capacity. Diastolic  $\text{Ca}^{2+}$  was imaged by laser scanning confocal microscopy.

**SUMMARY OF RESULTS:** Pathological remodeling was evidenced by increased LV cardiomyocyte lengths and widths. Spontaneous  $\text{Ca}^{2+}$  waves were measured by confocal linescanning after 488nm excitation and recording emission at 505-530nm in intact Fluo3-loaded cardiomyocytes (2uM) at 37°C, at  $[\text{Ca}^{2+}]$  1.2mM and 5.0mM. These studies showed that spontaneous wave frequency was higher at 5.0mM than 1.2mM  $\text{Ca}^{2+}$ . Post-MI HF cardiomyocytes had twice the wave frequency compared to sham-operated controls. Regular exercise training post-MI improved exercise capacity and induced reverse remodeling. Exercise training reduced the frequency of spontaneous waves at both  $\text{Ca}^{2+}$  1.2mM and 5.0mM, although it did not completely normalize spontaneous  $\text{Ca}^{2+}$  waves. Exercise training also increased the ratio between aborted and complete waves at  $\text{Ca}^{2+}$  1.2mM, but not  $\text{Ca}^{2+}$  5.0mM. Finally, we repeated these studies in the presence of the nitric oxide synthase inhibitor L-NAME, to study the contribution of nitric oxide. This did not have any effects.

**CONCLUSION:** This study suggests that exercise training partly improves the control of diastolic  $\text{Ca}^{2+}$  by reducing the frequency by which spontaneous  $\text{Ca}^{2+}$  waves are generated and by improving the ability of the cardiomyocyte to eliminate a spontaneous wave after its generation, but before its propagation. This therefore also suggests a mechanism by which exercise training may reduce the incidence of cardiac arrhythmias in post-MI HF.

**Endurance Training On Jak/stat Activation In The Left Ventricle Of Rat**

Yunhong Wang<sup>1</sup>, Xuezhong Yang<sup>2</sup>, Chaoshu Tang<sup>3</sup>. <sup>1</sup>*Capital college of physical education, Beijing, China.* <sup>2</sup>*Beijing University of Chinese Medicine, Beijing, China.* <sup>3</sup>*Beijing University, Beijing, China.*

Email: yhwang21@yahoo.com.cn

(No relationships reported)

The activation of Janus Kinase(JAK)/ signal transducers and activators of transcription(STAT) pathway has been reported to induce cardiac hypertrophy in genetically hypertensive and experimental post-myocardial infarction rats, as well as in isolated ventricular myocytes subject to mechanical stretch. Our previous study showed that acute exercise induced JAK/STAT pathway activation; however, no reports have documented the activation of JAK/STAT pathway in the myocardium of exercise-induced cardiac hypertrophy.

**PURPOSE:** To evaluate endurance training on JAK/STAT3 pathway and Suppressor of cytokine signaling (SOCS) expression in myocardium in order to understand the mechanism of JAK/STAT3 pathway in exercise induced cardiac hypertrophy.

**METHODS:** Male Sprague-Dawley rats(220±5g) were randomly divided into sedentary and exercise groups, rats in exercise group were submitted to grade treadmill training for 10 weeks, then sacrificed at 0hour and 24 hours after last exercise respectively. phosphorylated (p) - STAT3, STAT3, JAK1, JAK3 and SOCS1, SOCS2,SOCS6 expression in left ventricle determined with either western blot or immunohistochemistry.

**RESULTS:** The heart/body weight ratio of exercised rats significantly higher in comparison with the sedentary rats ( $p<0.05$ ); the percentage of JAK1 positive cells significantly increased immediately after the last running in exercised rats( $p<0.01$ ); however, the percentage of JAK3 positive cells showed no change either immediately or 24 hours after last exercise ( $p>0.05$ ); p-STAT3/STAT3 ratio increased immediately after last exercise ( $p<0.05$ ); while the percentage of SOCS1 and SOCS2 positive cells increased remarkably both immediately ( $p<0.01$ ,  $p<0.05$ ) and 24 hours ( $p<0.05$ ) after last exercise, while SOCS6 expression showed no changes in exercised groups compared with the sedentary group( $p>0.05$ ).

**CONCLUSIONS:** Exercise training that induced activation of JAK/STAT3 pathway might be related to the exercise-induced cardiac hypertrophy, the different responses of JAK1 and JAK3 might indicate the different functions of JAKs in exercised heart and the expression changes of SOCS1 and SOCS2 might be involved in regulating JAK/STAT3 signal pathway in exercised-induced cardiac hypertrophy.

**1923 Board #64 May 28 9:00 AM - 10:30 AM****Effects Of Grade Classification On High School Football Players' 40 Yard Dash Times**Emily C. Thevis, Brian J. Campbell, Bradley Burkhalter, Torie Guidry, Michael A. Schultz. *University of Louisiana at Lafayette, Lafayette, LA.*

Email: ect0190@louisiana.edu

(No relationships reported)

Traditionally, 40-yd. dash (40YD) time is used to assess the speed of football players. Times are typically recorded without protective gear worn in a game. Studies have shown a significant increase in the time a player runs the 40YD in full equipment. However, there are many variables that may affect individual high school player's time change when timed in the 40YD with and without football equipment including pad weight, position, or workout regimen. Another serious consideration is player classification in school. As players mature through high school via age and strength training, player functional strength would seem to increase.

**PURPOSE:** To determine if grade classification of high school athletes affects difference in 40YD times with and without equipment on (DT).

**METHODS:** The 40 yard dash times of 69 high school football players were recorded using computerized timing software and a high-speed camera (30 frames/sec). Two trials were performed for each condition: wearing shorts and a T-shirt with no equipment (NEP) and wearing full game equipment (EP). The faster time for each condition was used in data collection. Difference in times EP and NEP was calculated and the times of the freshman (FR) and seniors (SR) were extracted for analysis. An independent samples T-test was used to determine if FR or SR were affected differently by equipment weight, based on their difference in 40YD times (DT).

**RESULTS:** There is a significant increase in DT for FR ( $0.1975 \pm 0.06406s$ ) compared to SR ( $0.1422 \pm 0.0253s$ ) ( $p \leq .05$ ).

**CONCLUSIONS:** The results suggest that senior football players are better suited to handle the weight of football equipment when running the 40YD. Although both SR and FR players had an increase in time for the 40YD EP, SR times were less affected by the additional weight. This may be due to the higher maturity level and longer involvement in a strength training program of seniors. If coaches utilize traditional 40YD methods without equipment, FR players should be expected to translate less of that speed onto the field than upperclassmen.

**1924 Board #65 May 28 9:00 AM - 10:30 AM****A Comparison Of Physical Activity Levels Between Children With And Without A Congenital Heart Defect.**Lauren A. Ewalt<sup>1</sup>, Ann M. Swartz<sup>1</sup>, Scott J. Strath<sup>1</sup>, Michael J. Danduran<sup>2</sup>, Victoria A. Moerchen<sup>1</sup>, Jerome Carson Smith<sup>1</sup>. <sup>1</sup>University of Wisconsin-Milwaukee, Milwaukee, WI. <sup>2</sup>Children's Hospital of Wisconsin, Milwaukee, WI.

Email: lewalt17@gmail.com

(No relationships reported)

**PURPOSE:** To describe and compare daily physical activity (PA) levels of children with and without a congenital heart defect (CHD). Secondly, to compare groups for time spent in moderate intensity PA (MPA), vigorous intensity (VPA), sedentary behavior, and physical education (PE), sport, and recess.

**METHODS:** Twenty-one children with mild to moderate CHD (16 females,  $10.6 \pm 3.4$  y) were matched for gender and age group (6-11 y, 12-15 y, 16-19 y) with 21 children without CHD (16 females,  $10.8 \pm 3.2$  y). Participants wore an accelerometer (Actigraph 7164, Fort Walton Beach, FL) and completed a PA log for seven consecutive days. Moderate intensity PA was defined as 4.0-6.9 METs and VPA was defined as greater than or equal to 7 METs (Wickel & Eisenmann, 2007). Sedentary behavior was defined by any accelerometer activity count being less than or equal to 50 counts/30 sec. The amount of time spent in the three structured physical activities (PE, sport, and recess) were self-reported on the PA log. Paired sample t-tests were utilized to compare daily PA levels, total time spent in MPA (min/day), VPA (min/day), sedentary behavior (min/day), and PE (min/week), recess (min/week), and sport (min/week) between the two study groups.

**RESULTS:** There were no statistical differences in total PA level ( $p=0.297$ ), time spent in MPA ( $p=0.250$ ), VPA ( $p=0.220$ ), sedentary behavior ( $p=0.712$ ), physical education ( $p=0.978$ ), and recess ( $p=0.217$ ) between children with and without CHD. However, children with CHD spent significantly less time participating in sport than children without CHD (CHD:  $51.6 \pm 91.8$  min/week; Non-CHD:  $185.8 \pm 216.7$  min/week,  $p=0.025$ ).

**CONCLUSIONS:** Although children with CHD had similar overall PA levels as children without CHD, they spent over two less hours per week participating in sport. An additional study with a larger sample size and qualitative methods to determine exposure to sport among children with CHD would address not only activity but also participation among this at-risk population.

---

**1925 Board #66 May 28 9:00 AM - 10:30 AM****Assessing Physical Activity In Girls Using Accelerometry - 60s Versus 10s Sampling Intervals**Matthew Yao, Panagiota Klentrou, Lauren Corbett, Izabella Ludwa, Bareket Falk. *Brock University, St. Catharines, ON, Canada.*

(No relationships reported)

Children exhibit physical activity patterns mainly comprised of sporadic and intermittent bouts, each lasting under 15s in duration. Despite this fact, most studies utilize a 60s accelerometry sampling interval to objectively quantify physical activity in youths. This relatively long sampling interval may underestimate children's true physical activity behaviour.

**PURPOSE:** To assess the difference in intensity, duration and number of continuous bouts of physical activity in children and adolescents when using accelerometry intervals of 60s vs. 10s.

**METHODS:** A total of 106 girls and adolescents (mean =  $13.0 \pm 2.6$  yrs old) wore ActiGraph GT1M accelerometers for all waking hours (except while bathing, swimming, etc.) over seven days. Accelerometers were set at 10s epochs and the raw data was subsequently re-integrated into 60s epochs. From data of both epoch lengths, daily bouts of moderate (MPA; 3-5.9 METs), vigorous (VPA; 6-8.9 METs) and very vigorous (VVPA;  $\geq 9$  METs) activities were quantified using a Visual Basic data reduction program. The number of continuous 5 min, 10 min and 20 min bouts at each intensity was also calculated.

**RESULTS:** There was no difference in total MPA minutes between the 10s and 60s analysis. Total VPA, and VVPA were 80.4%, and 61.5% greater in the 10s sampling than in the 60s integrated sampling, respectively ( $p < 0.01$ ). When examining continuous bouts of activity, the 10s analysis generally resulted in more continuous bouts compared with the 60s analysis, especially when examining 5 min bouts of MPA (19.1%), 20 min bouts of VPA (14.6%), and of VVPA (0.9%) ( $p < 0.01$ ).

**CONCLUSION:** The commonly used 60s accelerometry sampling interval underestimates the amount of physical activity that children and adolescents engage in, especially at the higher intensity levels. Thus, a sampling interval of 10s or less is warranted to better assess physical activity levels of different intensities in children and adolescents.

**1926 Board #67 May 28 9:00 AM - 10:30 AM****Physical Activity And Overweight In Low Socioeconomic Status, Elementary And Middle School Students**

Elayna H. Dush<sup>1</sup>, Rebecca A. Rudey<sup>2</sup>, Joshua J. Ode<sup>1</sup>. <sup>1</sup>Saginaw Valley State University, University Center, MI. <sup>2</sup>Michigan State University, East Lansing, MI.  
Email: ehdush@svsu.edu  
(No relationships reported)

Previous research estimates that 32% of US children and adolescents are classified as overweight (Ogden, 2008). In addition, nearly 70% participate in physical activity for  $\geq 60$  min on  $\geq 5$  days/wk (Pate, 2002). However, minimal research has focused on physical activity levels and overweight status in low socioeconomic status (SES) children.

**PURPOSE:** The purpose of this study was to examine physical activity participation and overweight status in low SES elementary and middle school students.

**METHODS:** Students ( $n=124$ ; 52% female, 83% African American) in grades 3-8 attending a low SES urban charter school (97% free/reduced lunch) participated in a fitness assessment and physical activity survey during the winter 2008 semester. BMI ( $\text{kg}/\text{m}^2$ ) was calculated from measured height and weight. Centers for Disease Control and Prevention BMI-for-age and sex growth charts were used to classify youth as overweight ( $>85$ th percentile). Students self reported physical activity and were classified as being physically active if they performed 60 minutes of physical activity on  $\geq 5$  days per week. Chi-square analysis was used to assess gender, racial, and grade differences in overweight and physical activity.

**RESULTS:** Only 39% of children participated in physical activity for  $\geq 60$  min on  $\geq 5$  days/wk and 47% were classified as overweight. Females (27%) were less likely than males (52%) to be physically active ( $p=0.015$ ). Furthermore, females (58%) were more likely than males (34%) to be overweight ( $p=0.011$ ). Race and grade level were not significantly related to physical activity levels or overweight status.

**DISCUSSION:** The prevalence of overweight and physical inactivity is alarmingly high in low SES children. Females were more likely to be overweight and less likely to participate in physical activity. These results suggest that physical activity interventions should target girls at an early age in low SES populations.

**After-school Fitness Performance Is Not Altered Following Physical Education Lessons In Adolescent Athletes**

Avery D. Faigenbaum, FACSM<sup>1</sup>, James E. McFarland<sup>2</sup>, Erin Buchanan<sup>1</sup>, Nicholas A. Ratamess<sup>1</sup>, Jie Kang<sup>1</sup>, Jay R. Hoffman, FACSM<sup>1</sup>. <sup>1</sup>The College of New Jersey, Ewing, NJ. <sup>2</sup>Hillsborough High School, Hillsborough, NJ.  
Email: faigenba@tcnj.edu  
(No relationships reported)

Physical education (PE) provides a unique opportunity for school-age youth to establish healthy habits, although some young athletes are exempt from PE and others do not participate due to a concern regarding the lingering effects of fatigue on after-school fitness performance.

**PURPOSE:** To examine the effects of different PE lessons on after-school fitness performance in young athletes.

**METHODS:** On nonconsecutive days, 20 high school athletes (14-18 yrs) participated in 3 different 43 min PE lessons which consisted of walk/jog aerobic exercise (AE), multi-set resistance training with progressive loads (RT), or basketball skill training (BS). Fitness performance was assessed after-school following each lesson and after a control day without PE. Subjects had  $2.8 \pm 1.1$  hr to recover from PE before fitness testing.

**RESULTS:** There were no significant differences in sit and reach flexibility ( $34.1 \pm 6.5$ ,  $34.7 \pm 1.3$ ,  $33.5 \pm 7.2$ ,  $33.6 \pm 7.3$  cm), vertical jump ( $46.3 \pm 14.7$ ,  $46.2 \pm 13.6$ ,  $46.4 \pm 13.4$ ,  $45.6 \pm 14.2$  cm), long jump ( $175.0 \pm 36.4$ ,  $174.2 \pm 36.3$ ,  $172.7 \pm 35.8$ ,  $171.9 \pm 34.7$  cm), seated medicine ball toss ( $348.9 \pm 121.8$ ,  $342.0 \pm 120.6$ ,  $353.9 \pm 123.6$ ,  $348.4 \pm 129.1$  cm), pro-agility shuttle run ( $5.8 \pm 0.5$ ,  $5.7 \pm 0.53$ ,  $5.8 \pm 0.52$ ,  $5.8 \pm 0.5$  sec), 20 m sprint ( $3.7 \pm 0.4$ ,  $3.7 \pm 0.4$ ,  $3.7 \pm 0.3$ ,  $3.7 \pm 0.3$  sec), and 200 m sprint ( $36.3 \pm 4.7$ ,  $35.1 \pm 4.0$ ,  $35.9 \pm 5.9$ ,  $35.4 \pm 5.4$  sec) between groups following AE, RT, BS or the control day, respectively.

**CONCLUSION:** These findings suggest that a moderate intensity exercise lesson or skill-based PE class will not have an adverse effect on after-school fitness performance in adolescent athletes.

**Physical Fitness: A Discriminant Analysis In The Determination Of Childhood Obesity**

Susanne Ring-Dimitriou<sup>1</sup>, Daniel Weghuber<sup>2</sup>, Eveline Ledl-Kurkowski<sup>2</sup>, Elisabeth Ardel-Gattinger<sup>3</sup>, Serge P. von Duvillard, FACSM<sup>1</sup>, Günter Amesberger<sup>1</sup>, Josef Niebauer<sup>2</sup>, Erich Müller<sup>1</sup>. <sup>1</sup>University of Salzburg, Hallein, Austria. <sup>2</sup>Paracelsus Medical University, Salzburg, Austria. <sup>3</sup>University of Salzburg, Salzburg, Austria.  
Email: susanne.ring@sbg.ac.at  
(No relationships reported)

The improvement in physical fitness (PF) via exercise participation and training is an important part of prevention programs in childhood obesity; however, its assessment is seldom reported as part of the screening procedure.

**PURPOSE:** We investigated the discriminate potential of PF together with selected screening variables of anthropometric measurements of body weight, height, body mass index, BMI-SDS (standard deviation score), percentile (of BMI-SDS) and blood plasma measurements of total cholesterol, triglycerides, low density lipoprotein, high density lipoprotein, blood glucose, insulin, leptin and adiponectin in 10-12 yrs old normal weight (NW) and overweight (OW) children.

**METHODS:** Twenty-six NW and 25 OW children participated in a physical fitness test battery (PFTB-PR), in a graded cycle spirometry test ( $1 \text{ W} \cdot \text{kg}^{-1} \text{ BW}$ ,  $10 \text{ W} \cdot \text{min}^{-1}$ ), and 5.5 ml venous blood collection in fasting state. The discriminate potential of PF was analyzed with discriminant analysis (DA, direct entry method) after a multivariate analysis of variance (MANOVA) was completed. DA was conducted separately for anthropometric variables, PF, and blood measurements. A loading of  $a \geq 0.6$  was used to select the most discriminate variables of each construct. Thereafter, the DA was conducted with all remaining variables (percentile; PFTB-PR, maximal workload,  $P_{\text{max}}$ , peak oxygen uptake,  $\text{VO}_{2\text{peak}}$ ; leptin).

**RESULTS:** NW ( $11.5 \pm 0.8$  yrs,  $41.8 \pm 8.8$  kg,  $17.9 \pm 2.1$  BMI) differed significantly from OW ( $11.3 \pm 1.0$  yrs,  $70.4 \pm 18.8$  kg,  $29.1 \pm 5.1$  BMI) in most of the variables after MANOVA testing. DA revealed that in addition to percentile ( $a=0.80$ ),  $P_{\text{max}}$  ( $a=-0.78$ ),  $\text{VO}_{2\text{peak}}$  ( $a=-0.76$ ), PFTB-PR ( $a=-0.74$ ), and leptin ( $a=0.64$ ) separated very well the NW from OW. Only one OW subject was classified as NW, whereas 100% of NW children were classified correctly. The group separation by the discriminant function (non-standardized)  $d = -2.2 + (\text{percentile} \times 0.66) - (\text{PFTB-PR} \times 0.03) - (\text{VO}_{2\text{peak}} \times 0.001) - (P_{\text{max}} \times 0.41) + (\text{leptin} \times 0.02)$  was significant as measured by Wilks'  $\lambda = .14$  with  $\chi^2(5, N=51) = 90.50$  at  $p = .0001$ .

**CONCLUSION:** The discriminant analysis revealed that PF variables are strong and useful indicators to separate between normal-weight and overweight 10-12 year old children, and should be included in screening procedures.

**Energy Expenditure In Children During Rock Climbing Activity**

Phillip B. Watts, FACSM, Megan L. Ostrowski. Northern Michigan University, Marquette, MI.  
Email: pwatts@nmu.edu  
(No relationships reported)

The activity of rock climbing has been implemented in some school physical education programs however there have been no published studies on the physiological demands and energy costs of climbing in children.

**PURPOSE:** The purpose of this study was to measure energy expenditure in children during climbing activities typical of school-based programs.

**METHODS:** Twenty-nine children (18 male, 11 female; mean age = 10.9±1.7 yr) participated in the study. All subjects had some recreational climbing experience. Prior to participation, each subject and his/her parent read and signed informed consent. Subjects were familiarized with the climbing terrain and instrumentation employed prior to data collection. A commercially available climbing structure (ht = 2.44 m; circumference = 8.20 m) fit with modular hand and foot holds provided continuous climbing terrain. The specific pattern of hand and foot hold placement was designed to ensure that the exertion level was submaximal during the trials of this study. Subjects were instructed to climb at a comfortable pace. Following an initial 5-min rest each child climbed one sustained 5-min bout followed by a 5-min rest for a total of 10 min (SUS). This period was immediately followed by five 1-min climbing + 1-min rest intervals for a second total of 10 min (INT). Expired air was analyzed continuously via a portable system (Viasys/Jaeger Oxycon Mobile). Energy expenditure (EE) in kcal was determined from the expired air data via the Weir method for averaged 10-second intervals throughout climbing and rest periods.

**RESULTS:** Total EE (climbing + rest) was significantly higher for INT than for SUS (39.3±13.1 vs 34.3±11.3 kcal;  $p<.01$ ). Elevated EE did not return to resting level between the 1-min intervals of climbing in INT. The mean total EE for the full 20-min protocol (SUS + INT) was 73.7±24.2 kcal. Total EE was significantly correlated with body mass;  $r=0.86$ . Mean average and peak metabolic equivalents (METs), calculated from oxygen consumption, were 6.4±1.3 and 9.1±2.1 METs respectively over the full 20-min protocol.

**CONCLUSIONS:** The rock climbing tasks employed in this study produced EE and MET levels similar to what have been reported in children for stair climbing, pickup basketball games, soccer, and easy jogging.

**Validation Of The Progressive Aerobic Cardiovascular Endurance Run Test For Children 7-13 Years Old**

Tracy J. Lightburne, Charilaos Papadopoulos, Kirk Mathias, Ethan Bergman. *Central Washington University, Ellensburg, WA.* (Sponsor: Chris Ingalls, FACSM)

Email: tracylightburne@yahoo.com

*(No relationships reported)*

The measurement of physical fitness in children has continuously been a topic of interest to physical educators, health agencies, exercise physiologists and coaches. A test often used in physical education classes is the PACER test, a progressive, multistage maximal exercise test that closely resembles a graded, speed-incremented treadmill test used in the laboratory to directly measure maximal oxygen consumption ( $O_{2max}$ ). The PACER test has been shown to be a valid predictor of  $O_{2max}$  when conducted on adolescents and adults; however, the results have not been substantiated in children.

**PURPOSE:** The purpose of this study was to investigate the validity of the PACER test for use with children between the ages of 7 and 13 years old.

**METHODS:** Twenty subjects volunteered to complete a PACER test and a  $O_{2max}$  test within a 2 wk period. During the PACER test, the subjects completed as many laps as possible within a 20-m distance. Heart rate (HR) and ratings of perceived exertion (RPE) were measured and recorded. The  $O_{2max}$  test was performed on a treadmill, in which oxygen consumption, RPE, and HR were monitored and recorded. Pearson's correlation coefficient was used to determine the relationship between the number of laps completed from the PACER test and measured  $O_{2max}$ . Independent t tests were used to determine significant differences between males and females, and younger and older age groups. To determine significant difference between measured relative  $O_{2max}$  and estimated  $O_{2max}$ , a dependent t test was used.

**RESULTS:** The number of laps completed correlated significantly ( $r = 0.71$ ;  $P < 0.05$ ) with  $O_{2max}$ . There was a significant difference in relative  $O_{2max}$  (49.1±6.4 vs. 41.7±5.9 ml·kg<sup>-1</sup>·min<sup>-1</sup>,  $P<0.05$ ) and number of laps completed (55.7±20.1 vs. 36.0±11.3,  $P<0.05$ ) during the PACER test between males and females. A significant difference was also found in absolute  $O_{2max}$  (1.28±0.2 vs. 1.99±0.4 L·min<sup>-1</sup>,  $P<0.05$ ) between the younger and older individuals. Additionally, the paired t test indicated a significant difference ( $P<0.05$ ) between measured  $O_{2max}$  and predicted  $O_{2max}$ .

**CONCLUSION:** Based on these results and this population, it may be concluded that the PACER test is a valid test of cardiorespiratory endurance for children 7-13 years old. However, a better equation is needed to predict  $O_{2max}$ .

**Muscle Phosphocreatine Kinetics In Children And Adults During High-intensity Exercise**

Craig A. Williams, Rebecca J. Willcocks, Alan R. Barker, Jonathan Fulford, Neil Armstrong, FACSM. *University of Exeter, Exeter, United Kingdom.*

Email: c.a.williams@exeter.ac.uk

*(No relationships reported)*

**PURPOSE:** To compare the age and sex differences in the kinetic response of muscle PCr during high-intensity exercise in children and adults.

**METHODS:** Eleven adults (6 men 25 ± 5 y and 5 women 23 ± 3 y) and 11 children (6 boys 13 ± 0.2 y and 5 girls 13 ± 1.3 y) exercised using their right leg on a quadriceps ergometer within a 1.5 Tesla MR scanner. Following habituation, each participant completed an incremental test to exhaustion. After a minimum 48 hours recovery, participants completed two to four constant work rate bouts on separate days. Exercise bouts consisted of 2 min rest and 7 min exercise, at an intensity equivalent to 20 % of the difference between the workload at the intracellular P<sub>i</sub>/PCr threshold and the maximal workload. <sup>31</sup>P spectra were collected every 6 s using a 6 cm surface coil positioned beneath the right quadriceps muscle. The breakdown of muscle PCr at the onset of exercise was modelled using a single-exponential function until the onset of the PCr slow component (SC). This point was identified using an iterative fitting window - where the time constant diverged from a plateau, a PCr SC was deemed to emerge. Data are reported as mean ± standard deviation and 95 % confidence intervals (CI) are presented. A two by two factorial ANOVA was utilised to determine group differences.

**RESULTS:** No significant interaction effect was found for the fundamental time constant (boys: 31 ± 10, CI 5; girls: 31 ± 10, CI 6; men: 44 ± 20, CI 6; women: 29 ± 14 s, CI 6 s;  $P=0.26$ ), or the fundamental amplitude (boys: -39 ± 10; girls: -42 ± 9; men: -36 ± 9; women: -48 ± 9 %;  $P=0.23$ ), or the SC PCr (as a % of the difference between the fundamental amplitude and end exercise PCr) which was similar across groups (boys: 6 ± 1; girls: 13 ± 8; men: 8 ± 5; women: 8 ± 6 %  $P=0.15$ ). The end-exercise PCr revealed a significant sex difference ( $P=0.03$ ) but no significant age or interaction effect (boys: 55 ± 10; girls: 46 ± 14; men: 56 ± 11; women: 44 ± 8 %). There was no significant difference between age ( $P=0.22$ ) or sex ( $P=0.13$ ) for the PCr cost of contraction at end-exercise (boys: 1.7 ± 0.5; girls: 1.3 ± 0.5; men: 1.4 ± 0.4; women: 1.2 ± 0.2 mM·W<sup>-1</sup>  $P=0.13$ ).

**CONCLUSION:** The kinetics of muscle PCr during high intensity exercise are similar in 13 y old children and adults, suggesting the phosphate-linked control of oxidative metabolism, at least during high-intensity exercise, is adult like by this age.

**Substrate Utilization And Hormonal Response During Treadmill Exercise In Females At Different Maturity Stages**

Lucía R. Martínez<sup>1</sup>, Ruth Rosario<sup>2</sup>, Barbara Segarra<sup>2</sup>, Farah Ramírez-Marrero, FACSM<sup>1</sup>, Ivonne Ramírez<sup>1</sup>, Enrique U. Pérez<sup>1</sup>. <sup>1</sup>University of Puerto Rico, Río Piedras Campus, San Juan, Puerto Rico. <sup>2</sup>University of Puerto Rico, Medical Science Campus, San Juan, Puerto Rico.

Email: rosarito@onelinkpr.net

*(No relationships reported)*

It has been suggested that metabolic and hormonal responses to exercise may be age or maturity dependant; however, existing data is not conclusive.

**PURPOSE:** To determine differences in substrate utilization and hormonal responses to exercise in females at different maturity stages.

**METHODS:** Thirty healthy active females were divided into 3 groups based on maturity stage: pre-menarcheal (PMen)(Tanner I-II) (age 10.1 ± 1.4 yr), menarcheal (Men)

(Tanner III-IV) (age  $13.2 \pm 0.6$  yr), and adults (Ad) (age  $23.3 \pm 4.5$  yr). After a 12 hr fast subjects completed a 40 min treadmill protocol at 60% of their  $\text{VO}_{2\text{max}}$ . Blood samples were obtained at rest, min 20, and min 40 of the exercise protocol for glucose, lactate, FFA, insulin, human growth hormone (HGH), epinephrine (Epi), and norepinephrine (NE) analyses. ANOVA with repeated measures was used to compare differences between the groups and across time.

**RESULTS:** RER was higher in Men at min 20 and 40 of exercise. From rest to min 40, Men and Ad glucose increased from 84.6 to 94.3 mg/dl and 76.3 to 88.7 mg/dl, respectively. Resting glucose was higher in PMen (90.4 mg/dl). Only Men lactate increased from rest to min 20 (0.77 to 1.58 mmol/L,  $P < 0.05$ ). Only Ad increased FFA from rest (0.2 mEq/L) to min 20 (0.41 mEq/L) and 40 (0.56 mEq/L). Insulin did not change during exercise, but Ad had a lower resting insulin compared to PMen and Men (4.5, 8.2 and 10 uU/dl, respectively). All groups increased HGH from rest to min 20 (increased 16, 19.6 and 8.9 ng/ml in PMen, Men and Ad, respectively), but only PMen and Men had higher values at min 40. Resting NE was higher in PMen (399 pg/ml) than in Ad (164 pg/ml). At min 20 NE was higher only in Men (744 pg/ml), and was higher compared to Ad (394 pg/ml). Epi and NE were higher at min 40 in Men and Ad.

**CONCLUSIONS:** These results suggest that among females there are maturity dependent differences in substrate utilization and hormonal responses to exercise at 60% of  $\text{VO}_{2\text{max}}$ .

**Skeletal Age With The Fels And Tw3 Methods In The Assessment Of Biological Maturation Among Adolescent Soccer Players**

Manuel J. Coelho-e-Silva<sup>1</sup>, Antonio J. Figueiredo<sup>1</sup>, Maria E. Pena Reyes<sup>2</sup>, Robert M. Malina, FACSM<sup>3</sup>. <sup>1</sup>University of Coimbra, 3040-156 Coimbra, Portugal. <sup>2</sup>Escola Nacional de Historia e Antropologia, Mexico, Mexico. <sup>3</sup>University of Texas, Tarleton State University, Austin, TX.

Email: mjcesilva@hotmail.com

(No relationships reported)

**PURPOSE:** Skeletal age [SA] is an indicator of biological maturity status that is useful from childhood through adolescence in contrast to those limited to the pubertal years (secondary sex characteristics, age at peak height velocity). Skeletal age varies, however, with method of assessment. The present study compares the SA of adolescent soccer players 13-15 years of age assessed with the Tanner-Whitehouse and Fels methods.

**METHODS:** The sample included 72 Portuguese youth soccer players 13.3-15.3 years with at least two years experience in the sport. Chronological age (CA) was the difference between date of examination and date of birth as recorded on official birth certificates. Posterior-anterior hand-wrist radiographs of the left hand were taken on all players. SA was assessed with the Fels (Roche *et al.*, 1988) and Tanner-Whitehouse radius-ulna-short bone (TW3, Tanner *et al.*, 2001) methods. Players were classified as late, average (on time) or early on the basis of the difference between SA and CA: Late - SA behind CA by more than 1.0 year, Average - SA within plus/minus 1.0 year of CA, Early - SA in advance of CA by more than 1.0 year. In addition to descriptive statistics, concordance between maturity groups based on the two methods was tested with the Kappa statistic.

**RESULTS:** Chronological ages ranged from 13.3 to 15.3 years, while SAs ranged from 12.01-17.67 years with the Fels method and from 11.05-16.42 years with the TW3 method. Variation in SA was almost three times the variation in CA. Classification of players by maturity status varied with method of SA assessment: TW3 - Late 17%, On time 57%, Early 26%; Fels - Late 5%, On time 63%, Early 32%. Concordance between methods was 81% (Kappa=0.65±0.08,  $p < 0.001$ ).

**CONCLUSIONS:** Skeletal ages based on the Fels and TW3 methods are not equivalent and reflect in part real inter-individual differences and methodological differences. Although variation in skeletal maturity status within a two year competitive age group is considerable, there is reasonable concordance between classifications of players as late, on time and early in maturity status.

**1934 Board #75 May 28 9:00 AM - 10:30 AM**

**Comparison Of Different Stage Lengths For Physical Working Capacity Tests**

Justin R. Bland, Karin A. Pfeiffer, FACSM, Joey C. Eisenmann. Michigan State University, East Lansing, MI.

(No relationships reported)

In recent investigations, researchers have used either a 2-min or 3-min protocol for physical working capacity (PWC) assessment as a measure of aerobic fitness in children and adolescents.

**PURPOSE:** The purpose of this study was twofold: 1) compare different PWC tests in youth using 2-, 3-, and 6-minute stage lengths, and 2) examine the relationship between  $\text{PWC}_{170}$  and peak oxygen consumption ( $\text{VO}_{2\text{peak}}$ ).

**METHODS:** Seventeen youth (9 girls, 8 boys) aged 11-16 years ( $13.3 \pm 2.0$  yrs) participated in this study. Each participant visited the laboratory on two separate occasions within two weeks and performed three PWC tests (2-, 3-, 6-min stages) on a cycle ergometer. The first visit comprised of anthropometric measurements and one or two of the PWC tests; the second visit involved the remaining PWC test(s). The order of PWC tests was randomized and counterbalanced, with tests separated by 30 minutes of rest. On the day that two PWC tests were performed, participants continued the second test until exhaustion to assess  $\text{VO}_{2\text{peak}}$ . During each PWC test, heart rate (HR) was recorded every 30-sec and within the last 10-sec of each stage. Each PWC test consisted of at least two, but usually three, stages of increasing loads with the goal of reaching a  $\text{HR} \geq 165 \text{ b} \cdot \text{min}^{-1}$ . A fourth stage was completed if participants did not achieve  $165 \text{ b} \cdot \text{min}^{-1}$  within three stages. Individual regression lines were created to predict workload at  $\text{HR} = 170 \text{ b} \cdot \text{min}^{-1}$  for each test. Repeated measures ANOVA was used to compare  $\text{PWC}_{170}$  values. Pearson correlation was used to assess the relationships between  $\text{VO}_{2\text{peak}}$  and the different  $\text{PWC}_{170}$  stage lengths.

**RESULTS:** There were significant differences in  $\text{PWC}_{170}$  values among stage lengths ( $F(2,14)=9.3$ ,  $p < 0.0001$ ). Post-hoc analyses showed differences between the 2- and 6-minute stage lengths ( $111.3 + 27.1$  vs.  $92.5 + 22.2$  watts;  $p < 0.05$ ) and 3- and 6-minute stage lengths ( $104.2 + 30.0$  vs.  $92.5 + 22.2$  watts;  $p < 0.05$ ). Correlations between  $\text{VO}_{2\text{peak}}$  and the different stage lengths were  $r = 0.28$ ,  $0.39$ , and  $0.37$  ( $p > 0.05$ ) for 2-, 3-, and 6-min stages, respectively.

**CONCLUSION:** The lack of difference between the 2- and 3-min stage lengths may indicate that either is acceptable for determination of  $\text{PWC}_{170}$ . However,  $\text{PWC}_{170}$  (determined by different stage lengths) showed poor associations with  $\text{VO}_{2\text{peak}}$ .

Research was funded by the Spencer Foundation.

**1935 Board #76 May 28 9:00 AM - 10:30 AM**

**Substrate Use In Obese And Lean Prepubescent Children.**

P. Brophy, B R. Schmitt, L Westerkamp, G Geyer, G Dubis, R C. Hickner, FACSM. East Carolina University, Greenville, NC.

(No relationships reported)

**Purpose-**To examine differences in substrate oxidation between non-trained, healthy, lean and overweight children exercising at the same absolute and relative submaximal intensities on a treadmill. **Methods-** Forty three lean ( $n=17$ ) and overweight ( $n=26$ ), prepubescent (8-11yr) children walked on a treadmill at a speed of 2.5 mph for five minutes and then at a speed to produce a HR of 140bpm for 5 minutes. Directly after the second 5-min stage they completed a graded exercise test. Oxygen consumption and fat oxidation was determined using indirect calorimetry. Body composition was determined using dual energy X-ray absorptiometry (DEXA). **Results-** Maximal oxygen consumption of the overweight group (OG) ( $1.81 \text{ L} \cdot \text{min}^{-1}$ ) was higher than the lean group (LG) ( $1.53 \text{ L} \cdot \text{min}^{-1}$ ;  $p=.009$ ). Sub maximal  $\text{VO}_2$  at 2.5 mph in the OG ( $0.75 \pm 0.14 \text{ L} \cdot \text{min}^{-1}$ ) was higher than in the LG ( $0.54 \pm 0.09 \text{ L} \cdot \text{min}^{-1}$ ;  $p < 0.05$ ) while the respiratory exchange ratios (RER) were the same in both groups. This higher  $\text{VO}_2$  was consistent with a higher absolute rate of carbohydrate oxidation in the OG ( $2.18 \pm 0.084 \text{ kcal/min}$ ) than LG ( $1.35 \pm 0.6 \text{ kcal/min}$ ;  $p < 0.05$ ). There was no significant difference in absolute rate of fat oxidation between the groups when exercising at the same absolute intensity ( $p=0.121$ ). When accounting for fat-free mass (FFM), the overweight group oxidize a

significantly greater amount of CHO ( $0.0675 \pm 0.023$  kcal/kg FFM than the LG ( $0.0498 \pm 0.02$  kcal/kg FFM) while the fat oxidized per kg FFM was the same in both groups ( $p=.562$ ). The relative sub-maximal  $\text{VO}_2$  (HR of 140 bpm) in the OG was higher than the lean group ( $p=.001$ ). The absolute rate of CHO oxidation was still higher in the OG than the LG ( $p=.03$ ) but in FFM the CHO oxidation was the same in both groups ( $p=.55$ ). Both groups oxidized fat similarly in absolute terms ( $p=.323$ ) and relative to FFM ( $p=.765$ ). Conclusion - Even though overweight children have significantly greater sub maximal oxygen consumption and a greater amount of lean mass compared to lean children, they are no more effective at utilizing fat during sub max exercise; however, in absolute terms, overweight children oxidize carbohydrates at a higher rate than their lean counterparts.

**Active Transportation, BMI And Sports Participation Among Adolescent Girls**

Jorge Mota, José C. Ribeiro, Joana Carvalho, Maria P. Santos. *Research Centre in Physical Activity health and Leisure, Porto, Portugal.*

Email: [jmota@fade.up.pt](mailto:jmota@fade.up.pt)

(No relationships reported)

**PURPOSE:** The aim of this study was to assess the relationship between commuting to and from school (active vs. passive), BMI and physical activity participation (organized vs. non-organized) out side school in a sample of adolescent girls.

**METHODS:** This is an epidemiologic descriptive study. The sample comprised 266 girls aged 13-17 years-old. Questionnaires were used to describe travel mode to school and to estimate sports participation. Socioeconomic position was established by parental occupation and educational level. BMI was also analyzed. Girls were grouped into active (AT) or passive (PT) travelers depending on their travel mode.

**RESULTS:** Obese girls reported to significantly be PT. AT girls reported to be more engaged in non-organized sports than their PT counterparts. Logistic regression analysis showed that the likelihood of AT increased by around 50% with increasing non-organized sports participation ( $\text{OR} = 0.50$ ;  $p \leq 0.01$ ) and decreased BMI ( $\text{OR} = 0.56$ ;  $p \leq 0.05$ ), which means that girls with higher BMI (overweight/obese group) are likely to be less active commuters.

**CONCLUSIONS:** Active transportation must be taking into account as a mean to increase level of physical activity.

(No relationships reported)

Several studies have associated short duration of sleep with increased obesity in children and adolescents (daily recommended between 5 and 10 years of age is 10 hours or more and for more than 10 years of age at least 9 hours). The duration of sleep is a potential modifiable risk factor with clinical implications especially for treatment of obesity.

**PURPOSE:** Evaluate the effects of a unique multidisciplinary program of exercise and health education on the quality and quantity of sleep in children and adolescents.

**METHODS:** Twelve boys and fourteen girls ( $12.9 \pm 2.9$  yrs), participated in the study. The intervention consisted of a unique program of physical activity, including a variety of games that were enjoyable, maintained interest, and motivated subjects to adhere. Activity sessions were offered one time per week, two hours each session, for twelve months. In addition, a health education program was offered to the subjects one time each month, one hour per session. Sleep habits was evaluated by self reported questionnaire completed by the subjects each day for 15 days. Obesity was measured by BMI. Results of sleep habits were evaluated by a t-test of mean differences from the beginning to the end of the program.

**RESULTS:**

Table 1. Evaluation of sleep habits in obese children according to age				
	Between 5 and 10 years		> 10 years	
	T 0	T + 1	T 0	T + 1
Time of going to bed (hour)	$22.42 \pm 0.8$	$22.09 \pm 0.9^*$	$23.35 \pm 1.1$	$22.71 \pm 1.2^*$
Wake-up time (hour)	$8.16 \pm 0.9$	$8.36 \pm 1.1^{**}$	$7.71 \pm 0.9$	$7.85 \pm 0.9$
Total time of sleep (hour)	$9.72 \pm 0.8$	$10.28 \pm 0.9^*$	$8.27 \pm 1.1$	$9.08 \pm 1.2^{**}$
Quality of sleep	$71.52 \pm 14.2$	$73.64 \pm 14.3^{**}$	$55.64 \pm 15.1$	$57.43 \pm 16.7^*$

\*  $p < 0.001$  ; \*\*  $p < 0.05$

Results (Table 1) showed that quality and quantity of sleep improved in the subjects of the two age groups ( $p < 0.05$ ). It was observed at the same time that obesity was significantly reduced from 30.9 to 29.8,  $p < 0.05$ .

**CONCLUSIONS:** From the study results it was concluded that a multidisciplinary program of exercise and health education in obese children reduced BMI and improved quality and quantity of sleep, and achieved recommendations for duration of sleep to minimize health problems associated with sleep disorders.

(No relationships reported)

The prevalence of obesity in youth continues to increase and is associated with numerous physical health as well as cognitive and psycho-social maladaptive behaviors. For

example, Li et al (2008) documented the association between overweight and decreased cognitive function among children.

**PURPOSE:** Evaluate changes of academic performance following one year of a multidisciplinary program of exercise and health education.

**METHODS:** Twelve boys and fourteen girls (12.9 ± 2.9 yrs), participated in the study. The intervention consisted of a unique program of physical activity, including a variety of games that were enjoyable, maintained interest, and motivated subjects to adhere. Activity sessions were offered one time per week, two hours each session, for twelve months. In addition, a health education program was offered one time each month, one hour per session. Academic performance was evaluated by interview and a review of the academic records of each subject. Obesity was measured by BMI. Results of academic performance were evaluated by a t-test of mean differences from the beginning to the end of the program.

**RESULTS:** Findings of the study suggest a significant improvement ( $p < 0.001$ ) in academic performance in three of the four evaluations (self-esteem, self evaluation of academic performance, ability to work alone) in children and adolescents (Table 1). It was observed at the same time that obesity was significantly reduced from 30.9 to 29.8,  $p < 0.05$ .

Tableau 1. Evaluation of academic performance in obese children			
	T 0	T + 1	
Changes in class standing	96.67 ± 18.7	98.12 ± 22.9	NS
Self esteem	6.59 ± 2.3	9.59 ± 1.5	< 0.001
Self evaluation of academic performance	9.39 ± 3.8	12.39 ± 3.3	< 0.001
Ability to work alone	9.17 ± 3.7	12.39 ± 2.7	< 0.001

NS : Non significant

**CONCLUSIONS:** It was concluded that a multidisciplinary program of exercise and health education in obese children and adolescents reduced BMI and improved academic performance, self esteem, self evaluation of academic performance, and ability to work alone.

**Predictors Of Swimming Critical Velocity In Juvenile Talented Swimmers**

Ricardo J. Fernandes, João Silva, Ricardo Alves, Pedro Morouço, André F. Seabra, João P. Vilas-Boas. *Faculty of Sport, Porto University, Porto, Portugal.*

Email: ricfer@fade.up.pt  
(No relationships reported)

The Critical Velocity (CV) - the maximal velocity sustainable for a long period of time without exhaustion - is considered to be a relevant performance determinant factor in swimming, and particularly related to the aerobic markers of swimming ability. Moreover, aerobic training and performance capacity are traditional concerns of swimming coaches. Thus, it seems relevant to determine which are the parameters, from those traditionally included in follow-up programs of young swimming talents, that are able to better explain the variance of CV.

**PURPOSE:** To assess the parameters from training background, strength, flexibility, hydrodynamics and hydrostatics, that better predicts CV.

**METHODS:** 100 juvenile swimmers of the Portuguese National Swimming Team - 52 males (15.8±0.4 yrs) and 48 females (13.8±0.4 yrs) were involved in a talent follow-up project that aimed to monitor the evolution of 33 variables from the above listed domains of characterization parameters. CV was assessed as the slope of a regression line computed between the maximum intensity 200 and 800 m front crawl swimming distance and the corresponding time. Multiple regression analysis was used to study the factors associated with CV.

**RESULTS:** The multiple regression models identified that the CV could be predicted, for an  $r = .69$  ( $p < .001$ ), by the following equation:  $CV = 0.741 - 0.06 (\% \text{ body fat}) + 0.009 (\text{bi-acromiale breadth}) + 0.009 (\text{"water" training time}) + 0.01 (\text{gliding})$ . Together, these variables accounted for 48% of the variance in the CV performance. This estimated model predicted an average score of 1.20±0.05 m/s, while the true average score was of 1.26±0.07 (corresponding to 1min 23.3s±3.6s and 1min 19.3s±3.7s, respectively, at the 100 m). Results pointed out that the main predictors of CV are anthropometric, training background and gliding variables, commonly associated with aerobic training and hydrodynamics. As a consequence, it may be sustained that CV, as a marker of aerobic performance ability, is both influenced by the amount of training and hydrodynamics.

**CONCLUSIONS:** It is considered that the combination of "water" training time, bi-acromiale breadth and gliding (positive effect), and % of body fat (inverse effect), can be used as good predictor of the swimmer's performance at intensities corresponding to aerobic training regimens.

**The Effects Of A Personalized Aerobic Exercise Program In Obese Adolescents: An Early Adherence Study**

Melissa Spezia Faulkner, Sara Fleet Michaliszyn, Scott Going, Omar Contreras, Kimberly Romney. *University of Arizona, Tucson, AZ.*

Email: mfaulkner@nursing.arizona.edu  
(No relationships reported)

Regular physical activity increases levels of fitness and decreases risks for both cardiovascular disease and diabetes. Establishing and maintaining daily physical activity is particularly important for adolescents as they are experiencing a 34% overweight prevalence rate. Current physical activity recommendations for youth include 60 minutes of at least moderate activity every day. It is unknown if personalizing an aerobic exercise program specifically targeted to obese youth will improve their physical activity adherence.

**PURPOSE:** The purpose of this investigation is to describe early adherence to a 16-week personalized aerobic exercise program for sedentary, obese adolescents and to examine associations between adherence and perceived barriers.

**METHODS:** We are reporting activity adherence assessed via accelerometry for the initial 40 days of the study. Body composition was assessed via bioelectrical impedance analysis using the Quantum X<sup>®</sup>. Cardiovascular fitness was measured by  $VO_{2peak}$  during progressive cycle ergometry.

**RESULTS:** The sample consisted of 10 (4 males, age 14.5 ± 1.7 yrs.; 6 females, age 14.8 ± 1.9 yrs.) obese adolescents with BMI > 99<sup>th</sup> percentile (8 Hispanic, 2 Non-Hispanic). Average accelerometer wear time was 13.5 hours/day. On average, youth spent 78.7% of the day in sedentary activity, 13.1% in light activity, 7.3% in moderate activity and 0.9% in vigorous activity. Thirty-two percent of the time obese youth achieved the recommended 60 min·d<sup>-1</sup> of moderate to vigorous physical activity (MVPA). Daily duration of MVPA appeared close to current recommendations, although was quite variable (mean 53.6 ± SD 35.4 min·d<sup>-1</sup>). Adolescents' perceptions of barriers to exercise were negatively associated with participation of at least 60 min·d<sup>-1</sup> of MVPA

( $r = -.697$ ,  $P = 0.03$ , point-biserial correlation).

**CONCLUSIONS:** Adolescents met the recommended level of daily MVPA for approximately one-third of the initial 40 days of the personalized intervention. Perceived barriers to exercise could be influencing their consistent adherence to the recommended frequency of 7 days per week.

**Effect Of Maturation On Anthropometrical And Fitness Variables In 14 Year-Old Boys**

Fabício B. Alves, Wagner de Campos, Sergio G. da Silva. *Universidade Federal do Paraná, Curitiba, Brazil.*  
Email: fabriciobalves@yahoo.com  
(No relationships reported)

Maturity can discriminate performance in individuals of similar age and because of this the use of maturity levels should be used to detect differences in fitness and body composition in youngsters.

**PURPOSE:** To examine the differences in anthropometrical and fitness variables between different maturational stages in 14 year-old boys.

**METHODS:** The sample was composed by 38 boys in the maturity level three (ML-3) and by 68 boys in the maturity level four (ML-4), in the age of 14 years old. The measurements of sexual maturation were made according to the procedures suggested by FAULKNER (1996), fat percentage was calculated by the equation of BOILEAU et al. (1985), blood pressure (BP) was collected by the procedures suggested by ACSM (2003), sit-and-reach test and hand grip test were performed according to JOHNSON and NELSON (1986) and  $\text{VO}_2$  max was estimated using the 20-m Shuttle Run test developed by LÉGER et al (1986). Mann-Whitney U test was used to examine the difference between the means of anthropometric and fitness variables due to maturational levels.

**RESULTS:** Chronological age was similar for ML-3 and ML-4 ( $14.4 \pm 0.2$  and  $14.4 \pm 0.2$  years). However, differences were found for body weight ( $50.7 \pm 10.8$  and  $58.3 \pm 11.3$  Kg), height ( $161.3 \pm 9.4$  and  $168.3 \pm 7.7$  cm), lean body mass ( $41.0 \pm 6.9$  and  $46.3 \pm 7.1$  Kg), grip strength of right hand ( $32.2 \pm 6.2$  and  $38.0 \pm 6.8$  Kg) and grip strength of left hand ( $30.2 \pm 6.2$  and  $35.2 \pm 6.9$  Kg),  $p < 0.05$ . No differences were found for BMI ( $19.3 \pm 3.2$  and  $20.5 \pm 3.7$  Kg/m<sup>2</sup>), fat percentage ( $18.1 \pm 6.7$  and  $19.5 \pm 7.4$  %), fat mass ( $9.6 \pm 5.3$  and  $11.9 \pm 6.3$  Kg), flexibility ( $22.3 \pm 6.9$  and  $22.8 \pm 7.1$  cm), predicted  $\text{VO}_2$  max ( $43.4 \pm 6.6$  and  $44.1 \pm 5.6$  ml/kg/min), systolic BP ( $110.0 \pm 15.5$  and  $114.0 \pm 13.6$  mmHg) and diastolic BP ( $66.4 \pm 10.0$  and  $69.0 \pm 9.9$  mmHg).

**CONCLUSIONS:** The self-assessment of the male reproductive tract development was useful to detect differences in anthropometric, body composition (lean body mass) and fitness (muscular power) variables in pubertary men.

**Short Duration Jumping Increases Lean Tissue And Reduces Fat In Adolescent Boys But Not Girls**

Benjamin K. Weeks, Belinda R. Beck, FACSM. *Griffith University, Gold Coast, Queensland, Australia.*  
Email: B.Weeks@griffith.edu.au  
(No relationships reported)

The dramatic rise in prevalence of chronic diseases, such as obesity, cardiovascular disease, and musculoskeletal conditions, is matched by a clear reduction in levels of physical activity among children and adolescents. There is an urgent need to implement preventative strategies during childhood that are community-based, widespread, and effectively target body systems most at risk in later life.

**PURPOSE:** To determine the effect of a regular, school-based, short duration, high intensity jumping regime on muscle, bone, and fat tissue in healthy adolescent boys and girls.

**METHODS:** We replaced regular warm up activities with jumping in the twice-weekly PE classes of early high school students for 8 months to observe the effect on lean and fat tissue. A total of 99 adolescents (46 boys, 53 girls;  $13.8 \pm 0.4$  years) volunteered to participate. Intervention group subjects performed ten minutes of high intensity jumping activity, while control subjects performed their regular PE warm-up (i.e. jogging and stretching). Anthropometrics, Tanner staging, peak height velocity, and whole body bone mineral content (BMC), lean tissue, and fat mass (DXA-derived) were measured at baseline and follow-up. Physical activity was determined by questionnaire.

**RESULTS:** There were no differences in any measured variable between control and intervention groups at baseline. No group differences were detected for 8-month change in anthropometric or maturity measures for boys or girls. Analysis of 8-month change in grouped data revealed that jumpers increased whole body BMC ( $p = 0.001$ ) and lean tissue mass ( $p = 0.001$ ) significantly more than controls. Sex-specific analysis, however, showed that intervention boys gained more whole body BMC ( $p = 0.001$ ) and lean tissue mass ( $p = 0.001$ ) and lost more fat mass ( $p = 0.03$ ) than controls, while intervention girls improved only whole body BMC ( $p = 0.003$ ) over controls.

**CONCLUSIONS:** Short duration, high intensity jumping activity during adolescence appears to improve bone, lean tissue, and fat in a sex-specific manner. We found that boys gained more lean tissue and bone mass and lost more fat mass, while girls gained more bone mass with no differences in lean or fat tissue.

**Agreement Between Body Mass Index and Percent Body Fat In Determining Clinical Cutpoints For Youth**

Kelly R. Laurson<sup>1</sup>, Joey C. Eisenmann<sup>2</sup>, Greg J. Welk, FACSM<sup>3</sup>. <sup>1</sup>*Illinois State University, Normal, IL.* <sup>2</sup>*Michigan State University, East Lansing, MI.* <sup>3</sup>*Iowa State University, Ames, IA.*  
Email: klaurso@ilstu.edu  
(No relationships reported)

**PURPOSE:** A major uncertainty in clinical and epidemiological research relates to the level of uniformity between the clinical cutpoints used in conjunction with body mass index (BMI), waist circumference (WC), and percent body fat (%BF). The purpose of this study was to examine the diagnostic performance of BMI and WC in relation to an estimate of %BF in children and adolescents.

**METHODS:** Clinical data on youth (5-18 years old) were obtained from 3 cross-sectional waves (1999-2000, 2001-2002, 2003-2004) of the National Health and Nutrition Examination Survey ( $n = 8,228$ ). Percent fat was derived from the skinfold thicknesses, stature and body mass were used to calculate BMI, and WC was also measured. Receiver operator characteristic (ROC) analysis was employed to determine optimal cutpoints between the various adiposity indices using previously recommended BMI, WC, and %BF cutoff values. Sex- and ethnicity-specific %BF percentiles were also created and used to explore diagnostic agreement among the aforementioned indices.

**RESULTS:** The optimal %BF values associated with an overweight BMI in boys ranged from 14%-23% across the age range in all ethnicities. The corresponding values for girls were slightly higher and covered a larger range (16%-33%). For both sexes, the 85<sup>th</sup> BMI percentile corresponded with slightly lower %BF values for black youth. However, at the 95<sup>th</sup> BMI percentile, the values for boys were almost identical ranging from 17%-28% fat. In girls, the %BF values were lower for blacks than for white or Mexican American girls.

**CONCLUSIONS:** The findings of this study suggest that a single-value %BF cutoff (such as the 25% or 30% thresholds currently used in FITNESSGRAM) is not appropriate for use across the pediatric age range. Instead, using %BF percentiles may improve diagnostic agreement with the current BMI thresholds of overweight and obesity, especially for females. Further, the results indicate that BMI and %BF association is modified by ethnicity. The optimal cutoffs are provided for each adiposity index, based on the sum of sensitivity and specificity.

**1944 Board #85 May 28 9:00 AM - 10:30 AM**  
**Lean Mass As A Predictor Of Bone Mineral Density In Prepubertal Children**

Amber R. Yudell<sup>1</sup>, Abby L. Richey<sup>1</sup>, Rudy J. Valentine<sup>1</sup>, Sigurbjörn Á. Arngrímsson<sup>2</sup>, Darla M. Castelli<sup>1</sup>, Charles H. Hillman<sup>1</sup>, Ellen M. Evans, FACSM<sup>1</sup>. <sup>1</sup>*University of Illinois Urbana-Champaign, Urbana, IL.* <sup>2</sup>*University of Iceland, Laugarvatn, Iceland.*

Email: ayudel2@illinois.edu

(No relationships reported)

The relative contribution of lean tissue and fat mass as predictors of bone mineral density (BMD) varies across the adult lifespan, especially during midlife and old age. The relative influences of fat and lean mass on BMD in prepubertal children remains inadequately characterized. Relations between body composition and bone status may be influenced by the obesity epidemic, low physical activity rates and suboptimal nutritional practices in children with the latter behaviors potentially impacting attainment of peak bone mass and subsequent risk for osteoporosis later in life.

**PURPOSE:** To determine if fat or lean mass explains the greatest variance in BMD in prepubertal children, and if the contribution of the respective body composition components is impacted by sex.

**METHODS:** Whole body (WB), lumbar spine (LS), femoral neck (FN) and hip (HIP) BMD, and total fat and lean mass were determined by dual energy X-ray absorptiometry (DXA) in 96 prepubertal children [9.2±1.3 y; males (n=49) and females (n=47)].

**RESULTS:** Mean WB BMD was 0.83±0.08 g/cm<sup>2</sup> (WB Z-score=0.19). Fat (12.3±7.9 kg) and lean mass (28.9±6.7 kg) both correlated with WB BMD (r=0.45, r=0.77, respectively) and regional BMD (r range=0.36 to 0.67; all p<0.01). However, the relationships between fat and all BMD measures were eliminated after controlling for lean mass (all p>0.05). Alternatively, when accounting for the influence of fat mass, the relationship between lean mass and BMD persisted (r range=0.53 to 0.72, all p<0.01). Using linear regression, fat mass was not an independent predictor at any site whereas lean mass was an independent predictor of WB, LS, FN, and HIP BMD (all p<0.01), explaining 60%, 44%, 41% and 39% of the variance, respectively. Sex was also an independent predictor of LS BMD explaining 11% of the variance with females having greater LS BMD; however, sex was not a predictor at the WB or FN and HIP sites.

**CONCLUSIONS:** Although fat and lean mass both influence BMD in prepubertal children, lean mass is the most significant independent predictor of BMD. These results encourage health behaviors that enhance lean mass, specifically physical activity, to optimize bone mineral accrual prior to adulthood.

(No relationships reported)

Obesity poses a substantial health risk to children across the world. Excess body fat is associated with increased morbidity and mortality in adults. Globally, the medical community is encouraging children to engage in more aerobic exercise as part of a healthier lifestyle.

**PURPOSE:** The objective of the present study was to determine the relationship between aerobic (cardio-respiratory) fitness and body fat percentage in both non-overweight and overweight 8-year-old school children. Our study was based on the hypothesis that high aerobic fitness would be associated with lower levels of total and central adiposity.

**METHODS:** A cross-sectional study was conducted in a random sample of 10 elementary schools. The study participants were a 245 healthy second-grade elementary school children aged 8.9 ± 0.4 yrs (125 boys, 120 girls), all of whom were recruited in the OLIMP study (Obesity and Physical Activity among Serbian School Children).

Anthropometric data (height, body mass, waist circumference, five skin-fold thickness measurements) were collected and body fat percentage was calculated. Body mass index (BMI) sex- and age-specific cut-off points were used to define overweight and obesity. Children were placed in two groups: overweight/obese and non-overweight. Aerobic fitness was assessed with the multi-stage shuttle run fitness test. Subjects were grouped into high (upper two quintiles) and low (lower two quintiles) aerobic fitness based on age and sex distributions.

**RESULTS:** Body mass index, waist circumference, five skin-fold thicknesses and total body fat were lower in overweight and obese children with high aerobic fitness in comparison with youths at the same BMI category with low fitness level (p < 0.01). The beneficial effect of high aerobic fitness was also present in non-overweight children (p < 0.01). Finally, aerobic fitness was moderately inversely correlated with total body fat in the whole group of subjects (r = - 0.48, p < 0.01). Indicators of local and total adiposity were lower in overweight and obese children with high aerobic fitness.

**CONCLUSIONS:** Increasing aerobic fitness correlates with lower rates of obesity in 8-year-old children. Further studies may help illuminate whether these decreased levels of obesity translate into decreased morbidity and mortality.

**Levels Of Physical Fitness As Predictors Of Overweight And Obesity In Rural Youth**

Jose Pedro Fonseca, Maria Joao CA Almeida, Ana Jose Rodrigues, Rui F. Andrade, Ricardo D. Silva. *University of Madeira, Funchal, Portugal.*

Email: jalmeida@uma.pt

(No relationships reported)

There has been a worldwide increase in the prevalence of obesity in children and adolescents with a subsequent increase in the prevalence of obesity-associated morbidities. Several studies have suggested a decrease in physical fitness among young people.

**PURPOSE:** The purpose of the present study was to determine the risk of a young person to present a high or very high percentage of body fat (%BF) high, when his/her level of physical fitness is below the healthy fitness zone (HFZ).

**METHODS:** The sample of this study consisted of 91% of a school population from a rural area of Madeira Island, Portugal, totalling 790 children and adolescents of both genders, aged between 10 and 17 years of age. Percentage body fat (%BF) was estimated by measuring skinfolds and Slaughter et al. (1988) equations, classified in categories according to Lohman (1987). Physical fitness was assessed with the Fitnessgram test battery (Cooper Institute for Aerobics Research, 2002).

**RESULTS:** Of the 5 fitness tests, all of them except for the seat-and-reach test, were found predictors of a high or very high %BF when the scores were below the HFZ. The risk was higher for the Pacer test (OR=3.65, CI 95%: 2.50 - 5.35), followed by push-ups test (OR=1.62, CI95%: 1.11-2.37), and the curl-ups test (OR=1.61, CI 95%: 1.08-2.39).

**CONCLUSIONS:** The subjects falling below the HFZ have a higher risk of high or very high %BF when compared with their peers classified in or above the HFZ. The risk was higher for the Pacer, curl-ups and push-ups tests.

**Relationships Between Body Composition Variables And Lower Limb Morphology In Children**

Jesus B. Exposito<sup>1</sup>, José Ramón Cruz Alvero<sup>2</sup>, Martín MC Fernández<sup>2</sup>, José Carlos F. Garcia<sup>3</sup>, Elvis A. Carnero<sup>4</sup>, Ana D. Quiterio<sup>4</sup>. <sup>1</sup>Instituto Martiricos, Málaga, Spain. <sup>2</sup>Sport Medicine School of Malaga, Málaga, Spain. <sup>3</sup>Faculty of Education Sciences, Málaga, Spain. <sup>4</sup>Faculty of Human Movement, Lisbon, Portugal.

Email: jesusbarreraexposito@gmail.com

(No relationships reported)

Pain and lesions during the practice of sports and exercise are often attributed to the lower limbs morphology. Childhood and adolescence may a critical period to consolidate a good morphology. Nevertheless, the knowledge about the relationships between lower limbs morphology alterations and body composition in youth and children is lacking. It has been hypothesized that the overload resulting from overweight during growth is associated with some morphologic alterations (mainly in the knee and feet).

**PURPOSE:** To explore the relationships between anthropometric variables, percent of fat mass (%FM) and skeletal muscle mass, and leg and foot morphotypes.

**METHODS:** One hundred fifty children aged 12-18 years (75 boys and 75 girls) were assessed. %FM was estimated using Slaughter's equation with skinfolds. Morphological characteristics were assessed with goniometers. Ischiotibial shortening was assessed by lumbovertical (LV), EPR and the fingers-foot distance (FFD). Genu varum, genu valgum and foot morphotype were measured using a mechanical podometer. Pearson's correlation coefficient was used to test the association between variables. Significance was set at  $p < 0.05$  level.

**RESULTS:** A significant correlation between genu varum and height was observed ( $r = -0.23$ ,  $p = 0.004$ ). Genu valgum morphotype was positively associated with weight ( $r = 0.5$ ,  $p < 0.001$ ), BMI ( $r = 0.59$ ,  $p < 0.0001$ ) and %FM ( $r = 0.54$ ,  $p < 0.001$ ). Height was negatively associated with hamstring flexibility: EPR ( $r = -0.23$ ,  $p = 0.03$ ), LV ( $r = -0.24$ ,  $p = 0.002$ ), and FFD ( $r = -0.21$ ,  $p = 0.008$ ). Significant positive relationships were found between flat foot and body weight ( $r = 0.34$ ,  $p = 0.001$ ), BMI ( $r = 0.36$ ,  $p = 0.0001$ ) and %FM ( $r = 0.23$ ,  $p = 0.004$ ), while bare foot was not significantly associated with any of the anthropometric variables analyzed.

**CONCLUSIONS:** This was the first study to show that BMI, %FM and weight were negatively correlated with genu valgum morphotype and flat foot. Moreover, height was associated with genu varum and hamstring muscle shortening. The novel contribution of the current findings is that they have shown that childhood obesity is a risk for morphological alterations, indicating an interaction between physiological and biomechanical variables. The mechanisms upon which these interactions are established require further research.

**Effectiveness Of A Summer Training Program On Sprint Acceleration Of High School Athletes**

Christopher Siegel, Bryan Christensen. *North Dakota State University, Fargo, ND.* (Sponsor: Donna J. Terbizan, FACSM)

Email: csiegel@alexortho.com

(No relationships reported)

Sprint acceleration is a key factor in an athlete's success to out-accelerate and out-run an opponent. There are many types of conditioning programs that athletes can use to improve their overall speed. A good conditioning program should focus on the acceleration phase of the sprint as well as the entire distance.

**PURPOSE:** To investigate the effectiveness of a seven-week training program on the 9.144 m (10 yard) sprint acceleration performance of high school students who were enrolled in a summer sports enhancement camp.

**METHODS:** Eighteen high school athletes, ten male (56%) and eight female (44%), between the ages of 15 and 18, who were involved in a high school sport participated in a four day a week, seven week, non-sport specific summer sports enhancement camp. Students and their parents signed informed consent forms to participate in the study. To determine the student's initial acceleration, all athletes completed a ten-minute warm-up consisting of a jog, dynamic stretching, form running, and static stretching. Upon warm-up completion, the athletes were instructed in the proper technique needed to use the electronic timing system and contact switch used to measure their 9.144 m sprint time. Each athlete was given two attempts at sprinting through the timing system with the faster of the two attempts recorded. Students then participated in the summer sports enhancement camp for 7 weeks. When the camp was completed, post-testing occurred using the same method as the pre-test.

**RESULTS:** A paired sample T-test revealed no significant differences between pre-test sprint acceleration times and post-test sprint acceleration times with ( $p = 0.52$ ). After the implementation of the four-day-a-week training program over seven weeks, 55.6% (10) of the participants showed a slower sprint acceleration time, 38.9% (7) showed an improvement in sprint acceleration times, and 5.6% (1) of the participants showed no change in sprint acceleration time.

**CONCLUSION:** The results of this study indicated that the implementation of the summer training program did not have an affect on the improvement of sprint acceleration times of the high school athletes involved.

**1949 Board #90 May 28 9:00 AM - 10:30 AM**  
**Validity Of The 20-m Msrt As A Predictor Of Vo2peak In Lisbon Elementary School Children**

Pedro X. Castanheira<sup>1</sup>, Helena Santa-Clara<sup>1</sup>, Paula M. Bruno<sup>1</sup>, José P. Almeida<sup>1</sup>, Elvis Carnero<sup>1</sup>, Luís B. Sardinha<sup>1</sup>, Bo Fernhall, FACSM<sup>2</sup>. <sup>1</sup>Faculty of Human Kinetics, Lisbon, Portugal. <sup>2</sup>University of Illinois at Urbana-Champaign, Champaign, IL.

Email: xavier\_xavier@sapo.pt

(No relationships reported)

Several studies have validated the 20-m multistage shuttle-run test (MSRT) in children by measuring the  $VO_{2peak}$  value in the laboratory and relating this to the number of laps completed.

**PURPOSE:** The aim of this study was to examine the validity of the FITNESSGRAM's MSRT software reports as a predictor of  $VO_{2peak}$  in Lisbon healthy school children, by measuring the  $VO_{2peak}$  during the actual 20-m shuttle run performance.

**METHODS:** Ninety subjects, 45 boys and 45 girls aged 8-10 years, performed the MSRT and their  $VO_{2peak}$  was determined in field using a portable gas analyzer (K4b<sup>2</sup>, Cosmed, Rome, Italy). Height and weight were measured with standard anthropometric methods, percentage of fat (%Fat) was estimated from skinfold thickness, and the number of completed laps during the shuttle run was recorded and estimated  $VO_{2peak}$  values were derived via established FITNESSGRAM's equation. The determined peak  $VO_2$  value was considered the highest attained value during the last minute of the test.

**RESULTS:** The mean determined  $VO_{2peak}$  value of  $49.6 \pm 9.0$  ml.kg<sup>-1</sup>.min<sup>-1</sup> ( $53.3 \pm 9.2$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in boys and  $45.9 \pm 7.3$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in girls) was compared to the mean estimated  $VO_{2peak}$  value of  $47.8 \pm 2.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup> ( $48.9 \pm 2.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in boys and  $46.7 \pm 2.2$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in girls) and this difference was significant ( $P = 0.02$ ). The  $r$  was 0.72 and 22.2% of the difference scores fell outside 9 ml.kg<sup>-1</sup>.min<sup>-1</sup> of the measured  $VO_{2peak}$  SD. The mean difference was higher in boys ( $4.4 \pm 7.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>,  $P < 0.001$ ) than in girls ( $-0.7 \pm 6.2$  ml.kg<sup>-1</sup>.min<sup>-1</sup>,  $P = 0.445$ ).

**CONCLUSION:** These results suggest that the FITNESSGRAM's MSRT software reports underestimate the  $VO_{2peak}$  values determined by the K4b<sup>2</sup> in boys, but are suitable for girls.

**Gender Differences In Functional Movement Screen And Y-balance Test Scores In Middle School Aged Children**

Robert J. Butler<sup>1</sup>, Bryant Elkins<sup>2</sup>, Kyle B. Kiesel<sup>1</sup>, Phillip J. Plisky<sup>2</sup>. <sup>1</sup>University of Evansville, Evansville, IN. <sup>2</sup>ProRehab-PC, Evansville, IN. (Sponsor: Mitchell J. Rauh, FACSM)

Email: rb83@evansville.edu

(No relationships reported)

Poor static and dynamic postures have been related to musculoskeletal injury. These postures can cause poor arthrokinematics, which in time may lead to pain and disability. Recent research has suggested that better functional movement and dynamic balance are associated with reduced injury rates. However, there are no published reports in this area on middle school aged children and whether gender differences exist in this age group.

**PURPOSE:** To examine gender differences in functional movement quality and dynamic balance, as measured by the Y-Balance testing protocol, in middle school aged children.

**METHODS:** Two physical education classes of middle school aged students (13 boys and 19 girls) were recruited for the study. Informed consent was obtained from the students and the students' parents. All students participated in dynamic balance testing using the anterior, posteromedial, and posterolateral reach directions of the Star Excursion Balance Test as measured by the Y-Balance testing device. Scores on anterior, posteromedial, posterolateral, and composite reach distances were normalized to leg length. In addition to Y-Balance testing, all students participated in the Functional Movement Screen. The Functional Movement Screen consisted of 7 tests: squat, lunge, hurdle step, push up, shoulder mobility, active straight leg raise, and rotary stability test. Independent samples t-tests were used to examine differences between boys and girls for the Y-Balance Test scores while Mann-Whitney U tests were used to examine differences in the functional movement tests due to the rank-order nature of the data.

**RESULTS:** Girls performed better on the squat, lunge, straight leg raise, and shoulder mobility compared to boys ( $p < 0.05$ ). There were no statistically significant differences between girls and boys for the hurdle step, push up, rotary stability or any of the Y-Balance Test reach scores ( $p > 0.05$ ).

**CONCLUSION:** Girls and boys of middle school age may exhibit different qualities of functional movements. Studies focused on improving functional movements in middle school aged children should consider these findings when developing interventions aimed at improving functional movements.

**Longitudinal Modeling Of Physical Activity, Body Fatness And Blood Pressure During Childhood**

Joey Eisenmann<sup>1</sup>, Adam Baxter-Jones<sup>2</sup>, Gregory Welk, FACSM<sup>3</sup>, Jerod Tucker<sup>3</sup>, Kate Heelan<sup>4</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>University of Saskatchewan, Saskatoon, SK, Canada. <sup>3</sup>Iowa State University, Ames, IA. <sup>4</sup>University of Nebraska-Kearney, Kearney, NE.

Email: jce@msu.edu

(No relationships reported)

Our understanding of the inter-relationships among habitual, free-living physical activity and body fatness and resting blood pressure (BP) in children are based mainly upon cross-sectional studies. However, such studies cannot distinguish the effects of normal growth and maturation from the effects of physical activity on physical traits. To distinguish the independent effects of physical activity in the growing child, individual growth trajectories must be identified using longitudinal data.

**PURPOSE:** The purpose of this study was to investigate the independent effects of a) physical activity on fat mass and BP development and b) fat mass on BP development; whilst accounting for the confounding effects of growth.

**METHODS:** Subject were 173 (86 girls and 87 boys) children participating in a mixed-longitudinal study. Age at entry was 4 to 8 years of age. Stature, body mass, body fatness, resting BP and moderate-to-vigorous physical activity (MVPA) were assessed annually for 3 to 4 years. Data were analyzed using multi-level random effects models.

**RESULTS:** BP increased with chronological age, and MVPA decreased in the older age groups. In girls but not boys, when the confounders of age and stature were controlled, it was found that MVPA had a significant time-dependant effect on fat mass accrual ( $-0.03 \pm 0.01$  g;  $p < 0.05$ ). The difference in mean arterial pressure between the normal weight and obese at each age was  $7 \pm 1$  mm Hg. There was no significant influence of MVPA on BP development in boys or girls, even when removing fat mass as a confounder.

**CONCLUSIONS:** Habitual MVPA had a small influence on the growth of fat mass in girls but not resting BP once age and stature were accounted. In turn, fat mass influenced BP development in both sexes; however, the differences in fat mass and BP are already apparent at age 4 years. Thus, further investigation into the influence of prenatal and early growth and the role of physical activity and other environmental factors during this period is warranted.

**Effects Of A Sports Performance Training Program On Adolescent Athletes.**

Rachel J. Hazuga, Rebecca A. Battista, Glenn Wright, Dennis Kline, Carl Foster, FACSM. University of Wisconsin-La Crosse, La Crosse, WI.

(No relationships reported)

It is well established that resistance training can be safe and effective for children and adolescents. In addition, improvements in sports performance can be further developed through plyometric training and general instruction of fundamental movements.

**PURPOSE:** The purpose of this study was to determine the effects of a training intervention that combined strength, plyometric, and speed and agility training on sports performance in adolescents.

**METHODS:** Twelve middle and high school girls and boys (aged  $14.7 \pm 1.7$  years) participated in a seven week youth sports performance training (YSPT) intervention. The YSPT program met three days a week on non-consecutive days for ninety minutes. At baseline and after training all participants performed a static and countermovement vertical jump, push-ups, pro agility run, overhead medicine ball toss, and 40 yard dash. These skills were assessed for quality of the skill using a 1-5 Likert scale. Weight, height, sitting height, and years of experience playing sports and strength training were recorded.

**RESULTS:** While vertical jump, overhead medicine ball toss, and the 40 yard dash all improved, the paired samples t-test revealed significant improvements only in push-ups ( $29.5 \pm 18.6$ ,  $38.8 \pm 15.8$ ,  $P = 0.0$ ) and pro agility ( $5.2 \pm 0.4$ ,  $5.1 \pm 0.3$  sec,  $P = 0.024$ ) from baseline to after training. The Wilcoxon test demonstrated significant improvements in the quality of the skill only for pro agility. Pearson correlations performed between age and change in performance showed moderate relationships in vertical jump, overhead medicine ball toss, and 40 yard dash.

**CONCLUSIONS:** These findings suggest that a short-term youth training program that focuses on sports performance may have a positive effect on upper body muscular strength and endurance and agility in adolescents. While this study supports positive adaptations to training in adolescents, it also suggests researchers should continue to investigate the effects of learning a skill on performance in this age group.

**A Passive Dynamic Model For Simulation Of Interpersonal Synchronization During Side By Side Walking**

Jeff Nessler. California State University, San Marcos, San Marcos, CA.

Email: jnessler@csusm.edu

(No relationships reported)

Unintentional synchronization of stepping occurs frequently during side by side walking, yet little is known regarding the physiological mechanisms that underlie this coupling.

Our preliminary data suggest that this behavior varies among subject pairs, due in large part to differences in the leg length of each individual. Because an individual's leg length is a potential determinant of their preferred walking speed, analysis of a simple walking model may lend insight to this phenomenon.

**PURPOSE:** To examine the relationship between leg length and over-ground velocity in a passive dynamic walking model as a first step toward a model of gait entrainment, and to compare results to empirical data.

**METHODS:** A simplified model of bipedal locomotion based on an inverted double pendulum was utilized to simulate human gait. An additional term was introduced to simulate hip actuation via spring, acting on the angle between the walker's legs to allow for control of cadence. Simulations were performed for 100 steps, and leg length (L) was progressively increased for each case. At each value for L, the spring stiffness (K) was altered to maintain a consistent cadence. Simulation results were compared with data obtained from 27 pairs of subjects of varying leg lengths walking on side by side treadmills.

**RESULTS:** Synchronization of cadence was successfully achieved in the model by varying K for values of L up to 130%. Beyond this level, hip actuation alone was not sufficient to achieve synchronization. In addition, over-ground velocity was not maintained at a consistent level across changes in K and L. For small increases in L, simulations indicated that K required for synchronization increased in a curvilinear fashion, suggesting that increased effort is required for synchronization in partners with differing leg lengths. This idea was supported in the laboratory, where subjects that exhibited synchronization had significantly smaller differences in leg length ( $3.7 \pm 2.1$  cm vs  $7.3 \pm 5.2$  cm,  $p=0.02$ ).

**CONCLUSIONS:** These results suggest that interpersonal synchronization may require additional effort and may present an increasingly complex dynamical problem for the CNS as the difference in subject leg length is increased. Further investigation and development of this model will be necessary to fully understand this behavior.

**Optimizing Movement Performance Through Understanding: An Application Of Dynamic Systems**

Jay Polsgrove, *University of Southern Indiana, Evansville, IN.*

Email: mjpolsgr@usi.edu

(No relationships reported)

Dynamic systems theory suggests that a system in transition is in the process of developing new movement patterns. More precisely, as attractors lose stability the behavior of interest becomes more varied and less reliable. This loss of stability can be captured as an increase in the standard deviation or patterning of the behavior of interest and may reflect an increase in the systems adaptability.

**PURPOSE:** To provide evidence that increasing the cognitive understanding of systemic function facilitates the development of adaptability (i.e. increased variability of behavior) in older women who have had a knee joint replaced.

**METHODS:** A mixed method approach was used to provide evidence of performance change with a cognitive systemic training intervention. Four women from 59 to 72 years old who had had a knee replacement within the last year served as participants. Subjects were placed into 2 groups (n=2). Group 1 (experimental) took part in 10 training sessions over a 5-week period. Sessions utilized a systems approach to facilitate an optimization of movement through an expanded understanding of movement. Group 2 (control) took part in only 2 data collection sessions separated by 5 weeks. This group took place in no additional activity. Quantitative measures were collected for both groups prior to and following the 10 training sessions.

**RESULTS:** Group 1 showed increases in stride and step time, stride length, and stride velocity compared to Group 2. The standard deviation for Group 1 showed a 12-fold difference in gait time and a 4-fold difference in gait length compared to Group 2. Additionally, characteristic measures: Group 1 had a change of ROM during stride for hip, knee and ankle as compared to no change in Group 2.

**CONCLUSIONS:** These results support the systems perspective that the development of new patterning may be reflected through directional change, increased variance, and characteristic modification. The data indicates that the development of movement behavior occurred, thus suggesting that patients who have undergone knee replacement may benefit from a cognitive systemic training intervention.

**Instrumentation And Calibration Of Track And Field Starting Blocks For The Measurement Of Kinetic Data**

Samuel C. Johnson, Glenn M. Street, David W. Bacharach, FACSM, *St. Cloud State University, St. Cloud, MN.*

Email: josa0303@stcloudstate.edu

(No relationships reported)

**INTRODUCTION:** Several studies have been performed to measure kinetic properties of the sprint start in track and field. Many of these studies have been conducted in labs using starting blocks mounted over force platforms to measure reaction force (RF) in the blocks. However, a lab without a force plate would need to spend \$20,000 to \$30,000 for the purchase and installation of such hardware and software. This solution also leaves the sprinter in the restricted atmosphere of the lab, unless a specialized track surface with mounts for a force plate are available. More recently, instrumented starting blocks have become commercially available but cost upwards of \$20,000, and for many research labs the limited utility of a set of instrumented blocks does not justify the cost.

**PURPOSE:** To provide a cost-effective solution for collecting force data from a set of starting blocks while keeping the surrounding environment comparable to a competition setting.

**METHODS:** To simplify this introductory project, only one side of a standard Olympic style track and field starting block (wedge) was customized to measure RF. To do so, a plate was fabricated to sandwich four uniaxial load cells (Transducer Techniques MLP-500) to the starting wedge. Uniaxial load cells were used to keep costs lower but have the limitation of only providing RF perpendicular to the surface of the wedge. The cost of hardware for this specific application was less than \$3,200. The device was then calibrated using a least squares technique.

**RESULTS:** After using a least squares calibration to produce regression coefficients for the four load cells in the system, the customized plate was loaded with known weights in the range of 30 to 100lbs. The regression predicted the known weights with less than 1% error. A shear force component may be added with one additional load cell mounted perpendicular to the face of the wedge. A fully functional set of blocks (two wedges capable of measuring perpendicular and shear force under each foot with modular amplifiers for each load cell) would be expected to cost approximately \$7,000.

**CONCLUSION:** It is possible to construct a cost-effective, working set of instrumented starting blocks that accurately (<1% error) measures forces.

**Reactive Oxygen Species As Signaling Molecules Of Contraction-mediated Metabolic Responses In Skeletal Muscle**  
Leonardo D. Silveira, FACSM, Carlos HJ Pinheiro, FACSM, Everardo M. Carneiro, Rui Curi, *University of Sao Paulo, Sao Paulo, Brazil.*

Email: lrs@icb.usp.br  
(No relationships reported)

Reactive oxygen species (ROS) are expected to be enhanced during exercise to an extent that could affect cell viability. However, changes on redox balance is important for many cellular processes including metabolism.

**PURPOSE:** This study evaluated the effects of changes on intracellular balance redox on contraction-mediated metabolic responses muscle cells.

**METHODS:** Muscle steam cells were isolated from rats. The cells were treated with N-Acetylcysteine (NAC) (800 $\mu$ M) or induced to contractions by electrostimulation during 30 min. ROS; translocation and mRNA of glucose transporter 4 (GLUT-4); uptake of 2-deoxyglucose (2-DG); oxidation of palmitate; activities and mRNA of hexokinase (HK), phosphofructokinase (PFK), citrate synthase (CS) and carnitine palmitoyl transferase 1 (CPT-1) were evaluated.

**RESULTS:** NAC removed the H<sub>2</sub>O<sub>2</sub> produced in baseline (75 $\pm$ 8 vs 40 $\pm$ 3U, p<0.05) and during muscle contractions (122 $\pm$ 6 vs 59 $\pm$ 6U, p<0.05). In baseline, the antioxidant decreased mRNA of GLUT-4 (100 $\pm$ 6 vs 57 $\pm$ 3UA, p<0.05) and PFK-1 (0.16 $\pm$ 0.1 vs 0.13 $\pm$ 0.08UA, p<0.05), increasing the expression of CPT-1 (100 $\pm$ 6 vs 192 $\pm$ 3UA, p<0.05) and CS (98 $\pm$ 4 vs 160 $\pm$ 11 UA, p<0.05). Whereas the oxidation of palmitate (0.07 $\pm$ 0.01 vs 0.093 $\pm$ 0.014  $\mu$ mol, p<0.05) and CS activity (0.8 $\pm$ 0.08 vs 1.9 $\pm$ 0.1 nmol/min, p<0.05) were increased. The removal of intracellular H<sub>2</sub>O<sub>2</sub> during muscle contractions decreased the translocation of GLUT-4 (137 $\pm$ 13 vs 102 $\pm$ 5UA, p<0.05), uptake of 2-DG (0.266 $\pm$ 0.01 vs 0.177 $\pm$ 0.02  $\mu$ mol/mg, p<0.05) and activity of PFK-1 (0.20 $\pm$ 0.033 vs 0.15 $\pm$ 0.02 nmol/min, p<0.05). H<sub>2</sub>O<sub>2</sub> increased glucose uptake (0.1 $\pm$ 0.01 vs 0.6 $\pm$ 0.01  $\mu$ mol/mg, p<0.05), and the activities of HK (0.18 $\pm$ 0.02 vs. 0.145 $\pm$ 0.01 nmol/min, p<0.05) and PFK-1 (1.7 $\pm$ 0.2 vs 1.04 $\pm$ 0.1 nmol/min, p<0.05) compared to control. Muscle contraction increased activity of CS (0.18 $\pm$ 0.02 vs 0.145 $\pm$ 0.01 nmol/min/mg, p<0.05) and oxidation of palmitate (0.065 $\pm$ 0.007 vs 0.11 $\pm$ 0.01  $\mu$ mol/mg, p<0.05).

**CONCLUSIONS:** the contraction-induced H<sub>2</sub>O<sub>2</sub> is associated with glucose uptake, activation of glycolytic enzymes and expression of genes related to glucose metabolism. In contrast, at low intracellular level of H<sub>2</sub>O<sub>2</sub> there was an increasing in activity and mRNA of CPT-1, suggesting that ROS regulates the metabolism of glucose and fatty acids in skeletal muscle cells. Support: FAPESP/CNPq.

---

**1957 Board #98 May 28 8:00 AM - 9:30 AM**  
**The Effects Of Gradual Intensity Decrement Running On Fat Metabolism**

Sandy S. Hsieh, FACSM, Huan-Chieh Chen, *National Taiwan Normal University, Taipei City, Taiwan.*  
Email: t08028@ntnu.edu.tw  
(No relationships reported)

Exercise is essential for a sound weight control program. However, what mode of exercise is optimal to metabolize fat is not clear.

**PURPOSE:** To investigate the effects of gradual intensity decrement running on fat metabolism and energy expenditure.

**METHODS:** Twelve healthy males served as subjects (age 25.2  $\pm$  2.4 yrs; height 176.9  $\pm$  6.6 cm; weight 70.2  $\pm$  9.0 kg; body fat 17.6  $\pm$  5.2 %; VO<sub>2</sub>max 48.2  $\pm$  5.3 ml/kg/min). The ACSM policy regarding human subjects and informed consent was followed. Subjects performed the same duration (60 min, each 10-min period represented one stage) treadmill running with constant intensity exercise (CIE, 5% below AT VO<sub>2</sub>) and with gradual intensity decrement exercise (GDE, 5% below AT VO<sub>2</sub> with a decrease of 5% every 20 min). A repeated-measures design (seven days apart) was used, and the testing order was counterbalanced. A MetaMax 3B was used to measure VO<sub>2</sub> and RER. SPSS software (13.0) was used for data analysis and the significance level was set at p<.05.

**RESULTS:** CIE was significantly higher than GDE at the 3<sup>rd</sup>, 5<sup>th</sup>, and 6<sup>th</sup> stages of the energy expenditure (122.8  $\pm$  26.9 vs. 114.1  $\pm$  24.3 kcal; 124.1  $\pm$  23.5 vs. 103.0  $\pm$  23.8 kcal; 124.9  $\pm$  23.6 vs. 102.8  $\pm$  25.3 kcal). CIE was also significantly higher than GDE for total energy expenditure (1600.1  $\pm$  323.7 vs. 1283.3  $\pm$  228.0 kcal). The RER of GDE was significantly lower than CIE at the 5<sup>th</sup> and 6<sup>th</sup> stages (0.80  $\pm$  0.06 vs. 0.83  $\pm$  0.06; 0.79  $\pm$  0.06 vs. 0.83  $\pm$  0.06). There was no significant difference in the amount of fat burned for both modes of exercise (374.3  $\pm$  149.0 vs. 380.9  $\pm$  113.8 kcal). Although the ratio of fat utilization showed no significant difference, GDE was slightly higher than CIE during the last 3 stages of exercise. On the rating of perceived exertion (RPE), GDE was significantly lower than CIE at the 3<sup>rd</sup>, 4<sup>th</sup>, 5<sup>th</sup>, and 6<sup>th</sup> stages (10.6  $\pm$  1.4 vs. 12.0  $\pm$  1.9; 10.8  $\pm$  1.9 vs. 12.3  $\pm$  2.2; 10.4  $\pm$  2.2 vs. 12.7  $\pm$  2.4; 10.3  $\pm$  2.4 vs. 13.0  $\pm$  2.6).

**CONCLUSIONS:** Although CIE burns more calories than GDE, fat metabolism was not significantly higher than GDE. However, due to the intensity decrease during exercise, GDE would make people feel that exercise was easier, and this may lengthen exercise duration. Therefore, GDE may be a better mode of exercise for weight control.

**High-Fat Diet Based on Brazilian Diet Profile Induces Obesity and Hyperglycemia in Wistar Rats.**

Luciana O. Pereira, Antonio H. Lancha Jr. *University of Sao Paulo, sao paulo, Brazil.*  
Email: loquendo@usp.br  
(No relationships reported)

Obesity has been reported as a worldwide epidemic, independently of economic, social conditions. The cause of increased mortality and morbidity associated with obesity has been focused by many studies

**PURPOSE:** The aim of this study was to develop a high fat diet based on the dietary intake of Brazilian obese women able to induce obesity in healthy female rats.

**METHODS:** The diet was formulated with lard as fat source (38.7% of calories), casein as protein source (17.1% of calories) and starch as carbohydrate source (44.2% of calories). Female Wistar rats were fed either with high fat diet (FD) or with the control diet (CD) for 40, 60 and 120 days

**RESULTS:** After 40 days eating the high fat diet, rats presented the same body weight in both groups; however, the rats fed with a high fat diet presented higher brown adipose tissue mass compared with the control rats, and also, more fat in their carcass (CD 78.88 $\pm$ 14.24; FD 112.41 $\pm$ 21.98). Evidences of fat accumulation were more exacerbated when diet was held for 60 and 120 days. We could also identify impairment in glucose tolerance, hyperinsulinemia (29.7%) and hyperglycemia (9.3%) after the intake of the high fat diet. The rats that fed on the high fat diet for 60 days presented impaired Glut 4 (CD 0.7356 $\pm$ 0.0501 vs. FD 0.6086 $\pm$ 0.0571) and insulin receptor (CD 0.9689 $\pm$ 0.1458 vs. FD 0.3046 $\pm$ 0.0842) gene expression.

**CONCLUSIONS:** The high fat diet developed in this study was efficient in inducing obesity and glucose intolerance in healthy female Wistar rats.

(No relationships reported)

Background: Obesity does not predispose to chronic disease in fit men.

**PURPOSE:** To investigate if fat distribution might help to explain why the 'fat-fit' are protected from the ravages of obesity.

**METHODS:** Magnetic resonance imaging was used to assess total and regional body fat and magnetic resonance spectroscopy was used to assess liver fat in 13 slim-fit men, 4 slim-unfit men, 12 fat-fit men, and 13 fat-unfit men aged 45 $\pm$ 6 years. Waist girth at the narrowest part of the torso was used to distinguish slim men ( $\leq$ 90 cm) and fat men ( $\geq$ 100 cm). Maximal aerobic power (l $\cdot$ min<sup>-1</sup>) was used to distinguish fit men (above average for age) and unfit men (average or below for age). We excluded fit men who had not trained regularly in the last

two years. General linear model analysis of variance and Bonferroni *post hoc* tests were used to compare groups. Data are mean $\pm$ SD.

**RESULTS:** Total fat was not significantly different in the slim-fit and the slim-unfit (15.2 $\pm$ 4.0 and 19.8 $\pm$ 5.5 l, respectively), but was higher in the fat-fit and the fat-unfit (37.3 $\pm$ 11.4 and 37.5 $\pm$ 6.9 l, both  $p < 0.05$  compared to slim men and NS for inter-group comparison). Abdominal subcutaneous adipose tissue was not significantly different in the slim-fit and the slim-unfit (3.0 $\pm$ 1.4 and 3.5 $\pm$ 1.4 l, respectively), but was higher in the fat-fit and the fat-unfit (9.4 $\pm$ 4.2 and 8.0 $\pm$ 1.8 l, both  $p < 0.05$  compared to slim men and NS for inter-group comparison). Visceral adipose tissue was not significantly different in the slim-fit and the slim-unfit (1.4 $\pm$ 0.8 and 3.1 $\pm$ 1.3 l, respectively), but was higher in the fat-fit (4.8 $\pm$ 1.0 l,  $p < 0.05$  compared to the slim-fit) and higher still in the fat-unfit (7.2 $\pm$ 2.4 l,  $p < 0.05$  compared to every other group). Liver fat (geometric mean) was not significantly different in the slim-fit (0.41 $\pm$ 0.54), the slim-unfit (1.61 $\pm$ 1.59) and the fat-fit (5.90 $\pm$ 6.14), but was higher in the fat-unfit (24.08 $\pm$ 24.2,  $p < 0.05$  compared to every other group). Significant differences remained when total, abdominal subcutaneous, and visceral fat were expressed as percentages (data not shown).

**CONCLUSIONS:** These data suggest that favourable levels of visceral and liver fat may help to explain why the fat-fit enjoy protection from the ravages of obesity.

Effect of 12-wk walking exercise training on regulation of SREBP1c mRNA in adipose tissue in middle aged obese women

Adipose tissue functions as an endocrine organ and secretes numerous proteins in response to a variety of stimuli and lipid synthesis. Sterol regulatory element binding protein 1c (SREBP1c) is a master regulator of lipogenic gene which is expressed in liver and adipose tissue, while SREBPs involved in fat cell differentiation and lipid accumulation. It was demonstrated that SREBP-1c mRNA levels decreased in streptozotocin induced diabetic rats and showed reversed insulin sensitivity. Despite the potential importance of SREBP1c, little is known about the regulation of SREBP1c with exercise training.

**Objectives:** This study was performed to investigate the effect of 12-wk walking exercise program on lipogenic gene expressions in subcutaneous abdominal adipose tissue in obese middle aged women.

**METHODS:** Fourteen obese middle aged women (45-50 years) who met ITF criterion for abdominal obesity with waist circumference ( $\geq 80$ cm) participated in this study. The subjects performed walking exercise program of 3 days per week for 12 weeks without diet control. Calorie expenditure was monitored by commercial calorimeter during the exercise to burn 400kcal per a session. Before and after exercise program, abdominal subcutaneous fat biopsies were taken and the samples used to measure the levels of SREBP-1c, FAS, PPARgamma, UCP2, and CPT1 mRNA by real-time PCR.

**RESULTS:** SREBP-1c mRNA ( $p < .001$ ) significantly increased with 12-wk walking exercise program whereas other adipocyte-related transcription factors, such as FAS, PPARgamma, UCP2, and CPT1 mRNA unchanged.

**CONCLUSION:** The present study demonstrated that insulin resistance may be positively controlled by increased lipid infiltration in adipose tissues after 12-wk walking exercise training

Key words: exercise training, SREBP-1c, FAS, PPARgamma, UCP2, and CPT1 mRNA, real-time PCR.

**Exercise-induced Oxidative Cpt I Modification And Lipid Metabolism In Skeletal Muscle**

Wataru Aoi<sup>1</sup>, Yoshikazu Takamin<sup>2</sup>, Yukari Kawai<sup>2</sup>, Yuji Naito<sup>2</sup>, Toshikazu Yoshikawa<sup>2</sup>. <sup>1</sup>*Kyoto Prefectural University, Kyoto, Japan.* <sup>2</sup>*Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Email: waoi@koto.kpu-m.ac.jp

(No relationships reported)

Oxidative modification of protein impairs its function. Reactive oxygen species generated from mitochondrial during exercise may oxidize mitochondrial protein and partly limit the function. A rate limiting step of lipid metabolism in myocyte is entry of long chain fatty acids into mitochondria via carnitine palmitoyltransferase I (CPT I) located on the mitochondrial membrane.

**PURPOSE:** We investigated the level of oxidative CPT I modification in prolonged exercise associated with lipid utilization in skeletal muscle.

**METHODS:** ICR mice (8 weeks old) were divided into four different groups: sedentary, sedentary treated with astaxanthin (an antioxidant), running exercise, and exercise treated with astaxanthin. After 4 weeks of treatment, exercise groups performed treadmill running. The respiratory exchange ratio (RER) and substrate utilization were calculated from the level of oxygen consumption and carbon dioxide production during exercise. Immediately after running, gastrocnemius muscle and blood sample were collected for the biochemical measurements.

**RESULTS:** Modification of CPT I by hexanoyl-lysine, one of the lipid peroxides, was increased by exercise, while astaxanthin reduced such oxidative stress-induced modification ( $p < 0.05$ ). An increase of the interaction between CPT I and FAT/CD36 in muscle during exercise was facilitated by astaxanthin ( $p < 0.05$ ). RER was significantly decreased in the mice fed an astaxanthin-containing diet compared with those on a normal diet ( $p < 0.05$ ).

**CONCLUSIONS:** Our results suggested that prolonged exercise increases oxidative CPT I modification, which leads to partly limit lipid metabolism.

**Relationship Between Vo2 At Lactate Threshold And Maximal Fat Oxidation Across Age, Fitness, And Sex**

Arthur Weltman, FACSM, Siddhartha S. Angadi, Corey A. Rynders, Nathan Y. Weltman, Glenn A. Gaesser, FACSM. *University of Virginia, Charlottesville, VA.*

Email: alw2v@virginia.edu

(No relationships reported)

**PURPOSE:** To investigate the relationship between VO<sub>2</sub> at lactate threshold (LT) and VO<sub>2</sub> at maximal rate of fat oxidation (FATMAX) across age, fitness status and sex.

**METHODS:** 77 men and 76 women (Age- 33.2 $\pm$ 1.7, 29.4 $\pm$ 1.4; BMI-26.3 $\pm$ 0.5, 29.1 $\pm$ 0.9; %body fat-22.5 $\pm$ 1.1, 35.1 $\pm$ 1.2; VO<sub>2peak</sub>-32.9 $\pm$ 1.1, 23.9 $\pm$ 1.1 respectively) completed a continuous incremental VO<sub>2peak</sub>/LT protocol. Fat oxidation rates were determined using indirect calorimetry and averaged over the last minute of each 3-min stage. The highest recorded fat oxidation rate was chosen as FATmax. The breakpoint in the VO<sub>2</sub>-blood lactate relationship was chosen as LT.

**RESULTS:** VO<sub>2</sub> at FATmax preceded VO<sub>2</sub> at LT in both men and women (48% v. 54% & 42% v. 47% VO<sub>2peak</sub>,  $p = 0.014$ ,  $p < 0.001$ , respectively). The relationship between VO<sub>2</sub> at FATmax and VO<sub>2</sub> at LT remained constant across young and older subjects (18-35yrs -  $r = 0.81$   $p < .001$ ;  $> 50$ yrs -  $r = 0.74$ ,  $P < .001$ ), across VO<sub>2peak</sub> after controlling for age (highest quartile v. lower 3 quartiles -  $r = 0.58$ ,  $r = 0.52$ ,  $p < .001$ , respectively), and was maintained irrespective of sex (M -  $r = 0.80$ , F -  $r = 0.77$ ,  $p < .001$ ). RPE at Fatmax was lower than RPE at LT in all comparisons: young (10.6  $\pm$  0.2 vs. 9.3  $\pm$  0.2), least fit (10.9  $\pm$  0.6 vs. 9.0  $\pm$  0.2) women (10.5  $\pm$  0.2 vs. 9.0  $\pm$  0.2) (all  $p < .001$ ); old (12  $\pm$  1.5 vs. 9.4  $\pm$  0.3,  $p = .085$ ), most fit (11.1  $\pm$  0.3 vs. 10.7  $\pm$  0.5,  $p = .33$ ) and men (11.5  $\pm$  0.9 vs. 9.8  $\pm$  0.3,  $p = .075$ ).

**CONCLUSIONS:** We conclude that the relationship between VO<sub>2</sub> at LT and VO<sub>2</sub> at FATMAX is robust and not affected by age, sex, or fitness status.

Email: hasaki@hus.oiu.ac.jp

(No relationships reported)

**PURPOSE:** Ketone bodies (3-hydroxybutyrate, acetoacetate and acetone) is synthesized from a chemical reaction of fatty acids and acetyl CoA in the liver. Mobilization of fatty acids from adipose tissue is accompanied by elevation of ketone bodies in blood. A portion of free ketone bodies in circulation is expired from alveolar to expired air as acetone. Recently, a device for detecting acetone in expired air has been developed. The purpose of this study was to determine the responses of acetone in expired air during exercise and to discuss whether the responses of acetone reflect fat mobilization and/or utilization during the exercise.

**METHODS:** Twenty female college students carried out graded bicycle testing and prolonged walking or running testing on a treadmill. In the former, they performed the exercise with an increasing load of 12 watts every minute until near exhaustion. In the latter, they did treadmill walking or running for 2 hours at a load corresponding to the heart rate inducing their maximal fat combustion rate which was found in the previous testing. During both exercises expired gas was collected into Douglas bags so that acetone, oxygen intake and carbon dioxide excretion could be analyzed, from which the fat combustion rate was calculated.

**RESULTS:** In the graded bicycle testing, acetone in the expired air exponentially increased from about 50%  $\dot{V}O_{2max}$ , at which the maximal fat combustion rate and anaerobic threshold were found. In the prolonged walking or running testing, the acetone level gradually increased during exercise. A significant correlation was found between the acetone levels and fat combustion rate.

**CONCLUSIONS:** Acetone in expired air can be an indicator for fat utilization during endurance exercise at constant intensity levels.

**Expression Of Novel Organic Cation/carnitine Transporter (octn2) In The Skeletal Muscle**

Yasuro Furuichi, Kazumi Masuda, Tomoko Sugiura, Yukio Kato, Takashi Kitaura, FACS. Kanazawa university, Kanazawa, Japan.

Email: furuichi@ed.kanazawa-u.ac.jp

(No relationships reported)

The primary function of L-carnitine is to facilitate the transport and the metabolism of long-chain fatty acids into the mitochondria for beta-oxidation and energy production. Since L-carnitine is unable to be synthesized in skeletal muscle, this molecule has to be influx from the blood. However, the mechanism of trans-sarcolemmal L-carnitine transport system remains unclear. Novel organic cation transporter 2 (OCTN2), a sodium-dependent solute carrier, transports L-carnitine from the plasma into cells and is expressed in tissues such as kidney, liver and intestine. Although OCTN2 is also assumed to transport L-carnitine across plasma membrane in skeletal muscle cell, there has been no report to detect the expression of OCTN2 in skeletal muscles.

**PURPOSE:** The purpose of the present study was to show the expression of OCTN2 in various skeletal muscles. Additionally, we compared the OCTN2 expressions between metabolically heterogeneous rat hindlimb muscles in order to establish relationship between the amount of OCTN2 and capacity of muscle fatty acid oxidation.

**METHODS:** Experiments were performed on male Wistar rats (12-wk old). Hindlimb muscles (m. soleus, m. plantaris, red and white portions of m. gastrocnemius), hearts and kidneys were homogenized in RIPA buffer and centrifuged to remove nuclear fractions and debris. The supernatant was used for analysis of Western blotting, and the expression of OCTN2 was investigated.

**RESULTS:** OCTN2 was detected in heart and in red muscles (m. soleus and red portion of m. gastrocnemius), but not detected in m. plantaris and white portion of m. gastrocnemius. Expression of OCTN2 in kidney was more than ten times higher than heart and red skeletal muscles. The difference of expression level of OCTN2 gene product among kidney and other tissues agree to that for rat OCTN2 mRNA observed in the previous studies.

**CONCLUSIONS:** In spite of small amount relative to kidney, OCTN2 was detectable in skeletal muscles especially slow-twitch red muscles, indicating that OCTN2 might contribute to fatty acid oxidation in skeletal muscles. These results suggest that OCTN2 transports L-carnitine from plasma into muscle cells, especially more in highly oxidative muscles.

**Metformin And AICAR Regulate Fatty Acid Metabolism In L6 Myotubes Via Different Cellular Mechanisms**

Lindsey D. Bogachus, Lorraine P. Turcotte, FACS. University of Southern California, Los Angeles, CA.

(No relationships reported)

AMP-activated protein kinase (AMPK) is a key regulator of glucose and fatty acid (FA) metabolism. Metformin and AICAR are potent activators of AMPK.

**PURPOSE:** To elucidate whether Metformin and AICAR regulate glucose and FA metabolism via different AMPK-induced cellular mechanisms.

**METHODS:** L6 skeletal muscle cells were treated with AICAR (A group; 2 mM, 2 hrs), or low or high amounts of Metformin (LM group; 800  $\mu$ M, 24 hrs or HM group; 2 mM, 3 hrs), and were subsequently incubated  $\pm$  Insulin (I condition; 100 nM, 15 min). After treatment(s), glucose uptake and FA uptake and oxidation were measured using [2-<sup>3</sup>H]deoxyglucose or [1-<sup>14</sup>C]palmitic acid. The phosphorylation state of AMPK $\alpha_1$ , AMPK $\alpha_2$ , Acetyl CoA Carboxylase (ACC), and Insulin Receptor Substrate-1 (IRS-1) as well as the content of plasma membrane (PM) Glut4 and CD36 were measured. The effects of the pharmacological treatments on metabolic parameters were assessed with ANOVA.

**RESULTS:** Compared to the control condition, A, LM and HM increased glucose uptake by 38 $\pm$ 5%, 40 $\pm$ 2% and 74 $\pm$ 7% ( $P$ <0.05). In each group, I significantly increased glucose uptake by 14-26% ( $P$ <0.05). A increased FA uptake by 16 $\pm$ 6% ( $P$ <0.05) and FA oxidation by 32 $\pm$ 4% ( $P$ <0.05). LM and HM decreased FA uptake by 19-27% ( $P$ <0.05) and FA oxidation by 11-14% ( $P$ <0.05). I significantly increased FA uptake and decreased FA oxidation in all groups ( $P$ <0.05). A, LM and HM increased total AMPK phosphorylation by 36 $\pm$ 5%, 82 $\pm$ 8% and 72 $\pm$ 6% ( $P$ <0.05). LM and HM increased AMPK $\alpha_1$  phosphorylation by 58-65% ( $P$ <0.05). A, LM and HM significantly increased AMPK $\alpha_2$  phosphorylation and the increase was significantly higher in A than LM or HM. I did not affect AMPK phosphorylation. As expected, A increased ACC phosphorylation (50 $\pm$ 7%,  $P$ <0.05). However, LM and HM did not change ACC phosphorylation. ACC phosphorylation was not affected by I in any of the groups. The insulin-induced increase in IRS-1 tyrosine phosphorylation was higher in LM than in A ( $P$ <0.05). PM CD36 content was increased by A treatment alone (44 $\pm$ 5%) and with I in both control (31 $\pm$ 5%) and A groups (64 $\pm$ 3%) ( $P$ <0.05). PM Glut4 content was increased by I, A, LM, and HM ( $P$ <0.05).

**CONCLUSION:** In L6 myotubes, Metformin and AICAR regulate FA uptake and oxidation via different intracellular mechanisms partially due to the preferential activation of different AMPK isoforms.

---

**Resistance Exercise Produces A Metabolic Gene Expression Signature Similar To Endurance Exercise**

Dongmei Liu<sup>1</sup>, Emidio Pistilli<sup>2</sup>, Laurie Gutmann<sup>2</sup>, Eric Hoffman<sup>3</sup>, Gustavo Nader<sup>4</sup>, Paul Gordon, FACS. <sup>1</sup>University of Michigan, Ann Arbor, MI. <sup>2</sup>West Virginia University, Morgantown, WV. <sup>3</sup>Children's National Medical Center, Washington, DC. <sup>4</sup>Karolinska Institute, Stockholm, Sweden.

Email: dongmei@med.umich.edu

(No relationships reported)

Resistance training (RT) has been proposed as a beneficial intervention modality for patients with metabolic syndrome and type II diabetes because of increasing evidence that similar metabolic benefits may be achieved with RT as with endurance training. Much of the improvements resulted from exercise training are associated with transient modifications in skeletal muscle induced by an acute bout of exercise.

**PURPOSE:** to examine the transcriptional regulation of metabolic genes in skeletal muscle induced by an acute bout of resistance exercise (RE).

**METHODS:** Subjects (11 female and 12 male, 18 to 40 y) trained the non-dominant elbow flexors for 12 weeks resulting in a 14.2 +/- 6.2 % increase in muscle volume and a 59.7 +/- 20.4% increase in 1RM strength. Six days after the last exercise session, an acute bout of RE was performed and bilateral biopsies were taken 4 hr post-exercise from both the trained and the untrained arms. RNA was extracted and prepared for expression profiling using the Affymetrix Human Genome U133 Plus 2 chips. Absolute expression values were calculated using MAS.5 and dChip and analysis was carried out using Gene Spring.

**RESULTS:** RE induced augmented mRNA levels of regulators implicated in 1) mitochondrial biogenesis including PGC1- $\alpha$  ( $\uparrow$ 2.88,  $p=0.0015$ ), SIRT1 ( $\uparrow$ 1.25,  $p=0.0152$ ) and PRKAG2 ( $\uparrow$ 4.80,  $p=0.0009$ ); 2) insulin signaling including IRS2 ( $\uparrow$ 3.42,  $p=0.0010$ ), RRAD ( $\uparrow$ 5.01,  $p=0.0007$ ) and NR4A1 ( $\uparrow$ 4.48,  $p=0.0020$ ); and 3) capillary biogenesis including VEGF ( $\uparrow$ 1.85,  $p=0.0027$ ), HIF1A ( $\uparrow$ 1.67,  $p=0.0004$ ) and CYR61 ( $\uparrow$ 3.02,  $p=0.0045$ ). Transcriptional modification of key lipid metabolism genes favored fatty acid repartitioning towards esterification with mRNA levels for LPL and CPT1B being decreased (LPL,  $\downarrow$ 1.71 fold,  $p=0.0001$ ; CPT1B,  $\downarrow$ 1.42 fold,  $p=0.0246$ ), and for FABPs being increased (FABP4,  $\uparrow$ 1.56 fold,  $p=0.0003$ ; FABP5,  $\uparrow$ 1.50,  $p=0.0065$ ).

**CONCLUSION:** Similar to endurance exercise, acute RE exhibits favorable regulation of metabolic gene transcription in skeletal muscle, implying, in part, an explanation for the beneficial role of resistance training in treating metabolic disturbances.

**Effect Of High-intensity Resistance Training On Twenty-four-hour Respiratory Quotient**

Kazunori Ohkawara, Shigeho Tanaka, Michiya Tanimoto, Motohiko Miyachi, Kazuko Ishikawa-Takata, Izumi Tabata, FACSM. *National Institute of Health and Nutrition, Tokyo, Japan.*

Email: ohkawara@nih.go.jp

(No relationships reported)

**PURPOSE:** To investigate the effect of high-intensity resistance training (RT) on twenty-four-hour respiratory quotient (24-h RQ) by cross-sectional and interventional settings.

**METHODS:** 1) Sedentary subjects ( $41.7 \pm 9.7$  yr,  $n = 7$ ) and subjects performing habitually high-intensity RT ( $41.6 \pm 6.9$  yr,  $n = 8$ ) participated in the cross-sectional study. Twenty-four-hour energy expenditure (EE) under free living condition was measured by doubly-labeled water (DLW) method, and all meals in 3 days before the chamber measurement were provided to all subjects according to the results from DLW method. Then, 24-h RQ was measured by a metabolic chamber. 2) Fifteen young adults participated in the interventional study. They were randomly divided into control (C) group ( $20.5 \pm 1.2$  yr,  $n = 8$ ) and RT group ( $20.9 \pm 1.8$  yr,  $n = 7$ ). RT group performed high-intensity (80 - 90% one-repetition maximum) RT on 2 days per week for 3 months. Before and after the training period, 24-h RQ was measured by a metabolic chamber under the well controlled-condition.

**RESULTS:** 1) In the cross-sectional study, there was a trend that fat-free mass (FFM) in subjects performing high-intensity RT was larger than that in sedentary subjects. However, no difference was observed in 24-h RQ between two groups. 2) In the interventional study, subjects in RT group significantly ( $P < 0.05$ ) increased FFM and absolute 24-h EE after the training period. However, there was no significant time-by-group interaction in 24-h RQ.

**CONCLUSIONS:** These results suggest that there is no effect of high-intensity RT on 24-h RQ measured by a metabolic chamber. In other words, although high-intensity RT enhances absolute 24-h EE induced by increasing FFM, it may not lead to the improvement of fat oxidation capacity in human subjects.

**Total Energy Expenditure, Body Water Turnover, Hydration Status, And Blood Composition During The Western States 100**

John Cuddy, Dustin Slivka, Walter Hailes, Charles Dumke, FACSM, Brent C. Ruby, FACSM. *University of Montana, Missoula, MT.*

(No relationships reported)

Ultra-endurance running is a unique sport that requires great physical stamina, mental resiliency, and metabolic demand.

**PURPOSE:** The purpose of this study was to measure total energy expenditure, total body water turnover (rH<sub>2</sub>O), and select blood markers for individuals competing in the Western States 100 ultra-endurance race.

**METHODS:** Participants (N=10) were provided with an oral dose of 2H<sub>2</sub>O18 a few days prior to the race. Urine and blood samples, along with body weight, were collected at multiple time points, including pre, mid, and post race.

**RESULTS:** Total energy expenditure during the race was  $66 \pm 12$  MJ ( $15,860 \pm 2,938$  kcal). Average finish time for subjects was  $26.8 \pm 3.1$  hours. Total body water turnover during the race was  $19.4 \pm 3.2$  liters ( $259 \pm 42$  ml.kg<sup>-1</sup>.1.24 hours). Urine specific gravity was significantly higher at mid and post compared to pre, ( $1.015 \pm 0.008$ ,  $1.029 \pm 0.005$ , and  $1.023 \pm 0.008$  for pre, mid, and post, respectively,  $p < 0.05$ ). Urea nitrogen (BUN) and creatinine were outside normal range and were higher mid and post compared to pre. Body weight was significantly reduced at midpoint compared to pre, but the post body weight did not differ from pre ( $71.2 \pm 11.8$ ,  $69.9 \pm 10.8$ , and  $70.3 \pm 10.8$  for pre, mid, and post, respectively,  $p < 0.05$ ).

**CONCLUSION:** During the Western States 100, energy expenditure averaged  $592 \pm 91$  kcal.hr<sup>-1</sup> and water turnover averaged  $0.7 \pm 0.1$  L.hr<sup>-1</sup>. The elevation of BUN and creatinine was slightly above the upper end of typical reference ranges (5% and 12% higher for mid and post BUN; 9% and 6% higher for mid and post creatinine, respectively), demonstrating reduced kidney function compared to normal exercise patterns. This study demonstrates some of the highest rates of human energy expenditure for a 24 hour period. Similarly, subjects experienced large amounts of water flux, signs of dehydration and renal dysfunction, but maintained sufficient energy and sodium supplementation to finish.

**Initial Hydration Status And Fluid Balance During Exercise Of Coaches And Fitness Trainers**

María de Lourdes Mayol-Soto, Nidia Rodríguez-Sánchez, Analí López-Fernández. *Gatorade Sports Science Institute, Mexico City, Mexico.*

Email: lourdesmayol@prodigy.net.mx

( M. Mayol-Soto, Gatorade Sports Science Institute, Consulting Fee.)

Current hydration guidelines emphasize the need to personalize fluid replacement strategies due to the extent variation on sweat rates between individuals. Also, it is recognized the importance of begin exercise well hydrated. Coaches and fitness trainers are key advising athletes and fitness enthusiast about having adequate hydration habits during exercise.

**PURPOSE:** To determine initial hydration status and fluid balance during an exercise bout on coaches and fitness trainers who were participating in a sports science course.

**METHODS:** Data were collected from 217 subjects (131 males and 86 females; age  $30.6 \pm 8.9$  years) during one 45-60 min exercise bout. Data were obtained during 4 separate sessions carried out at morning with a mean WBGT in the range of  $17.9\text{--}23.8^\circ\text{C}$ . Exercise bout consisted of intermittent exercise that combines martial arts and kickboxing (Body Combat). Subjects collected a urine sample from their first void of the morning and urine specific gravity (USG) was measured to determine initial hydration status. Subjects were weighted nude before and after the exercise session. During exercise, all subjects had free access to sports drinks bottles, which were weighed before and after training. Urine output was also monitored.

**RESULTS:** 112 subjects (51.9%) appeared to be inadequately hydrated before exercise because they showed  $\text{USG} \geq 1.020$ ; 20 of them (9.3%) with a  $\text{USG} \geq 1.030$ . The sweat volume lost was  $880\text{--}356$  mL ( $200\text{--}2162$  mL) and  $518\text{--}177$  mL ( $88\text{--}1010$  mL) for men and women respectively; fluid intake was  $733\text{--}293$  mL ( $38\text{--}1356$  mL) in men and  $600\text{--}299$  mL ( $0\text{--}1740$  mL) in women. On average, men replaced  $98\text{--}74\%$  and women  $129\text{--}81\%$  of their sweat losses, but this ranged from none to  $600\%$ . 144 subjects (66.4%) maintained their body mass (BM) (range from  $-0.5$  to  $0.5\%$ ), while 34 subjects (15.7%) gained more than  $0.5\%$  of their BM and 39 subjects (18%) had a BM loss  $>0.5\%$  (only one subject finished exercise with a BM loss  $>2\%$ ).

**CONCLUSIONS:** There was a large variation between individuals in the sweat rate and drinking behavior. A significant percentage of the subjects arrived already hypohydrated to the exercise bout, even though they have knowledge about hydration. Coaches and fitness trainers should develop a personalized hydration strategy to help athletes and match their sweat losses.

##### Effect Of Ramadan On Hydration Status And Concentration In Military Cadets In The United Arab Emirates

Tom Loney, James M. Carter, Graham F. Nicholson, Mark P. Rayson. *Optimal Performance Limited, Abu Dhabi, United Arab Emirates.*

Email: t.loney.uae@gmail.com

(No relationships reported)

The mission of the Military High School (MHS) is to develop the mind, body and soul of future officers for the United Arab Emirates (UAE) Armed Forces. During the holy month of Ramadan Muslim students at the MHS abstain from fluid and food from sunrise to sunset whilst still participating in an academic and a reduced military program.

**PURPOSE:** To investigate the effect of Ramadan on hydration status and concentration in Emirati adolescents.

**METHODS:** Nineteen males (age  $16.5 \pm 1.1$  yr, body mass  $74.4 \pm 17.5$  kg, height  $1.71 \pm 0.06$  m) from the MHS (Al Ain, Abu Dhabi, UAE) were tested during four 3-day monitoring periods: pre-Ramadan ( $\text{Ram}_{\text{pre}}$ ); during the second and fourth week of Ramadan ( $\text{Ram}_{\text{wk2}}$  and  $\text{Ram}_{\text{wk4}}$ ); and post-Ramadan ( $\text{Ram}_{\text{post}}$ ). During each 3-day monitoring period, hydration status (urine osmolality [ $\text{U}_{\text{osm}}$ ]) was measured bi-daily (morning and evening) and visual scanning ability (100-digit concentration grid) was assessed on days one and three. Mean ambient temperature decreased from  $37.5^\circ\text{C}$  to  $31.0^\circ\text{C}$  during the study period.

**RESULTS:** Seventy-one percent of all samples were above the recommended osmolality suggested for euhydration ( $700 \text{ mOsmol.kg}^{-1}$ ; ACSM Position Stand 2007: *Med Sci Sports Exerc*, 39, 377-390); 17% were  $\geq 1000 \text{ mOsmol.kg}^{-1}$ . Mean  $\text{U}_{\text{osm}}$  ranged from  $743 \pm 132$  to  $884 \pm 167 \text{ mOsmol.kg}^{-1}$  during the study period. Compared to baseline ( $\text{Ram}_{\text{pre}}$ ),  $\text{U}_{\text{osm}}$  remained relatively stable at  $\text{Ram}_{\text{wk2}}$  ( $-2 \pm 101 \text{ mOsmol.kg}^{-1}$ ,  $p > .05$ , effect size [ES] =  $0.01$ ) and then decreased at  $\text{Ram}_{\text{wk4}}$  ( $-103 \pm 103 \text{ mOsmol.kg}^{-1}$ ,  $p < .05$ , ES =  $0.83$ ) and  $\text{Ram}_{\text{post}}$  ( $-72 \pm 140 \text{ mOsmol.kg}^{-1}$ ,  $p > .05$ , ES =  $0.49$ ). Mean concentration grid score increased from baseline to  $\text{Ram}_{\text{wk4}}$  ( $9 \pm 4$  vs.  $15 \pm 9$ ,  $p < .05$ , ES =  $0.86$ ) and  $\text{Ram}_{\text{post}}$  ( $9 \pm 4$  vs.  $18 \pm 13$ ,  $p < .05$ , ES =  $0.96$ ).

**CONCLUSIONS:** Ramadan did not negatively affect hydration status or concentration; rather, both improved during the latter stages. However,  $\text{U}_{\text{osm}}$  data indicate that the majority of students were in a constant state of hypohydration. Consequently, visual cognitive processes (e.g. concentration) may be sub-optimal. Action is required to raise awareness of hydration among these future officers and to devise optimal hydration strategies for extreme environmental conditions and in situations where normal drinking and eating habits are altered.

*This work was sponsored by the United Arab Emirates Armed Forces.*

##### Hydration Status In Young Males Following Fasting And Prescribed Fluid Intake

Amy L. Morgan, FACSM<sup>1</sup>, Debra Boardley<sup>2</sup>. <sup>1</sup>Bowling Green State University, Bowling Green, OH. <sup>2</sup>University of Toledo, Toledo, OH.

Email: amorgan@bgsu.edu

(No relationships reported)

Exercise performance and thermoregulatory ability can be compromised by dehydration. Therefore, it is of interest to determine how younger individuals respond to 12-hours of fluid restriction or prescription.

**PURPOSE:** The purpose was to determine whether 1) a 12-hour fast would elicit clinical signs of dehydration and 2) there are differences in hydration status between 12 hours of fluid restriction and fluid prescription in young adult males.

**METHODS:** Sixteen men (18-25 yr), free from fluid altering medications underwent three distinct trials separated by at least 7 days. Indicators of hydration status were assessed in urine and blood prior to and at the completion of each 12-hour trial. The trials were 1) ad libitum - eat and drink freely throughout, 2) fasting - refrain from all food and drink, and 3) prescribed intake - eat same foods as ad libitum day and drink  $3.0 \text{ mL/kg}$  caffeine and alcohol free fluid each hour. Thirst was assessed prior to, midway, and at the completion of the 12-hours. The following were measured pre and post - hemoglobin (g/dL), hematocrit (%), serum and urine osmolality ( $\text{mOsm/kg}$ ) and creatinine. Change in plasma volume (PV%), glomerular filtration rate (GFR), and fractional excretion of water ( $\text{FeH}_2\text{O}$ ) were calculated for each trial.

**RESULTS:** PV% decreased ( $-3.13 \pm 6.3$ ) during the fasting day and increased during both the control ( $3.94 \pm 5.8$ ) and the prescribed intake ( $2.34 \pm 9.7$ ) trials; there was no significant difference between trials. During the fasting day, there was a significant decrease in serum osmolality and an increase in urine osmolality, while urine osmolality was reduced during both the control and prescribed intake days. For all trials, baseline urine osmolality fell above normal values.  $\text{FeH}_2\text{O}$  was significantly greater during the prescribed intake day ( $62.8 \pm 37.1\%$ ) than during the control day ( $35.7 \pm 14.7\%$ ). Thirst was reduced during the prescribed intake day and unchanged during both other days.

**CONCLUSION:** Most indicators of hydration status were maintained within normal range during the fasting day, suggesting that young males are able to maintain adequate hydration status following a 12-hour fast. Because some loss in PV was noted, active individuals should be encouraged to take in fluid within 12 hours of exercise to maximize performance and thermoregulatory abilities.

##### Efficacy Of Prevailing Fluid Intake Recommendations For Elite Marathon Running

Barry W. Fudge<sup>1</sup>, Yannis P. Pitsiladis, FACSM<sup>2</sup>. <sup>1</sup>University of Glasgow & Scottish Institute of Sport, Glasgow & Stirling, respectively, United Kingdom. <sup>2</sup>University of Glasgow, Glasgow, United Kingdom.

Email: barry.fudge@sisport.com

(No relationships reported)

Prevailing fluid intake recommendations promote drinking *ad libitum* 0.4-0.8 L·h<sup>-1</sup> during exercise (ACSM, *Med Sci Sports Exerc* 39, 2007). Modelling this fluid intake range in a general population (i.e., 50-90 kg subjects running at 8.5-15 km·hr<sup>-1</sup> in cool (18 °C) and warm (28 °C) ambient conditions) predicts 0.4-0.8 L·h<sup>-1</sup> is sufficient to maintain body mass (BM) loss < 3% and prevent BM gain (Montain et al., *Br J Sports Med* 40, 2006). The calculations are not, however, applicable to elite marathon runners. Furthermore, although the principle of *ad libitum* fluid intake is in agreement with previous observations in elite Kenyan endurance runners during an important period of training (e.g., Fudge et al., *Med Sci Sports Exerc* 40, 2008), there is almost no information on what the best marathon runners actually drink when racing.

**PURPOSE:** To evaluate whether the fluid intake recommendations of drinking *ad libitum* 0.4-0.8 L·h<sup>-1</sup> are appropriate for elite marathon running.

**METHODS:** A retrospective video analysis of the drinking behaviors of the winning male and female runners was undertaken during the 2006 and 2007 London Marathons. To supplement this analysis, a mathematical model was used to predict required fluid intake to prevent a > 3% BM loss or BM gain when BM, running speed and ambient conditions were systematically varied (i.e., 45-75 kg subjects running at (hr:min) 2:04 and 2:30 marathon pace in cold (7.3 °C) and warm (24.8 °C) ambient conditions).

**RESULTS:** The derived total drinking durations of 56, 38, 43 and 31 sec of the winning runners equate to fluid intake rates of approximately 1.5, 1.1, 1.1 and 0.9 L·h<sup>-1</sup>, respectively. The mathematical model predicts that *ad libitum* 0.4-0.8 L·h<sup>-1</sup> is insufficient to prevent > 3% BM loss or BM gain across all conditions modelled.

**CONCLUSIONS:** Fluid intake behaviors of elite endurance runners during a major city marathon do not reflect prevailing fluid intake recommendations. This is corroborated by the mathematical model as it predicts prevailing fluid intake recommendations of 0.4-0.8 L·h<sup>-1</sup> are insufficient to maintain BM loss < 3% and prevent BM gain. Therefore, an *ad libitum* fluid intake strategy may be the best hydration strategy for competitive marathon running in temperate conditions as long as BM loss is kept within acceptable limits, possibly < 3%.

**The Effects Of Different Sodium And Carbohydrate Concentration And pH On The Intestinal Fluid Absorption In Humans**

Melissa L. Tippet, Kristin L. Osterberg, Craig A. Horswill, Xiaocai Shi, FACSM. *Gatorade Sports Science Institute, Gatorade R&D, Barrington, IL.*  
Email: melissa.tippet@gatorade.com  
( M.L. Tippet, PepsiCo, Salary.)

To be an effective fluid replacement beverage during activity, a beverage must provide enough energy to sustain performance and yet be absorbed rapidly in the small intestine. Although the effect of carbohydrate (CHO) on fluid absorption is well-established, the interactive impact of sodium and CHO concentrations and the effect of pH on fluid absorption are still not clear.

**PURPOSE:** To determine the effects of different levels of sodium content at two different CHO concentrations on water absorption. Secondly, we compared the effect of pH on water flux.

**METHODS:** Seven male subjects were perfused with six beverages (60 min per beverage) at a rate of 15 ml/min in a randomized order using the triple lumen perfusion technique. Water absorption from each solution was calculated based on changes of polyethylene glycol (PEG) concentration in the intestinal samples. Test beverages included water (W, pH = 7), a flavored water placebo (WP, pH = 3), a 3% CHO (sucrose and dextrose) solution with either 18 mEq sodium (LCLS) or 72 mEq sodium (LCHS), and a 6% CHO (sucrose and dextrose) solution with either 18 mEq sodium (HCLS) or 72 mEq sodium (HCHS). Beverage osmolality ranged from 0 to 381 mOsm/kg. A two-factor repeated measures ANOVA was used to determine the significance in water flux ( $\alpha=0.05$ ).

**RESULTS:** CHO concentration ranging from 0 up to 6% did not significantly affect mean water flux ( $-19.7 \pm 3.6$ ,  $-16.3 \pm 2.6$ , and  $-14.0 \pm 0.9$  ml·cm<sup>-1</sup>·h<sup>-1</sup> for W, LCLS, and HCLS, respectively) over the 60 minutes of perfusion. Likewise, the sodium content at either CHO concentration did not affect water flux ( $-12.2 \pm 1.2$  and  $-10.7 \pm 1.0$  ml·cm<sup>-1</sup>·h<sup>-1</sup> for LCHS and HCHS, respectively). Finally, there was no significant difference in water flux based on pH (W:  $-19.7 \pm 3.6$  ml·cm<sup>-1</sup>·h<sup>-1</sup> vs. WP:  $-14.0 \pm 2.7$  ml·cm<sup>-1</sup>·h<sup>-1</sup>).

**CONCLUSIONS:** Increasing the sodium content to 72 mEq in either a 3% or a 6% CHO solution did not facilitate the rate of intestinal fluid absorption. In addition, a decrease of beverage pH from 7 to 3 did not appear to significantly influence intestinal absorption of fluid.

**Rate Of D2O Accumulation With Rehydration Using Three Different Drinks**

Jennifer F. Klau, Matthew S. Gano, Elaine C. Lee, Linda M. Yamamoto, Brendon P. McDermott, Rebecca M. Lopez, Jeffrey M. Anderson, Jeff S. Volek, Lawrence E. Armstrong, FACSM, William J. Kraemer, FACSM, Carl M. Maresh, FACSM. *University of Connecticut, Storrs, CT.*  
Email: jennifer.klau@uconn.edu  
(No relationships reported)

The availability of fluid consumed for thermoregulation and hydration depends on the rate of gastric emptying and fluid absorption in the intestine. Deuterium Oxide (D<sub>2</sub>O) accumulation serves as a marker of fluid uptake and allows for the assessment of the relative temporal availability of a fluid after ingestion.

**PURPOSE:** To compare the rate of D<sub>2</sub>O accumulation during rehydration with three different beverages at rest.

**METHODS:** Twelve males (mean  $\pm$  SD age, 25  $\pm$  3y; mass, 75.91  $\pm$  5.94kg) completed three dehydration trials in a randomized, blocked experimental design. Subjects walked for 1 hour (3.9  $\pm$  0.3mph; 1.5  $\pm$  0.6% incline) in 30  $\pm$  1°C, rh 50  $\pm$  7% followed by a 24h fluid restriction resulting in dehydration of  $-2.69 \pm 1.11$ . Subjects then ingested D<sub>2</sub>O (0.15 g/kg body weight) in either distilled water (WA), a carbohydrate - electrolyte (CE) beverage, or a flavored vitamin drink (VF) in four equal boluses consumed during the initial 5 minutes of a 60 minute rehydration/seated rest period. The total volume of fluid consumed was 50% of body weight lost. Plasma D<sub>2</sub>O and serum osmolality (Osm) were measured at 0, 4, 8, 12, 16, 20, 45 and 60 min. Thirst was assessed at 0, 4, 12, 20 and 60 min. Two-way and one-way repeated-measures ANOVA were conducted with alpha set at 0.05. Post hoc analyses were adjusted using a Bonferroni correction.

**RESULTS:** There was no interaction ( $p>0.05$ ) between beverage and D<sub>2</sub>O accumulation or beverage and attenuation of thirst. Mean D<sub>2</sub>O accumulation in plasma increased ( $p<0.05$ ) at every time point after ingestion except between minutes eight and 12 and between minutes 45 and 60. D<sub>2</sub>O accumulation increased 51.85  $\pm$  11.64% four minutes after ingestion and 78.21  $\pm$  2.98% during the 60 minutes. Serum Osm declined ( $p<0.05$ ) from min 0 to min 60 min in VF and WA, but not in CE. Mean thirst was 7  $\pm$  1 pre-rehydration and 3  $\pm$  2 at 60 min. Decrease in thirst was greater ( $p<0.05$ ) for VF than CE, but not for VF compared to WA or WA compared to CE.

**CONCLUSION:** Using D<sub>2</sub>O accumulation as a marker of fluid uptake, rehydration resulted in a similar rate of uptake among trials. Drink VF attenuated thirst more than CE and WA. Supported by glacéau (a division of The Coca-Cola Company).

**The Effect Of Sodium And Carbohydrate In A Rehydration Food On Subsequent Exercise Performance**

Huimin Yan, Todd M. Weber, Zebblin M. Sullivan, Rick L. Sharp, FACSM, Douglas S. King, FACSM. *Iowa State University, Ames, IA.*  
Email: yhuimin@iastate.edu  
(No relationships reported)

**PURPOSE:** To determine the effectiveness of a high sodium and carbohydrate meal on endurance exercise performance following exercise- and heat-induced dehydration.

**METHODS:** Twelve male subjects were dehydrated by ~3 % of body mass with exercise and heat exposure. In a randomly assigned, counterbalanced design, subjects were rehydrated at room temperature with either 175 ml of chicken noodle soup (SOUP: Campbell Soup Company, Camden, NJ) or an artificially sweetened placebo (CON) at the beginning of the 120 min rehydration period and 20 min later. Water was ingested every 20 min during the remaining 100 min of rehydration. Soup contained 161.0 mmol/l Na<sup>+</sup>, 5.3 mmol/l K<sup>+</sup>, and 32.6 g total carbohydrate. CON contained 14.4 mmol/l Na<sup>+</sup>, 16.0 mmol/l K<sup>+</sup>, and no carbohydrate. Total fluid ingestion was matched with body fluid loss during dehydration. After rehydration,

subjects performed 30 min of steady state exercise at 68%  $\text{VO}_{2\text{peak}}$ . Subjects then performed a time trial in which they accumulated as rapidly as possible the amount of work equal to 30 min of exercise at 70%  $\text{VO}_{2\text{peak}}$  in a thermoneutral environment (25 C and 40% relative humidity).

**RESULTS:** There was no significant difference in percent recovery of body mass during rehydration (CON:  $79.4 \pm 3.3\%$ ; SOUP:  $80.9 \pm 3.4\%$ ). Time trial performance was significantly improved in SOUP ( $30.6 \pm 0.8$  min) compared with CON ( $33.2 \pm 1.4$  min;  $p=0.031$ ). The rate of carbohydrate oxidation tended to be higher in SOUP ( $2.33 \pm 0.09$  g/min) compared with CON ( $2.18 \pm 0.11$  g/min;  $p=0.076$ ). No differences in heart rate or ratings of perceived exercise were found during post-rehydration exercise.

**CONCLUSIONS:** These results suggest that ingesting chicken noodle soup after exercise in the heat improves subsequent endurance exercise capacity, possibly through enhanced CHO oxidation.

**Pickle Juice Inhibits Gastric Emptying In Rested, Euhydrated Humans.**

Kevin C. Miller, Gary W. Mack, FACSM, Kenneth L. Knight, FACSM. *Brigham Young University, Provo, UT.*

Email: kevin\_miller@byu.net

(No relationships reported)

Approximately 25% of athletic trainers use pickle juice (PJ) to treat exercise associated muscle cramps (EAMC). Some claim 30-60 ml of PJ can relieve EAMC within 35-secs of ingestion due to its high sodium ( $\text{Na}^+$ ) content. Since little absorption occurs in the stomach, if true, the gastric emptying rate of PJ must be fast. No data exist examining the effect of PJ on gastric emptying.

**PURPOSE:** To compare gastric emptying and changes in plasma sodium ( $\text{Na}^+$ ), and plasma volume (PV) following ingestion of large volumes of PJ and deionized water (DIW).

**METHODS:** Ten healthy, euhydrated male subjects (mean  $\pm$  SE, age =  $25.4 \pm 0.7$  yrs; ht =  $177.1 \pm 1.6$  cm; mass =  $77.9 \pm 3.8$  kg) ingested 7 ml\*kg<sup>-1</sup> body weight of PJ or DIW at rest on 2 days separated by  $\geq 72$  hrs. Gastric volume was determined at 1, 5, 10, 20, 30, and 40 min using a phenol red dilution technique. Blood samples were collected before ingestion and at 5, 10, 20, 30, and 40 min postfluid ingestion and analyzed for Hct, [Hb], and  $\text{Na}^+$ .

**RESULTS:** Initial fluid intake was  $624.5 \pm 27.4$  ml for PJ and  $659.5 \pm 43.8$  ml for DIW. Both fluids emptied within the first 5 min postingestion (PJ =  $219.2 \pm 39.1$  ml, DIW =  $305 \pm 40.5$  ml,  $P < 0.05$ ). PJ failed to empty after the first 5 min ( $P > 0.05$ ) where as gastric volume decreased to  $39.9 \pm 20.2$  ml by 40 min with DIW ( $P < 0.05$ ). DIW emptied significantly faster than PJ between 20 and 40 min postingestion ( $P < 0.05$ ). Within 5 min of PJ ingestion, PV decreased  $4.8 \pm 1.6\%$  while  $\text{Na}^+$  increased  $1.6 \pm 0.51$  mM ( $P < 0.05$ ). Similar changes in PV and  $\text{Na}^+$  occurred following DIW ingestion. Calculated  $\text{Na}^+$  content was unchanged for both PJ and DIW ( $P > 0.05$ ) indicating that the increase in  $\text{Na}^+$  was due to the rapid PV shift and not absorption of the ingested  $\text{Na}^+$ .

**CONCLUSIONS:** The initial rapid decrease in gastric volume in the first 5 min with both fluids is attributable to an increase in gastric distension. Once this volume stimulus was gone, PJ failed to empty. This effect may be due to PJ's high osmolality ( $1325 \pm 1.0$  mOsm\*kg H<sub>2</sub>O<sup>-1</sup>), acidity (pH =  $3.2 \pm 0$ ), or both. Cardiovascular reflexes in response to gastric distension resulted in rapid PV shifts and a significant rise in  $\text{Na}^+$  over 40 min (PJ =  $<4.2 \pm 0.84$  mM, DIW =  $<1.5 \pm 0.7$  mM) despite no significant changes in  $\text{Na}^+$  content. It is unlikely that 30-60 ml of PJ relieves EAMC by rapidly altering  $\text{Na}^+$  because gastric emptying of PJ is extremely slow.

<sup>5</sup>Signal Nutrition, Fairhaven, NJ. (Sponsor: Dan Heil, FACSM)

Email: john.seifert@montana.edu

( J.G. Seifert, PacificHealth Laboratories, Contracted Research.)

Previous research has shown that a carbohydrate-protein sports drink (CHOP) improves rehydration after exercise compared to a carbohydrate-only sports drink (CHO).

However, little is known how composition of sports drinks impacts gastric emptying during exercise. Numerous gastric emptying studies have been limited to sampling only at pre- and post exercise. This study was completed by sampling <sup>13</sup>CO<sub>2</sub> at regular intervals during exercise to assess gastric emptying rate during exercise.

**PURPOSE:** To compare the gastric emptying rate of a CHOP sports drink to a CHO sports drink during moderate intensity, steady state exercise.

**METHODS:** 12 healthy subjects cycled for 60min at 65%  $\text{VO}_{2\text{max}}$  while ingesting 300 mL of either a 6% CHO + 1.5% protein sports drink (osmolality: 441 mOsm/kg H<sub>2</sub>O) or a 6% CHO only sports drink (osmolality: 406 mOsm/kg H<sub>2</sub>O). Each drink contained 100 mg <sup>13</sup>C labelled-NaC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> to serially assess gastric emptying. Beverage ingestion occurred following a 10 min warmup and 13 min of steady state exercise. <sup>13</sup>CO<sub>2</sub> was then collected every 5 min for 45 min after ingestion. Venous blood glucose, HR, and RPE were collected at 15 min intervals during exercise.

**RESULTS:** ANOVA analysis indicated that there were no differences ( $p > 0.05$ ) between treatments in gastric emptying, as measured by the appearance of exhaled <sup>13</sup>CO<sub>2</sub> (CHOP:  $14.1 \pm 6.1$ ; CHO:  $13.7 \pm 6.2$ ), or in blood glucose (CHOP:  $4.9 \pm 9$  mM/L; CHO:  $4.8 \pm 9$  mM/L). Gastric emptying peaked approximately 25 min after beverage ingestion for both treatments. No differences between treatments were observed for HR (CHOP:  $139 \pm 11$  bpm; CHO:  $138 \pm 10$  bpm) or RPE (CHOP:  $13.1 \pm 1.0$ ; CHO:  $13.2 \pm 1.3$ ).

**CONCLUSION:** Multiple studies have shown endurance and post exercise rehydration benefits of CHOP ingestion. This study demonstrates that a CHOP sports drink has similar gastric emptying characteristics during exercise to that of a CHO sports drink.

**Differential Accuracy Of Physical Activity Self-Report By Body Mass Index**

Erica Warner<sup>1</sup>, Kathleen Y. Wolin<sup>2</sup>, Gary G. Bennett<sup>1</sup>. <sup>1</sup>Harvard School of Public Health, Boston, MA. <sup>2</sup>Washington University School of Medicine, Saint Louis, MO.

Email: erica\_warner@dfci.harvard.edu

(No relationships reported)

Many epidemiologic studies rely on self-reported measures such as the International Physical Activity Questionnaire-Short Form (IPAQ-S) in their assessment of physical activity. Previous work in this population showed moderate correlations between this self-report measure and accelerometer data which varied by gender. What remains

unknown is whether reporting varies by body mass index (BMI).

**PURPOSE:** To determine whether agreement between self-reported physical activity and accelerometer measures varies by BMI.

**METHODS:** 135 Blacks residing in low-income housing completed the IPAQ-S and wore an accelerometer for up to 6 days. Both 1- and 10-minute accelerometer bouts were used to define time spent in light, moderate, and vigorous physical activity. Trained research staff measured participant height and weight. BMI was calculated as weight in kilograms divided by height in meters squared.

**RESULTS:** There were 31 people with BMI of 18-24.9, 30 with a BMI of 25-29.9 and 74 with a BMI of 30 or greater. Agreement between the IPAQ-S and accelerometer determined physical activity did vary by BMI. For a 10-minute bout, correlations were 0.38 (BMI <25), 0.57 (BMI 25-29.9) and 0.15 (BMI 30+). For a 1-minute bout, correlations were 0.34, 0.44, and 0.24 respectively. When we classified participants based on attainment of physical activity recommendations, agreement was much better among non-obese persons and significantly lower for 10-minute bouts compared to 1-minute bouts (non-obese: 1-minute kappa = 0.48, 10-minute kappa = 0.023; obese: 1-minute kappa = -0.024, 10-minute kappa = -0.020).

**CONCLUSION:** Correlations between self-reported physical activity and accelerometer data were consistently lowest for obese persons compared to those of lower BMI. When classifying participants according to attainment of physical activity recommendations, there was no agreement between instruments among obese persons for either bout length. Among those with a BMI of 18-29.9 there was moderate agreement for a 1-minute bout, and no agreement for a 10-minute bout.

**PURPOSE:** To describe systematic and random errors in, and validity coefficients and attenuation factors associated with, a physical activity (PA) questionnaire using a measurement error correction (MEC) model. Three reference measures were used to fit MEC models and we describe our results in light of the limitations of each.

**METHODS:** Participants were 147 men and 151 women enrolled in two prospective cohort studies in Shanghai. Over 12-months, they completed two physical activity questionnaires (Q) and four 7-day measures by PA log (PAL) and Actigraph (A). PA energy expenditure was estimated for each measure, including two values from the PAL. The first (PAL1) reflected all activity reported each day, while the second (PAL2) was matched to specific behaviors assessed on Q. To describe systematic (activity-related and person-specific biases) and random errors in Q, and associated validity and attenuation factors (AF), we fit the model of Kipnis (AJE 158:14, 2003) to Q with each reference measure. Simulation studies were conducted to evaluate the impact on results for Q when reference measures violate the assumption that they are free of systematic errors in estimating the true PA levels for Q.

**RESULTS:** MEC results indicated that systematic errors were lowest for Q when compared with the PAL2 reference measure, followed by PAL1 and A. Person-specific bias in Q was substantially larger when A was the reference measure. Validity coefficients (r) and attenuation factors (AF) for Q were highest when PAL2 was the reference (r=0.70 and AF=0.56), followed by PAL1 (r=0.55 and AF=0.55), and A (r=0.26 and AF=0.13). Lower AF values indicate more attenuation. Results were similar for men and women. Simulations indicated that larger violations of the systematic error assumption in the reference measures can result in an apparent inflation of activity-related and person-specific biases in Q.

**CONCLUSION:** We found less systematic error, higher validity coefficients, and less attenuation in Q when reference measures were closely matched to Q (PAL2). When implementing MEC models for PA exposures it may be preferable to employ self-reported reference measures that can be closely matched to the Q being evaluated, even if they are susceptible to person-specific biases.

**A Correction Factor Improves Met Estimates Of Physical Activities**

Sarah L. Kozey, M.S., Kate A. Lyden, M.S., Staudenmayer W. John, PhD, Patty S. Freedson, PhD, FACSM. *University of Massachusetts, Amherst, MA.*

Email: skozey@kin.umass.edu

(No relationships reported)

The standard 1 MET = 3.5 ml·kg<sup>-1</sup>·min<sup>-1</sup> generally overestimates resting metabolic rate (RMR) for low-fit, overweight, older and female individuals. It is unknown what effect this systematic error has on MET estimates of physical activities in self-report instruments (SRI).

**PURPOSE:** To examine differences in activity METs estimated using measured RMR (measMET) compared to 3.5 ml·kg<sup>-1</sup>·min<sup>-1</sup> (calcMET) and corrected METs (corrMET= mean calcMET \*(3.5/Harris-Benedict RMR)) in sub-groups by age group, BMI category, gender and fitness.

**METHODS:** 252 subjects were classified as: normal weight (NW = BMI < 25 kg·m<sup>-2</sup> n=159) or overweight (OW= BMI ≥ 25 kg·m<sup>-2</sup> n=93), male (n=118) or female (n=134), age group (by decade 20,30,40, or 50 y n=70, 69, 53 and 59, respectively) and fitness quintiles (low to high fit; n= 30, 31, 73, 88 and 39, respectively). RMR was measured after a 15 minute rest following a 4-hr restriction of food, caffeine and exercise. Subjects completed 6 treadmill activities at 3 speeds (1.34, 1.56, 2.23 m·sec<sup>-1</sup>) at 0% and 3% grade and 5 self-paced activities of daily living (ADL). Each activity was performed for 7 minutes while wearing a portable metabolic unit to measure VO<sub>2</sub>. Average MET differences (calcMET-measMET and corrMET-measMET) were computed by sub-group.

**RESULTS:** The (mean ±SD) measMET was 6.1 ±2.64 (n=2555). CalcMET (Mean (95% CI)) was (0.51(0.59,0.42) METs) less than measMET. CorrMET was not statistically different from measMET (0.02 (-0.11,0.06) METs). calcMET underestimated measMET for most individuals who were low fit (-1.04(-1.38,-0.71) METs), OW (-0.65(-0.81,-0.49) METs), older (50-60yrs,-0.67(-0.87,0.47)METs) and female (-0.55(-0.68,-0.41) METs). Differences between corrMET and measMET were less than calcMET and measMET for all subgroups.

**CONCLUSION:** SRI's that transform activity into MET metrics (e.g. MET hrs·day<sup>-1</sup>) using the Compendium of Physical Activities which assumes the 3.5 ml·kg<sup>-1</sup>·min<sup>-1</sup> baseline, will lead to less precise estimates of self-reported physical activity particularly in individuals who are overweight, older, low fit and women. The Harris-Benedict based correction factor improves MET estimates and reduces the systematic error observed within sub-groups.

**Relationship Between Self-perceived And Measured Health-related Physical Fitness Among College Students**

Courtney M. Monroe, David Q. Thomas, FACSM, Kristen M. Lagally, FACSM, Anne Cox. *Illinois State University, Normal, IL.*

Email: cmmonro@ilstu.edu

(No relationships reported)

Possessing a limited perception of personal, health-related fitness could potentially exacerbate existing health problems or lead to harmful health consequences in the future. College students' perceptions of their own fitness level in comparison to their actual fitness level has not been examined in detail, specifically from a multi-component perspective.

**PURPOSE:** To examine the relationship between college students' self-perceived physical fitness level and measured level of physical fitness (specifically cardiorespiratory endurance, body composition, flexibility, and muscular endurance).

**METHODS:** Twenty students (10 male and 10 female, mean age 20.4 years, SD + 1.27) participated in the study. Institutional Review Board approval was obtained. Each subject completed an informed consent, a medical health history, a Physical Activity Readiness Questionnaire, and five scales from a modified version of the Physical Self-Description Questionnaire (PSDQ). Then, each subject underwent four fitness tests: air displacement plethysmography (body composition), submaximal treadmill test (cardiorespiratory endurance), standardized curl-up test (muscular endurance), and standardized sit-and-reach test (flexibility).

**RESULTS:** Descriptive statistics (means and standard deviations) were calculated for all data, and Pearson Product-Moment Correlations were used to ascertain the relationship between scores from the health-related physical fitness tests and both the scores from the corresponding self-perceived fitness scales and scores from a global physical self-concept scale. A significant relationship was found between self-perceived body composition as determined with the PSDQ and measured body fat ( $r = -0.62$ ,  $p < 0.05$ ), as well as self-perceived cardiorespiratory endurance as determined with the PSDQ and measured cardiorespiratory endurance ( $r = 0.47$ ,  $p < 0.05$ ). No other significant relationships were found.

**CONCLUSIONS:** While the subjects' perception of their own body composition and cardiorespiratory endurance was significantly related to actual measures of these variables, perception of actual muscular fitness and actual flexibility was lacking. Further research is necessary to ascertain why these relationships occurred.

(No relationships reported)

**PURPOSE:** The purpose of this study was to develop a new non-exercise  $\dot{V}O_{2max}$  prediction model using an objectively measured physical activity (PA) variable in Japanese women.

**METHODS:** The present study included 189 Japanese women aged from 20 to 69 years old. Eighty-seven subjects in the Prediction group used to develop the prediction model were collected from two independent institutions, and 102 subjects in the Validation group used to determine the accuracy of the new prediction model were collected from another institution. All participants were measured for  $\dot{V}O_{2max}$  by using a maximal incremental test on a bicycle ergometer, age (yrs), a PA variable determined by pedometer-determined daily step counts (SC, steps-day<sup>-1</sup>), and BMI (kg·m<sup>-2</sup>) defined as body mass divided by height squared.

**RESULTS:** PA variable SC was significantly related to  $\dot{V}O_{2max}$  (partial correlation coefficient  $r = 0.40$ ,  $P < 0.001$ ) after adjusting for BMI and age. A new non-exercise model was developed by multiple regression to estimate  $\dot{V}O_{2max}$  from age, BMI, and SC ( $R = 0.71$ ,  $SEE = 5.33 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ,  $P < 0.001$ ). When the  $\dot{V}O_{2max}$  prediction equation was applied to the Validation group, predicted  $\dot{V}O_{2max}$  correlated well with measured  $\dot{V}O_{2max}$  ( $r = 0.81$ ,  $P < 0.001$ ), and SEE<sub>1</sub> and TE were 3.25 and 3.43 mL·kg<sup>-1</sup>·min<sup>-1</sup> respectively.

**CONCLUSIONS:** This study demonstrated that SC was useful in predicting  $\dot{V}O_{2max}$  variance and helped the present non-exercise  $\dot{V}O_{2max}$  prediction model generate relatively accurate estimations of  $\dot{V}O_{2max}$  in Japanese women.

(No relationships reported)

**PURPOSE:** Conventional treadmill provides manually adjustable but fixed speed during exercise. A newly developed treadmill which senses human position on the treadmill and subsequently adjusts its speed to the runners is evaluated in terms of energy requirements of the exercise.

**METHODS:** Eight healthy young adults ( $n=9$  23±4 yrs, 65±11 kg, 169±6 cm) were recruited and participated in two exercise tests; 1) running on a position sensitive treadmill while varying speed (FTT) and 2) running on a conventional treadmill at a fixed speed (CTT). At FTT, subjects were asked to run at approximately 55-65% of pre-determined individual maximal work capacity for 20 min. And speeding-up and slowing-down of the running was determined by subjects. Once FTT was completed, an average speed of the running was calculated. At CTT, subjects ran on a treadmill at the fixed speed calculated from FTT for 20 min matching exercise distance. No testing order effects were noticed. During the tests, oxygen uptake ( $\dot{V}O_2$ ), respiratory exchange ratio (RER), and heart rate (HR) were measured, and EE was calculated.

**RESULTS:** The average treadmill speed was 7.69±1.16 kph for both FTT and CTT. The average  $\dot{V}O_2$  in FTT (29.9±4.4) was higher than that in CTT (27.1±5.9 mL·kg<sup>-1</sup>·min<sup>-1</sup>) ( $P < 0.05$ ). The calculated total EE during the exercise was higher in FTT (191.1±52.5) compared to CTT (175.0±58.7 kcal) ( $P < 0.05$ ). The average HR during exercise was not different between FTT (136.4±14.8) and CTT (134.7±16.3 bpm). No differences were found in RER between conditions.

**CONCLUSIONS:** Running on treadmill at moderate intensity with varying speed required higher energy expenditure than running at a fixed speed when the running duration and distance were matched. It appears that varying running speed on a position sensitive treadmill can be a potential exercise modality to increase energy expenditure.

(No relationships reported)

**PURPOSE:** Energy expenditure (EE) during walking and/or running on a fast response treadmill (FT), which is highly responsive to the position of the runner and can adjust its speed for the runner, has been compared to EE of conventional treadmill (CT). In the study, the speed of FT could vary simultaneously according to runner's position while the speed of CT was fixed at one speed.

**METHODS:** Thirteen healthy collegiate men ( $n=7$ ; 27±7 yrs, 74±10 kg, 173±4 cm) and women ( $n=6$ ; 23±4 yrs, 52±2 kg, 162±4 cm) underwent two tests; FT-test and CT-test. At FT-test, subjects walked and/or ran at varying FT speed with their choices at about 40-50% of pre-determined individual maximal aerobic capacity for 30 min. After FT-test, an average speed of FT-test was calculated, and the speed was applied to CT-test matching exercise duration and distance to FT-test. No testing order effects were found. During the tests, oxygen uptake ( $\dot{V}O_2$ ), respiratory exchange ratio (RER), and heart rate (HR) were measured, and EE was calculated. Before and after the exercise, blood samples were drawn for analyses of glucose, lactate, and triglycerides.

**RESULTS:** The average treadmill speed was 6.53±0.47 kph (6.72±0.37 for men, 6.30±0.51 for women) in both tests. The average  $\dot{V}O_2$  was 23.0±2.6 (23.9±2.7 for men, 21.8±2.0 for women) and 21.7±2.9 mL·kg<sup>-1</sup>·min<sup>-1</sup> (22.8±2.9 for men, 20.4±2.5 for women) for FT and CT, respectively ( $P < 0.05$ ). The total EE during the test for FT (212.8±50.2 kcal; 253.9±24.5 for men, 164.8±14.6 for women) was higher than for CT (201.2±51.8 kcal; 242.3±27.4 for men, 153.3±20.5 for women) ( $P < 0.05$ ). HR was also higher for FT (119.6±9.2) than CT (115.1±9.1 bpm) ( $P < 0.05$ ). RER during exercise was similar at both treadmills (0.84±0.04 for FT, 0.83±0.05 for CT). No differences were found in blood

variables between FT and CT.

**CONCLUSIONS:** At an identical exercise duration and distance, varying treadmill speed during exercise induced higher energy expenditure than fixed treadmill speed. It appears speed variations during treadmill exercise may require more energy metabolism than constant speed although the mechanism is unclear.

#### **Quantitative Motor Unit Analysis And Motor Unit Number Estimates In Healthy Subjects And Patients With Lateral Epicondylitis**

Kristina M. Calder<sup>1</sup>, Daniel W. Stashuk<sup>2</sup>, Linda McLean<sup>1</sup>. <sup>1</sup>*Queen's University, Kingston, ON, Canada.* <sup>2</sup>*University of Waterloo, Waterloo, ON, Canada.* (Sponsor: David Gabriel, FACSM)

Email: calderkristina@hotmail.com

(No relationships reported)

Lateral epicondylitis (LE) is a condition that is caused by repetitive wrist extension activities and involves inflammation of the extensor tendon attachments at the lateral epicondyle. Symptoms associated with LE have been demonstrated to diminish with manual cervical manipulation, and electromyographic (EMG) signal abnormalities have been identified in individuals with LE suggestive of a cervical radiculopathy component.

**PURPOSE:** This study was designed to determine: (i) if the quantitative EMG parameters related to motor unit potential (MUP) morphology, motor unit (MU) firing patterns or motor unit number estimates (MUNEs) detected from the affected extensor carpi radialis brevis (ECRB) muscle of patients with LE are different from those detected in healthy control subjects and whether these measures are suggestive of nerve pathology in patients.

**METHODS:** Ten patients (47.9 ± 10.2 years) with clinically determined LE and eight healthy subjects (30.9 ± 7.9 years) participated in the study. Maximum M-waves, and needle- and surface- detected EMG data were recorded from the ECRB muscle during 30-second contractions performed at 10% of maximum voluntary contraction force. DQEMG<sup>TM</sup> was used to extract needle-detected and surface- detected (S) MUP morphology and MU firing rates. Maximum M-wave amplitudes were divided by the amplitude of the mean SMUP in each subject to obtain MUNEs. Kruskal-Wallis tests were used to determine between-group differences.

**RESULTS:** Patients with LE had significantly larger MUP area-to-amplitude ratio (1.70 ± 0.58 vs. 1.23 ± 0.41), MUP duration (10.08 ± 3.10 ms vs. 6.90 ± 2.36 ms), SMUP amplitude (118.87 ± 111.10 µV vs. 60.15 ± 27.00 µV), and SMUP area (536.8 ± 528.1 µVms vs. 297.4 ± 189.5 µVms) compared to healthy control subjects (p<0.05). MU firing rates were significantly higher in the healthy control subjects (14.29 ± 2.47 Hz) than patients with LE (13.72 ± 2.69 Hz; p<0.05). The MUNEs were not significantly different between the groups (p>0.05).

**CONCLUSIONS:** The MUP morphology differences between patients with LE and healthy control subjects are suggestive of neurogenic changes in the MUs of the ECRB muscle in the patients with LE; however the MUNEs did not suggest that there was any axonal loss.

#### **The Role Of Neural Tension In Hamstring Flexibility**

Christopher J. Johnson, Ryan H. Morrison, Malachy P. McHugh, FACSM. *Nicholas Institute of Sports Medicine and Athletic Trauma, New York, NY.*

Email: mchugh@nismat.org

(No relationships reported)

**PURPOSE:** The Slump Test is used to assess adverse neural tension in patients with low back and hamstring injuries, and involves tensioning the neural tissues by flexing the cervical and thoracic spine during hamstring stretch. It is not known if this neural tension increases resistance to stretch. Therefore, the purpose of this study was to determine if neural tension, via the Slump Test, during passive hamstring stretch, affects maximum range of motion (ROM), stretch discomfort, resistance to stretch, or the electromyographic (EMG) response to stretch in healthy subjects.

**METHODS:** Resistance to stretch, EMG response, ROM and stretch discomfort were measured bilaterally during passive hamstring stretches with and without neural tension (n=8, age 39±13 yr, weight 154±24 lb). Stretches were performed on an isokinetic dynamometer (5°/s) with subjects seated, the test thigh flexed 45° above the horizontal, and the seat back at 90° to the horizontal. Knees were passively extended from 90° flexion to maximum stretch tolerance. Starting leg (right or left) and test sequence (stretch with or without neural tension) were alternated between subjects (each stretch separated by 4 min). Stretch-induced EMG signals were normalized to maximum contractions performed prior to stretches. For neural tension stretches the cervical and upper thoracic spine were manually flexed by a physical therapist (Slump Test).

**RESULTS:** Maximum ROM was 8±5° less for the stretches with neural tension versus stretches without neural tension (P<0.01). Stretch discomfort and EMG response were not different between stretches with and without neural tension (discomfort: 7±1 vs. 6±2, P=0.29; EMG: 3±5% vs. 5±5%, P=0.1). Resistance to stretch was progressively greater with increasing ROM for stretches with neural tension versus without neural tension (P<0.001). During the neural tension stretches resistance to stretch at maximum ROM was 12% greater than resistance at the same angle during stretches without neural tension (P<0.05).

**CONCLUSIONS:** Maximum ROM was decreased and passive resistance to stretch was increased by increasing neural tension during passive hamstring stretch. This effect was not due to an increased EMG response to stretch. These data indicate that passive extensibility of neural tissues can limit hamstring flexibility.

#### **Neuromuscular Fatigue Following Repetitive Endurance Cycling.**

Emma Z. Ross<sup>1</sup>, Warren Gregson<sup>2</sup>, Karen Williams<sup>2</sup>, Keith George<sup>2</sup>. <sup>1</sup>*Brunel University, Middlesex, United Kingdom.* <sup>2</sup>*Liverpool John Moores University, Liverpool, United Kingdom.* (Sponsor: Dr Richard Godfrey, FACSM)

Email: emma.ross@brunel.ac.uk

(No relationships reported)

It is well known that both central and peripheral factors contribute to muscle fatigue following a single bout of prolonged exercise lasting several hours. However, little is known about the cumulative fatiguing effects of repeated bouts of prolonged exercise.

**PURPOSE:** To determine the effects of 20 days of repetitive endurance cycling within a 22 day period, on peripheral and central contributions to fatigue.

**METHODS:** Eight well-trained male cyclists completed 20 prolonged cycling stages interspersed by two rest days (day 9 and 16), which replicated the 2007 Tour de France route and schedule (mean daily distance and cycling time, 165 ±66 km, 522 ±111 min, respectively). Isometric knee extensor torque and electromyographic responses of the Vastus Lateralis in response to percutaneous electrical stimulation and transcranial magnetic stimulation (TMS) were measured before, on day 9, day 16 and 2 d following completion of the Tour. Post exercise measurements on day 9 and 16 were taken >18 h after cessation of the previous exercise bout.

**RESULTS:** Maximal voluntary contraction of the knee extensors decreased by  $20 \pm 10\%$  ( $P < 0.01$ ) during the Tour, but recovered after 2 d of rest. Peripherally evoked M-wave and potentiated twitch responses were also significantly decreased on day 9 and 16, up to  $31 \pm 21\%$  and  $22 \pm 18\%$ , respectively ( $P < 0.05$ ), but returned to baseline values following 2 d recovery. Voluntary activation was reduced to  $75 \pm 8\%$  ( $P < 0.05$ ) during the Tour, and remained significantly depressed ( $79 \pm 7\%$ ,  $P < 0.05$ ) following completion of the Tour. Amplitude of motor evoked potentials, elicited by TMS were also decreased by  $44 \pm 28\%$  ( $P < 0.01$ ) on day 9 and remained significantly depressed during the remainder of, and following, the Tour.

**CONCLUSIONS:** A reduction in knee extensor strength which occurs following repetitive prolonged cycling exercise is a result of both central and peripheral processes. A reduced sarcolemmal excitability and impairment of contractile mechanisms exists following repetitive prolonged exercise bouts, even after a substantial recovery period. These peripheral changes are accompanied by an enduring reduction in corticomotor output, which persists even following 2 d rest.

**Adaptations Of The Neuromuscular Junction To Exercise Training In Young And Aged Rats**

Michael R. Deschenes, FACSM, Mackenzie A. Roby, Emily K. Glass. *College of William & Mary, Williamsburg, VA.*

Email: mrdesc@wm.edu

(No relationships reported)

Although the effects of aging on training-induced remodeling of skeletal muscle have been well studied, little is known regarding the capacity of aging to influence exercise-induced adaptations of the neuromuscular junction (NMJ).

**PURPOSE:** This study aimed to determine whether aged and young adult NMJs responded differently to the same program of endurance training.

**METHODS:** Twenty young adult (8 mo old) and 20 aged (24 mo old) male Fischer 344 rats were randomly assigned to either exercise trained or control groups (4 groups, N=10/group). Trained rats from each age group participated in an identical 10 week program of treadmill running (5days/wk) while age matched controls remained sedentary in their cages. Following the 10 week intervention, all rats were euthanized and soleus muscles were removed and quickly frozen at resting length. Muscles were sectioned and stained with cytofluorescent techniques to visualize pre-synaptic nerve terminal branches, and post-synaptic acetylcholine receptors. Pre- and post-synaptic images were collected with confocal microscopy and used to quantify various parameters of NMJ morphology. Myofiber profiles (fiber size and composition) were determined with standard histochemistry and light microscopy. Data were analyzed with a 2 way ANOVA with main effects of age and treatment.

**RESULTS:** Young adult, but not aged rats demonstrated significant ( $P < 0.05$ ) training-induced increases in pre-synaptic nerve terminal branch number, total branch length, and branching complexity. Similarly, when examining post-synaptic morphology, only young rats displayed significant training-induced increments in perimeter length around endplate regions, and expanded areas occupied by acetylcholine receptors. And although myofibers of aged control rats were smaller than their younger counterparts, training elicited a significant increase in fiber size only among aged rats restoring their size to that observed among younger ones.

**CONCLUSIONS:** Our data show that aging blunts the adaptability of the NMJ to endurance exercise training. This is meaningful because failure of neuromuscular transmission is an important contributor to muscle fatigue, thus limiting exercise performance and associated health benefits.

Supported by the NIH grant R15 AG17440.

**Dose-response Relationship For Neuromuscular Electrical Stimulation To The Quadriceps After Total Knee Arthroplasty**

Jennifer E. Stevens-Lapsley, Jaclyn E. Balter, Donald G. Eckhoff, Wendy M. Kohrt, FACSM. *University of Colorado Denver, Aurora, CO.*

(No relationships reported)

**INTRODUCTION:** Neuromuscular electrical stimulation (NMES) has been shown to be effective in aiding the recovery of quadriceps femoris muscle strength after total knee arthroplasty (TKA). Yet, the training intensity (dosage) has not been well described. The purpose of this investigation was to establish a dose-response relationship for NMES in patients after TKA and examine immediate changes in quadriceps muscle fatigue and activation.

**SUBJECTS:** Fifteen patients with end-stage osteoarthritis were studied (67.7±19.4 years; 9 women, 6 men). Patients were simultaneously enrolled in a clinical trial for NMES for which exclusion criteria included the following: uncontrolled hypertension, uncontrolled diabetes, BMI >35, other significant lower extremity orthopaedic problems, or neurological impairments.

**METHODS:** Quadriceps isometric strength and activation were assessed preoperatively and again at 3wks and 6wks after TKA using an isokinetic dynamometer. Muscle activation was quantified using a doublet interpolation technique. NMES training intensities at 3 and 6wks were monitored by logging the electrically elicited knee extension torque and expressing this torque as a percentage of the involved quadriceps muscles' maximal voluntary contraction torque. All patients participated in a standardized rehabilitation program for 9wks after TKA plus NMES treatment using an Empi 300PV 2x/day for 15 minutes/session for 6wks beginning 2 days after TKA.

**RESULTS:** Higher NMES doses more effectively attenuated the quadriceps strength loss at 3wks ( $R^2=0.45$ ;  $p < 0.05$ ) compared to lower doses, but this relationship was weaker at 6wks. Furthermore, quadriceps strength loss at 3wks was significantly attenuated in the NMES group (24.2±23.2% loss) compared to previously reported 60% losses using similar methods in the absence of NMES. After a single session of NMES (at 3wks), average quadriceps muscle fatigue was 8.2±12.7% and activation dropped less than 1% ( $p > 0.05$ ).

**CONCLUSION:** Higher NMES doses were associated with less quadriceps strength loss than lower doses. Early NMES after TKA may help attenuate quadriceps strength loss to enhance functional performance after TKA when used at sufficiently high intensities.

**In Vivo Force Transmission In The Lower Leg During Voluntary And Stimulated Muscle Contraction**

Jens Bojsen-Moller<sup>1</sup>, Sidse Schwartz<sup>2</sup>, Taija Finni<sup>3</sup>, Kari Kalliokoski<sup>4</sup>, S Peter Magnusson<sup>2</sup>. <sup>1</sup>Bispebjerg Hospital, University of Copenhagen, Copenhagen, Denmark, <sup>2</sup>Norwegian School of Sport Sciences, Oslo, Norway. <sup>3</sup>Bispebjerg Hospital, University of Copenhagen, Faculty of Health Sciences, Copenhagen, Denmark. <sup>4</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>5</sup>Turku PET Centre, University of Turku, Turku, Finland.

(No relationships reported)

Force transmission from muscle to bone may occur in a more complex manner than previously appreciated. For example, it has been shown in animals that force transmission between synergists and antagonists muscles may take place, and further, that lateral force transmission may occur within the load bearing tissues such as tendons and aponeuroses. The mechanisms that underlie tendon injury are elusive, however, heterogenous muscle activation and non-uniform force transmission between muscles and/or within tendons may potentially play a role.

**PURPOSE:** To determine if lateral force transmission occurs within and between superficial and deep plantarflexor muscles in humans in vivo.

**METHODS:** Seven subjects performed 4 types of either active contractile tasks or passive joint manipulations with the limb positioned in two different joint configurations (extended and flexed knee): 1) voluntary plantarflexion, 2) voluntary hallux flexion, 3) passive hallux extension and 4) selective percutaneous stimulation of one superficial plantarflexor muscle (medial gastrocnemius (MG)). Muscle displacement during manipulations were determined by ultrasonography obtained at a proximal and distal site for 3 muscles (MG (proximal site), soleus (SOL) (proximal and distal site), flexor hallucis longus (FHL) (distal site)). Neural activation of muscles was assessed by EMG.

**RESULTS:** During passive hallux extension the FHL tendon underwent  $5 \pm 1$  mm (mean±sem) displacement in distal direction without any movement in the adjacent SOL muscle. The

FHL tendon moved  $4 \pm 1$  mm in proximal direction during selective FHL contraction without any movement in SOL. During full plantar flexion SOL and MG displacement was similar in the proximal direction ( $\sim 7 \pm 1$  mm) while FHL only displaced  $2 \pm 1$  mm. Percutaneous stimulation of MG generated  $3 \pm 1$  mm of displacement of GM and  $2 \pm 1$  mm in SOL in the proximal direction while FHL remained fixed.

**CONCLUSIONS:** The present data suggest that lateral force transmission occurs between the superficial plantar flexor muscles (GM and SOL), and that the deep flexor muscle FHL, which is also a strong plantar flexor muscle, seems to be an independent actuator.

**Linear And Control Entropy Analysis Of Electromyography And Mechanomyography Signals During The Wingate Anaerobic Test**

William J. Armstrong<sup>1</sup>, Erik M. Bollt<sup>2</sup>, Megan E. Gebrad<sup>3</sup>, Nicole A. Stegenga<sup>3</sup>, Stephen J. McGregor<sup>4</sup>. <sup>1</sup>Western Oregon University, Monmouth, OR. <sup>2</sup>Clarkson University, Potsdam, NY. <sup>3</sup>Hope College, Holland, MI. <sup>4</sup>Eastern Michigan University, Ypsilanti, MI.  
Email: armstroj@wou.edu

*(No relationships reported)*

**PURPOSE:** Tools from non-linear dynamical systems analysis may provide unique insight into the nature of fatigue during maximal exercise. Control entropy (CE) is a novel method to quantify the complexity of non-linear dynamic physiological signals and is indicative of control systems constraints. Therefore, the effects of fatigue on surface electromyography (SEMG) and mechanomyography (MMG) were studied during the Wingate anaerobic test (WAnT) using CE analysis.

**METHODS:** Twelve trained (6 M / 6 F) intercollegiate athletes volunteered to participate in procedures approved by the Hope College HSRB. MMG and SEMG of the rectus femoris (RF) and vastus medialis (VM) muscles of the dominant leg were recorded using accelerometers (ACC, ADXL330, Analog Devices, Inc., Norwood, MA) and surface electrodes. Measurements collected at a rate of 1000 Hz were amplified and recorded using Biopac (GA) EM100C, MP150 and AcqKnowledge v3.8.2 software, respectively. Participants performed a 30-second WAnT on a Lode Excalibur cycle ergometer at 0.075 kp/kg of body weight. Linear comparisons of changes in the mean amplitude, peak-peak amplitude, and mean power density for both the MMG and EMG signals were made using repeated measures ANOVA ( $\alpha \leq 0.05$ ). CE of raw MMG and SEMG signals were calculated and tested for significance using Matlab (The Mathworks, MA).

**RESULTS:** Significant differences were observed between genders ( $p < 0.05$ ); and there were significant effects of time (VM; RF) for mean MMG ( $p < 0.001$ ), mean VM SEMG ( $p < 0.05$ ), p-p MMG ( $p < 0.001$ ), and p-p SEMG ( $p < 0.05$ ). Fatigue Index (FI) calculations for MMG-FI and WAnT-FI ( $0.826 \pm 0.010$  and  $0.491 \pm 0.192$ , respectively) revealed a moderately high correlation ( $r = 0.725$ ,  $p = 0.012$ ). CE increased significantly in both MMG and EMG at the start of the WAnT. CE of MMG remained elevated for duration, while EMG declined as fatigue ensued.

**CONCLUSIONS:** SEMG and MMG signals reflect the changes in power output seen in the WAnT. These may provide supplemental information in assessing anaerobic power. In particular, changes in CE indicate that constraints are reduced in both neurological and muscular system components during the WAnT and may provide unique insight into the nature of fatigue from supramaximal exercise.

**Voluntary Activation Of The Knee Extensors Can Be Assessed Reliably Using Transcranial Magnetic Stimulation**

Stuart Goodall, Lee M. Romer, Emma Z. Ross. Brunel University, Middlesex, United Kingdom. (Sponsor: Professor Alison McConnell, FACSM)  
Email: sgoodall\_01@hotmail.com

*(No relationships reported)*

Voluntary activation (VA) is often quantified by comparing the extra force elicited by motor nerve stimulation during a maximal voluntary contraction (MVC) with that produced at rest by the same stimulus. Transcranial magnetic stimulation (TMS) has recently been used to assess VA, where the presence of a superimposed twitch (SIT) during a MVC suggests that incomplete activation is present due to sub-optimal drive from the motor cortex. With TMS, however, it is inappropriate to compare extra force evoked during a contraction to that evoked at rest because corticospinal excitability increases during muscle activity. A method has been devised for the upper limb muscles (Todd et al., 2004) whereby the resting motor cortical output can be estimated by extrapolation of the linear relationship between SIT amplitude and voluntary force. It is unknown whether this method can be used to assess VA of the lower limb.

**PURPOSE:** To investigate whether the TMS extrapolation method can reliably predict VA and detect fatigue of the knee extensors.

**METHODS:** On two occasions, force and EMG responses to TMS were measured from 12 healthy male subjects during isometric knee extension. The size of the resting twitch evoked by TMS was estimated using linear extrapolation, and the level of voluntary drive was quantified using the equation:  $VA (\%) = (1 - SIT/ERT) \times 100$ . To assess fatigue, VA was measured before, immediately after and 30 min after a 2 min isometric MVC. Repeated measures ANOVA was used to assess differences within and between days, whilst reliability was assessed using the intraclass correlation coefficient ( $ICC_{2,1}$ ) and coefficient of variation (CV). Paired samples t-tests were used to determine differences pre- and post-fatigue.

**RESULTS:** SIT amplitude decreased linearly with increasing voluntary force between 50 and 100% MVC. VA measurements were reliable within-day ( $CV = 3.4\%$ ;  $ICC_{2,1} = 0.92$ ,  $p < 0.001$ ) and between-day ( $CV = 5.4\%$ ;  $ICC_{2,1} = 0.94$ ,  $p < 0.001$ ). Immediately after the sustained MVC, VA was reduced by  $16 \pm 9\%$  (mean  $\pm$  SD,  $p < 0.001$ ).

**CONCLUSION:** TMS can be used to reliably measure VA and assess supraspinal fatigue of the knee extensors.

**Acute Effects Of Passive Stretching On The Electromechanical Delay**

Katherine M. Hoge, Eric D. Ryan, Trent J. Herda, Pablo B. Costa, Ashley A. Walter, Travis W. Beck, Jeffrey S. Stout, FACSM, Joel T. Cramer, FACSM. University of Oklahoma, Norman, OK.  
Email: katiehoge@ou.edu

*(No relationships reported)*

**INTRODUCTION:** The electromechanical delay (EMD) is the latency between muscle stimulation and its resultant force production. The EMD may be influenced by the excitation-contraction coupling process and the muscle's series elastic component (SEC). If a bout of stretching affects the SEC, then it may affect the EMD.

**PURPOSE:** To examine the acute effects of passive stretching on the EMD.

**METHODS:** Sixteen men (mean  $\pm$  SD age =  $21.1 \pm 1.7$  yrs; body mass =  $75.9 \pm 11.4$  kg; height =  $176.5 \pm 8.6$  cm) volunteered for this study. Each subject's foot was stabilized in a custom-built apparatus designed to measure plantar flexion force with a knee joint angle of  $180^\circ$  and ankle joint angle of  $90^\circ$ . The apparatus was also attached to a Biodex System 3 dynamometer (Biodex Medical Systems, Inc., Shirley, NY) that stretched the plantar flexor muscles by passively dorsiflexing the foot at  $5^\circ \cdot s^{-1}$  until a constant-torque threshold was achieved and held at a point of discomfort. Nine repetitions of each stretch were held for 135 s with 10 s rest between repetitions. Before and after the stretching, a supramaximal stimulus was applied to the tibial nerve in the popliteal fossa. Twitch force was recorded from a load cell, while EMG signals were recorded from bipolar, preamplified electrodes placed over the soleus and gastrocnemius muscles. The sampling rate was 2 KHz. EMD was calculated as the time (ms) from the onset of the M-wave to the onset of the twitch response as determined by two separate investigators. A paired samples t-test was used to compare the EMD values at pre- and post-stretching.

**RESULTS:** There was an 11.2% increase ( $p = 0.031$ ) in EMD from pre- (mean  $\pm$  SD =  $5.09 \pm 0.49$  ms) to post-stretching ( $5.66 \pm 0.77$  ms).

**CONCLUSION:** These findings suggested that 20 min of constant-torque passive stretching increased the EMD of the plantar flexors, which may have reflected stretching-induced changes in the SEC. It is possible that the muscle required more time to overcome the increase in compliance and musculotendinous laxity in order to transfer force to the bone as a result of the stretching. In addition, the lower average EMD values in this study compared to previous studies may have been due to the knee joint angle that placed more resting tension on the plantar flexor muscles. **ACKNOWLEDGEMENTS:** This study was funded in part by the NSCA Foundation, Colorado Springs, CO.

**Voluntary Activation At Short And Long Muscle Lengths In The Human Elbow Extensors**

Arthur J. Cheng, Charles L. Rice. *The University of Western Ontario, London, ON, Canada.* (Sponsor: Anthony A. Vandervoort, FACSM)

Email: acheng24@uwo.ca

(No relationships reported)

**PURPOSE:** To evaluate whether muscle length (shortened, or slack versus lengthened muscle) affected voluntary activation when calculated using the twitch interpolation method and compared to two extrapolation methods.

**METHODS:** Twelve healthy men [mean age 26.9(4.3)yrs] performed elbow extensor voluntary contractions at short (20° of elbow flexion) and long muscle lengths (120°). In each condition, doublets were evoked during 5s voluntary contractions at 5%, 10%, 20%, 40%, 60%, 80%, 100% of maximum voluntary contraction torque (MVC), and at rest post-MVC. Voluntary activation at each length was calculated using the formula:  $1 - (\text{interpolated doublet} / \text{post-MVC doublet}) \times 100\%$ . Because the post-MVC doublet amplitude is reduced in the shortened position, voluntary activation also was estimated using linear and non-linear extrapolations of voluntary and interpolated torques at values greater than 20% of MVC.

**RESULTS:** MVC torques were similar at 20° (57 Nm), and 120° (52 Nm). Interpolated doublet amplitude (0.8 Nm) was unaffected by joint angle, but the post-MVC doublet torque (normalized to MVC torque) was 32% lower at 20° than at 120°. Non-linear extrapolations created a 24% increase in post-MVC doublet amplitudes versus a 6% increase estimated from linear extrapolations. Using the predicted post-MVC doublet at the short length improved voluntary activation by 18-33% for submaximal contraction intensities (< 60% of MVC). However, maximal voluntary activations (during MVCs) when calculated, or predicted by both linear and non-linear extrapolations were not affected by muscle length changes (94-96%).

**CONCLUSION:** Voluntary activation of the elbow extensors was length-dependent with lower voluntary activation at submaximal intensities at short lengths. Compared to the calculated twitch interpolation method, in this muscle group, non-linear extrapolation improved the ability to assess voluntary activation below 60% of MVC by accounting for the diminished post-MVC doublet amplitude in a shortened length.

**Velocity Dependent Motor Unit Discharge Rates Of The Anconeus During Elbow Extension**

Brad Harwood, Andrew W. Davidson, Charles L. Rice. *The University of Western Ontario, London, ON, Canada.* (Sponsor: A.A. Vandervoort, FACSM)

Email: bharwoo2@uwo.ca

(No relationships reported)

Most of our understanding about motor unit properties has been derived in animals and humans from isometric contractions, in which joint angle does not change. Due to the technical difficulty of recording single motor unit action potentials during movement, especially at higher velocities, limited information exists about motor unit firing rates (MUFRs) during lengthening and shortening contractions. The unique mechanical and muscle group features of the anconeus muscle may offer a model to provide reliable recordings of MUFRs during large and fast movements of the elbow joint.

**PURPOSE:** To determine the effect of velocity of elbow joint extension on MUFRs of the anconeus.

**METHODS:** Motor unit recordings (n=594) from five healthy young men (~25yrs) were collected from the anconeus during 120° range of motion of elbow extension at different velocities. Using a Biodex dynamometer, subjects first performed three brief maximal isometric contractions (MVC) at an angle of 60° of elbow flexion (0° = full extension) to determine the preload (30% MVC) for the dynamic contractions. Then, five maximal velocity elbow extensions (Max) were performed to determine the target peak velocities for the subsequent extensions. Subjects completed a number (20-40) of brief (<1s) elbow extensions at each target peak velocity (20, 40, 60, and 80% Max all at a constant load of 30% MVC) with two minutes rest between each set of extensions. Single motor unit action potentials were recorded on two independent channels, each from two pairs of indwelling wire electrodes inserted ~3cm distal to the olecranon process of the ulna in the belly of the anconeus.

**RESULTS:** MUFRs during MVC (~32Hz) were 25% lower compared with MUDRs at maximal preloaded velocity of ~500°/s (~42Hz). From 20% to 80% Max, MUFRs increased nonlinearly from ~13Hz to ~23Hz.

**CONCLUSIONS:** The anconeus may be a useful model to explore MUFRs during dynamic contractions. Preliminary results indicate that higher rates than isometric MVC are recorded during high velocity contractions, and changes in rates are related to changes in velocity.

**Neuromuscular And Perceptual Aspects Of Eccentric Muscle Damage And Recovery**

Steven J. Elmer, Kimberly E. Hall, Stephanie R. Peters, James C. Martin, FACSM. *University of Utah, Salt Lake City, UT.*

Email: steve.elmer@utah.edu

(No relationships reported)

Strength loss following damaging eccentric exercise ( $E_{dam}$ ) has been widely studied but changes in functional (power) and perceptual (perceived exertion and mood states) responses have received less attention.

**PURPOSE:** The purposes of this investigation were to: 1) quantify neuromuscular function during  $E_{dam}$ , 2) evaluate changes in maximal power ( $P_{max}$ ), muscle soreness (SOR), rating of perceived exertion (RPE), and mood states, and 3) test the hypothesis that the joints that absorb the greatest eccentric work would exhibit the greatest reductions in power during recovery.

**METHODS:** Twenty-two trained cyclists (age:  $31 \pm 7$ yrs) performed eccentric cycling ( $-70 \pm 4$ kJ) with their right leg (damage) and concentric cycling ( $69 \pm 3$ kJ) with their left leg (control). Single-leg  $P_{max}$  was assessed with inertial-load cycling and biomechanical joint powers at the ankle, knee, and hip were determined using inverse dynamic techniques. SOR associated with a squat movement was measured using a visual analog scale. RPE during a standardized submaximal cycling task was assessed with a Borg scale, and mood states were quantified using a profile of mood states questionnaire (POMS). Measures were evaluated at six time points (baseline, 0, 24, 48, 72, 96hr post  $E_{dam}$ ). Differences in dependent variables were assessed using repeated measures ANOVA procedures.

**RESULTS:** The knee absorbed more work (63%) during  $E_{dam}$  than the ankle, hip, and upper body (7%, 23%, and 6%, respectively). Compared to baseline,  $P_{max}$  decreased (0-72hr), SOR increased (0-96hr), and RPE increased (0-72hr) in the damaged leg. Total mood disturbance increased only at the 0 hr time point. No alterations were observed in relative joint powers during sprint cycling.

**CONCLUSION:** Multi-joint eccentric exercise produced greater alterations in neuromuscular and perceptual responses compared to equally matched concentric exercise. RPE provided more functional indications of recovery compared to SOR as participants were able to perform challenging submaximal exercise despite being sore for several days.

The lack of alterations in relative joint powers did not support our hypothesis, suggesting that individual variability in joint power production/absorption strategies may have been a factor.

**An Electromyographic Analysis Of Three Abdominal Core Muscles: Comparing The Crunch To The Plank**

Anthony Caterisano, FACSM, Jaimie M. Grossnickle, Brian T. Patrick, Raymond F. Moss, Lane Salter, Nicholas Basinger. *Furman University, Greenville, SC.*

Email: tony.caterisano@furman.edu

*(No relationships reported)*

Clinical observations suggest a growing interest among fitness trainers to incorporate Pilates exercises into workout routines, instead of abdominal crunches, as a way of developing core strength. One particular exercise, the plank, is often included in these workouts as a way to target core muscles such as the rectus abdominis and external oblique muscles.

**PURPOSE:** To monitor the muscle activation during the plank exercise compared to an abdominal crunch exercise, with both performed to exhaustion, in activating abdominal and external oblique muscles.

**METHODS:** Ten trained, college-age males (mean age = 20.8 yrs) volunteered to perform abdominal crunches and the plank exercise to exhaustion, in separate trials while the electrical activity of the upper rectus abdominis (URA), lower rectus abdominis (LRA) and external oblique (EO) were monitored via electromyography (EMG). The muscle electrical activity was measured using a Biopac™ bipolar electrode EMG system in which data were normalized as a percent of a maximum isometric abdominal curl against resistance. The order of trials was randomized and performed with 48 hours between trials. Data were analyzed using a 2 X 3 linear model ANOVA with a Scheffe post hoc test.

**RESULTS:** The results showed that the crunch (URA =  $10.66 \pm 4.46\%$ ; LRA =  $11.87 \pm 4.30\%$ ; EO =  $13.79 \pm 3.06\%$ ) elicited a significantly higher ( $P < 0.05$ ) level of muscle activity than the plank (URA =  $8.54 \pm 2.23\%$ ; LRA =  $8.75 \pm 3.19\%$ ; EO =  $10.29 \pm 2.25\%$ ) in all three muscle groups tested.

**CONCLUSIONS:** These results suggest that the crunch stimulates a larger percent of maximum electrical activity than the plank exercise in the three areas of the abdominal muscles tested, when completed to exhaustion. This further suggests that the crunch may be a more effective way to elicit greater muscle stimulation than the plank exercise for better potential core strength gains.

**The Effect Of Crunch Exercise Speed On Electromyographic Activity Of Three Abdominal Muscles**

Jaimie M. Grossnickle, Anthony Caterisano, FACSM, Brian T. Patrick, Raymond F. Moss, Nicholas Basinger, Lane Salter. *Furman University, Greenville, SC.*

*(No relationships reported)*

In studies using electromyography (EMG) to analyze the electrical activity of the abdominal muscles during core strengthening exercises, the data are typically collected for a fixed period of time or repetitions, early in the activity. A previous study found no significant difference in EMG activity between a 2 second and a 4 second crunch speed during this aforementioned initial phase. However, it is common practice to perform crunches to the point of fatigue, therefore making it relevant to consider the electrical activity at exhaustion.

**PURPOSE:** To look at the influence of speed of repetitions on the electrical activity of the abdominal muscles during crunches performed to fatigue.

**METHODS:** 10 trained, college-age male subjects (mean age = 20.8 yrs.) performed four second abdominal crunches (FS) and two second crunches (TS), in time to a metronome, to exhaustion in two separate trials. Electrical activity of the upper rectus abdominis (URA), lower rectus abdominis (LRA), and external oblique (EO) muscles were recorded using a Biopac™ bipolar electrode EMG system in which data were normalized as a percent of a maximum isometric abdominal curl against resistance. The order of trials was randomized and performed with 48 hours between trials. Data were analyzed using a 2 X 3 linear model ANOVA with a Scheffe post hoc test.

**RESULTS:** Crunches performed at a faster speed were found to have significantly more electrical activity than slower crunches at fatigue ( $p < 0.01$ ). The comparisons of the fast crunch to the slow crunch by muscle were as follows: URA,  $10.65 \pm 4.46\%$  vs.  $8.04 \pm 1.84\%$ ; LRA,  $11.86 \pm 4.27\%$  vs.  $8.64 \pm 2.26\%$ ; EO,  $13.79 \pm 3.05\%$  vs.  $8.86 \pm 3.07\%$ .

**CONCLUSION:** Contrary to the findings of the previous research which only looked at the initial repetitions, a faster 2 second crunch elicits greater EMG activity than a slower 4 second crunch when completed to fatigue.

**The Effects Of Parallel Versus Perpendicular Electrode Orientations On EMG Amplitude And Mean Power Frequency From The Biceps Brachii**

Jorge Zuniga M. Zuniga, Terry J. Housh, FACSM, Clayton L. Camic, Michelle Mielke, C. Russell Hendrix, Glen O. Johnson, FACSM, Richard J. Schmidt. *University of Nebraska-Lincoln, Lincoln, NE.*

*(No relationships reported)*

**PURPOSE:** The purpose of this study was to examine the influence of electrode orientation on the electromyographic (EMG) amplitude and mean power frequency (MPF) versus isometric torque relationships for the biceps brachii muscle.

**METHODS:** Ten adults [five men (mean  $\pm$  SD age =  $23.8 \pm 2.8$  years) and five women (mean  $\pm$  SD age =  $23.8 \pm 2.2$  years)] volunteered to participate in the investigation. Two separate bipolar surface EMG electrode arrangements (20 mm center to center) were placed on the dominant arm over the biceps brachii muscle. One EMG arrangement was placed parallel and the other perpendicular to the direction of the muscle fibers of the biceps brachii. The subjects performed two maximal, 6-second isometric muscle actions at a forearm flexion angle of  $60^\circ$  above the horizontal plane to determine maximal voluntary isometric contraction (MVIC). The subjects then performed a series of randomly ordered submaximal muscle actions in 10% increments from 10 to 90% MVIC. Paired t-test were used to examine mean differences between the two electrode orientations for absolute and normalized EMG amplitude and MPF values at each torque levels.

**RESULTS:** The mean absolute EMG amplitude values for the parallel electrode orientation were greater ( $p < 0.05$ ) than those for the perpendicular orientation at all isometric torque levels except 10% MVIC. For normalized EMG amplitude, there were no significant ( $p > 0.05$ ) mean differences between the parallel and perpendicular EMG electrode orientations for any of the %MVIC values. Furthermore, there were no significant mean differences between the parallel and perpendicular EMG electrode orientations for absolute or normalized EMG MPF for any of the %MVIC values.

**CONCLUSIONS:** These findings indicated that, unlike absolute EMG amplitude, normalized EMG amplitude values were not affected by electrode orientation. Thus, normalization can be used to reduce the effects of electrode orientation on EMG amplitude during isometric muscle actions of the biceps brachii. Furthermore, electrode orientation had no effect on absolute or normalized EMG MPF.

## The Effect Of Electrode Orientation On Electromyographic Amplitude And Mean Power Frequency Versus Isometric Torque Relationships

Clayton Camic, Michelle Mielke, C. Russell Hendrix, Jorge Zuniga, Terry J. Housh, FACSM, Glen O. Johnson, FACSM, Richard J. Schmidt.  
*University of Nebraska-Lincoln, Lincoln, NE.*  
Email: clcamic@unlserve.unl.edu  
(No relationships reported)

**PURPOSE:** To examine the influence of electrode orientation on the electromyographic (EMG) amplitude and mean power frequency (MPF) versus torque relationships for the vastus lateralis (VL) during isometric muscle actions of the leg extensors.

**METHODS:** Eleven subjects ( $x \pm SD$  age =  $23.9 \pm 3.0$  yrs) volunteered to perform isometric muscle actions of the dominant leg extensors on a Cybex II dynamometer. The subjects performed two maximal isometric muscle actions to determine MVC and then a series of randomly ordered submaximal muscle actions in 10% increments from 10% to 90% MVC. Two separate bipolar electrode arrangements were oriented over the VL muscle. The first electrode arrangement (parallel) was placed one-third of the distance between the lateral border of the patella and the anterior superior iliac spine and in line with the approximate pennation angle (20%) of the muscle fibers of the VL. The second electrode arrangement was oriented perpendicular to the parallel electrodes. Paired *t*-tests were used to examine mean differences between the two electrode orientations for absolute and normalized EMG amplitude and MPF values at each torque level.

**RESULTS:** The mean absolute EMG amplitude and MPF values for the parallel electrode orientation were greater ( $P < 0.05$ ) than those for the perpendicular orientation at all ten isometric torque levels (except 20% MVC for MPF). The mean normalized EMG amplitude and MPF values for the parallel electrode orientation were greater than those for the perpendicular electrode orientation at 50 and 60% MVC, and 100% MVC, respectively.

**CONCLUSIONS:** In general, there was no effect of electrode orientation on the mean normalized EMG amplitude and MPF values. These findings indicated that normalization can be used as an effective method for reducing the influence of electrode orientation on EMG amplitude and MPF during isometric muscle actions.

**2001 Board #142 May 28 9:00 AM - 10:30 AM**  
**Neuromuscular Activation Of Vastus Intermedius Muscle During Isometric Knee Extension At Various Force Intensities**  
Kohei Watanabe, Hiroshi Akima. *Nagoya university, Nagoya, Japan.* (Sponsor: Katsumi ASANO, FACSM)  
Email: kwatanabe@nagoya-u.jp  
(No relationships reported)

An investigation of the electromyography (EMG)-force relationship is one of the essential approaches to understand motor control in human skeletal muscle. For the quadriceps femoris (QF) muscle group, which plays an important role in human movement, EMG-force relationship is not fully understood, since it has been considered surface EMG can be recorded from only three superficial muscle components of QF muscle group. Recently, we reported the methodology recording the surface EMG from the remaining muscle component of the QF muscle group, the vastus intermedius (VI) muscle. Information about the activation of the VI muscle would be helpful to improve understanding of motor control of QF muscle group.

**PURPOSE:** The purpose of our study is to compare the EMG-force relationship of the VI muscle with that of the other components of the QF muscle group in order to characterize neuromuscular activation of the VI muscle.

**METHODS:** Thirteen healthy men performed maximal voluntary contraction (MVC) and submaximal contraction during isometric knee extension at 10% of the MVC to 90% of the MVC at intervals of 10% of the MVC level. Surface EMG was detected from four muscle components of the QF muscle group, i.e. VI, vastus lateralis (VL), vastus medialis and rectus femoris (RF) muscles. The electrode for the VI muscle was located at superficial region of this muscle defined by guidance of ultrasonography. Root mean squares (RMS) of EMG were calculated for each force level. RMS of submaximal contractions were normalized by the MVC. The difference between exerted force in the relative scale and normalized RMS were calculated at each force level and summed up for individual muscle components.

**RESULTS:** Normalized RMS in the VI muscle was significant lower than in the VL muscle at a lower force level (20% and 40% of MVC,  $p < 0.05$  each) and lower compared to the RF muscle at a higher force level (from 60% to 90% of MVC,  $p < 0.05$  each). Sum of difference in EMG-force relationship of VI muscle from the identity line was significantly larger than RF muscle ( $p < 0.05$ ).

**CONCLUSIONS:** These results suggest that neuromuscular activation in the VI muscle is relatively lower than that of the other components of QF muscle group during submaximal knee extension contractions. In addition, the EMG-force relationship of the VI muscle negatively deviates from the identity line.

(No relationships reported)

**PURPOSE:** To examine the test-retest reliability of the slopes (*b* terms) and y-intercepts (*a* terms) of the absolute linear and log-transformed exponential regression models that can be applied to the mechanomyographic amplitude (MMG<sub>RMS</sub>) versus torque (TQ) relationship.

**METHODS:** Fifteen participants (mean  $\pm SD$  age =  $23 \pm 4$  yrs) completed ten randomly-ordered isometric leg extensions from 5 to 95% of the maximal voluntary contraction (MVC) during three separate trials. MMG<sub>RMS</sub> was recorded from the vastus lateralis. Intraclass correlation coefficients (ICCs) and standard errors of measurement (SEMs) were calculated for test-retest reliability.

**RESULTS:** ICCs for the *b* and *a* terms were 0.89 and 0.90 for the log-transformed and 0.85 and 0.76 for the absolute relationships, respectively. The SEM (expressed as a percentage of the mean value) for the *b* and *a* terms were 9.7% and 16.4% for the log-transformed and 18.9% and 57.1% for the absolute relationships, respectively.

**CONCLUSIONS:** These findings suggested that the *b* and *a* terms from both the absolute linear and log-transformed exponential MMG<sub>RMS</sub> versus TQ relationships were relatively reliable (ICCs), however, the SEMs for the log-transformed relationships were lower than the linear models. Furthermore, the *b* term from the log-transformed relationships may provide meaningful information regarding the nonlinear characteristics (plateau points) of the MMG<sub>RMS</sub> versus TQ relationship, whereas the *a* term may indicate upward or downward shifts in MMG<sub>RMS</sub> across the TQ spectrum. Thus, the log-transformed MMG<sub>RMS</sub> versus TQ relationships may offer an attractive alternative method for reliably quantifying and tracking changes in the TQ-related patterns of response for MMG<sub>RMS</sub> on a subject-by-subject basis.

(No relationships reported)

Low-level repetitive muscle activity, especially with ensuing fatigue, is a risk factor for work related muscle pain (WRMP); however, the mechanism is unclear. Fatigue in this context is determined by evaluating the muscle contractile properties as generated with low frequency electrical stimulation (ES). Near infrared spectroscopy (NIRS) is useful for studying hemodynamics. Identifying fatigue and its physiological attributes may shed light on the link between low-level activity and WRMP.

**PURPOSE:** To determine the muscle contractile properties and hemodynamics before and after a sustained submaximal contraction.

**METHODS:** Subjects (n = 11; 26 ± 4 yrs) were equipped with electrodes for ES and NIRS on the forearm over the finger flexor digitorum muscle. Testing entailed ES (2 Hz; five trains of 15 twitches), followed by upper arm venous occlusion (VO, 50 mmHg for 1 min). Test times in min were before (0m), just after a sustained contraction (15m), and 45m, 75m and 135m. The sustained contraction consisted of 10% MVC for 15 min. During ES the hand was secured in a rig with load cell. Thus, force, contraction time (cont) and ½ relaxation time (½Rx) were determined. For VO, slopes calculated for NIRS derived total hemoglobin (HbT) and deoxyhemoglobin (Hb) were used as estimates of blood flow and oxygen consumption, respectively. Changes in time were tested with one-way ANOVA; if significant post-hoc testing was done.

**RESULTS:** Decreases in force, cont, and ½Rx, and increase in Hb were detected (P < 0.05). Data are below with \* depicting differences relative to 0m.

	0m	15m	45m	75m	135m
Force (N)	2.27 ± 0.83	1.67 ± 0.91*	1.86 ± 1.03	1.78 ± 0.89*	1.89 ± 0.85
Cont (ms)	53.8 ± 5.00	50.7 ± 4.44*	51.0 ± 4.76*	51.9 ± 4.51*	52.5 ± 5.52
½Rx (ms)	47.7 ± 6.40	41.8 ± 4.95*	43.0 ± 6.30*	44.7 ± 5.66	46.3 ± 6.19
HbTslope (% • sec <sup>-1</sup> )	0.13 ± 0.07	0.11 ± 0.06	0.13 ± 0.10	0.10 ± 0.04	0.12 ± 0.04
Hbslope (% • sec <sup>-1</sup> )	0.09 ± 0.06	0.13 ± 0.06*	0.10 ± 0.05	0.09 ± 0.03	0.09 ± 0.04

**CONCLUSION:** Contractile data confirmed fatigue and showed prolonged recovery; whereas Hbslope indicated increased consumption immediately post contraction but with quick recovery.

**Electromyographic Activities Of The Hamstring Muscles In Patients With Acl Reconstruction Using Semitendinosus Tendon**

Akie Nishino<sup>1</sup>, Fuminari Kaneko<sup>2</sup>, Issei Ogasawara<sup>3</sup>, Hiroaki Kanehisa<sup>4</sup>, Toru Fukubayashi<sup>5</sup>. <sup>1</sup>ASICS Corporation, Kobe, Japan. <sup>2</sup>Sapporo Medical University, Sapporo, Japan. <sup>3</sup>Japan Institute of Sports Sciences, Tokyo, Japan. <sup>4</sup>The University of Tokyo, Tokyo, Japan. <sup>5</sup>Waseda University, Tokorozawa, Japan.

Email: nishino-ak@asics.co.jp

(No relationships reported)

Semitendinosus (ST) tendon is commonly used as a replacement graft during anterior cruciate ligament (ACL) reconstruction. However, patients with ACL reconstruction using ST tendon have shown considerable decrease in the strength capability of knee flexors in deep knee flexion. A prior study has indicated that electromyographic (EMG) activities of ST at deeper knee angle were relatively higher than those of the semimembranosus (SM) and biceps femoris (BF) in healthy subjects. After ST tendon removal, it is assumed that EMG activities of ST are modified, which would cause the weakness of knee flexion.

**PURPOSE:** The purpose of this paper is to clarify the effect of ST tendon harvest on EMG activities of ST and other hamstring muscles.

**METHODS:** Eight male patients with harvesting ST tendon for ACL reconstruction (postoperative period: 17±6 months) participated in this study. EMG activities of ST, SM and BF were detected using bipolar fine wire electrodes during maximum voluntary isometric contraction (MVC) at 15, 60 and 90 degrees of knee flexion in prone position. Isometric knee flexion torque during MVC was also measured using a dynamometer. The reconstructed and the contralateral limbs were tested separately.

**RESULTS:** Knee flexion torque of the reconstructed limb was lower than that of the contralateral limb at 60 and 90 degrees of knee flexion. When comparing the reconstructed and the contralateral limbs, only ST showed difference in EMG activity as a function of knee flexion angle particularly at 60 and 90 degrees of knee flexion, where the percentage values were lower for the reconstructed limb (Table 1).

**CONCLUSION:** The results of this study denote that removal of ST tendon induces a decline in the EMG activities of ST at deeper knee angle.

Table 1 EMG of each muscle. All values are expressed as a percentage relative to value at 15 deg.			
	15 deg.	60 deg.	90 deg.
ST of reconstructed limb (%)	100±0	106±29	84±25
ST of contralateral limb (%)	100±0	114±33	105±30
SM of reconstructed limb (%)	100±0	115±69	75±55
SM of contralateral limb (%)	100±0	104±40	75±49
BF of reconstructed limb (%)	100±0	91±22	68±48
BF of contralateral limb (%)	100±0	94±17	77±36

**Changes In Fatigability Of Muscles By Immobilization And Training Measured By Frequency Spectrum Analysis**

Young-Hee Lee. Yonsei University Wonju College of Medicine, Wonju, Republic of Korea. (Sponsor: IN DEOK KONG, FACSM)

Email: lee02@yonsei.ac.kr

(No relationships reported)

It is generally well accepted that immobilization and training induces changes in morphological, physiological and biochemical characteristics of skeletal muscle. A number of studies have investigated the effect of immobilization or training to fiber composition, or the fatigability of limb muscles using various methods, but results have been

inconsistent. Power spectrum of myoelectric signal has been used to monitor fatigue of skeletal muscle. We designed this study to compare changes of fatigability by immobilization or training of four human extremity muscles, which was known to have different fiber type composition respectively, during sustained muscle contraction using myoelectrical frequency spectrum analysis

**PURPOSE:** To evaluate the effects of immobilization and strengthening exercise on fatigability of different skeletal muscles using of frequency spectrum analysis.

**MATERIALS AND METHODS:** Four muscles(biceps brachii, ten triceps brachii, eighteen tibialis anterior and seventeen soleus) of control(50 male), cast immobilized(31 male) and trained group(17 male) were participated. The frequency spectrum was obtained using 1,024 point Fast Fourier Transformation of myoelectric signal during sustained isometric contraction at 80% MVC. The rate of decline in MPF(Mean Power Frequency) over time, indicative of the fatigue rate, was derived from the slope of the linear regression. We compared the change in fatigability between each muscle tested, as well as between the control group and immobilized group using ANOVA test.

**RESULTS:** Statistical analysis showed that immobilized triceps(-1.48±0.81Hz/sec) had less steep slope value than control groups(-2.16±0.77Hz/sec) ( $p < 0.05$ ), which means the fatigability of triceps was decreased by immobilization. In contrast, the immobilized soleus(-1.18±0.96Hz/sec) showed steeper slope values than control groups(-0.44±0.33Hz/sec), and this change was statistically significant, which means the fatigability of soleus was increased by immobilization. The trained group did not show difference in fatigability of any muscles comparing control group.

**CONCLUSION:** There were differences in changes of fatigability by immobilization of different skeletal muscles according to their muscle fiber compositions.

#### **Enhancement Of Jump Performance After A 5RM Squat And The Role Of Postactivation Potentiation**

Cameron J. Mitchell<sup>1</sup>, Digby G. Sale<sup>2</sup>. <sup>1</sup>*Brock University, St. Catharines, ON, Canada.* <sup>2</sup>*McMaster University, Hamilton, ON, Canada.* (Sponsor: David Gabriel, FACSM)

Email: cam.mitchell@brocku.ca

(No relationships reported)

Previous research has indicated that a heavy resistance exercise may enhance the performance of a subsequent biomechanically similar explosive movement. The most commonly proposed mechanism to explain this enhancement is postactivation potentiation (PAP).

**PURPOSE:** To evaluate whether a 5 repetition maximum (RM) squat exercise increases the performance of a subsequently performed set of countermovement jumps (CMJ) and whether a 5RM squat performance is associated with twitch potentiation.

**METHODS:** Eleven athletes experienced in the squat exercise completed 4 laboratory sessions with each session separated by 3-4 days. In each session 5CMJ were performed. In two of the sessions, the 5CMJ were followed by 8 min of rest and then performance of another 5CMJ or evoked twitch torque of the knee extensors. The other two sessions were identical, except that 5RM squat exercise was performed midway through the rest period. In those sessions in which evoked twitch torque was evaluated, a baseline twitch was also performed before the initial 5CMJ performance. The percent difference in 5CMJ performance (pre-post rest) in the 4 sessions was compared using one-way ANOVA with repeated measures.

**RESULTS:** Following the 8-min rest there was a  $4.3 \pm 12.6\%$  decrease in twitch torque and a  $1.4 \pm 4.1\%$  decrease in CMJ height, although these differences were not significant. Following the 5RM squat between CMJs, resulted in a  $9.6\% \pm 13.7\%$ ,  $p < 0.05$  increase in twitch torque and a  $2.8 \pm 2.9\%$   $p < 0.05$  increase in CMJ height.

**CONCLUSIONS:** The concurrent increases in CMJ performance and in twitch torque suggests that a 5RM squat results in PAP, which contributes to improved performance.

#### **An Arm And A Leg: Site Specific Bmc Predictors In Female Division Ii Collegiate Athletes**

Carmen Chrisman, Michelle Gray. *University of Central Oklahoma, Edmond, OK.*

Email: carmen.chrisman@gmail.com

(No relationships reported)

It has previously been reported that lean body mass (LBM) and fat mass (FM) are positive indicators of bone mineral content (BMC). However, the individual relationships of these components to site specific BMC across female athletic populations are unclear.

**PURPOSE:** The aim of this investigation was to determine the relationships of arm and leg LBM and FM to arm and leg BMC in female Division II collegiate athletes.

**METHODS:** The participants were female athletes ( $20.25 \pm 2.15$  years) representing Division II collegiate soccer ( $n = 8$ ) and softball ( $n = 21$ ). LBM, FM, and arm and leg BMC were measured via total-body dual energy X-ray absorptiometry (iDXA). An independent samples t-test was used to determine if differences existed between the two athletic groups. Multiple regression analyses were then applied to determine the relationships between the independent (LBM and FM) and dependent (arm and leg BMC) variables.

**RESULTS:** No significant differences ( $p > .05$ ) were found between the two groups for either arm or leg BMC; therefore, multiple regression analyses were subsequently performed with all athletes representing one group. When leg fat and lean mass were entered into the multiple regression analysis,  $62.2\%$  ( $F[2,26] = 21.43$ ,  $p < .0001$ ) of the variation was accounted for in leg BMC. Upon further analysis, it was determined out of the two independent variables, lean mass of the legs had a greater unique contribution ( $32.4\%$ ) when compared to fat mass of the legs ( $.03\%$ ). The contribution of fat and lean mass to the arms was determined to be insignificant accounting for less than 1% of the variability ( $R^2 = 0.8\%$ ,  $F[2,26] = 0.108$ ,  $p > .05$ ).

**CONCLUSION:** Based on the results, lean body mass is a significant predictor of BMC in the legs for female Division II soccer and softball collegiate athletes. This information is consistent with previous findings for similar female Division I athletic populations and can potentially be used to design and implement training programs that will help increase or maintain BMC throughout life.

#### **Estrogen Receptor-alpha Genotype Affects Exercise And Nutrient Intake-related Change Of Bone Mass.**

Hiroyo Kondo<sup>1</sup>, Hidemi Fujino<sup>2</sup>, Takuro Funahashi<sup>3</sup>, Koji Suzuki<sup>4</sup>. <sup>1</sup>*Suzuka University of Medical Science, Suzuka, Japan.* <sup>2</sup>*Himeji Dokkyo University, Himeji, Japan.* <sup>3</sup>*Will Oguchi Sports Club, Oguchi, Japan.* <sup>4</sup>*Mie University, Tsu, Japan.*

Email: hiroyo@suzuka-u.ac.jp

(No relationships reported)

Bone mass is affected not only by environment factors, e.g., physical activities and foods, but also by gene polymorphism.

**PURPOSE:** The present study was to determine whether gene polymorphism in the estrogen receptor (ER) alpha gene (ESR1) affect bone mass. And, the interaction between

genes and physical activities and/or dietary intakes on bone mass in young women.

**METHODS:** Seventy 20-23 years old Japanese women were chosen for the study. They were either very active physically (exercise three times per week) or not active. Food frequency questionnaires were used to estimate calcium intake. Bone mass was measured by quantitative ultrasound measurement (QUS). Genomic DNA was extracted from buccal cell. The ESR1 polymorphisms at intron I (*Pvu II* for a T/C substitution and *Xba I* for an A/G substitution) were genotyped using the PCR-RFLP. The relationships between ER1 genotype and physical activity, and/or dietary were evaluated.

**RESULTS:** There were no significant differences between bone mass and ER1 genotypes. However, body weight, BMI and high physical activity showed the positive correlation with bone mass in the Pp heterozygote ( $P < 0.01$ ). Furthermore, bone mass was higher in the individual who eats fish (three times per week) in the Xx heterozygote ( $P < 0.01$ ).

**CONCLUSIONS:** Our data suggested that physical exercise or a correct calcium intake is more important to bone mass for young women with Pp heterozygote or Xx heterozygote of ER alpha gene, respectively.

Email: hanjoon@ulsan.ac.kr

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effect of varying bench press grip on the EMG activity of the upper body muscle during bench press exercise.

**METHODS:** 12 male students (22.5±2.7 yrs) were participated. To assess the myoelectric activities of selected muscles, surface electrodes were attached to pectoralis major, trapezius, front deltoid and triceps brachii. IEMG and NEMG were measured for each muscles. For each variable, one-way repeated ANOVA was used to determine whether these were significant difference among three grip bench press. From the above experiment, this study analyzed muscle activities and participations in wide grip (WD), normal grip (NM), and narrow grip (NR) during bench press. When a significant difference was found in three grip bench press, post hoc analysis were performed using Tukey procedure. Significant level was .05.

**RESULTS:** IEMG of triceps brachii muscle was significantly affected depending on the change of bench press grip (WD 35.42±9.25% vs NM 52.68±11.02%,  $p < .05$ ). NEMG of pectoralis major was significantly different between WD and NM & NR grip (30.91±6.93% vs 17.61±3.75 & 15.56±5.53,  $p < .05$ ). NEMG of trapezius was significantly different between WD and NR (3.63±1.21 vs 10.86±2.23,  $p < .05$ ). NEMG of triceps brachii was significantly difference between WD and NM (28.17±4.39 vs 40.97±7.53,  $p < .05$ ).

**CONCLUSIONS:** Pectoralis major muscle activity reduced as a grip narrow. And muscle activity of trapezius and triceps brachii increased as a grip narrow.

**Effects Of Loading And Unloading On Physical Performance And Cardiovascular Function In Rats**

Fatima T. Silva, Ilya Bederman, Alex Liggett, Marco Cabrera, FACSM. *Case Western Reserve University, Cleveland, OH.*

Email: fatima.silva@case.edu

(No relationships reported)

**PURPOSE:** Skeletal muscles are vulnerable to rapid and marked remodeling induced by the levels of mechanical load placed on the body. Under reduced levels of mechanical load, muscle mass will decrease (atrophy), while under increased load, the muscle mass will increase (hypertrophy). The cardiovascular system also undergoes profound changes when the body is exposed to various load levels. Our aim was to determine the effect of altered energy states (loading/unloading) on performance and cardiovascular parameters. More specifically, we compared the deleterious effect of a short period of unloading vs. the beneficial effects of two distinct periods of training.

**METHODS:** We measured O<sub>2</sub> uptake (VO<sub>2</sub> ml/kg/min), CO<sub>2</sub> output (VCO<sub>2</sub> ml/kg/min), respiratory exchange ratio (RER), and blood lactate (mmol/L) before and after suspension and training. In addition, Mean (MBP), Systolic (SBP), Diastolic (DBP) blood pressures and heart rate (HR) were measured by tail-cuff. Adult rats underwent either one week of hindlimb suspension (HSU) or two and four weeks of exercise training on a motorized treadmill, 5 d/wk, 45 min/d. Training intensity was ~75% VO<sub>2</sub>max.

**RESULTS:** We observed ~30% increase after unloading in basal VO<sub>2</sub> (19.8±1.6 vs. 27.2±2.1), VCO<sub>2</sub> (16.2±1.3 vs. 21.5±1.8) and lactate (1.9±0.1 vs. 2.5±0.4). We also found an increase of heart rate ~7% (403±33 vs. 431±21) and decrease in 6% tail blood flow (44.7±11 vs. 41.9±12, µl/min). Two or four weeks of exercise training did not change resting systolic diastolic or mean blood pressures; however, significantly reduced HR by 7%, 411±25 vs. 399±33 and 388±40, for controls and two or four-week loading, respectively. During the maximal exercise test, two and four weeks of training increased total running time by 30% and 53%, peak speed by 23% and 36%, VO<sub>2</sub> by 13% and 41%, and VCO<sub>2</sub> by 13% and 39%, respectively. In contrast, unloading decreased running time by 27%, peak speed by 21%, and peak lactate by 30%; however, no changes were observed in peak VO<sub>2</sub> and VCO<sub>2</sub>.

**CONCLUSION:** Our data suggests that the increase in baseline values in HSU animals is due to the stress of unloading. Data also shows that while 1 week of HS does not affect aerobic capacity, it impairs exercise performance. On the contrary, exercise training greatly improves both physical performance and aerobic capacity.

**Reduced Leg Muscle Oxygenation During Underwater Treadmill Walking**

Kazuki Esaki<sup>1</sup>, Koichi Kaneda<sup>2</sup>, Daisuke Sato<sup>2</sup>, Hitoshi Wakabayashi<sup>3</sup>, Tohru Takemasa<sup>2</sup>, Takeo Nomura<sup>2</sup>, Takafumi Hamaoka, FACSM<sup>4</sup>, Toshihito Katsumura<sup>1</sup>. <sup>1</sup>*Tokyo Medical University, Tokyo, Japan.* <sup>2</sup>*University of Tsukuba, Tsukuba, Japan.* <sup>3</sup>*Kyushu University, Fukuoka, Japan.* <sup>4</sup>*National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)

Email: dzh01750@nifty.com

(No relationships reported)

Central circulation and whole body metabolism adjustments, in particular, have been investigated using respiratory gas analysis and heart rate (HR) measurement. However, local muscle circulation and oxidative metabolism have never been investigated during underwater walking.

**PURPOSE:** The purpose of this study was to determine muscle oxygenation in the lower extremities during underwater walking on a treadmill.

**METHODS:** Eight healthy men (age 25 ± 3 y.r., height 175 ± 4 cm, weight 69.6 ± 5.7 kg, BMI 23 ± 2, VO<sub>2</sub>max 56.7 ± 5.9 ml/kg/min) performed a treadmill walking test twice, once in water and once on land. Each subject began underwater treadmill walking at 1.0 km/h in 0.5 km/h increments at intervals on 2 minutes until 3.5 km/h. Each subject also began land-treadmill walking at 2.0 km/h in 1.0 km/h increments at intervals of 2 minutes until 7.0 km/h. The HR was continuously monitored by a telemeter. Muscle electromyographic (EMG) activity was monitored in the vastus lateralis (VL) and the medial head of the gastrocnemius (MG). The muscle oxygenation level was continuously monitored in the VL and the MG using near-infrared spectroscopy (NIRS).

**RESULTS:** Muscle oxygenation decreased greater during underwater walking than during land walking both in the VL and in the MG. There is no significant difference in the EMG activity between the two conditions in both muscles. The combination of EMG and NIRS results indicate that the greater decrease in the muscle oxygenation is due to reduced muscle perfusion resulting from the facilitated venous return to central circulation during underwater walking.

**CONCLUSIONS:** The results of this study indicate that the greater decrease in the muscle oxygenation is due to reduced muscle perfusion resulting from facilitated venous

return to central circulation during underwater walking.

**b-adrenergic Stimulation And Whole Body Protein Turnover**

Matthew M. Robinson<sup>1</sup>, Christopher Bell<sup>1</sup>, Jennifer C. Richards<sup>1</sup>, Wyatt F. Voyles<sup>2</sup>, Benjamin F. Miller, FACSM<sup>1</sup>. <sup>1</sup>Colorado State University, Ft. Collins, CO. <sup>2</sup>Medical Center of the Rockies Foundation, Ft. Collins, CO.

Email: matthew.robinson@colostate.edu

(No relationships reported)

Recent evidence in animals indicates that exercise-induced changes in mitochondria turnover are largely the result of an increase in beta-adrenergic (b-AR) stimulation. If true, increases in b-AR stimulation may induce increases in protein turnover, a necessary process for exercise-induced adaptation. We hypothesized that in human subjects, b-AR stimulation would increase whole body protein turnover and synthesis.

**PURPOSE:** To evaluate the effects of b-AR stimulation on whole body protein turnover (WBPT) in resting humans.

**METHODS:** Six healthy untrained subjects ( $19.8 \pm 1.5$  yrs) received isovolumetric intravenous infusions of either saline (CON) or the non-selective b-AR agonist isoproterenol (ISO, 12 ng/kg fat free mass/min for 60 minutes) on two separate days. WBPT was determined using a 6-hour primed continuous infusion of  $[1,2]^{13}\text{C}$ -leucine (0.8 mg/kg prime, 1.25 mg/min infusion, and 0.5 mg/kg  $\text{NAH}^{13}\text{CO}_3$  prime) with breath and plasma samples collected hourly. CON or ISO infusions were performed between 1h and 2h. Plasma enrichment of  $\alpha$ -ketoisocaproate acid (KIC) was determined by gas chromatography mass-spectrometry (GC-MS), while breath enrichment of  $^{13}\text{CO}_2$  was determined by isotope ratio mass-spectrometry (IRMS). Calculations of leucine rate of appearance ( $R_a$ ), rate of oxidation ( $R_{ox}$ ), and non-oxidative leucine disposal (protein synthesis, NOLD) were made according to the single pool model. Statistical significance was set at  $p=0.05$  and data are displayed as mean $\pm$ SD.

**RESULTS:** Leucine  $R_a$  was not significantly different between trials ( $p=0.62$ ). However, there was a trend toward an interaction of time and treatment for  $R_{ox}$  ( $p=0.099$ ) and NOLD ( $p=0.092$ ). The trend towards a significant increase of NOLD after ISO was largely the effect of an increased ( $p<0.05$ ) rate of NOLD immediately post infusion (ISO:  $93.9 \pm 7.27$  vs. CON:  $80.13 \pm 13.15$   $\mu\text{mol/kg/min}$ ).

**CONCLUSIONS:** Our results suggest that in the one-hour period during b-AR stimulation there is an increase in whole body protein synthesis, which may contribute to observed post-exercise increases in protein turnover.

**Anaerobic Work Capacity From Linear And Nonlinear Mathematical Models**

C. Russell Hendrix, Terry J. Housh, FACSM, Glen O. Johnson, FACSM, Michelle Mielke, Clayton L. Camic, Jorge M. Zuniga, Richard J. Schmidt. University of Nebraska-Lincoln, Lincoln, NE.

Email: rhendri7@unlserve.unl.edu

(No relationships reported)

The critical torque (CT) test for isometric muscle actions provides estimates of two parameters; CT and anaerobic work capacity (AWC). Theoretically, CT is the maximal isometric torque that can be maintained without fatigue and AWC is the total "isometric work" associated with stored energy sources within the muscle.

**PURPOSE:** The purpose of this study was to determine if there were differences between the estimates of AWC from two linear and two nonlinear mathematical models.

**METHODS:** Nine adults (4 men, 5 women; age  $\pm$ SD =  $21.6 \pm 1.2$  yr) volunteered for this study. The first of five visits served as an orientation. Maximum voluntary isometric contraction (MVIC) of the dominant leg extensors was determined during the second visit. During visits 2-5, each subject performed one continuous, fatiguing, isometric muscle action to voluntary exhaustion to determine the time to exhaustion (limit time;  $T_{lim}$ ) and total isometric work performed (limit work;  $W_{lim}$ ) at a randomly ordered percentage of MVIC (30%, 45%, 60%, or 75%). The  $T_{lim}$ ,  $W_{lim}$ , and torque values were used in two linear and two nonlinear mathematical models to calculate four separate estimates of AWC.

**RESULTS:** A one-way repeated measures ANOVA indicated no significant differences between the estimates of AWC from the four mathematical models. In addition, the AWC estimates were highly intercorrelated at  $r = 0.986$  to  $0.999$ .

**CONCLUSION:** The results of the current study indicated that linear and nonlinear mathematical modeling of the  $T_{lim}$ ,  $W_{lim}$ , and torque data had no effect on estimates of AWC during isometric muscle actions of the leg extensors. Thus, the four mathematical models examined in the present study can be used to estimate the total isometric work that can be performed from stored energy sources within the muscle.

**The Use Of Diagnostic Ultrasound To Evaluate The Optimum Depth For Muscle Biopsy Of The Vastus Lateralis Muscle.**

Anthony D. Webbom, FACSM<sup>1</sup>, Paul Castle<sup>2</sup>, Peter Watt<sup>1</sup>. <sup>1</sup>Univ. of Brighton, Eastbourne, United Kingdom. <sup>2</sup>Univ. of Bedford, Bedford, United Kingdom.

Email: nickwebbom@sportswise.org.uk

(No relationships reported)

**PURPOSE:** Biopsy of the vastus lateralis (VL) muscle is a common procedure in sports science. A depth of 3 to 4cm has commonly been described in the literature as the level at which the biopsy should be taken without consideration for individual variation. During studies to ensure accurate placement of muscle temperature probe we observed that for many athletes a depth of 3-4cm would result in a biopsy from the vastus intermedius (VI) or even the femur (F). The purpose of the study was to identify the optimum depth for biopsy of VL and to reduce erroneously biopsying the incorrect muscle group.

Method: Using diagnostic ultrasound (Sonosite Micromaxx) the depth from the skin surface to the centre of VL, the junction between the VL and VI, and to F, was recorded in 21 male active subjects. The measurement was taken at the midpoint between the greater trochanter and the lateral femoral condyle.

**RESULTS:** The mean depth to the centre of VL was 1.75cm (sd 0.25). The mean depth to the surface of VI was 2.76cm (sd 0.36) and to F 4.43cm (sd 0.6). A 3cm depth would biopsy VI in 16/21 subjects.

**CONCLUSION:** Current protocols overestimate the depth for muscle biopsy which may result in sampling VI rather than VL. At a depth between 3 and 4cm it is more likely

that the biopsy is from VI. In male subjects a maximum depth of 2cm should be used if VL biopsy is required or preferably individual assessment should be made using diagnostic ultrasound.

**Free Radical Detection In Exercised Thoroughbred Muscles By Electron Magnetic Resonance**

Minako Kawai, Yoshio Minami, Taiko Migita, Akana Yamaguchi, Hirofumi Miyata. *Yamaguchi Univ., Yamaguchi, Japan.*  
Email: hiro@yamaguchi-u.ac.jp  
(No relationships reported)

**PURPOSE:** To find a new parameter indicating muscle physiological condition in Thoroughbred horses, we examined time-dependent recovery of glycogen content and sarcoplasmic reticulum (SR)  $\text{Ca}^{2+}$ -ATPase activity of skeletal muscle after intensive treadmill running. In addition to the biochemical analysis, we determined a free radical generation in the muscle by using electron paramagnetic resonance (EPR).

**METHODS:** Six male Thoroughbred horses that weighed  $476 \pm 32$  kg were used in this study. Before the exercise test, all horses stayed on the pasture in the daytime and were accustomed to running on a treadmill for a short time. Two repeated 50-second running sessions were performed on a 7% incline treadmill (approximately 100%  $\text{VO}_{2\text{max}}$ ). Muscle samples of the middle gluteal muscle were taken before exercise (pre) and 1 min, 20 min, 60 min, and 24 h after exercise. Muscle fiber type composition was determined in the pre muscle samples by immunohistochemical staining with monoclonal antibody to myosin heavy chain. SR  $\text{Ca}^{2+}$ -ATPase activity of the muscle and glycogen content of each muscle fiber type were determined with biochemical analysis and quantitative histochemical staining, respectively. Furthermore, we measured the free radical in the homogenate using EPR at room temperature, and the amount was expressed as relative EPR signal intensity.

**RESULTS:** Type IIA and Type IIX fibers were the highest in number and area percentages, respectively ( $45.0 \pm 5.1\%$ ,  $45.2 \pm 5.4\%$ ). As compared to the pre value, the glycogen content of each muscle fiber type was reduced by 15%-30% at 1 min, 20 min, and 60 min after the exercise and recovered to the pre value at 24 h after exercise test. The mean value of the SR  $\text{Ca}^{2+}$ -ATPase activity showed a slight decrease immediately after exercise and a complete recovery at 24 hours after exercise. While, the mean value of relative EPR signal intensity showed a significant increase immediately after exercise, and an incomplete recovery at 24 hours after exercise.

**CONCLUSIONS:** These results indicate that 24 hours after short-term intensive exercise is enough time to recover glycogen content and SR  $\text{Ca}^{2+}$ -ATPase, but not in relative EPR signal intensity. Although further studies are needed, the EPR signal might be a useful parameter to detect muscle physiological conditions, at least in Thoroughbred horses.

 **$\text{VO}_2$  On-kinetics In Isolated Canine Muscle *In Situ* During Slowed Convective  $\text{O}_2$  Delivery**

Matthew L. Goodwin<sup>1</sup>, Andrés Hernández<sup>1</sup>, Nicola Lai<sup>2</sup>, Marco E. Cabrera, FACSM<sup>2</sup>, L. Bruce Gladden, FACSM<sup>1</sup>. <sup>1</sup>Auburn University, Auburn, AL.  
<sup>2</sup>Case Western Reserve University, Cleveland, OH.  
Email: GOODWML@auburn.edu  
(No relationships reported)

Numerous studies have measured heart rate, cardiac output, and limb blood flow as proxies for exercising muscle blood flow; and pulmonary oxygen uptake ( $\text{VO}_2$ ) and limb  $\text{O}_2$  as proxies for exercising muscle  $\text{VO}_2$ . However, relatively few studies have characterized  $\text{O}_2$  delivery on-kinetics and  $\text{VO}_2$  on-kinetics directly across a contracting muscle. Furthermore, to our knowledge, no one has altered only the time course of the transition between metabolic rates, leaving resting and steady state  $\text{O}_2$  delivery unchanged.

**PURPOSE:** To slow the blood flow on-kinetics (via pump perfusion control), and thereby  $\text{O}_2$  delivery on-kinetics to a contracting isolated muscle *in situ* and determine the resultant  $\text{VO}_2$  on-kinetics.

**METHODS:** A step change in metabolic rate was elicited by stimulating canine gastrocnemius-plantaris muscles ( $n=6$ ) via their sciatic nerves (6-8 V, 0.2 ms duration, 50 Hz, 200 ms train) at a rate of 0.5 Hz. With arterial  $\text{O}_2$  concentration maintained constant, in random order trials, blood flow tau was set at a control transition speed between rest and contractions (determined in pilot work) of 20 sec (CT20) or was slowed to tau values of 45 sec (EX45) and 70 sec (EX70). Resting and steady state (4 min of contractions) blood flows were not altered between the transition conditions. An indwelling venous oximeter continuously measured venous  $\text{O}_2$  saturation, from which a  $\text{a-vO}_2$  difference was determined.  $\text{VO}_2$  was calculated on a contraction-by-contraction basis from  $\text{a-vO}_2$  difference and blood flow.

**RESULTS:**  $\text{VO}_2$  average mean response time ( $\text{MRT} = \tau + \text{time delay}$ ) values for EX45 and EX70 were significantly different from each other and from CT20 (mean  $\pm$  S.D.; CT20= $19.9 \pm 3.8$ , EX45= $26.3 \pm 5.9$ , and EX70= $31.7 \pm 4.1$  sec).  $\text{VO}_2$  on-response MRT values were linearly related to the blood flow on-response MRT values ( $R=0.99997$ ).

**CONCLUSIONS:** These results suggest that in this highly-oxidative muscle, blood flow and thereby  $\text{O}_2$  delivery is finely matched to  $\text{O}_2$  demand in the transition from rest to contractions at a submaximal metabolic rate, and that there is little "buffer" of blood flow/ $\text{O}_2$  delivery during this transition.

**2017 Board #158 May 28 8:00 AM - 9:30 AM**  
**Viscoelastic Creep In Human Skeletal Muscle**

Eric D. Ryan, Trent J. Herda, Pablo B. Costa, Ashley A. Walter, Katie M. Hoge, Travis W. Beck, Jeffery R. Stout, FACSM, Joel T. Cramer, FACSM.  
University of Oklahoma, Norman, OK.  
Email: eryl@ou.edu  
(No relationships reported)

**INTRODUCTION:** Viscoelastic creep can be defined as the increase in tissue length under a constant force or torque.

**PURPOSE:** To examine viscoelastic creep in the plantar flexor muscles.

**METHODS:** Thirteen healthy participants (mean age  $\pm$  SD =  $22 \pm 3$  yrs; stature =  $168 \pm 12$  cm; mass =  $69 \pm 17$  kg) performed four 30-s constant-torque passive stretches of the plantar flexor muscles on a calibrated Biodex System 3 dynamometer. Each 30-s passive stretch was completed by the dynamometer lever arm by passively dorsiflexing the foot at  $5^\circ/\text{s}$  to the point of discomfort, but not pain as acknowledged by the participant. This was quantified as the maximum tolerable passive torque threshold (i.e. 33 N-m), which was held constant for all 4 stretches while the change in dorsiflexion position was monitored under the constant passive torque. Each 30-s passive stretch was separated by 20 s of rest. Position ( $^\circ$ ) values were sampled from the dynamometer at 1 KHz during the stretches and were quantified at every 5-s period (0, 5, 10, 15, 20, 25, and 30 s). In addition, the percent change in position was quantified for each 5-s epoch (0-5, 5-10, 10-15, 15-20, 20-25, and 25-30 s) relative to the total increase in range of motion (ROM) for each 30-s stretch. A two-way repeated measures ANOVA [stretch  $\times$  time;  $4 \times 7$ ] was used to analyze the absolute changes in position, whereas a two-way repeated measures ANOVA [stretch  $\times$  time;  $4 \times 6$ ] was used to analyze the percent changes in ROM.

**RESULTS:** For each 30-s stretch, the absolute position increased such that  $0 < 5 < 10 < 15 < 20 < 25 < 30$  s ( $P < 0.05$ ). At all time points, the position for stretch 1 was less than stretches 2 - 4 ( $P < 0.05$ ), and stretch 2 was less than stretches 3 - 4 ( $P < 0.05$ ). There were no differences at any time points between stretches 3 and 4 ( $P > 0.05$ ). The percent changes in ROM were the same for stretches 1, 2, 3, and 4 during each epoch ( $P < 0.05$ ), however, as the stretch progressed for 30 s, the relative increases in ROM diminished.

**CONCLUSIONS:** During these constant-torque stretches, most of the increases in range of motion occurred as a result of the first two 30-s stretches, since there were no differences in dorsiflexion position between stretches 3 and 4. In addition, the relative changes in ROM that occurred during each of the four 30-s stretches were the same, but the greatest increases (42%) occurred during the first 5-s.

2018 Board #159 May 28 8:00 AM - 9:30 AM

**Time-to-fatigue And Intramuscular Ph Measured Via Nirs During Handgrip Exercise In Trained And Sedentary Individuals**

Meghan Everett<sup>1</sup>, Stuart Lee<sup>1</sup>, Leah Stroud<sup>1</sup>, Pete Scott<sup>2</sup>, Ronald Hagan<sup>1</sup>, Babs Sollers<sup>3</sup>. <sup>1</sup>NASA-JSC, Houston, TX. <sup>2</sup>UMASS Medical School, Worcester, MA. <sup>3</sup>NASA-JSC, Worcester, MA.

Email: meghan.e.everett@nasa.gov

(No relationships reported)

**INTRODUCTION:** In exercising muscles force production and muscular endurance are impaired by a decrease in intramuscular pH. The effects of aerobic training (AT) on preventing acidosis and prolonging exercise time in muscles not specifically targeted by the training are unknown.

**PURPOSE:** To compare interstitial pH, measured non-invasively with near infrared spectroscopy (NIRS), in the flexor digitorum profundus (FDP) during rhythmic handgrip exercise in sedentary subjects and those who participate in AT activities that target the lower body.

**METHODS:** Maximal isometric force (MIF) was measured on three separate days in AT (n=5) and sedentary (n=8) subjects using a handgrip dynamometer (HGD). Isometric muscular endurance (IME) was measured during five trials, each separated by at least 48 hrs. For each IME trial subjects rhythmically squeezed (4 sec at 40% of MVC) and relaxed (2 sec) to fatigue or failure to reach the target force in three consecutive contractions or four non-consecutive contractions. Interstitial pH was derived from spectra collected using a NIRS sensor adhered to the skin over the FDP. The first four IME trials served to familiarize subjects with the protocol; the fifth trial was used for analysis. NIRS-derived pH was averaged in 30 sec increments. Differences between groups for MIF and exercise time were tested using paired t-tests. A repeated measures ANOVA was used to analyze effects of AT and exercise time on pH.

**RESULTS:** MIF was not different between groups (mean  $\pm$ SD; aerobic=415.6 $\pm$ 95.4 N vs. sedentary =505.1 $\pm$ 107.4 N). Time to fatigue was greater in the AT than in the sedentary group (mean  $\pm$ SD: 611 $\pm$ 173 sec vs. 377 $\pm$ 162 sec, p<0.05). pH was not different between groups at any time point. Average pH decreased (p<0.05) in both groups from rest (pH=7.4) through 90 sec of exercise (pH=6.9), but did not decrease further throughout the remainder of exercise.

**CONCLUSION:** Although between group differences in pH were not detected, differences during the onset of exercise may exist with a more frequent sampling. AT individuals appear to better tolerate decreased interstitial pH and are able to continue submaximal muscular work, possibly due to psychological familiarization to muscular fatigue and/or systemic physiological benefits.

2019 Board #160 May 28 8:00 AM - 9:30 AM

**The Arm Of The Professional Tennis Player**

H Olmedillas<sup>1</sup>, F Idoate<sup>2</sup>, S Alayón<sup>3</sup>, A Carreras<sup>3</sup>, A Guadalupe-Grau<sup>1</sup>, C Dorado<sup>1</sup>, JAL Calbet<sup>1</sup>, J Sanchís-Moysi<sup>1</sup>. <sup>1</sup>University of Las Palmas Gran Canaria, Las Palmas, Spain. <sup>2</sup>Clinica San Miguel, Pamplona, Spain. <sup>3</sup>Hospital San Roque, Maspalomas, Spain.

Email: holmedilla@becarios.ulpgc.es

(No relationships reported)

Professional tennis players have a marked inter-arm symmetry due to 10-20% greater muscle mass in the dominant compared to the non-dominant arm. However, the effect of tennis on individual muscles has not been previously studied.

**PURPOSE:** The aim of this study was to describe the effect of professional tennis participation on the individual muscle volumes of the dominant arm, and the changes elicited in the morphology of the triceps brachii muscle, using the non-dominant arm as a control.

**METHODS:** Fifteen professional tennis players (22 $\pm$ 4 years) were divided into two groups: one underwent muscle volumes examination by magnetic resonance imaging (n=8) in both arms, and the other group a body composition examination (DXA, n=7) and muscle biopsies from both triceps brachii (short head, n=7).

**RESULTS:** Muscle fiber type distribution was similar in both arms. The dominant arm had 15% higher lean mass (DXA) than the non-dominant arm (P<0.05). The type 1, 2a and 2x muscle fibers of the dominant arm were hypertrophied compared to the non-dominant arm by 20 (4962  $\pm$  452 and 4210  $\pm$  460  $\mu$ m<sup>2</sup>, P < 0.01), 22 (7700  $\pm$  873 and 6311  $\pm$  707  $\mu$ m<sup>2</sup>, P < 0.01) and 34% (7058  $\pm$  878 and 5225  $\pm$  451  $\mu$ m<sup>2</sup>, P < 0.01), respectively. Compared to the contralateral arm, the dominant arm had a 10% greater mean muscle volume (P < 0.001). All the muscle groups of the dominant arm were hypertrophied compared to the non-dominant arm: the deltoid muscle 13 % (P < 0.001), the arm flexors 9 % (P < 0.05) and the triceps brachii 13 % (P < 0.05). The volume of the superficial flexor muscles of the forearm was 12 % higher in the dominant compared to the contralateral forearm (P < 0.05). No significant differences were observed between the dominant and non-dominant forearm in deep flexors, mobile pad, forearm extensors and supinator muscle volumes (P = 0.62, P = 0.23, P = 0.98 and P = 0.59, respectively).

**CONCLUSIONS:** Professional participation in tennis elicits an harmonic muscle hypertrophy in the dominant arm, where individual muscle maintain between them the same proportions observed in the contralateral arm. However, the forearm muscles show great variability between tennis players.

Granted by (BF2003-09638, BFU2006-13784, PI2005/177 and FEDER). The authors wish to thank Hospital San Roque Maspalomas (Grupo San Roque) and Sánchez-Casal Tennis Academy.

**Monitoring Total And Free IGF-I In Serum Vs. Transdermal Body Fluid Biocompartments: Effects Of Endurance Exercise**

Dennis E. Scofield<sup>1</sup>, Bradley C. Nindl, FACSM<sup>1</sup>, Holly L. McClung<sup>1</sup>, James P. McClung<sup>1</sup>, Kevin R. Rarick<sup>2</sup>, Joseph R. Pierce<sup>1</sup>, Roger A. Fielding, FACSM<sup>3</sup>, Andrew J. Young, FACSM<sup>1</sup>. <sup>1</sup>US Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>University of Iowa, Iowa City, IA. <sup>3</sup>Tufts University, Boston, MA.

Email: dennis.scofield@amedd.army.mil

(No relationships reported)

**PURPOSE:** Examination of hormones in transdermal body fluid (TBF) instead of blood may provide more physiologically relevant information due to closer proximity to tissue and cells. No previous study has determined whether total and free insulin-like growth factor-I (IGF-I) in TBF and serum differ during rest and exercise.

**METHODS:** 10 healthy men (mean $\pm$ SD, 23 $\pm$ 3 years old, 178 $\pm$ 3 cm tall, 79 $\pm$ 7 kg) with a VO<sub>2 peak</sub> of 44 $\pm$ 3 mL/kg/min had blood obtained by venipuncture and TBF obtained using a patented and proprietary methodology that uses minimally-invasive vacuum pressure in combination with a laser microporation process in the stratum corneum during an exercise and a control condition (i.e. laying supine quietly). Exercise consisted of 60 minutes of cycling at 60% VO<sub>2 peak</sub>. Post-exercise time points 40, 105, and 225 minutes were pooled for both TBF and serum samples allowing for adequate volumes for analysis. Total and free IGF-I were measured using immunoassays. Repeated-measures ANOVA (biocompartment x condition x time) was used for statistical analysis. Data were log transformed to ensure normal distribution.

**RESULTS:** Total IGF-I concentration in TBF was significantly lower than serum pre-exercise (serum, 483 $\pm$ 142 ng/mL; TBF, 100 $\pm$ 30 ng/mL), and post-exercise (serum, 432 $\pm$ 105 ng/mL; TBF, 127 $\pm$ 67 ng/mL). Total IGF-I in TBF significantly increased from baseline in the control condition (pre, 107 $\pm$ 39 ng/mL; pool, 198 $\pm$ 91 ng/mL), but not the exercise condition (pre, 100 $\pm$ 30 ng/mL; pool, 127 $\pm$ 67 ng/mL). Free IGF-I concentrations were not significantly different between serum and TBF pre-exercise (serum, 2.4 $\pm$ 1.7 ng/mL; TBF, 2.0 $\pm$ 0.9 ng/mL), but were ~12% greater in TBF post-exercise (serum, 2.5 $\pm$ 2.1 ng/mL; TBF, 2.8 $\pm$ 0.9 ng/mL). Proportion of free to total IGF-I in TBF increased ~29% post-exercise, while serum levels remained unchanged.

**CONCLUSION:** This study demonstrates the utility of a minimally invasive method for monitoring total and free IGF-I in TBF during exercise recovery. Our data confirm the working hypothesis that measurement of IGF-I in various biocompartments yield different information. The higher post-exercise free IGF-I in TBF vs. the circulation does suggest that the biologically active form of IGF-I is more proximal to cells/tissues and readily available to mediate exercise-induced responses.

Email: joseph.pierce@amedd.army.mil

(No relationships reported)

Insulin-like growth factor-I (IGF-I) is a regulator of skeletal muscle growth/metabolism, and is located across different biocompartments (blood, interstitial fluid, and skeletal muscle), highlighting both systemic and local influences. Concomitant examination of exercise-induced IGF-I responses in these biocompartments has not been examined previously.

**PURPOSE:** To examine potential disparate regulation in IGF-I between biocompartments with differing proximities to skeletal muscle *via* I.V. catheter, skeletal muscle microdialysis (MD), and muscle biopsy (MB).

**METHODS:** Seven volunteers (3 men and 4 women; age:  $24 \pm 6$  yr) performed an acute bout of plyometric exercise (10 sets of 10 reps at 40% of 1-RM). Subjects had blood drawn and vastus lateralis MB's taken PRE and POST ( $\sim 120$  min) exercise. Interstitial fluid (ISF) from MD catheters in the vastus lateralis was collected for 60 min PRE ( $\sim 60$  min pre) and 60 min POST ( $\sim 60$ - $\sim 120$  min post) exercise, and was corrected for ethanol relative recovery. Serum and ISF free IGF-I concentrations were measured *via* ELISA, while MB's were analyzed for IGF-I mRNA (qRT-PCR) and protein (immunoblot). To make comparisons between varying units of biological samples, data analysis was performed on the POST vs. PRE fold change.

**RESULTS:** Raw serum free IGF-I concentrations trended to significantly increase PRE to POST ( $1.0 \pm 0.6$  to  $1.2 \pm 0.6$  ng/mL;  $p=0.06$ ), while MD free IGF-I concentrations did not change ( $11.2 \pm 8.6$  to  $15.0 \pm 10.0$  ng/mL;  $p=0.19$ ). The gradient difference between MD and serum IGF-I was more than 25-fold, but did not change PRE to POST exercise ( $p=0.65$ ). When expressed as fold change relative to PRE, only serum IGF-I trended to significantly increase  $\sim 120$  min POST ( $1.2 \pm 0.2$  fold change;  $p=0.06$ ), while fold changes of IGF-I in the other biocompartments were not altered following exercise (MD:  $1.8 \pm 1.5$ , mRNA:  $8.9 \pm 15.5$ , MB:  $0.9 \pm 0.4$ ;  $p \geq 0.2$ ).

**CONCLUSION:** Trends for increased circulating free IGF-I observed  $\sim 120$  min post-plyometric exercise were not accompanied by significant local IGF-I increases in muscle ISF, mRNA, or protein. However, the difference between ISF IGF-I and circulating IGF-I (ISF/serum ratio of  $>25$ -fold), a gradient higher than previously reported, suggests that conventional measures of IGF-I (serum) may not reflect expected local observations in muscle.

(No relationships reported)

Glycolysis dominates energy provision in long sprint events like 200 to 400 m running, 50 m swimming, 500 m speed skating or short term flat out testing like the Wingate Anaerobic Test (WAnT). High glycolytic rates lead to the accumulation of lactate and a drop in pH with an impeding effect on glycolytic key enzymes. After bicarbonate ingestions an increase in minimum power has been reported in the WAnT. However, many athletes are reluctant to use this legal ergogenic aid because it is ingested 2 to 3 hours pre exercise and may also cause performance detrimental side effects like severe gastrointestinal distress and diarrhea.

**PURPOSE:** To examine the effect of a controlled hyperventilation-induced hypocapnic alkalosis (HYP) on WAnT performance and metabolism.

**METHODS:** Ten male subjects (age:  $26.6 \pm 4.9$  yrs, height:  $184.4 \pm 6.1$  cm, body mass:  $81.0 \pm 7.2$  kg) performed a WAnT after a standardised preparation without (CON) or with HYP in randomised order. Mechanical power ( $P_{\text{mech}}$ ), blood lactate concentration (BLC) and acid base status and oxygen uptake were analysed.

**RESULTS:** HYP decreased ( $p < 0.05$ )  $p\text{CO}_2$  ( $22.5 \pm 1.6$  vs.  $40.5 \pm 2.8$  mmHg) and increased ( $p < 0.05$ ) pH ( $7.61 \pm 0.03$  vs.  $7.41 \pm 0.01$ ) pre WAnT. Average  $P_{\text{mech}}$  ( $713.5 \pm 43.9$  vs.  $681.1 \pm 40.8$  W), maximum BLC ( $15.2 \pm 2.0$  vs.  $14.4 \pm 1.9$  mmol  $\text{L}^{-1}$ ) and the increase in  $p\text{CO}_2$  during WAnT ( $14.7 \pm 3.3$  vs.  $3.5 \pm 2.7$  mmHg) were higher ( $p < 0.05$ ), minimum pH ( $7.16 \pm 0.03$  vs.  $7.15 \pm 0.02$ ) was unchanged, and oxygen uptake during WAnT ( $867 \pm 191$  vs.  $940 \pm 184$  ml) was lower ( $p < 0.05$ ) at HYP than at CON.

**CONCLUSIONS:** Controlled hyperventilation-induced hypocapnic alkalosis increased WAnT performance based on an increase in the glycolytic energy, which is higher than a corresponding decrease in aerobic energy.

(No relationships reported)

Exercise adherence has typically been determined only from attendance records, ignoring exercise intensity and duration.

**PURPOSE:** Develop and validate an exercise adherence summary score (the heart rate physical activity score: HRPAS) that includes exercise intensity, duration and frequency and is suitable for use in large field studies.

**METHODS:** Data were collected over four years of an exercise intervention study (TIGER Study) using computerized heart rate monitors (Polar) to measure exercise heart rate, duration and frequency. The 1,459 participants who enrolled in the study were young college-age adults ( $21.7 \pm 4.5$  y) with an average BMI of  $26.5 \pm 6.2$ , sedentary (estimated  $\text{VO}_{2\text{max}} = 38.2 \pm 7.7$  ml/kg/min), primarily female (60.9%); and racially/ethnically diverse, (Non-Hispanic White [29.2%], African American [28.0%], Hispanic [23.1%], and Asian [7.4%]).

**RESULTS:** A total of 31,308 heart rate monitor observations were recorded during a 15-week intervention of exercise three days per week over four years. Of all observations,

94% were judged to be suitable for analysis. Participants exercised at a mean intensity of 68% of estimated maximum heart rate, and a mean duration of 37 minutes per session. A heart rate physical activity score (HRPAS) was calculated as the product of intensity and duration summed over the total number of workouts. HRPAS was associated with improvements in percent body fat ( $t = -4.46$ ,  $p < 0.001$ ) and estimated  $\text{VO}_2\text{max}$  ( $t = 3.83$ ,  $p < 0.001$ ). For example, an accumulated HRPAS of 1,000 over a 15-week exercise training program was associated with a 2.3% loss of body fat and an increase in  $\text{VO}_2\text{max}$  of 2.7 ml/kg/min.

**CONCLUSIONS:** Heart rate monitoring is practical for use in a large field study and provides an objective measure of exercise adherence that incorporates intensity, duration, and frequency. HRPAS was positively associated with improvements in body fat and aerobic capacity and provides a valid exercise adherence model.

The Physical Activity (PA) Guidelines recommend development of improved objective PA assessment methods to enhance the precision of PA dose exposure estimates. Accelerometers are used to assess PA, but transforming the movement signals into an accurate estimate of energy expenditure remains elusive. Combining a physiological measure known to be affected by exercise to the motion measure from accelerometer estimates may improve prediction of PA energy expenditure.

**PURPOSE:** To determine whether combining accelerometer counts (AC) with measured ventilation (VE) or breathing frequency (BF) improves predicted PA energy expenditure.

**METHODS:** Fourteen (9W,5M) adults completed 3 treadmill (0.67, 1.34, 2.0 m/s) and 2 activities of daily living (sweep, move box). An accelerometer was worn while simultaneously measuring energy expenditure, VE and BF using a portable metabolic system. Energy expenditure was predicted from AC, VE and BF using multiple linear regression. The regression models were evaluated using a 'leave one subject out' cross validation.

**RESULTS:** For all activities, combining AC with VE improved (19%) predicted energy expenditure compared to AC alone. Combining AC with BF also improved predicted energy expenditure (10%). Bias was low for the AC prediction model and AC times VE or BF interaction models, indicating that the error in energy expenditure prediction is mainly due to variability.

Independent Variables	AC	AC,VE & Interaction	AC,BF & Interaction
Root Mean Square Error (METs)	0.913	0.742	0.822
Bias (METs)	-0.007	-0.002	-0.031

**CONCLUSION:** Combining AC with measured VE or BF as predictor variables improved PA energy expenditure estimate. Future research will focus on the development of a device to measure VE and BF combined with accelerometer output to enhance the accuracy of free-living energy expenditure estimates.

**Physical Activity Energy Expenditure Predictions Using Accelerometry And Heart Rate**

Adam P. Carreiro, Cheryl A. Howe, Sarah L. Kozey, Patty S. Freedson, FACSM. University of Massachusetts, Amherst, MA.

Email: acarreir@kin.umass.edu

(No relationships reported)

Accelerometers are commonly used in the quantification of physical activity. The accuracy of this method is inherently limited as it relies on a single physical measure for conversion to a physiological variable in the estimation of physical activity energy expenditure (PAEE). Therefore, the addition of a physiological input, such as heart rate (HR), may improve the accuracy of this conversion.

**PURPOSE:** To assess the benefit of adding heart rate to a linear regression model (LRM; Freedson Equation) on the accuracy of PAEE prediction.

**METHODS:** Thirty-two healthy adults (16 men, age=38.2 ± 12.1 y, BMI=23.2 ± 2.0 kg•m<sup>-2</sup>) completed 6 treadmill activities (TM) at 3 speeds (1.34, 1.56, 2.23 m•sec<sup>-1</sup>) at 0% and 3% grade and 5 self-paced activities of daily living (ADL). Each activity was performed for 7 minutes while wearing an accelerometer, heart rate monitor, and portable metabolic unit. Differences between the criterion and each model were assessed by a repeated measures ANOVA.

**RESULTS:** Overall, predicted PAEE using the HRM was more strongly correlated with the criterion compared to the LRM ( $r=0.86$  and  $0.68$ , respectively). However, accuracy of predicted PAEE, regardless of model, was inconsistent among individual activities independent of PA intensity; HRM PAEE prediction was more strongly correlated for TM at 1.56 m•sec<sup>-1</sup> and 3% grade ( $r=0.75$  HRM,  $r=0.67$  LRM), but LRM was more strongly correlated with PAEE for ascending stairs ( $r=0.79$  LRM,  $r=0.60$  HRM). Overall, differences in PAEE between the criterion and each of the models were not significant among all activities (HRM, adjusted  $p=0.62$ ; LRM, adjusted  $p=0.46$ ). Further, differences between the criterion and both models were not significant for TM (adjusted  $p=0.41$  and adjusted  $p=0.74$ , respectively). Significant differences for ADL were observed between the criterion and LRM (adjusted  $p<0.0001$ ), but not between the criterion and HRM (adjusted  $p=0.26$ ).

**CONCLUSION:** These data suggest the addition of heart rate to a LRM improves accuracy in measurement of PAEE for grouped activities. Further, HRM estimates of PAEE exhibited improved accuracy in the assessment of unstructured activities, which contribute to total daily energy expenditure.

**GPS Watches For Estimating Energy Expenditure And Promoting Physical Activity**

Nobuko Hongu, Barron J. Orr, Jamie M. Wise, Stephanie A. Sanchez, Kristin D. Wisneski, Martha P. Kataura, Martha I. Mosqueda, Scott B. Going. The University of Arizona, Tucson, AZ (Sponsor: Linda K. Houtkooper, Ph.D., R.D., FACSM)

Email: hongu@email.arizona.edu

(No relationships reported)

**PURPOSE:** Recently, global positioning system (GPS) watches have been introduced commercially, transforming frequent measurements of time and location into energy expenditure (EE) estimates (through derivations of distance, speed and pace). Our approach for promoting physical activity (PA) exploits recent innovations in GPS, geographic information systems (GIS), and interactive Internet map services. Our overall aim is to provide opportunities for sustained PA among intervention participants while also engaging those who do not typically participate in the traditional exercise, fitness or PA programs.

**METHODS:** Our work includes validating geospatial technology for measurement of EE and using it to promote PA. For validation, 9 females and 7 males, aged 18-27 years

(BMI 19.1-26.6) wore 4 different GPS watch models and walked at 3 different speeds (3, 5 and 7 km/hr) covering a known distance on a 400-m track. We compared EE measured by each GPS watch to accelerometer estimates (RT3) using mixed-effect linear regression. Through a formative and participatory process, we have also developed an education approach and associated materials designed to encourage PA without PA being the main focus of the project. To test our approach, we introduced GPS, GIS and interactive Internet mapping to groups of adolescents involved in five civic engagement projects.

**RESULTS:** Three GPS units significantly underestimated EE and one significantly overestimated EE compared to accelerometer (24+/-3, 28+/-2, 29+/-3, 85+/-3 kcal vs. 54+/-3 kcal;  $p<0.001$ ). These differences were not significant after adjustment for body weight and walking speeds (-6+/-18, -2+/-18, 0+/-18, 55+/-18 kcal vs. 23+/-18 kcal;  $p>0.2$ ). Use of the technology in non-traditional PA setting led to enhanced levels of PA that youth reported "was fun".

**CONCLUSION:** Commercial GPS watches provide an approximation of EE. They also provide coordinates of activity and points of interest when linked to GIS and web mapping. We found incorporation of the technology into projects not focused on PA per se led to greater PA in youth who were not participants in traditional PA programs.

(No relationships reported)

To design effective weight management programs, there is a need to develop devices that accurately estimate daily physical activity energy expenditure (PAEE). Dual sensor devices that simultaneously measure heart rate and accelerometry, and estimate PAEE via a constrained branched algorithm have recently been developed.

**PURPOSE:** To assess the accuracy achievable by dual sensor device and an unconstrained branched algorithm (BA) assessment of daily-living physical activity energy expenditure (PAEE) within a sedentary population.

**METHODS:** Sedentary men (n=8) and women (n=8) first performed a treadmill calibration protocol, during which heart rate (HR), accelerometry (ACC), and PAEE were measured in 1-minute epochs. From these data, HR-PAEE, and ACC-PAEE regressions were constructed and used in a BA model to predict PAEE from ACC and HR data collected during a subsequent daily-living protocol. We used simulated annealing to optimize the BA parameters, and assessed the stability of the BA parameters by repeating the optimization 50 times to determine the distribution of parameter solutions. Criterion PAEE was measured during both protocols via indirect calorimetry. The accuracy achieved by the BA model was assessed by the root mean square of the difference between model-predicted and criterion PAEE.

**RESULTS:** Unconstrained optimization of BA parameters resulted in accurate estimates of PAEE. For men, estimates using individual calibration were more accurate than estimates using group calibration (1% vs. 5% error, respectively), while the opposite was true for women (14% vs. 7% error, respectively). PAEE estimation accuracy decreased when BA parameters optimized for the opposite sex were used, suggesting that BA parameters are sex-specific. Analyses of BA parameter stability by iterative optimization suggests that ACC and high intensity HR threshold values, as well as weighting of HR and ACC regressions at higher exercise intensities are the strongest determinants of accurate functioning of the algorithm.

**CONCLUSION:** Optimized branched algorithms are superior to other popular analytic techniques for predicting PAEE from HR and ACC in sedentary adults performing activities of daily living.

**Assessment Of Light Activities In Adults Using A Pattern-recognition Activity Monitor**

Miguel A. Calabro, Gregory J. Welk, FACSM, Pedro Silva. Iowa State University, Ames, IA.

Email: mcalabro@iastate.edu

(No relationships reported)

Non-exercise activity thermogenesis (NEAT) is the most variable component of energy expenditure (EE) in humans. The importance of NEAT in human energy balance supports the need for accurate and objective tools to measure light activity EE under free-living conditions. The Sensewear Pro armband (SWA) monitor integrates data from multiple sensors (including heat related sensors) and has potential for assessing the energy cost of light intensity, non-locomotor activities typically labeled as NEAT.

**PURPOSE:** The purpose of the study was to evaluate the accuracy of the SWA monitor for assessing light (fidgeting) activities.

**METHODS:** Fifteen males and 15 females (mean ages: 36.3±9.7 and 40.1±11.5, respectively) completed a resting metabolic rest assessment (RMR) and 4 light intensity activities (sitting, sitting/fidgeting, standing and standing/fidgeting) for intervals of 7 minutes each. Participants wore the SWA monitor and a portable metabolic analyzer (Oxycon Mobile, OM) during the activities. Data from the SWA monitor and the OM were processed on a minute-by-minute basis and merged by time. Percent increase over resting EE was computed for the SWA and OM. T-tests were computed to evaluate the accuracy of group level estimates of EE from the SWA.

**RESULTS:** The percent increases in EE for the 4 activities were as follows: sitting (23.9%), sitting/fidgeting (33.4%), standing (18.2%) and standing/fidgeting (51.3%). The corresponding increases in estimated EE by the SWA were as follows: sitting (6.3%), sitting/fidgeting (39.3%) standing (3.4%) and standing/fidgeting (69.9%). Differences in EE estimation were non-significant for sitting/fidgeting ( $p=0.49$ ) and standing/fidgeting ( $p=0.09$ ), and were significant for sitting ( $p=0.006$ ) and standing ( $p=0.03$ ).

**CONCLUSION:** The results demonstrate that the SWA is able to detect subtle changes in EE during light lifestyle activities. Because participants did not engage in locomotor activities during the protocol, it is likely that the heat flux variables detected the increased EE associated with the fidgeting activities. Additional work is needed to better understand the potential of the SWA for assessing light activities and NEAT.

(No relationships reported)

It is critical that researchers, practitioners, and the public understand the limitations of pedometers as objective measures of physical activity. However, there is limited research on factors that affect pedometer accuracy.

**PURPOSE:** To determine the effect of leg-length, pedometer tilt, sex, and walking speed on the accuracy of a spring-levered pedometer during treadmill walking.

**METHODS:** Twenty-nine men (age: 25.3 +/- 5.8 yr; BMI: 25.6 +/- 2.7 kg/m<sup>2</sup>) and 30 women (age: 21.6 +/- 1.9 yr; BMI: 22.4 +/- 2.3 kg/m<sup>2</sup>) were selected to participate in this study based on having an upper leg-length that was short (< 15%ile), normal (25-75%ile), or long (> 85%ile) relative to sex based on CDC-NHANES reference data. Pedometer tilt angle was measured using a magnetic protractor, with the participant standing in a neutral position. Each participant performed 3 minute walking trials on a treadmill at speeds of 59, 67, 80, 94, 107 m/min and at a self-selected pace (89.2 +/- 9.8 m/min) while wearing a spring-levered pedometer (Yamax Digiwalker SW-701) on the anterior aspect of the waistline. During each walking trial, two observers hand tallied the participant's step count.

**RESULTS:** Pedometer tilt angle was significantly associated with pedometer accuracy at treadmill walking speeds of 59 and 67 m/min ( $r > -0.38$ ,  $p < 0.003$ ), but not at the remaining treadmill speeds. After statistically controlling for the effects of pedometer tilt angle, there were no effects of leg-length ( $F(10, 84) = 0.95$ ,  $p = 0.49$ ) or sex ( $F(5, 42) = 0.80$ ,  $p = 0.47$ ) on pedometer accuracy. Pedometer accuracy significantly improved as walking speed increased ( $F(5, 42) = 5.85$ ,  $p < 0.001$ ). Specifically, the pedometer counted 85.6-93.2% of the observed steps at slower treadmill walking speeds (59 and 67 m/min) and 99.2-100.7% of the observed steps at moderate-to-fast treadmill walking speeds (80-107 m/min).

**CONCLUSION:** Individuals should recognize that more accurate step count data are obtained from spring-levered pedometers when the pedometer is placed in a more upright position on the waistband and when walking at faster paces. Furthermore, leg-length and sex do not affect pedometer accuracy at a range of treadmill walking speeds.

**2030      Board #171      May 28      8:00 AM - 9:30 AM**  
**Making Sense Of Pedometer Instructions**

Kenneth M. Bielak, FACSM, Lorraine S. Wallace, FACSM, Brian K. Linn. *University of Tennessee Graduate School of Medicine, Knoxville, TN.*  
Email: kbielak@utk.edu

(No relationships reported)

Physical activity (PA) is one of the most cost effective means maintaining health and fitness, while minimizing the cost burden of chronic illness. Pedometers are both a convenient and minimally invasive method of measuring PA. Well designed and reading level appropriate instructions accompanying pedometers are paramount in assuring accurate and reliable PA assessments. Unfortunately, disparities between reading demands of typical instructional materials and the actual literacy skills of American adults are well documented in the literature.

**PURPOSE:** To evaluate readability and related features of English-language instructions accompanying pedometers, including reading grade level, dimensions, text point size, use of illustrations, layout/formatting characteristics, and emphasis of key points (e.g., recommendation of 10 000 steps per day).

**METHODS:** We identified and purchased fifteen (n=15) pedometers currently available in the US. Reading grade level was calculated using Flesch Reading Ease (FRE). Text point size was determined by measuring the distance from the ascent line to the descent line with a C-Thru Ruler. Total number of illustrations was tallied. Illustration dimensions were measured to the nearest millimeter. We also assessed layout features using the established User-Friendliness Tool (UFT).

**RESULTS:** FRE scores ranged from 8<sup>th</sup> to 11<sup>th</sup> grade, while text point size averaged 6.9±1.9 (range=4-11). Pedometer instructions averaged 8.7±9.0 (range=0-36) illustrations, most about the size of a US quarter. While most pedometer instructions avoided use of specialty fonts (n=12; 80.0%), most used a minimal amount of white space, making directions difficult to read. Just 4 (26.7%) sets of instructions highlighted the widely established target goal of 10 000 steps per day.

**CONSLUTION:** Pedometer manufacturers should increase the size of instructions, thereby allowing for larger text size and illustrations, and increasing the amount of white space. Making these relatively small formatting changes would ensure that those electing to use a pedometer are able to understand and follow accompanying instructions.

**Validity Of The Walk4life Pedometer Based On Self-reported Mvpa**

Georita M. Frierson, PhD<sup>1</sup>, Merly Mathew, MPH<sup>2</sup>, Tiffany Gearhart, BS<sup>2</sup>, James R. Morrow, Jr., PHD, FACSM<sup>3</sup>. <sup>1</sup>*Southern Methodist University, Dallas, TX.*  
<sup>2</sup>*The Cooper Institute, Dallas, TX.* <sup>3</sup>*University North Texas, Denton, TX.* (Sponsor: James R Morrow, Jr., PhD, FACSM)

Email: frierson@smu.edu

(No relationships reported)

**BACKGROUND:** Physical activity (PA) can be assessed indirectly through self reports (SR) or directly through observation, accelerometry, pedometers, and doubly labeled water. In large epidemiological studies due to economical constraints, pedometers and SRPA are common methods to estimate amount of PA. The Walk4Life MVP pedometer measures steps, distance, total PA time, and MVPA time based on user defined steps per minute (SPM) as a lower limit for MVPA.

**PURPOSE:** To examine the relationship between two similar but different pedometers (Walk4Life and Accusplit Eagle 120 XL;AE) and SRPA data during a 7-day period in women being observed for musculoskeletal injuries in a prospective observational study. Method: Thirty females attended two sessions, 7 days apart. Following session 1, women wore the Walk4Life MVP and AE pedometers (different hips) continuously for 1 week. At session 2, women returned to the orientation site 1 week later and responded to BRFSS PA questions on a secure website as they had been doing for at least the previous 24 weeks. Participants reported days and min per day of moderate and vigorous (separately) PA as well as BRFSS physical activity questions about walking, strengthening activities, and typical work PA.

**RESULTS:** The AE and Walk4Life pedometers were highly correlated (.90;  $p < .001$ ). The average difference between pedometers steps was 175±9,600 (AE = 45,251 ±21,834; MVP = 45,426 ±20,993) across an average of 45,000 steps. SR MVPA and Walk4Life MVP recorded MVPA MET-mins per week correlated .41 ( $p < .03$ ).

**CONCLUSIONS:** The Walk4Life MVP pedometer appears to validly record steps and MVPA minutes when used at the group level. Careful pedometer placement and confirmation of steps should be monitored if individual results are to be utilized as is the case in all pedometer use. The Walk4Life MVP pedometer appears to be an inexpensive, valid alternative to more expensive accelerometers and pedometers.

Bassett, Jr., FACSM<sup>3</sup>, Catrine Tudor-Locke, FACSM<sup>4</sup>, Minsoo Kang<sup>1</sup>. <sup>1</sup>*Middle Tennessee State University, Murfreesboro, TN.* <sup>2</sup>*Case Western Reserve University, Cleveland, OH.* <sup>3</sup>*University of Tennessee, Knoxville, TN.* <sup>4</sup>*Pennington Biomedical Research Center, Baton Rouge, LA.*

Email: tvb2b@mtsu.edu

(No relationships reported)

Many have reported a range of the number of days needed to obtain reliable estimates of physical activity (PA) by examining the influences of many factors. One factor that has not been adequately addressed is the impact that season (i.e., winter, spring, summer) has on the number of days needed for reliable PA.

**PURPOSE:** The purpose of this study was to examine the impact that season has on PA variability in step counts, and based on the type of season, determine the minimum number of days necessary to achieve reliable estimates for step counts.

**METHODS:** Thirty-two participants (ages 18-30 years) wore an Omron pedometer (HJ-720) for 7 consecutive days with a randomly assigned start day during winter, spring, and summer. After the data were screened, mean ± SD for steps/day were computed. Further analysis was done using Generalizability theory approach. Participant (P), Season (S), and Day (D) were considered random facets in a fully crossed design (P x S x D). First a G-study was performed with all seasons together to determine the percentage of variance associated with

each facet and interactions in the model. Following the G-study, the data were analyzed based on each season through D-studies to determine the minimum number of days of data collection to achieve a desirable reliability coefficient ( $G \geq .80$ ).

**RESULTS:** The overall average step-count, considering all seasons, was  $6,937 \pm 3,847$ , and the averages for winter, spring, and summer were  $7,124 \pm 4,122$ ,  $7,758 \pm 4,304$ , and  $5,930 \pm 3,115$  steps/day, respectively. The results from the G-study showed that P accounted for 28% of the variance, S alone and the interaction (P x S) accounted for 8% of the variance, and D had little effect on the total variance. The interaction between P x S x D and unidentified error accounted for the majority of the variance (62%). Follow-up D-Studies for each season separately demonstrated that a minimum of 10, 7, and 7 days were necessary to achieve a G-coefficient  $\geq .80$  during the winter, spring, and summer respectively.

**CONCLUSIONS:** During the winter season, a larger amount of days was needed to achieve a desirable reliability level for step-count data. It appears that 7 days of data collection might not guarantee reliable estimates of step counts. Researcher and practitioners should be aware of this when making data collection plans.

**School And Class-level Intra-class Correlations For Pedometers In 3<sup>rd</sup> Grade Children**

Lauren A. Grieco, Esbelle Jowers, Shanna E. Smith, John B. Bartholomew, FACSM. *University of Texas at Austin, Austin, TX.*  
Email: lgrieco@mail.utexas.edu  
(No relationships reported)

Much of children's activity occurs at school. Given the unique environmental characteristics of schools, this creates a degree of shared variance amongst the children that violates the assumption of independence underlying the General Linear Model. The degree of shared variance at the nested level can be calculated through intra-class correlations (ICCs). As random assignment often occurs at the school level, these ICCs are critical in determining the number of schools required for adequate power. Studies have published ICCs at the school-level for accelerometers. Surprisingly, there is relatively little data on ICCs for pedometers. Nor is there much information for ICCs at the class-level. This is problematic as classroom teachers implement many interventions, which creates a second level of nesting (i.e. child within classes within schools) to be modeled.

**PURPOSE:** ICCs were calculated at the school (n=8), classroom (n=45) and within student levels (n=720) to determine if there was significant shared variance at each level of analysis.

**METHODS:** In-school steps were collected through pedometer counts over 5 school days. Research staff placed an OMRON HJ 104 pedometer on the hip of each child within 30 min of the onset of the school day, along with their removal within 30 min of dismissal. These procedures were repeated 6 months later.

**RESULTS:** ICCs were calculated as the amount of variance due to a specific level of the model (e.g., schools) by the total amount of variance (i.e., the sum of the variances from the school, teacher, child, and within-child levels of the model). The ICCs for the pedometers were: 0.06 for schools, 0.06 for teachers, and 0.27 for the students. These are in-line with other school-based data for accelerometers that found ICCs of .057 for schools during 7-day assessments.

**CONCLUSION:** Both the classroom and the school resulted in significant shared variance for the children nested within those levels. Thus, statistical models should be designed to model variance at both the classroom and school-levels. Interestingly, the magnitude of these effects was similar for studies of accelerometry. Thus, regardless of the mode of assessment, children show a consistent degree of shared variance at the school-level.

**3,500 Daily Steps Increment Enhances Exercise Tolerance At Anaerobic Threshold In Sedentary Men**

Luiz Guilherme G. Porto<sup>1</sup>, Keila E. Fontana<sup>2</sup>, Guilherme E. Molina<sup>2</sup>, Guilherme Rocco<sup>2</sup>, Luiz Fernando Junqueira Jr.<sup>3</sup>. <sup>1</sup>*Cardiovascular Laboratory - University of Brasilia and Brasilia University Center - UniCEUB, Brasilia, Brazil.* <sup>2</sup>*University of Brasilia Faculty of Physical Education, Brasilia, Brazil.* <sup>3</sup>*Cardiovascular Laboratory - University of Brasilia Faculty of Medicine, Brasilia, Brazil.*  
Email: luizporto@unb.br  
(No relationships reported)

Walking is the most feasible way of reaching the public health recommendations in physical activity (PA) programs. Pedometers are valid and widely used tools to evaluate patterns of walking. The ventilatory anaerobic threshold (AT) by respiratory gas exchange protocol may be employed as a marker of metabolic efficiency at a sub-maximal level of PA.

**PURPOSE:** To investigate the effectiveness of a pedometer-measured 3,500 steps/day increment on the improvement of physical performance at the AT.

**METHODS:** Nineteen healthy sedentary men, aged 19 - 46 years, clinically normal, with mean  $\pm$  sd BMI equal to  $24.6 \pm 2.7$  kg/m<sup>2</sup>, wore a Yamax-SW700 pedometer for 2 weeks, without any PA change, in order to quantify their habitual daily steps at baseline. After this control period, the new daily steps target was calculated by adding 3,500 steps to the baseline mean of week days. Thereafter, the subjects were submitted to the first cardiopulmonary exercise stress test (CPX) for determination of the AT. Following the first CPX, volunteers were oriented to achieve their new daily step target during 3 weeks (intervention phase). At the end of this period, a second CPX was performed to evaluate the effect of the increased number of daily steps on exercise tolerance at AT. The visual identification of AT in each CPX was done solely by one expert author, blinded to the volunteer identity and to the order of the CPX. Medians of weekends and week days steps counts were pair-wised compared by the Wilcoxon test. Differences were considered significant when a two-tailed "p" value was less than 5% ( $P < 0.05$ ).

**RESULTS:** Median (interquartile range) of daily steps in the intervention phase was 11,772 (8,998 - 18,620), whereas at baseline it was 7,295 (4,700 - 14,752) ( $p=0.0001$ ). Time until AT onset during CPX was higher after (359s; 179-521s) than before the increment of daily steps (340s; 208-436s) ( $p=0.027$ ). The distance attained at AT was higher after (398,6 m; 165,6 - 637,5 m) than before the intervention (372,2 m; 197,8 - 528,8 m).

**CONCLUSION:** The accumulated increment of 3,500 steps per day above the habitual pattern, during three weeks, was effective for improving exercise tolerance at AT, and thus increased the physical capacity, in healthy sedentary men.

**Influence of Pedometer Tilt Angle On Step Counting Validity During Controlled Treadmill Walking Trials**

Melissa Dock, Robert Pickels, Daniel P. Heil, FACSM. *Montana State University, Bozeman, MT.*  
Email: melissadock@gmail.com  
(No relationships reported)

Pedometers are assessment tools frequently used to monitor walking-related physical activity patterns of overweight and obese populations. However, there is a known association between increasing body mass index (BMI) and decreasing pedometer accuracy that may be attributed to pedometer tilt angle (TA). Currently, the specific TA where pedometers fail to count steps accurately is unclear.

**PURPOSE:** This study tested two popular pedometer mechanisms, accelerometry-(ACC) and pendulum(PND)-based, to determine the specific TA(s) where the pedometers failed to count steps accurately.

**METHODS:** Twenty subjects (10 men, Mean $\pm$ SD: 26 $\pm$ 4.5yrs, 75.7 $\pm$ 5.4 kg, 22.7 $\pm$ 1.6 kg/m<sup>2</sup> BMI; 10 women: 21.6 $\pm$ 3yrs, 56.7 $\pm$ 6.7 kg, 20.5 $\pm$ 1.8 kg/m<sup>2</sup> BMI) walked two sets of 21 trials at a combination of treadmill speeds (67.0, 80.4, 93.8 m/min) and TAs (-30,-20,-10, 0,+10,+20,+30°) while wearing two pedometers: 1) Experimental pedometer was attached to custom-built gimbal for altering TA; 2) Control pedometer was attached at TA=0°. Positive TAs indicated an anterior rotation about a medial-lateral axis while

negative TAs indicated a posterior rotation. Pedometers were worn on the left and right hips just anterior to the iliac crest in line with the mid-axillary line of the thigh. Mean step counts from the experimental pedometers (STEP<sub>E</sub>) were compared to the control pedometer (STEP<sub>C</sub>) by calculating the difference (DSTEP = STEP<sub>C</sub>-STEP<sub>E</sub>) and comparing the DSTEP values within pedometer mechanisms using 3-factor repeated measures ANOVA at a 0.05 alpha level.

**RESULTS:** Mean DSTEP values differed significantly by TA and speed. Specifically, mean DSTEP for the ACC pedometers differed significantly from 0 when TA was equal to  $\pm 10^\circ$  and treadmill speed was 67.0 m/min,  $\pm 20^\circ$  and  $\leq 80.4$  m/min and  $\pm 30^\circ$  and  $\leq 93.8$  m/min. Mean DSTEP for the PND pedometers were significantly different than 0 when tilt angle was equal to  $+10^\circ$  and treadmill speed was  $\leq 80.4$  m/min,  $\geq \pm 20^\circ$  and all treadmill speeds and  $-10^\circ$  and all treadmill speeds.

**CONCLUSIONS:** Increasing TA in either direction caused a decrease in pedometer accuracy for both pedometer mechanisms, although the ACC pedometers were less affected. Negative TAs had less effect on pedometer accuracy than positive TAs, and the combination of slower speeds and increasing positive TA had the greatest impact on step counting accuracy.

**Effects Of Seasonal And Monthly Variability On Measurement Of Pedometer Data**

Minsoo Kang<sup>1</sup>, David R. Bassett, FACSM<sup>2</sup>, Catrine Tudor-Locke, FACSM<sup>3</sup>, Tiago V. Barreira<sup>1</sup>, Barbara Ainsworth, FACSM<sup>4</sup>. <sup>1</sup>Middle Tennessee State University, Murfreesboro, TN. <sup>2</sup>The University of Tennessee, Knoxville, TN. <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>4</sup>Arizona State University, Mesa, AZ.  
Email: mkang@mtsu.edu  
(No relationships reported)

**PURPOSE:** The purpose of the study was to attempt to reduce measurement error in objectively measured physical activity (i.e., pedometer-determined steps per day) by controlling (a) the length of the measurement period and (b) the season or month of the year in which sampling was conducted.

**METHODS:** This was a secondary analysis of an existing data set of 23 individuals (7 men, 16 women; age =  $38 \pm 9.9$  years) residing in South Carolina and Tennessee. The step-count data were collected over a one-year period using Yamax SW 200 pedometers. For controlling seasons, the data set was separated by the four seasons, and the measurement periods of different lengths (2, 3, 4, 5, 6, 7, and 14 days) were randomly selected 10 times during each season. A similar approach was done with a division by months. For each month, a total of 10 step-count measurements were randomly selected from each of the following measurement periods: 2, 3, 4, 5, 6, 7, 8, 9, and 10 days. To determine valid estimates of step-count measurement, absolute percentage error (APE) was calculated. The year-round average was considered as a criterion measure. A smaller APE represents a better estimate of yearly physical activity.

**RESULTS:** The results by seasons demonstrated that spring and fall had the lowest APE values on six out of seven measurement periods. The difference in APE values among seasons, however, was not substantial. Except for the 2-day measurement period, there was at most a 3% difference in APE values across the four seasons at all measurement periods. From the month analysis, May had the lowest APE values (e.g., 7 days at 10.2%) on eight out of nine measurement periods. The months that include season changes (March, June, September, and December) presented the highest APE values. Those months showed APE values for the 7-day measurement period that were up to 9.7% higher than May.

**CONCLUSIONS:** The difference in APE values among seasons was trivial; however, they varied among different months. Targeting the data collection during the months that include no season changes (e.g., April and May) may reduce measurement error and provide more accurate yearly step-count estimates.

**Comparison Of Physical Activity Measurement Methods In Preadolescent Girls**

Melanie D. Hingle<sup>1</sup>, Scott B. Going<sup>2</sup>. <sup>1</sup>ARS-USDA Children's Nutrition Research Center, Houston, TX. <sup>2</sup>University of Arizona, Tucson, AZ.  
Email: hingle@bcm.edu  
(No relationships reported)

Children should accumulate at least 60 minutes of MVPA daily in order to achieve benefits. Valid PA measurement in children is necessary to establish dose-response associations with health outcomes and evidence-based recommendations. Self-report remains the most efficient way to obtain population-level data despite its limitations. Measurement of average steps/d using a pedometer presents an opportunity to evaluate convergent validity of self-report data with an objective measure.

**PURPOSE:** To evaluate convergent validity of pedometer steps with two PA self-reports and to test whether these instruments identify girls who meet PA guidelines.

**METHODS:** 201 4th and 6th grade girls wore pedometers for 7 continuous days and completed 2 self-administered PA recalls (PYPAC and 3DPAR). Girls were categorized as meeting or failing to meet PA recommendations based on average pedometer step counts. Total PA score (measured by PYPAC) and METS/day (measured by 3DPAR) were estimated for each girl. Pearson correlations were used to describe relationships between steps and physical activity scores for each instrument. Independent t-tests were used to test whether PA measured by recall differed between girls who met and did not meet guidelines.

**RESULTS:** 72% of 4th graders and 53% of 6th graders met recommended PA based on pedometer cut-points. In 4th graders, pedometer steps were positively associated with METS/d ( $r=0.18$ ,  $p<0.10$ ) but not General Activity Score ( $r^2=-0.02$ ,  $p=0.88$ ). In 6th graders, steps were positively associated with General Activity Score ( $r^2=0.13$ ,  $p=0.20$ ) but not METS/d ( $r^2=0.05$ ,  $p=0.64$ ); In 4th graders, there were no significant differences in either METS/d or General Activity Score based on pedometer groups, while in 6th graders, General Activity Scores were significantly higher for girls who met recommendations than those who did not ( $p<0.05$ ); there was no difference in METS/d between groups.

**CONCLUSIONS:** Pedometer step counts were weakly correlated with PA levels estimated using two self-report instruments; these relationships differed by grade. The PYPAC identified 6th grade girls who met physical activity guidelines, but not 4th graders. The 3DPAR was not able to distinguish between girls who did or did not meet guidelines. More research is needed to identify valid and reliable PA measures.

**2038 Board #179 May 28 8:00 AM - 9:30 AM**  
**Minute-by-minute Stepping Rate Of Daily Physical Activity In Normal And Overweight Adults**

Makoto Ayabe<sup>1</sup>, Junichiro Aoki<sup>2</sup>, Hideaki Kumahara<sup>1</sup>, Eiichi Yoshimura<sup>1</sup>, Sakiko Matono<sup>1</sup>, Takuro Tobina<sup>1</sup>, Keizo Anzai<sup>1</sup>, Akira Kiyonaga<sup>1</sup>, Hiroaki Tanaka<sup>1</sup>. <sup>1</sup>Fukuoka Univ., Fukuoka, Japan. <sup>2</sup>Juntendo Univ., Chiba, Japan.  
Email: ayabemakoto@adm.fukuoka-u.ac.jp  
(No relationships reported)

**PURPOSE:** The purpose of the present investigation was to compare the levels of physical activity (PA) based on the minute-by-minute stepping rate under free-living conditions between normal weight (NW) and overweight and obese (OB) individuals.

**METHODS:** A total 40 volunteers participated in the present investigation. These participants were divided into NW or OB according to the body mass index ( $<25$  kg/m<sup>2</sup> or  $\geq 25$  kg/m<sup>2</sup>). All participants wore a pedometer with a uni-axial accelerometer (Lifecorder-EX 4sec, Kenz, Japan) for 7 days continuously. The LC determined the number of steps and time spent in PA at  $<100$ , 100 to 129, 130 to 159,  $\geq 160$  steps/min according to the minute-by-minute stepping rate.

**RESULTS:** The time spent in PA at  $<100$  steps/min in the OB and NW subjects was  $267 \pm 85$  and  $300 \pm 81$  min/day ( $p = 0.221$ ). The time spent in PA at 100 to 129 steps/min in the OB and NW subjects was  $14 \pm 9$  and  $23 \pm 15$  min/day ( $p = 0.035$ ). The time spent in PA at 130 to 159 steps/min in the OB and NW subjects was  $0.8 \pm 1.3$  and  $5.8 \pm 6.9$  min/day ( $p = 0.003$ ). The time spent in PA at  $\geq 160$  steps/min in the OB and NW subjects was  $0.0 \pm 0.1$  and  $0.7 \pm 1.3$  min/day ( $p = 0.018$ ). The proportion of PA at  $<100$  steps/min in the

OB and NW subjects was  $95 \pm 4\%$  and  $91 \pm 5\%$  ( $p = 0.010$ ). The proportion of PA at 100 to 129 steps/min in the OB and NW subjects was  $5 \pm 3\%$  and  $7 \pm 4\%$  ( $p = 0.1316$ ). The proportion of PA at 130 to 159 steps/min in the OB and NW subjects was  $0.3 \pm 0.5\%$  and  $1.9 \pm 2.4\%$  ( $p = 0.007$ ). The proportion of PA at  $\geq 160$  steps/min in the OB and NW subjects was  $0.0 \pm 0.0\%$  and  $0.3 \pm 0.6\%$  ( $p = 0.031$ ).

**CONCLUSIONS:** These results indicate that the OB subjects spent a significantly shorter time in PA at 100 steps/min or a faster stepping rate. These findings constitute the original aspect of the present investigation where the OB subjects had a lower daily average stepping rate due to a shorter time of PA at  $\geq 100$  steps/min and a larger proportion of PA at  $< 100$  steps/min.

### 2039 Board #180 May 28 9:00 AM - 10:30 AM

#### Perceived Exertion During Acute Resistance Exercise Performed At Self-selected And Imposed Loads In Trained Women

Brian C. Focht, FACSM<sup>1</sup>, Matt Garver<sup>2</sup>, Josh Cotter<sup>2</sup>. <sup>1</sup>University of Delaware, Newark, DE. <sup>2</sup>The Ohio State University, Columbus, OH.

(No relationships reported)

Previous research has demonstrated that untrained women report significantly lower ratings of perceived exertion (RPE) during self-selected (SS) load bouts of acute resistance exercise (RE) when compared to sessions performed using typically imposed RE loads. However, the extent to which RPE responses differ between SS and imposed-load bouts of acute RE among trained women remains unclear.

**PURPOSE:** The purpose of this investigation was to examine RPE responses to self-selected and imposed-load bouts of acute RE in a sample of trained women.

**METHODS:** Twenty-one ( $M$  age = 23 years) recreationally-trained women completed acute bouts of RE using loads of 40% of one repetition maximum (1RM), 70% of 1RM, and a self-selected (SS) load. RE consisted of 3 sets of 10 repetitions for each of the leg extension (LE), leg curl (LC), lat pull-down (LPD), and chest press (CP) exercises. Assessments of RPE were obtained immediately after each set during the 3 RE conditions.

**RESULTS:** Results of separate 3 (Condition)  $\times$  3 (Set) repeated measures ANOVAs yielded significant main effects for Condition ( $p < 0.01$ ) and Set ( $p < 0.01$ ) for each exercise and significant Condition  $\times$  Set interactions ( $p < 0.05$ ) for both the LPD and CP exercises. Post-hoc analyses revealed that RPE increased from Set 1 to Set 3 for the CP and LPD exercises in both the 70% 1RM and SS conditions but did not increase across sets in the 40% condition. RPE were also found to be significantly higher in the 70% condition relative to the SS or 40% conditions and RPE reported during SS condition were higher when compared to the 40% condition for all exercises.

**CONCLUSIONS:** The present results suggest that RPE reported during SS bouts of RE differ significantly from RPE observed during imposed-load bouts of RE. Although evidence addressing RPE responses to acute RE remains limited, effort sense experienced during acute RE may serve as a salient determinant of the adoption and maintenance of regular RE behavior. Accordingly, the differences in RPE during acute RE observed in the present investigation may have valuable practical implications for the prescription of RE participation.

### 2040 Board #181 May 28 9:00 AM - 10:30 AM

#### Response Normalized Omni Rpe At The Ventilatory Breakpoint In Young Adult Males And Females

Suzette R. Bossart, Ryan J. Mays, Christina M. Ledezma, Natalie A. Donnelly, Fredric L. Goss, FACSM, Elizabeth F. Nagle, FACSM, Robert J. Robertson, FACSM. University of Pittsburgh, Pittsburgh, PA.

Email: srb18@pitt.edu

(No relationships reported)

Response normalized ratings of perceived exertion (RPE) corresponding to the ventilatory breakpoint ( $V_{pt}$ ) during cycling have been identified in children using the Children's OMNI Scale of Perceived Exertion. However, a normalized response has not been examined in adults using the OMNI-Cycle RPE Scale.

**PURPOSE:** To identify a response normalized RPE-Overall (O), RPE-Legs (L), and RPE-Chest/Breathing (C) corresponding to the  $V_{pt}$  in recreationally active males and females.

**METHODS:** Thirty-one recreationally active ( $< 150$  min $\cdot$ wk $^{-1}$  activity) males ( $n = 21$ ,  $20.7 \pm 2.6$  yrs) and females ( $n = 10$ ,  $21.4 \pm 2.6$  yrs) completed a load-incremented cycle ergometer protocol to measure  $VO_{2peak}$ . The Adult OMNI-Cycle RPE Scale was employed to measure RPE-O, L and C during the last 30 s of each exercise minute. The  $V_{pt}$  was determined for each subject as the % $VO_{2peak}$  at which  $Ve:VO_2$  increased without an accompanying increase in  $Ve:VCO_2$ . RPE-O, L and C corresponding to the  $V_{pt}$  were identified using individual linear regression analysis. All data are presented as means  $\pm$  SD.

**RESULTS:** Mean  $VO_{2peak}$  was  $42.9 \pm 6.7$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$  for males and  $34.8 \pm 5.3$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$  for females. Mean  $V_{pt}$  for males and females corresponded to  $70.9 \pm 6.9\%$  and  $74.4 \pm 4.9\%$  of  $VO_{2peak}$  and  $83.9 \pm 5.0\%$  and  $86.2 \pm 4.4\%$  of peak heart rate, respectively. Mean response normalized RPEs corresponding to the  $V_{pt}$  during cycle ergometry were: RPE-O =  $5.5 \pm 1.2$ , RPE-L =  $6.0 \pm 1.1$ , RPE-C =  $5.4 \pm 1.2$  for males and RPE-O =  $6.1 \pm 1.0$ , RPE-L =  $6.2 \pm 1.1$ , RPE-C =  $6.2 \pm 1.3$  for females. There was no interaction effect of gender and rating site. However, a rating site main effect was observed when RPE data were analyzed for the combined male and female groups. Analysis of response normalized values at the  $V_{pt}$  indicated that RPE-L  $>$  RPE-O ( $p < 0.05$ ) and RPE-L  $>$  RPE-C ( $p < 0.01$ ).

**CONCLUSIONS:** Response normalized OMNI RPEs at the  $V_{pt}$  were identified for undifferentiated and differentiated perceptual reports for adult males and females during cycling. These normalized responses were consistent with those reported previously for children. A normalized RPE- $V_{pt}$ : (1) reduces the need for pre-participation testing to prescribe exercise intensity (i.e.  $V_{pt}$ ) that provides an overload stimulus for cardiorespiratory training and (2) facilitates exercise intensity self-regulation by recreationally active young adults.

### 2041 Board #182 May 28 9:00 AM - 10:30 AM

#### Effect Of Adiposity On Physiological, Perceptual, And Affective Responses During Treadmill Walking At Self-selected Pace

Sergio G. DaSilva<sup>1</sup>, Cosme C. Buzzachera<sup>2</sup>, Hassan M. Elsangedy<sup>1</sup>, Kleverton Krinski<sup>1</sup>, Heriberto Colombo<sup>1</sup>, Raul osiecki<sup>1</sup>, Wagner Campos<sup>1</sup>, Carlo Baldari<sup>2</sup>, Laura Guidetti<sup>2</sup>, Fredric L. Goss, FACSM<sup>3</sup>. <sup>1</sup>Federal University of Parana, Curitiba, Brazil. <sup>2</sup>University of Rome, Rome, Italy. <sup>3</sup>University of Rome, Pittsburgh, PA.

Email: sergiogregorio@ufpr.br

(No relationships reported)

**PURPOSE:** To investigate the influence of adiposity on physiological, perceptual, and affective responses during treadmill walking at a self-selected pace.

**METHODS:** Forty-five previously sedentary women were assigned to one of three groups according to their percentage of body fat (% body fat): Low Tertile (LT,  $n = 15$ , age:  $28.1 \pm 5.7$  yr, % body fat:  $23.8 \pm 2.2$ ,  $VO_{2max}$ :  $39.7 \pm 6.7$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ), Medium Tertile (MT,  $n = 15$ , age:  $28.8 \pm 6.4$  yr, % body fat:  $28.5 \pm 0.8$ ,  $VO_{2max}$ :  $34.9 \pm 4.5$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ), and High Tertile (HT,  $n = 15$ , age:  $32.4 \pm 4.8$  yr, % body fat:  $32.1 \pm 2.0$ ,  $VO_{2max}$ :  $30.3 \pm 4.2$  ml $\cdot$ kg $^{-1}\cdot$ min $^{-1}$ ). Each participant performed an incremental treadmill test to

determine  $\text{VO}_{2\text{max}}$  and a 20-min treadmill walking bout at a self-selected pace. During 20-min of treadmill walking at a self-selected pace, the physiological (oxygen uptake,  $\text{VO}_2$ ) responses were recorded continuously. The perceptual (Borg-RPE for the overall body, 6-20) and affective (Feeling Scale, Hardy & Rejeski, 1989) responses were determined every 5 min throughout the test. A one-way ANOVA (adiposity) was used to examine group differences in physiological, perceptual, and affective responses during 20-min of treadmill walking at a self-selected pace.

**RESULTS:** The preferred walking pace did not differ between the groups ( $1.63 \pm 0.19$ ,  $1.60 \pm 0.20$ ,  $1.47 \pm 0.18 \text{ m}\cdot\text{sec}^{-1}$  for LT, MT, and HT, respectively), whereas the  $\% \text{VO}_{2\text{max}}$  was significantly higher ( $P < .05$ ) in HT ( $61.8 \pm 8.6\%$ ) compared to MT ( $55.8 \pm 6.8\%$ ) and LT ( $52.8 \pm 6.8\%$ ). The perceptual ( $11.8 \pm 1.5$ ,  $12.2 \pm 1.3$ , and  $11.7 \pm 1.1$ ) and affective ( $2.36 \pm 1.33$ ,  $1.80 \pm 1.74$ , and  $1.85 \pm 1.82$  for LT, MT, and HT, respectively) responses were similar between the groups.

**CONCLUSIONS:** The findings of this study indicate that adiposity influences physiological, but not perceptual and affective responses of previously sedentary women during treadmill walking at a self-selected pace.

This study was supported in part by grants from the Istituto per il Credito Sportivo (C. F. Buzzachera) and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (H. M. Elsangedy and K. Krinski).

**2042 Board #183 May 28 9:00 AM - 10:30 AM**  
**Cross-validation Of  $\text{VO}_{2\text{peak}}$  Prediction Equations Using Submaximal Omni Rpe Responses**

Ryan J. Mays, Michael Gallagher, Jr., Luke Haile, Fredric L. Goss, FACSM, Elizabeth F. Nagle, FACSM, Robert J. Robertson, FACSM. *University of Pittsburgh, Pittsburgh, PA.*

Email: rjm44@pitt.edu

(No relationships reported)

Ratings of perceived exertion (RPE) derived from the Adult OMNI RPE Cycle Scale have been used to develop statistical models to predict  $\text{VO}_{2\text{peak}}$  from submaximal cycle ergometer responses in college age males and females. However, cross-validation of these prediction models in an independent cohort of subjects has not been examined.

**PURPOSE:** The purpose of this study was to cross-validate statistical models for prediction of  $\text{VO}_{2\text{peak}}$  using RPE estimated during submaximal cycle ergometry.

**METHODS:** Recreationally active ( $< 150 \text{ min} \cdot \text{week}^{-1}$ ) males ( $n = 21$ ;  $20.6 \pm 0.58 \text{ yrs}$ ) and females ( $n = 9$ ;  $21.1 \pm 0.84 \text{ yrs}$ ) completed a load-incremented cycle ergometer protocol. Predictor variables of RPE-Overall (O), Legs (L), Chest/Breathing (C) and heart rate (HR) were recorded during each test stage. Data from the first three stages were entered into the prediction models.  $\text{VO}_{2\text{peak}}$  was estimated using previously developed 3 stage statistical models for each of the three RPE predictors and the HR predictor.

**RESULTS:** Mean measured and predicted  $\text{VO}_{2\text{peak}}$  ( $\text{L} \cdot \text{min}^{-1}$ ) for the 3 stage models are shown in Table 1. There were no significant differences ( $p > 0.05$ ) between measured and predicted  $\text{VO}_{2\text{peak}}$  for any of the models within either gender.

Table 1. Measured and predicted $\text{VO}_{2\text{peak}}$ (Data: mean + SE).					
Gender	Measured	RPE-O	RPE-L	RPE-C	HR
Males	$3.12 \pm 0.10$	$2.98 \pm 0.08$	$2.96 \pm 0.08$	$2.95 \pm 0.06$	$3.05 \pm 0.05$
Females	$2.06 \pm 0.04$	$2.06 \pm 0.04$	$2.01 \pm 0.06$	$2.01 \pm 0.05$	$2.18 \pm 0.06$

**CONCLUSION:** Previously developed statistical models for prediction of  $\text{VO}_{2\text{peak}}$  based on 3 stage submaximal cycle RPE responses are valid for use in recreationally active college age males and females.

**Perception Of Walking Effort Predicts One-year Weight Regain**

David Brock<sup>1</sup>, Paula Chandler-Laney<sup>2</sup>, Jessica Alvarez<sup>2</sup>, Barbara Gower<sup>2</sup>, Glenn Gaesser, FACSM<sup>3</sup>, Gary Hunter, FACSM<sup>2</sup>. <sup>1</sup>*University of Vermont, Burlington, VT.* <sup>2</sup>*University of Alabama at Birmingham, Birmingham, AL.* <sup>3</sup>*Arizona State University, Mesa, AZ.*

Email: david.brock@uvm.edu

(No relationships reported)

Background: Participation in physical activity is a critical factor in maintaining long-term weight loss. Perception of exercise difficulty could in part explain differences in recidivism after weight loss. We tested the hypothesis that inter-individual variation in perceptual responses to exercise was related to weight regain following weight loss.

**METHODS:** One-hundred and six weight-reduced premenopausal women (BMI  $< 25$ ) were used in this analysis. Submaximal and maximal fitness testing were performed after the completion of an investigator-administered weight loss program to determine physiological and perceptual responses to a standardized walk test. During the walk test, heart rate, ventilation, and respiratory exchange ratio data were summed as an index of physiological exertion and rating of perceived exertion was concurrently recorded as an index of perceived effort. Body composition was assessed following a subsequent one-year free-living period.

**RESULTS:** Over the one-year follow-up period, participants who had a greater relative perception of effort during the walk test regained a significantly greater amount of weight at one year ( $6.5 \pm 0.51 \text{ kg}$ , 95 % CI 5.48 to 7.50 kg,  $p = 0.008$ ) compared to participants whose perception of effort was more congruous with measured physiological effort ( $4.7 \pm 0.41 \text{ kg}$ , 95 % CI 3.90 to 5.50 kg).

**CONCLUSIONS:** These findings provide support for our hypothesis that individuals who over-perceive exercise exertion regain more weight following weight loss. This finding may have considerable practical application for implementing more precise treatment strategies to prevent recidivism after the completion of a successful weight loss program.

**A Comparison Of Subjective And Objective Measures Of Physical Exertion**

Monica Skatrud-Mickelson, Joan Benson, James C. Hannon, Susie McNutt, Eldon W. Askew. *University of Utah, Salt Lake City, UT.*

Email: monica.skatrud-mickelson@hitchcock.org

(No relationships reported)

Better methods are needed to improve the validity and reliability of physical activity (PA) assessment instruments when measuring intensity of PA. Research suggests people tend to overestimate level of exertion when self reporting activity on Physical Activity Questionnaires (PAQs).

**PURPOSE:** To compare a subjective method, Borg's Rate of Perceived Exertion (RPE) survey to an objective method utilizing ambulatory PA recorded by an accelerometer.

**METHODS:** Accelerometers were fitted around the waist and positioned on the right side according to manufacturer protocols on 117 participants, (43% male, 67% female, age range 18-74, BMI  $26.1 \pm 5.4$ , 53% reporting regular exercise). Participants performed three, 0.29-mile laps of increasing self-selected intensity, and then rated exertion by filling out a Borg's 15-point RPE form for each lap immediately following exercise. Exercise categories were divided into four intervals based on validated Hendelman 2 cut-points for comparing metabolic equivalents (METs) and subjective categories (i.e., light, moderate, hard, and very hard). A sub sample was selected to complete the same RPE survey 6 to 8 weeks later recalling their RPE during the three 0.29 mile laps, to assess differences over time. Chi-square tests, logistic regression, and Wilcoxon signed ranks tests measured differences between groups, develop odds ratios where appropriate, and measured discrepancies over time.

**RESULTS:** There were significant differences between genders and overall accuracy ( $\chi^2=10.9$ ,  $p=0.004$ ), as well as whether or not the individual self-reported exercising ( $\chi^2=15.5$ ,  $p<0.001$ ). Neither BMIs nor age had an impact on overall accuracy. Odds of underestimating RPE for a regular exerciser are 3.67 times greater than that of a nonexerciser while controlling for all other variables (95% CI=1.48, 9.11). In assessing differences over time, the sub sample underestimated RPE to a greater extent 6 to 8 weeks after the activity ( $Z=-2.324$ ,  $p=0.020$ ).

**CONCLUSION:** Males and those regularly exercising were more likely to underestimate exertion, while sedentary women tended to overestimate. Recall of PA intensity may decline over time. Misreporting exercise intensity on PAQs is more likely to occur in a subset of the population.

**Production Strategy During Self-regulated Cycle Ergometer Exercise**

Michael J. Welikonic, Christina M. Ledezma, Stephen J. Roy, Mark Lebder, George Panzak, Fredric L. Goss, FACSM, Elizabeth F. Nagle, FACSM, Robert J. Robertson, FACSM. *University of Pittsburgh, Pittsburgh, PA.*  
Email: mwelikonich@msn.com  
(No relationships reported)

During self-regulated exercise using a target rating of perceived exertion (RPE), some individuals may *overshoot* or *undershoot* the prescribed exertional level at the beginning of an exercise session. This is known as the Production Strategy component of the Intensity Self-Regulation Model (Wiser et al., 2007) and has not been examined in recreationally active adults.

**PURPOSE:** To examine production strategy during 21 min of self-regulated cycle ergometer exercise performed at a target RPE of 5 on the Adult OMNI-RPE Cycle Scale.

**METHODS:** Nine recreationally active males ( $20.4 \pm 2.8$  yrs) participated in this investigation. Initially, subjects underwent an estimation trial (EST) consisting of a load incremented cycle ergometer protocol to determine the  $\text{VO}_2$  corresponding to a target RPE of 5. 48 hrs later subjects performed a trial during which exercise intensity was self-regulated to produce a level of exertion just noticeably greater and just noticeably less than the target RPE of 5. This established the just noticeable difference (JND) in perceived exertion and its corresponding oxygen consumption ( $\text{VO}_2$ ) range. Exercise  $\text{VO}_2$  responses above and/or below the JND- $\text{VO}_2$  range indicated intensity self-regulation error for each subject. For the subsequent session, subjects completed a production trial (PROD) consisting of 21 min continuous self-regulated exercise at a target RPE of 5.

**RESULTS:** During the PROD trial, eight out of nine subjects exercised at an intensity that resulted in a  $\text{VO}_2$  below the JND- $\text{VO}_2$  range for at least one of the measurement time points, while the  $\text{VO}_2$  for one subject was within the JND- $\text{VO}_2$  range for the entire 21 min session. The mean ( $\pm$  SD) error below the JND- $\text{VO}_2$  range associated with a RPE of 5 ranged from  $0.26 (\pm 0.33)$  to  $0.46 (\pm 0.54) \text{ L}\cdot\text{min}^{-1}$ . 68.3% and 31.7% of the measurement time points for all subjects were below and within the JND- $\text{VO}_2$  range, respectively.

**CONCLUSIONS:** A majority of subjects used an undershoot Production Strategy in contrast to previous reports of an overshoot strategy in elite athletes and cardiac patients. The present results may lead to a more accurate application of exercise prescriptions for recreationally active adults where individual production strategies are employed.

**Session Perceived Exertion Response To A Load-incremented Perceptual Estimation Cycle Ergometer Protocol**

Maressa P. Krause, Luke Haile, Mike Welikonic, Robert C. Wilson, Fredric L. Goss, FACSM, Elizabeth F. Nagle, FACSM, Robert J. Robertson, FACSM. *University of Pittsburgh, Pittsburgh, PA.*  
Email: maressakrause@hotmail.com  
(No relationships reported)

Session RPE (S-RPE) is defined as the post-exercise rating of global exertion experienced during an entire exercise session. Thekkada et al. (2007) found S-RPE was higher than the mean RPE during a load-incremented estimation cycle ergometer protocol in young, recreationally active females. In contrast, Krause et al. (2008) found S-RPE did not differ from the mean RPE during an intermittent perceptual production cycle ergometer protocol in young, recreationally active males.

**PURPOSE:** To compare: 1) S-RPE with the mean RPE (M-RPE), and 2) Mean  $\text{VO}_2$  with the  $\text{VO}_2$  corresponding to both the S-RPE ( $\text{VO}_{2\text{-S}}$ ) and the M-RPE ( $\text{VO}_{2\text{-M}}$ ), as measured during a load-incremented perceptual estimation cycle ergometer protocol in recreationally active males ( $\leq 160 \text{ min}\cdot\text{wk}^{-1}$  physical activity).

**METHODS:** Thirty-nine (mean age  $20.7 \pm 2.45$  yrs) recreationally active males performed 2 min cycle stages, with progressive ( $75 \text{ W}\cdot\text{stage}^{-1}$ ) increases in power output until peak intensity. RPE was obtained at 1:45 of each stage using the Adult OMNI-Cycle Scale. S-RPE was obtained 7 min following exercise. M-RPE was the average of all stage-by-stage RPE. Mean  $\text{VO}_2$  was the average of each exercise minute value. Linear regression analysis was used to predict the  $\text{VO}_2$  corresponding to a scale category that was the same as the S-RPE and the M-RPE for each subject.

**RESULTS:** S-RPE (mean  $\pm$  SD;  $6.85 \pm 1.46$ ) differed from the M-RPE ( $4.23 \pm 1.33$ ) ( $p<0.001$ ).  $\text{VO}_{2\text{-S}}$  ( $2.74 \pm 0.80 \text{ l}\cdot\text{min}^{-1}$ ) differed from the mean  $\text{VO}_2$  ( $1.93 \pm 0.36 \text{ l}\cdot\text{min}^{-1}$ ) ( $p<0.001$ ).  $\text{VO}_{2\text{-M}}$  ( $2.06 \pm 0.39 \text{ l}\cdot\text{min}^{-1}$ ) was greater than the mean  $\text{VO}_2$  ( $1.93 \pm 0.36 \text{ l}\cdot\text{min}^{-1}$ ) ( $p<0.001$ ). Correlation analysis determined a moderate association between mean  $\text{VO}_2$  with  $\text{VO}_{2\text{-S}}$  ( $r=0.69$ ;  $p<0.001$ ) and a strong association between mean  $\text{VO}_2$  with  $\text{VO}_{2\text{-M}}$  ( $r=0.91$ ;  $p<0.001$ ). No significant association between M-RPE and S-RPE was noted.

**CONCLUSIONS:** The results indicated a positive relation between physiologic (i.e. mean  $\text{VO}_2$ ) criteria and both S-RPE and M-RPE. S-RPE was not representative of the average rating of global exertion experienced during the entire exercise test. Future research should continue to explore the underlying perceptual and physical substrata that contribute to the S-RPE.

**2047 Board #188 May 28 9:00 AM - 10:30 AM**  
**Rating Of Perceived Exertion In Cycle Ergometer: Effect Of Maximal Capacity Differences**

Baris Cakir, ozgur kasimay, omer U. erzengin, hizir kurtel. *marmara university, istanbul, Turkey.*  
Email: bariscakir@gmail.com  
(No relationships reported)

**PURPOSE:** To evaluate the physiological responses to exercise intensities determined by heart rate reserve (HRR) method and to detect whether perceived exercise intensity can be affected by individuals fitness level.

**METHODS:** Twenty sedentary participants of both sexes aged 20 to 41 (mean 26.9) participated. Rating of perceived exertion (RPE) scores were collected at different percentages of subjects' HRRs during graded exercise test on a cycle ergometer. Following the test, subjects were divided into two groups according to their maximal  $\text{O}_2$  uptakes ( $\text{VO}_{2\text{max}}$ ) as high ( $\text{MET} \geq 10$ ;  $n=9$ ), and low MET groups ( $\text{MET} < 10$ ;  $n=11$ ). After 48 hours, participants performed the steady state exercise test at a perceived exertion level of 13-14. For regression analysis the mean values for intercepts, slopes, and Pearson r correlations were determined.

**RESULTS:** In all HRR levels low MET group had significantly lower MET values ( $p<0.01-0.001$ ). Perceived exertion was significantly higher in low MET group compared to high MET group during graded exercise test. In steady state cycling test, low MET group exercised at higher relative  $\text{VO}_2$  values compared to high MET group ( $p<0.05-0.001$ ). The groups cycled at similar HRR percentages to a given RPE score.

**CONCLUSIONS:** Our results demonstrate that exercise intensity can be prescribed in individuals with different  $\text{VO}_{2\text{max}}$  levels by HRR percentages or by RPE scale methods considering the fact that individual oxygen consumptions may differ.

## Predicted And Actual Ratings Of Perceived Exertion During Cycle And Treadmill Exercise In Young Women

Melinda R. Bolgar<sup>1</sup>, Fredric Goss, FACSM<sup>2</sup>, Elizabeth Nagle, FACSM<sup>2</sup>, Robert Robertson, FACSM<sup>2</sup>. <sup>1</sup>Jacksonville State University, Jacksonville, AL.

<sup>2</sup>University of Pittsburgh, Pittsburgh, PA.

(No relationships reported)

**PURPOSE:** To examine the effect of aerobic training status on predicted and actual undifferentiated and differentiated ratings of perceived exertion (RPE) in young women.

**METHODS:** Subjects were 18-25 yr old women (19 untrained, 22 trained) who underwent two graded exercise tests (GXT) separated by 48 hours. The first GXT used a treadmill and employed a modified Bruce protocol terminated at  $\dot{V}O_{2max}$ . The second GXT used a load-incremented cycle ergometer test terminated at  $\dot{V}O_{2max}$ . Predicted RPE-Overall (O), -Legs (L), and -Chest (C) were recorded before the start of each GXT using a mode specific OMNI perceived exertion scale. Actual RPEs for both sessions were recorded immediately post-exercise and represented the global perceived exertion for the entire session. Six separate two way (training status (2) x time (2)) ANOVAs with repeated measures on time were computed.

**RESULTS:** Descriptive data for the sample were: RPE-O, -L, -C: range = 0 to 10; mean  $\dot{V}O_{2max}$  untrained = 33.40 ml/kg/min, mean  $\dot{V}O_{2max}$  trained = 43.3 ml/kg/min. No significant differences were found between predicted and actual RPEs for the untrained and trained groups (Table 1) during treadmill exercise. For both groups performing cycle ergometry, predicted RPE-O and -C were greater ( $p < 0.05$ ) than global RPE actually reported immediate post-exercise (Table 1).

Table 1: Mean RPE responses

	Time Point	Treadmill			Cycle Ergometer		
		RPE-O	RPE-L	RPE-C	RPE-O*	RPE-L	RPE-C*
Trained	Predicted RPE	7.23	6.91	6.95	7.67	8.24	7.86
	Actual RPE	6.82	6.91	6.91	6.76	7.90	6.86
Untrained	Predicted RPE	6.32	6.37	6.37	7.21	7.58	7.42
	Actual RPE	6.05	5.95	6.42	6.84	7.74	6.42

\*Indicates significant difference ( $p < 0.05$ ) between predicted and actual RPE for both groups

**CONCLUSION:** Based on the actual global perceptual experience there was a consistent over prediction in both RPE-O and RPE-C during cycle exercise in both groups. Such over prediction of actual exercise related exertional perceptions may pose psychological barriers to exercise adoption and maintenance.

<sup>1</sup>Nanyang Technological University, Singapore, Singapore. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA. <sup>3</sup>Texas A&M University, Texarkana, TX.

Email: govindasamy.b@nie.edu.sg

(No relationships reported)

The OMNI Scale of perceived exertion (category 0 to 10) has been validated for children and adults, primarily using ergometry, i.e. treadmill, cycle, step. The OMNI scale has not been validated for use with the Progressive Aerobic Cardiovascular Endurance Run (PACER) which is a validated field oxygen consumption test.

**PURPOSE:** To validate the OMNI Scale for use with the PACER. In addition direct kinematic observation was used to rate perceived exertion (OMNI Scale; RPE) during the PACER.

**METHODS:** 9 subjects (age  $24.9 \pm 3.8$ , BMI  $23.6 \pm 2.9$ , PACER  $\dot{V}O_{2peak}$   $44.3 \pm 7.0$ ) clinically normal adults participated in the study. A cross-sectional, perceptual estimation paradigm was used. Oxygen consumption (Cosmed K4 b<sup>2</sup>) ( $\dot{V}O_2$ : ml·min<sup>-1</sup>, ml·kg<sup>-1</sup>·min<sup>-1</sup>) and heart rate (HR beats·min<sup>-1</sup>) were measured at the end of each continuously administered incremental PACER stage. Subjects were instructed to run back and forth across a 20 meter distance at a pace that increased each minute. Subjects performed the exercise test to exhaustion. RPE for the overall body (RPE-O) was estimated by 3 trained observers and self rated by the subjects at the end of each PACER stage.

**RESULTS:** Subject self-rated RPE-O, Observer 1, 2, 3 RPE-O and  $\dot{V}O_2$  respectively for the first 4 stages were: Stage 1:  $1.2 \pm 0.4$ , O1  $1.0 \pm 0.5$ , O2  $0.9 \pm 0.6$ , O3  $1.0 \pm 0.5$ ,  $28.5 \pm 4$  Stage 2:  $2.8 \pm 0.7$ , O1  $1.8 \pm 0.7$ , O2  $1.8 \pm 0.8$ , O3  $2.1 \pm 0.6$ ,  $35.0 \pm 3.7$  Stage 3:  $4.6 \pm 1.6$ , O1  $2.8 \pm 1.7$ , O2  $3.6 \pm 0.9$ , O3  $3.1 \pm 1.0$ ,  $38.3 \pm 4.0$  Stage 4:  $6.3 \pm 2.3$ , O1  $4.1 \pm 2.0$ , O2  $5.1 \pm 1.6$ , O3  $4.6 \pm 1.5$ ,  $40.0 \pm 5.6$ . Linear regression analysis for the first 4 stages, showed that RPE-O, distributed as positive functions of both  $\dot{V}O_2$  ( $r = .86$ ) and HR ( $r = .86$ ). All regression functions were statistically significant ( $p < 0.01$ ). RPE responses between observers and subject self-rating were not significantly different for all stages ( $p < 0.05$ ).

**CONCLUSIONS:** OMNI Scale validity was established for use in conjunction with the PACER field oxygen consumption test. Findings also confirmed that direct kinematic observations were similar to self-ratings of RPE during the PACER. The utility of the OMNI scale for field settings is thus extended to the PACER. Valid observations of RPE in perceptual-based field exercise testing using the OMNI scale can enhance the effectiveness and efficiency of programs in health and fitness, the school and public health settings.

### Tracking Strength Changes And Safety Using Omni Scale Rpe During Resistance Training In Older Adults

Randall F. Gearhart Jr.<sup>1</sup>, Kristen M. Lagally, FACSM<sup>2</sup>, Steven E. Riechman<sup>3</sup>, Ryan D. Andrews<sup>4</sup>, Robert J. Robertson, FACSM<sup>5</sup>. <sup>1</sup>Ashland University, Ashland, OH. <sup>2</sup>Illinois State University, Normal, IL. <sup>3</sup>Texas A & M University, College Station, TX. <sup>4</sup>Precision Nutrition, Toronto, ON, Canada.

<sup>5</sup>University of Pittsburgh, Pittsburgh, PA.

Email: rgearhar@ashland.edu

(No relationships reported)

It has been shown that the OMNI resistance exercise scale (OMNI-RES) is an effective method to track both absolute and relative strength increases in older adults. What is unclear however, is if the OMNI-RES tracks strength increases in consequent to training intended to minimize injury risk.

**PURPOSE:** To: (1) use the OMNI-RES to track strength changes following a low-risk resistance training program and (2) examine the drop-out rate due to injury during a 12-week resistance exercise program guided by RPE in male and female hexagenarians.

**METHODS:** Twenty-two men ( $64.3 \pm 3.2$  yrs.) and 27 women ( $63.8 \pm 2.8$  yrs.) volunteered. Subjects underwent orientation to determine a pre-training resistance associated with RPEs of 4, 5, 6, 7-8 and 9. Training consisted of 8-12 repetitions (reps) with weights set at 75 % of 1-RM three days a week for 12 weeks. Seven exercises: leg press, lat pull down, chest press, leg extension, leg curl, arm extension, and arm curl were performed. Participants were instructed to perform as many reps as possible but not to exceed 12 reps. When a participant achieved three sets of 12 reps on an exercise, the weight was increased to a level that allowed only 8 reps. Subjects then underwent a post-training assessment to again determine the resistance associated with the criterion RPEs.

**RESULTS:** Subjects significantly increased strength in each of the seven exercises over the course of the 12-week resistance exercise program ( $p < .05$ ). Resistance at each RPE was lower post- than pre-training ( $p < .05$ ). Despite these significant increases in post-training 1-RMs, there were zero dropouts due to injury over the 12-week program.

**DISCUSSION:** With the current increase in resistance exercise prescriptions for an aging population, it was important to establish a safe method to gauge exercise intensity. It

#### Development Of Posture Control In Primary School Children Evaluated By A Balance Board Equilibrium Test

Junjiro Kubo, Yasuo Sengoku, Chiharu Takano, Hitoshi Miyake, Seidai Nishikawa, Katsuhiko Matsuda, Haruhiko Togari. *Heisei International University, kazo, Japan.*

Email: kubo@hiu.ac.jp

(No relationships reported)

Posture control has been evaluated as an integration of the center of pressure during upright posture on a flat surface. However, since this motor task is easy, variation are difficult to detect, especially in healthy people.

**PURPOSE:** To evaluate the development of posture control in primary school children utilizing a balance board equilibrium test, which is a more advanced motor task.

**METHODS:** 345 primary school children in the first to sixth grade (female: 164, male: 181) participated in this study. Height, body mass, and body fat percentage were measured. Posture control ability was evaluated as an integration of the center of pressure during upright posture (15sec) on a commercial balance board placed on an instrument to determine center of pressure (Active balancer, SAKAI Medical.Co.,Ltd, JAPAN). In addition, grip strength and squat jump were investigated.

**RESULTS:** The velocity of center of pressure was significantly lower between the second grade and the third grade ( $p<0.01$ ), but there was no significant difference after the third grade. There was no significant difference between females and males. Grip strength significantly increased from the first grade to the second grade ( $p<0.01$ ), and from the second grade to the third grade ( $p<0.01$ ). Squat jump significantly increased from the second grade to the third grade ( $p<0.01$ ), and from the fourth grade to the fifth grade ( $p<0.01$ ).

**CONCLUSIONS:** It was suggested that posture control highly developed during the second grade to the third grade period, and that the development of posture control was different from other motor developments.

### 2052 Board #193 May 28 8:00 AM - 9:30 AM

#### The Effect Of Localized Cold Exposure On Static And Dynamic Postural Stability

Shawn Henry, Alison Wan. *Pacific University, Forest Grove, OR.*

Email: henryso@pacificu.edu

(No relationships reported)

Decreased temperature, both whole-body and localized, potentially alters human movement function. Specifically, exposure to cold environmental temperature can lower intramuscular temperature and may affect postural stability.

**PURPOSE:** To investigate effects of localized lower-limb cold exposure on static and dynamic postural stability.

**METHODS:** Fourteen subjects (7 females, 7 males; body mass  $72.4 \pm 13.9$  kg; ht  $170.2 \pm 6.9$  cm) participated. A balance platform system was used to assess one-leg static postural stability (overall score), one-leg dynamic postural stability (overall score), and manipulation of center of pressure using Limits of Stability testing (LOS) on a moderately-challenging dynamic setting (composite score for anterior-posterior direction only). After establishing baseline (pretest), one leg was randomly chosen for cold exposure treatment (whole leg submersion at  $5^{\circ}\text{C}$  for 10 min) using contra-lateral leg as control. Post-testing followed treatment.

**RESULTS:** Two-way repeated measures ANOVA revealed no PrePost effect, ContCold effect, or PrePost x ContCold interaction for static postural stability ( $F_{1,13} = 0.59$ ,  $p=0.46$ ;  $F_{1,13} = 0.34$ ,  $p = 0.57$ ,  $F_{1,13} = 3.50$ ,  $p = 0.08$  respectively) or LOS ( $F_{1,12} = 0.16$ ,  $p=0.070$ ;  $F_{1,12} = 1.28$ ,  $p = 0.28$ ;  $F_{1,12} = 0.06$ ,  $p = 0.81$  respectively). Similarly, dynamic stability had no main effects ( $F_{1,13} = 0.28$ ,  $p = 0.61$ ;  $F_{1,13} = 0.31$ ,  $p = 0.59$ ), although an interaction was observed ( $F_{1,13} = 14.9$ ,  $p = 0.002$ ).

	CONT	COLD
	Pre-test, Post-test	Pre-test, Post-test
Postural Stability (Static)	$1.5 \pm 0.5$ , $1.2 \pm 0.4$	$1.3 \pm 0.8$ , $1.5 \pm 0.7$
Postural Stability (Dynamic)	$1.4 \pm 0.6$ , $1.7 \pm 0.8$	$1.6 \pm 0.8$ , $1.4 \pm 0.8$
LOS (Dynamic)	$35.6 \pm 12.0$ , $34.8 \pm 13.2$	$32.9 \pm 15.9$ , $35.3 \pm 15.3$

**CONCLUSION:** Localized cold exposure neither inhibited nor enhanced static postural stability or LOS performance. Similarly, cold exposure did not affect dynamic postural stability as measured by main effects, although the occurrence of an interaction complicates data interpretation.

---

### 2053 Board #194 May 28 8:00 AM - 9:30 AM

#### An Inverted Seated Posture Decreases Elbow Flexion Force and Muscle Activation.

David G. Behm, James Hearn, Farrell Cahill. *Memorial University of Newfoundland, St. John's, NL, Canada.*

Email: dbehm@mun.ca

(No relationships reported)

**PURPOSE:** While much is known about neuromuscular responses performed with an upright posture, muscle force and activation during an inverted posture have not been previously studied.

**METHODS:** To determine if postural-induced discrepancies exist, maximal voluntary contraction (MVC) elbow flexor force, MVC force produced in the first 100 ms (F100), MVC rate of force development, electromyographic (EMG) activity of the biceps and triceps and trunk musculature were investigated during isometric elbow flexion in both an upright and inverted seated posture. Heart rate and blood pressure were monitored with upright and inverted positions at rest.

**RESULTS:** Results showed significantly ( $p=0.01$ ) higher MVC force ( $543.6 \text{ N} \pm 29.6$  vs.  $486.5 \text{ N} \pm 23.0$ ), F100 ( $328.3 \text{ N} \pm 94.5$  vs.  $274.6 \text{ N} \pm 101.8$ ) and rate of force development ( $p=0.003$ ) ( $1851.9 \text{ N.s}^{-1} \pm 742.2$  vs.  $1591.0 \text{ N.s}^{-1} \pm 719.6$ ), in the upright versus inverted condition. Biceps (48%;  $p=0.01$ ) EMG activity was greater in the upright position. There was relatively greater co-contractions (86%,  $p=0.006$ ) with the inverted position. Heart rate (16.8%), systolic (11.6%), and diastolic (12.1%) blood pressures were also significantly ( $p<0.0001$ ) decreased with inversion.

**CONCLUSION:** These results illustrate decrements in neuromuscular performance with an inverted seated posture which may be related to an altered sympathetic response.

**The Effects Of Eight-week Archery Training On Postural Control In Young Children**

Alex J Y Lee<sup>1</sup>, Wei-Hsiu Lin<sup>2</sup>, Ying-Fang Liu<sup>3</sup>, Ping-Kun Chiu<sup>4</sup>. <sup>1</sup>National Hsinchu University of Education, HsinChu City, Taiwan. <sup>2</sup>National ChiaYi University, ChiaYi County, Taiwan. <sup>3</sup>Hsin Sheng College of Medical Care and Management, TaoYuan County, Taiwan. <sup>4</sup>National Taiwan Sport University, Taoyuan County, Taiwan.

Email: jylee@nhcue.edu.tw

(No relationships reported)

**PURPOSE:** To examine the effects of an eight-week archery training program on postural control (PC) in young children during the standard, aiming, and archery shooting standing posture.

**METHODS:** Thirty-two young children were recruited and grouped as experimental group (E, 16 children, Height 138.66±7.45 cm, Weight 34.47±9.29 kg) or control group (C, 16 children: Height 136.75±6.01 cm; Weight 36.34±6.92 kg). The E group underwent archery training for forty minutes a time, three times a week, for eight weeks, and the C group did not received any regular physical training. PC was evaluated by the measurement of COP displacement on a force platform as the COP radius, speed and sway area during each testing position. The training program was planned by expert archery coaches and based on the training of basic archery skill and coordination. Data were analyzed by the mixed design, two-way ANCOVA to determine if any difference in PC between groups before and after training during the standard posture. Repeated measures, dependent *t* test was also used to determine if any difference in PC before and after training during the aiming and shooting posture in experimental group. The significant level for statistic was set at *p*<.05.

**RESULTS:** 1. No significant differences were found in PC during each testing position before and after the eight-week period in C group; 2. The COP radius and sway area were significantly decreased after archery training in E group during the standard, aiming, and shooting posture, but not in the COP velocity.

**CONCLUSIONS:** This study demonstrated that regular eight-week archery training not only improved the performance of archery shooting, but also improved the PC during the standard, aiming, and shooting posture. The results of this study could provide a practical training regimen for archery coaching and understand the possible relationships between the archery performance and PC.

2055 Board #196 May 28 8:00 AM - 9:30 AM

**Dynamic Balance Assessment For Children With Down Syndrome**

Hung-Lien Lai, Li-Lan Fu. National Taiwan Sport University (Taoyuan), Taoyuan, Taiwan.

Email: bluebaw.banban@gmail.com

(No relationships reported)

For Down syndrome (DS), developmental dysfunctions include psychological and physical problems. Dynamic balance affects the performances of their daily life. There were many studies regarding static balance assessment under different sensory conditions. But, dynamic balance assessment in the limits of stability (LOS) for children with DS is still lacking.

**PURPOSE:** To assess dynamic balance performance in the limits of stability for children with DS.

**METHODS:** Subjects were eight children with DS (4 boys/4 girls, age 9.8 ± 2.1 yrs, height 126.5 ± 10.5cm) and eight healthy children (4 boys/4 girls, age 8.7 ± 0.5 yrs, height 130.3 ± 7.0cm). Both groups were assessed with clinical assessments including heel-toe walking for 15 steps and jumping squares (45 × 45cm<sup>2</sup>) with both feet on the floor(both recorded accomplish second and correct steps). Subjects were then assessed by the Basic Balance Master system including Rhythmic Weight Shifting (RWS) assessment (right/left, R/L; forward/backward, F/B) and the test of stability (LOSt)(F, B, R, L). Student *t*-test was used to compare the difference between DS and control group. The level of statistical significance was set at *p* < .05.

**RESULTS:** Significant difference was found between two groups for the heel-toe walking with correct steps, accomplish jumping time and correct jumping steps (all *p* < .05). In RWS, there was significant difference for fast speed on-axis velocity in RWS (F/B) (7.9 ± 1.9 vs. 9.8 ± 2.1 °/sec, *p* < .05), but not in RWS (R/L) between DS and control. All directional control (DCL) of RWS were significantly different between groups (*p* < .05). In LOSt, only F direction of movement velocity was significantly different between groups (5.0 ± 2.3 vs. 7.7 ± 2.5 °/sec, *p* < .05). All directions endpoint excursion of and directions of maximal endpoint excursion were significantly different between groups (*p* < .05). Besides, three directions (F, R, L) of DCL were significantly different between groups (*p* < .05), but not in B of DCL (22.6 ± 28.7 vs. 49.2 ± 22.4 %LOS, *p* > .05).

**CONCLUSIONS:** In general, DS children had poorer dynamic balance than control group. These data can be used in understanding deficit in children with DS. Further studies can focus on designing appropriate perception-motor and muscle strength training programs to improve their dynamic balance and prevent risk of fall.

2056 Board #197 May 28 8:00 AM - 9:30 AM

**Effects Of Physical Fitness Level And Anthropometric Parameters On Postural Sway In Girls**

Yukinori Shintaku, Sr.<sup>1</sup>, Tetsuo Ohkuwa<sup>2</sup>, Hiroshi Fujinaga<sup>3</sup>, Noriyuki Yamamoto<sup>4</sup>, Tadashi Wada<sup>5</sup>, Tadao Isaka<sup>6</sup>, Shigehiko Ogoh<sup>7</sup>. <sup>1</sup>Biwako Seikei Sports College, Otsu, Japan. <sup>2</sup>Nagoya Institute of Technology, Nagoya, Japan. <sup>3</sup>Wakayama University, Wakayama, Japan. <sup>4</sup>Japanese Red Cross Hokkaido College of Nursing, Kitami, Japan. <sup>5</sup>Kokushikan University, Tokyo, Japan. <sup>6</sup>Ritsumeikan University, Kusatsu, Japan. <sup>7</sup>University of North Texas Health Science Center, Fort Worth, TX.

(No relationships reported)

Postural sway has been widely used as a number of maintenance of balance. The balance ability in adults depends on their muscular strength and aerobic and anaerobic working capacity.

**PURPOSE:** The purpose of this study was to examine the influence of physical fitness level and anthropometric parameters on postural sway in girls at the age of three, four and five years.

**METHODS:** 504 children: 168 girls at the age of three years, 168 girls at four years and 168 girls at five years participated in this study. The height and weight of all subjects were measured, then the Caup's index (weight/height<sup>2</sup> × 1000) was calculated. Postural sway was measured by a portable grabicorder (GS-10A, ANIMA, Tokyo, Japan). The children were asked to stand upright on a pedometer and look at a target placed 2m away from them. The body sway was measured as each child stood without shoes for 30 seconds, and the measurements were stored on the floppy disk. On the physical fitness test, the 25m sprint run, hopping, standing-broad-jump, side-jump and one-leg standing were analyzed. Each girl performed the same test twice, and the better results for each set of tests were taken. Then the One-factor ANOVA (analysis of variance) was used to analyze the differences between the measurements on the three study groups. A post hoc test (Fisher's PLSD) was used to decompose significant effects.

**RESULTS:** It was found that LNG of five-year old group was lower than the three (*p*<0.001) and four year old groups (*p*<0.001). However, the height, weight, and physical fitness level increased significantly with increasing of age in all groups (*p*<0.001). Moreover, the physical-fitness tests show that LNG was correlated with the height of the three-year old group. The LNG was related with the results of the four year old group's standing-broad-jump (*p*<0.01) and side-jump-frequency (*p*<0.01) respectively. Also the LNG was related with the results of the five year old group's hopping (*p*<0.05), standing-broad-jump (*p*<0.05), and side-jump-frequency (*p*<0.01) respectively.

**CONCLUSIONS:** The results confirmed that the magnitude of the postural sway in girls at ages four and five depends on their physical fitness level. However, the three year old girls depend on their body height rather than their physical fitness level.

## The Effects Of Cold Temperature On Gait Initiation And Dynamic Balance In Young And Older Females

Christi Brewer<sup>1</sup>, Dwight Waddell<sup>1</sup>, Mic Dancisak<sup>2</sup>. <sup>1</sup>University of MS, University, MS. <sup>2</sup>Tulane University, New Orleans, LA.

Email: christileigh@gmail.com

(No relationships reported)

This is an ongoing study examining epidemiological evidence suggesting a non-slip related increase in the rate of falls during the winter for females versus males. Previous research has shown cold has no effect on quiet standing parameters in young versus old females.

**PURPOSE:** To examine the effects of cold temperature on gait initiation and *dynamic* balance in young and older females.

**METHODS:** Six older (70.5 ± 2.7 yrs) and seven younger (23.9 ± 2.4 yrs) females performed dynamic balance and gait initiation tests at thermal neutral (33°C) and cold conditions (3°C). Legs were cooled using liquid cooling garment pants. The NeuroCom Balance<sup>®</sup> Manager™ Equitest<sup>®</sup> system provided composite scores for dynamic balance assessment. Ground reaction forces were used to calculate COP traces during gait initiation. Three segments of the COP trace were recorded to analyze X (medio-lateral) and Y (fore-aft) displacement, velocity, and smoothness at each temperature. A 2x2 ANOVA was conducted on dynamic balance tests. A 2x5 repeated measures MANOVA was conducted for each segment of the COP trace. A one-way ANOVA was conducted on each segment at both temperatures to determine age differences.

**RESULTS:** Equitest<sup>®</sup> balance measurements revealed no effect of temperature, although age effects were confirmed. One-way ANOVA revealed a significant between-group difference for segment one x-velocity (p=.02) at thermal neutral. Repeated measures analyses revealed a significant temperature effect on all variables of segment three for young females (each with p<.01).

**CONCLUSION:** We believe our “to date” gait initiation results may be due to a relatively insufficient cold stimulus and limited subject power. The disappearance of a significant between-group difference at cold suggests that young females were more adversely affected by the cold stimulus, which we feel is due to adiposity factors at the induced temperatures. A significant body composition difference was observed between the two age groups (p=.001). This would explain lower leg skin temperatures in younger subjects during the testing, and subsequently, the significant finding of temperature effects for their segment three values. Currently, additional subjects are being recruited to increase analytical power.

---

### 2058 Board #199 May 28 8:00 AM - 9:30 AM Reducing Ankle Movement Has No Effect On Postural Control Dynamics

Sunghoon Shin. *U of Illinois, Champaign, IL.*

Email: sshin27@uiuc.edu

(No relationships reported)

**PURPOSE:** To determine the effect of restricting movement about the ankle on the dynamics of postural control.

**METHODS:** 19 young adults completed the Sensory Organization Test (SOT) in the Neurocom Equitest System to index postural control while either barefoot, ankles taped or wearing an ankle brace. The SOT consists of six different conditions which incrementally challenge the underlying postural control conditions. Center of pressure excursion in the anterior-posture (AP) and medial-lateral (ML) directions, total sway length and sway area (95% ellipse) were calculated. Approximate entropy (ApEn) was calculated for measuring the complexity of the ML and AP center of pressure (COP) signals.

**RESULTS:** As expected postural sway increased with increasing postural difficulty. However, there was no effect of ankle immobilization on postural sway parameters (p >.05). In the anterior-posterior direction ApEn increased with postural difficulty (0.38-0.50). In the mediolateral direction there was minimal changes in ApEn as a function of postural difficulty. There was no significant effect of restricting ankle motion of postural dynamics (0.62, 0.64, and 0.63).

**CONCLUSION:** Restricting ankle movement has no effect on the dynamics of postural control. The findings suggest that individuals are able to compensate for restricted ankle mobility and maintain their postural stability.

(No relationships reported)

In sports and daily living activity, it is important that muscular strength is coordinated as well. In particular, muscle coordination after ballistic movement and countermovement were most important factor to improve human movement. The control of local muscles during sports performance and daily living activity serves to stabilize a body during these maneuvers.

**PURPOSE:** The purpose of this study is to examine the muscular strength in posture control after rapid flexion and extension movement on the lower extremities.

**METHODS:** Twelve healthy male students participated in this study. EMG active surface electrodes (DL-142, S&ME, Japan) were applied. Eight muscles were selected for this study: lateral gastrocnemius, medial gastrocnemius, soleus, tibialis anterior, hamstrings, vastus lateralis, vastus medialis, rectus femoris. The ground reaction forces (GRF) exerted with the selected actions were recorded with a piezo-electric force platform (9281C, KISTLER, Swiss). The subjects were monitored by a video camera (HDR-HC9, SONY, Japan) of the sampling frequency of 60Hz by the sagittal plane to measure the angular displacement of the different joints. It makes subject to stand up on a force platform which is an apparatus for determining GRF and to perform the short ballistic movements which exerted rapidly flexion and extension on the lower leg joints.

**RESULTS:** The angular displacement was showed large differences between individual subjects to exert the selected actions, since it appears to exert the action with voluntary. The power curves were depicted a pattern of negative phase during joint flexion and positive phase during joint extension. The EMG activity increased in tibialis anterior muscle.

**CONCLUSIONS:** That indicating the greater computed power and work during upward action of a whole body than that during downward might be due to generating positive power and work, which is it in exerting antigravity work of body movement, on the muscles used in the selected actions. It is obscured what is the reason why that are generated on the greater power and work calculated in quickly returning to a starting level of a body position. It is seemed that an elastic energy stored into an active muscle-tendon complex which stretched immediately before shorting the active muscle-tendon complex.

### 2060 Board #201 May 28 8:00 AM - 9:30 AM Exploration Of A Novel Task For Improvement Of Balance In Older Adults

Jennifer M. Aldridge, Geoffrey Melcher, John A. Mercer, FACSM, Janet S. Dufek, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.*

(No relationships reported)

It is known that balance is compromised with aging as is evidenced by increased falls in the elderly.

**PURPOSE:** The purpose of this study was to examine the effects of a retro-locomotion training protocol on static balance characteristics for young and older adult participants. Owing to our interest in older adults, a priori, we chose to examine the pre-post effects of the intervention for this group.

**METHODS:** Healthy young adults (n=8; 21.4±2.3 yrs; 70.5±8.5 kg; 176.9±6.9 cm) and healthy older adults (n=8; 69.0±7.0 yrs; 68.6±15.7 kg; 166.1±11.8 cm) volunteered to participate in a training session tri-weekly for 2 weeks. Each session entailed walking backwards on either a treadmill or over ground for 10-15 minutes at preferred speed. Subjects also participated in 2 laboratory testing sessions that took place prior to the training session (pre) and after the completion of the 2 week training session (post). Timing

lights were used to measure over ground retro-locomotion velocity (OGRV). A treadmill was used to identify preferred retro-locomotion treadmill speed (RLTS). A balance platform was used to measure static balance with performance quantified via balance scores. Five balance tests were conducted: 1) normal stance, eyes open (NS-EO), 2) normal stance, eyes closed (NS-EC), 3) perturbed stance eyes open (PS-EO), 4) perturbed stance, eyes closed (PS-EC), and 5) limit of stability (LOS).

**RESULTS:** A mixed model factorial ANOVA ( $\alpha=.05$ ) showed no significant time x age interaction. Significant age (PS-EO,  $p=.007$ ; PS-EC,  $p=.008$ ) and time (PS-EC;  $p=.011$ ) main effects were identified. Dependent t-tests showed significant balance score improvements in the older adult group for PS-EC from pre to post ( $p=.048$ ,  $Mpre=82.47 \pm 6.31\%$ ,  $Mpost=86.46 \pm 4.32\%$ ) and suggested a trend toward balance improvement for PS-EO pre to post ( $p=.093$ ,  $Mpre=90.01 \pm 3.39\%$ ,  $Mpost=91.73 \pm 1.88\%$ ). Dependent t-tests showed significant increases in preferred RLTS for both older ( $p=.001$ ,  $Mpre=.41 \pm .10$  m/s,  $Mpost=.71 \pm .14$  m/s) and younger ( $p=.031$ ,  $Mpre=.60 \pm .12$  m/s,  $Mpost=.74 \pm .14$  m/s) adults, but was not significant for OGRV for either group.

**CONCLUSIONS:** These data are congruent with previous research indicating proprioceptive function decreases with age. Results further suggest that balance improves in older adults after retro-locomotion training.

**2061 Board #202 May 28 8:00 AM - 9:30 AM**  
**Return To Baseline Of Postural Control After Treadmill Run At Individual Anaerobic Threshold**

Emanuele Franciosi, Maria Chiara Gallotta, Gian Pietro Emerenziani, Carlo Baldari, Laura Guidetti. *University of Rome "Foro Italico" (IUSM), Rome, Italy.* (Sponsor: Alan C. Utter, FACSM)  
Email: emanuele.franciosi@iusm.it  
(No relationships reported)

**PURPOSE:** To verify whether balance ability is affected by treadmill run at individual anaerobic threshold (IAT) intensity in recovery time immediately after exercise (0min post), after 5 minutes (5min post), and after 10 minutes (10min post).

**METHODS:** 18 soccer players ( $21.8 \pm 1.4$  yrs) performed: a) pre-session test to determine subjects' anthropometric measurements and to depict the IAT intensity during an incremental treadmill running test; b) an experimental session to assess subjects' body sway before and after a 30min treadmill run at IAT intensity. Body sway was evaluated by posturographic tests performed before (pre) and after run at 0min post, 5min post, and 10min post both with eyes open (EO) and eyes closed (EC). Mean Radius (R) and mean Velocity (V) of center of foot pressure were recorded.

**RESULTS:** After IAT exercise, R was significantly affected by vision ( $p<0.01$ ) and time ( $p<0.01$ ). R with EO was significantly higher at 0min post vs pre ( $8.3 \pm 2.7$  mm vs  $5.8 \pm 1.5$  mm,  $p<0.01$ ), while no significant differences at 5min post and 10min post vs pre were found. R with EC was significantly higher at 0min post and 5min post ( $9.7 \pm 2.1$  mm and  $8.4 \pm 2.2$  mm) vs pre ( $6.6 \pm 1.9$  mm;  $p<0.01$  and  $p<0.05$  respectively), and no differences between 10min post vs pre were observed. V was significantly influenced by vision ( $p<0.01$ ) and time ( $p<0.01$ ). V values both with EO and EC were significantly higher at 0min post vs pre (EO:  $19.3 \pm 5.6$  mm/s vs  $12.2 \pm 1.8$  mm/s, EC:  $28.0 \pm 7.4$  mm/s vs  $21.5 \pm 6.5$  mm/s,  $p<0.01$  respectively), and these were not significantly different at 5min post and 10min post vs pre values. Both R and V values were significantly higher with EC vs EO ( $p<0.01$ ) at all time points. The ratio between EO and EC was not significantly different between time points both in R and V.

**CONCLUSIONS:** This study confirmed that there was an impairment of postural control after exercise at IAT intensity. In particular, IAT intensity induced higher destabilizing effect when postural trials were performed with EC. Destabilizing effect on postural control vanished within 5min in R (with EO) and V (with EO and EC), and 10min in R (with EC). Finally, removal of vision affected similarly to R and V variables.

---

**2062 Board #203 May 28 8:00 AM - 9:30 AM**  
**Postural Instability During Single Limb Stance For Individuals With Previous Ankle Injury.**

Kimberly A. Fournier<sup>1</sup>, Paul A. Borsa, FACSM<sup>1</sup>, Erik A. Wikstrom<sup>2</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>University of North Carolina, Charlotte, NC.  
Email: kfournier@hhp.ufl.edu  
(No relationships reported)

Up to 74% of people who sprain their ankle develop chronic ankle instability (CAI). Despite a history of lateral ankle trauma, some people can remain active without recurrent injury or loss of function (copers). Understanding the differences between copers and CAI patients may elucidate the mechanism present in copers but absent in CAI patients.

**PURPOSE:** To investigate postural instability during single limb stance in CAI, Copers and Controls.

**METHODS:** Twenty four CAI (age  $21.7 \pm 2.8$  yrs), 24 Copers (age  $20.8 \pm 1.5$  yrs), and 24 Controls (age  $21.8 \pm 2.6$  yrs) completed four, single limb, quiet stance trials (2 trials per limb, 30 seconds each). Copers and CAI patients had at least one previous moderate ankle sprain but copers resumed all pre-injury activity without limitation or recurrent injury while CAI patients had recurrent sprains and giving way episodes. Ground reaction forces (GRF), collected at 100HZ, were used to calculate the Center of Pressure (COP) location. GRF accelerations were doubly integrated to obtain estimates of the Center of Mass (COM) location. The distances between the COP and COM in the transverse plane (COP-COM moment arm) were then calculated to identify the peak moment arms in the mediolateral ( $X_{max}$ ), anteroposterior ( $Y_{max}$ ) and resultant ( $R_{max}$ ) directions as well as the mean resultant moment arm ( $R_{mean}$ ) for each trial. Limb averages were then submitted for statistical analysis.

**RESULTS:** Separate two-way ANOVAs (Limb x Group) indicated significant group main effects for  $X_{max}$ ,  $Y_{max}$ , and  $R_{mean}$ . Post hoc analyses revealed that CAI had larger  $X_{max}$  ( $1.21 \pm 0.25$  cm) and  $Y_{max}$  ( $1.16 \pm 0.21$  cm) peak moment arms when compared to controls ( $X_{max}$ :  $1.07 \pm 0.18$  cm,  $Y_{max}$ :  $1.01 \pm 0.16$  cm) (both  $p<0.02$ ) but copers ( $X_{max}$ :  $1.11 \pm 0.22$  cm,  $Y_{max}$ :  $1.08 \pm 0.19$  cm) and controls did not differ for  $X_{max}$  or  $Y_{max}$ . Both CAI and Copers had larger  $R_{mean}$  (CAI:  $0.35 \pm 0.06$  cm, Copers:  $0.33 \pm 0.06$  cm) values when compared to controls ( $0.30 \pm 0.04$  cm) ( $p<0.01$ ) but did not differ from each other.

**CONCLUSION:** The  $R_{mean}$  results indicate that individuals with previous ankle injury (CAI and Copers) have increased postural instability during single limb stance. However, CAI patients' inability to limit peak separations of the COP-COM moment arm may represent the mechanism absent in CAI patients.

Supported by the University of Florida, CHHP Opportunity Fund.

**2063 Board #204 May 28 8:00 AM - 9:30 AM**  
**A Comparison Of Balance And Proprioception By Gender And Age Group**

Audrey L. Millar, FACSM, Keith Ellis, Ashley Maycock, Keri Ray, Michael Schroder. *Andrews University, Berrien Springs, MI.*  
Email: lmillar@andrews.edu  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if balance and proprioception are different in adolescents during the pubertal years, as compared to adults, or any interaction between gender and age group.

**METHODS:** A sample of convenience was obtained from adults ( $>21$  yrs old) and adolescents (9 - 15 yrs, dependent upon the gender) in the local area. Balance was tested with the single leg balance tests - eyes open (EO) and closed (EC), the Star Excursion Balance Test (SEBT) - anteromedial (AM), medial (M), and posteromedial (PM) directions. Joint position sense was assessed by reproducing a single-leg squat. Leg length (in centimeters) was used adjust the SEBT scores. Subjects completed the tests in a random order.

**RESULTS:** A total of 47 adolescents (12.5 yrs; 28 females and 19 males) and 41 (23.4 yrs; 24 females and 17 males) adults participated in this study. The only significant difference between the adult and adolescent individuals was for the EC test, with the adults averaging  $17 \pm 1$  secs and the adolescents  $25 \pm 10$  (2 - 30 secs for both groups) ( $p=.001$ ).

However, while the majority in both groups had EC times of > 20 secs, the distribution was continuous for the adults but adolescents that scored below 15 secs were distinctly different from the majority. The SEBT scores were different between the groups initially; when corrected for leg length, the average values ranged from .92 to .98 and were not significantly different. There were no differences between the genders, but there were significant interactions ( $p < 0.05$ ) between gender and age group for all three of the dynamic balance tests. The females were consistently better during adolescence and worse for the adults, while the males had poorer balance during adolescence and better when adults. Proprioception was not different for any of the groups and there was a small, but significant ( $r = .24$ ,  $p = .024$ ) correlation between proprioception and EC time.

**CONCLUSIONS:** Contrary to our hypothesis, there were not significant differences in balance and proprioception during adolescence as compared to adults, except for the EC test, which was better for the adolescents. There were individuals who were significantly outside the norm for some of the balance tests, which might suggest that they could be at a greater risk for injuries. Further research will be needed to explore this question.

**2064 Board #205 May 28 8:00 AM - 9:30 AM**

**Kinematics Of Multi-directional Gait Initiation**

Srikant Vallabhajosula<sup>1</sup>, Thomas Buckley<sup>2</sup>, Shinichi Amano<sup>1</sup>, Chris J. Hass<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>Georgia Southern University, Statesboro, GA. (Sponsor: Paul Borsa, FACSM)

Email: svallabh@hnp.ufl.edu

(No relationships reported)

Turning while initiating gait, or multi-directional gait initiation (MdGI) is a common activity of daily living that challenges the postural control system, as it requires inter-segmental coordination to maintain stability. While forward gait initiation (GI) and turning while walking have been widely studied, performance during MdGI has not been sufficiently evaluated.

**PURPOSE:** To determine if aging and Parkinson's disease (PD) affect the kinematics of MdGI.

**METHODS:** Nine healthy young adults (HYA, age 28.4 ± 4y), nine healthy older adults (HOA, age 56.6 ± 9.7y) and 11 individuals with PD (PWP, age 63 ± 2y) participated in the study. An 8-camera motion capture system was used to capture the kinematic data at 120 Hz. Participants performed five GI trials in each of three directions: 45° medially (crossing in front of the body, C45), 45° laterally (O45) and 90° laterally (O90). Axial rotations in the transverse plane were evaluated for the head, trunk, and pelvis segments at three time instances - swing leg heel off (SWHO), swing leg toe-off (SWTO) and swing leg heel strike (SWHS). Spatio-temporal parameters were calculated for the swing and stance limbs.

**RESULTS:** Group x Segment ANOVA indicated that the PWP exhibited a delayed onset of pelvic rotation during C45 ( $P < 0.05$ ). Also for the C45 condition, the HYA achieved more pelvic rotation than head rotation while the other two groups exhibited more head rotation at SWHS ( $P > 0.05$ ). For O45 and O90, significant group main effects indicated that at SWHS the HYA exhibited greater rotations than both HOA and PWP. HOA produced greater axial rotations than PWP. For the C45 and O45 conditions, PWP had a lower swing leg step velocity than HOA and HYA ( $P < 0.05$ ). Also across all the conditions, the PWP produced consistently shorter step lengths than HYA ( $P < 0.05$ ).

**CONCLUSION:** HOA and PWP exhibit a slower and different turn pattern when compared to HYA during MdGI. The restricted range of motion using a more cautious approach may reflect an increased dependence on visual feedback in the HOA and PWP groups.

**Sex Differences In Calf Muscle Hemoglobin Oxygen Saturation In Patients With Intermittent Claudication**

Polly S. Montgomery, Steve M. Blevins, Raha Nael, Azhar Afaq, Kristy Scott, Donald E. Parker, Andrew W. Gardner. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

(No relationships reported)

**PURPOSE:** To compare the exercise performance and calf muscle hemoglobin oxygen saturation (StO<sub>2</sub>) between men and women with intermittent claudication, and to determine whether calf muscle StO<sub>2</sub> explains sex differences in exercise performance.

**METHODS:** Twenty-seven men and 24 women with peripheral arterial disease limited by intermittent claudication were studied. Patients were characterized on calf muscle StO<sub>2</sub> before, during, and after a graded treadmill test, as well as on demographic and cardiovascular risk factors, ankle/brachial index (ABI), ischemic window, initial claudication distance (ICD), and absolute claudication distance (ACD).

**RESULTS:** Women had a 45% lower ACD than men (296 ± 268 meters vs. 539 ± 288 meters;  $p = 0.001$ ) during the treadmill test. Calf muscle StO<sub>2</sub> declined more rapidly during exercise in women than in men, as the time to reach minimum StO<sub>2</sub> occurred 54% sooner in women (226 ± 241 sec vs. 491 ± 426 sec;  $p = 0.010$ ). Additionally, the recovery time for calf muscle StO<sub>2</sub> to reach the resting value after treadmill exercise was prolonged in women (383 ± 365 sec vs. 201 ± 206 sec;  $p = 0.036$ ). Predictors of ACD included the time from start of exercise to minimum calf muscle StO<sub>2</sub>, the average rate of decline in StO<sub>2</sub> from rest to minimum StO<sub>2</sub> value, the recovery half-time of StO<sub>2</sub>, and ABI ( $R^2 = 0.63$ ;  $p < 0.001$ ). The ACD of women remained lower after adjusting for ABI (mean difference = 209 meters;  $p = 0.003$ ), but was no longer significantly lower (mean difference = 72 meters;  $p = 0.132$ ) after further adjustment for the three calf muscle StO<sub>2</sub> variables.

**CONCLUSIONS:** In patients limited by intermittent claudication, women have greater impairment in calf muscle StO<sub>2</sub> during and following exercise than men, and the exercise-mediated changes in calf muscle StO<sub>2</sub> are predictive of ACD.

Supported by: NIA(R01-AG-2496 AWG); and GCRC (M01-RR-14467).

**2066 Board #207 May 28 9:00 AM - 10:30 AM**

**The Comparison Of Effectiveness On Balance And Isokinetic Strength Between Ball Exercise And Treadmill Walking In Post-stroke Patients**

Eun-kyung Park<sup>1</sup>, jin-wook chung<sup>1</sup>, young-soo jin<sup>1</sup>, kee-chan joo<sup>2</sup>. <sup>1</sup>asan medical center, seoul, Republic of Korea. <sup>2</sup>seowon university, cheounju, Republic of Korea.

Email: matiz7478@nate.com

(No relationships reported)

**PURPOSE:** To determine effectiveness of Ball exercise on balance and Isokinetic strength comparing to treadmill walking

**METHODS:** Forteen post-stroke patients were recruited to participate and divided into two groups; Ball exercise group(BG ; n=7, 45.7yrs±12.8) and treadmill walking group (TG ; n=7, 44.3yrs±9.3). In both groups patients were capable of independent walking without any support. Before and after 12 week exercise training. Balance and isokinetic strength were measured by using Berg Balance Scale, Biodex balance system and Cybex 770

**RESULTS:** After 12-week exercise training, points from Berg Balance Scale increased in both group;  $52 \pm 2.94$  to  $52.14 \pm 3.48$  in TG and  $49.42 \pm 4.89$  to  $52.28 \pm 2.87$  in BG. However independent t-test showed that there were significant difference between two groups in amount of changes(post-pre). Isokinetic Strength increased in both groups, but there were not significant difference between groups.

**CONCLUSIONS:** Improving gait ability is one of major goals in exercise for post-stroke patients. It requires improvement of both balance and leg strength. Comparing the effect of two exercise, we recommend post-stroke patient to be participated in various type of exercise, especially in ball exercise that is effective for increasing both balance and leg strength.

**2067 Board #208 May 28 9:00 AM - 10:30 AM**  
**Cancer Therapies And Cardiovascular Fitness: Testing In A Clinic Setting**

Jennifer K. LeMoine, Priscilla A. Furth. *Georgetown University Medical Center, Washington, DC.*  
Email: jl583@georgetown.edu  
(No relationships reported)

**PURPOSE:** Physical activity is a critical component of cancer survivorship, both during and after cancer treatment. Current recommendations from the American Cancer Society indicate a minimum of 30 minutes physical activity, 5 days/week to improve health and fitness. However, cancer survivors are often hesitant to begin exercising during or after treatment. Furthermore, some cancer treatments have been linked to alterations in cardiovascular function. This study was initiated to determine whether or not cardiovascular fitness varied by exposure to different types of cancer treatment.

**METHODS:** We conducted a chart review of 49 women ( $52 \pm 2$ y, BMI:  $26 \pm 1$ ) who attended an MD-directed fitness clinic for cancer survivors. Data included demographics, physical activity (PA) levels, and cancer treatment information (treatment type, duration, and time since treatment). Fitness assessments were conducted in-clinic via a modified, 3-minute step test.

**RESULTS:** Participants were diverse in age (30-39y: 14%, 40-49y: 33%, 50-59y: 24%, 60-69y: 24%, 70+y: 4%) and BMI (<20: 2%, 20-24: 40%, 25-29: 26%, 30-34: 24%, 35-39: 5%, 40+: 2%). Overall, 33% were sedentary (SED) and 67% were physically active (ACT:  $4.3 \pm 0.5$  hours/week PA). Cancer diagnoses were breast, ovarian, rectal cancer and Hodgkin's disease. Treatment types included surgery (86%), radiation (49%), herceptin (14%), chemotherapy (57%) and antiestrogen therapy (47%). Overall, 35 individuals (71%) completed the step test. Test completion and heart rate (HR) recovery were not influenced by cancer treatment type, duration, or time since treatment ( $P > 0.05$ ). Similarly, no effect was seen for age, BMI, or resting HR ( $P > 0.05$ ). Physical activity improved both step test completion (ACT: 83% vs. SED: 30%,  $P = 0.02$ ) and duration (ACT:  $176 \pm 6$  vs. SED:  $122 \pm 18$  sec,  $P < 0.001$ ). Significantly, no participants experienced any side effects from performing the step test.

**CONCLUSION:** Cardiovascular fitness was not affected by exposure to different types of cancer therapy. Instead, the key determinant of cardiovascular fitness in our clinic participants was current levels of physical activity. We were able to demonstrate that use of a modified step test to measure cardiovascular function in the clinic setting is feasible, safe, time-efficient and cost-effective.

**Aerobic Vs. Resistance Exercise In Igfbp-3 In African American Males And Prostate Cancer Cells Growth**

Vrenon Bond, FACSM<sup>1</sup>, Anwar Jackson<sup>1</sup>, Madiha Khan<sup>1</sup>, Rajagopalan Sridhar<sup>1</sup>, Valerie Cousins<sup>1</sup>, Raymond Blakely<sup>2</sup>. <sup>1</sup>Howard University, Washington, DC. <sup>2</sup>University of Maryland Eastern Shore, Princes Anne, MD.  
Email: vbond@howard.edu  
(No relationships reported)

The value of aerobic exercise (ex) on health benefits have been well investigated while the benefits of resistance ex have been mostly minimized to that of building muscle and improving performance. Aerobic physical activity has been linked to reducing the growth of prostate tumors by altering function of the insulin-like growth factors. Prostate cancer affects blacks disproportionately, and whether aerobic and resistance ex affects the insulin-like growth factor system similarly is not known.

**PURPOSE:** This pilot study investigated the influence of aerobic ex and resistance ex on the concentration of a substance (insulin-like growth factor binding protein-3 [IGFBP-3]) which attenuates the growth of prostate tumor cells.

**METHODS:** Subjects were 14 sedentary black males 18-29 yrs. Subjects were assigned to groups of an aerobic ex ( $n = 7$ ) and resistance ex ( $n = 7$ ). The aerobic ex regime consisted of 7 consecutive days of treadmill jogging at 70% of peak oxygen uptake ( $VO_{2peak}$ ). The resistance ex regime consisted of 7 consecutive days of strength training the major muscle groups of the upper and lower extremity performing 3 sets of 10 repetitions corresponding to 70% 1 repetition maximum. At the beginning and end of 7 days of aerobic/resistance ex, serum samples of the subjects were incubated with cultures of prostate LNCaP tumor cells. The serum concentration of IGFBP-3 and the relative cell growth were measured.

**RESULTS:** Characteristics of age, body weight and height,  $VO_{2peak}$ , % body fat, and maximum leg strength were not significantly different across groups. Baseline serum concentration of IGFBP-3 was similar between the aerobic and resistance ex groups ( $.056 \pm .03$  vs.  $.056 \pm .01$  ng/ml). Further, baseline serum growth rate of the tumor cells were similar between groups ( $.51 \pm .09$  vs.  $.50 \pm .14$  %). We observed the tumor cell growth rate after aerobic and resistance ex tended to be lower (11% and 21%), but the difference was not significant. There was a tendency for similar increases in IGFBP-3 after aerobic and resistance ex.

**CONCLUSION:** Aerobic ex vs. resistance ex showed similar clinical directional findings for and increase in IGFBP-3 and decrement in prostate tumor cell growth rate. This study provides evidence suggesting aerobic ex and resistance ex are equally effective in possibly inhibiting the evolution of prostate cancer.

**Comparison Of Peak Image Acquisition Characteristics Between Supine Bicycle And Treadmill Exercise Echocardiography**

Mian A. Yousuf, Shalabh Singhal, Stephanie Kelly, Mohammad Abdul-Waheed, Yukitaka Shizukuda. *University of Cincinnati, Cincinnati, OH.*  
(No relationships reported)

Exercise echocardiography (EE) using supine bicycle (SB) or treadmill (TM) is widely used to diagnose coronary artery disease (CAD). Among the two exercise modalities, it is believed that peak exercise workload achieved with EE using SB is less when compared to EE using TM due to a lower peak exercise heart rate. Despite this, the limited studies comparing the two modalities directly have shown that EE with SB has better sensitivity and comparable specificity to EE with TM. The delay in peak exercise imaging acquisition (occasionally >30 seconds) with EE with TM, done at a time when the patient is no longer exercising and cardiac workload is decreasing, may be an explanation of this.

**PURPOSE:** In this study, we aim to compare the exercise workload characteristics at peak image acquisition (IA) between EE with SB and EE with TM in evaluating CAD. Method: We retrospectively assessed peak exercise and peak IA exercise workload of 173 consecutive patients who underwent EE either with SB or TM to evaluate CAD in our institute from January 2007 to August 2008. Of these exercise echocardiograms, 21 were with SB (age  $49 \pm 9$ ) and 152 were with TM (age  $49 \pm 14$ ). Result: At peak exercise patients who underwent EE with TM had higher HR as compared to EE with SB, but comparable rate pressure product, an index of oxygen consumption (RPP; HR x systolic BP). The mean delay in image acquisition of EE with TM was  $11 \pm 4$  seconds (no delay in SB). However, at peak IA, both HR and RPP were comparable between the two tests. (percentage of predicted HR to maximum predicted HR;  $83 \pm 9$  vs  $88 \pm 8$ %,  $P = 0.13$ , RPP;  $2,56 \pm 4.70$  vs  $2.47 \pm 5.37$   $10^3$  bpm-mmHg,  $P = 0.55$ ).

**CONCLUSION:** Our results show that at peak IA there was no difference in HR and there was a trend towards higher systolic BP in EE with SB as compared to EE with TM. This suggests that workload characteristics of EE with SB at actual IA is not inferior to EE with TM for evaluating CAD.

**2070 Board #211 May 28 9:00 AM - 10:30 AM**  
**Exercise And Cardiac Function In Children And Adolescents With Friedrich's Ataxia.**

Bart E. Drinkard<sup>1</sup>, Michelle Kennedy<sup>1</sup>, Josh Woolstenhulme<sup>1</sup>, Scott M. Paul<sup>1</sup>, Jon Plehn<sup>1</sup>, Randall E. Keyser, FACS<sup>2</sup>, Nicholas Diprospero<sup>1</sup>. <sup>1</sup>NIH, Bethesda, MD. <sup>2</sup>NIH and George Mason University, Bethesda, MD.  
(No relationships reported)

Increased relative left ventricular wall thickness (IRWT) frequently occurs in individuals who have the autosomal disorder, Friedrich's Ataxia (FA).

**PURPOSE:** To examine cardiorespiratory function in children and adolescents (13.2±0.6 years, 20.1±3.7 BMI, M=23, F=22) who have FA.

**METHODS:** Cardiac output (Qt), stroke volume (SV), heart rate (HR) and maximum oxygen consumption (VO<sub>2</sub>) were measured at rest and during cycle ergometer tests to volitional exhaustion. Maximum a-VO<sub>2</sub> was calculated by dividing maximum VO<sub>2</sub> by maximum Qt. Cardiorespiratory data were obtained by open circuit spirometry and impedance cardiography.

**RESULTS:** 38 subjects (84%) had relative wall thicknesses that exceeded the index threshold of 0.40 for clinically significant IRWT (0.62±0.14), as determined by resting echocardiography. 7 subjects were without IRWT (0.34±0.04). Resting ejection fraction was (61±07%) in the youths with IRWT and (58±08%) without IRWT. Significant group differences in resting and maximum Qt, SV, HR, a-VO<sub>2</sub> or VO<sub>2</sub> were not observed. Maximum VO<sub>2</sub> was 755±275 mlO<sub>2</sub>/min and maximum a-VO<sub>2</sub> was 08±02 vol% for the entire sample. Cardiac function data for the entire sample is provided in the table.

Cardiac Function			
	Qt (ml/min)	SV (ml)	HR (beats/min)
Rest	6243±/- 2170	63±/-25	101±/-15
Maximum	10182±/- 3949	72±/-25	142±/-23

**CONCLUSION:** Compared to previous studies (Cooper, 1984; Vinet, 2002), maximum Qt, a-VO<sub>2</sub>, and VO<sub>2</sub> were markedly diminished in these youths with FA. SV failed to increase from rest to maximum exercise. The slight increase in Qt (p<0.0001) during exercise resulted almost entirely from the rise in HR (p<0.0001). Failure of SV to increase with strenuous exercise and decreased exercise capacity are often observed in patients who have severe left ventricular dysfunction.

**2071 Board #212 May 28 9:00 AM - 10:30 AM**  
**Changes In Heart Rate Recovery After High Intensity Training In Well-trained Cyclists**

Robert P. Lamberts, Jeroen Swart, Timothy D. Noakes, FACSM, Michael I. Lambert. *University of Cape Town, Cape Town, South Africa.*  
Email: robert.lamberts@uct.ac.za  
(No relationships reported)

**PURPOSE:** Heart rate recovery (HRR) after submaximal exercise improves after training. However, it is unknown if this also occurs in already well-trained cyclists.

**METHODS:** Therefore, 14 well-trained cyclists (VO<sub>2max</sub> 60.3 ± 7.2 ml·kg<sup>-1</sup>·min<sup>-1</sup>; relative peak power output 5.2 ± 0.6 W·kg<sup>-1</sup>) participated in an 8 sessions of week high intensity training program. Before and after high intensity training performance was assessed with a peak power output test including respiratory gas analysis (VO<sub>2max</sub>) and a 40km time trial. HRR was measured after every high intensity training session and 40km time trial (HRR<sub>40km</sub>).

**RESULTS:** After the training period relative peak power output improved by 4.7% (P = 0.000010) and mean relative power in the 40km time trial improved by 6.2% (P = 0.000007). Both HRR<sub>HIT</sub> (7 ± 6 beats; P = 0.001302) and HRR<sub>40km</sub> (6 ± 3 beats; P = 0.023101) also improved significantly after the training period. Good relationships were found between improvements in HRR<sub>40km</sub> and improvements in relative PPO (r = 0.73; P < 0.0001) and 40km time trial time (r = 0.96; P < 0.0001).

**CONCLUSIONS:** In conclusion, HRR is a sensitive marker which tracks changes in training status in already well-trained cyclists and has the potential to have an important role in monitoring and prescribing training.

**2072 Board #213 May 28 9:00 AM - 10:30 AM**  
**Left Ventricle Performance by Longitudinal Peak Systolic Strain Measurement In Young Athletes With Bicuspid Aortic Valve**

Laura Stefani, De Luca Alessio, Roberto Mercuri, Gabriele Innocenti, Loira Toncelli, Luigi Caselli, Brunello Cappelli, Giorgio Galanti. *Sport Medicine, Florence, Italy.*  
Email: laura-stefani@tiscali.it  
(No relationships reported)

Purpose : Strain (S) is a measure of the regional and global heart function. S has a role in the identification of the myocardial dysfunction in presence of valvular disease. Bicuspid Aortic Valve (BAV) is a congenital cardiac disease, common in athletes where the EF maintains normal value . BAV is usually studied for the possible complications of the aortic tract however few data on the behaviour of the Left Ventricle (LV) in young are available. This study aims to evaluate if the measurement of S of LV adds any more information in BAV athletes with normal EF.

**METHODS:** Three groups aged 25 ± 3 (20 trained athletes with BAV, 20 healthy athletes and 20 sedentary healthy subjects) were submitted to an echocardiographic exam evaluating the traditional echo-parameters . From four chamber view, using X-Strain software included in the MyLab 50 echo ( Esa Ote -Italy) the Longitudinal Peak Systolic Strain ( LPSS) at basal and medium-apical segments of Lateral Wall ( LW) and Inter Ventricular Septum (IVS) of LV were calculated ( Fig 1).

**RESULTS:** The S values are within the normal and validated range in all the segments considered without any statistical differences among the three groups. However in BAV athletes, the S of basal segments of LV tends to be particularly lower creating a significant gradient from basal to apical regions (table 1). EF is normal for all groups.

**CONCLUSIONS:** The evaluation of S in LV chamber of young trained BAV athletes confirms the normal LV performance. Despite of this there is a tendency in BAV to show the values of S in LV basal segments lower than in healthy subjects. The clinical implication of this will require further investigations.

Table 1

	S %IVSbasal	S%IVSmed-apic	P	S%LWbasal	S%LWmed-apic	P
BAV	-17.7± 2.7	-21± 3.5	.001	-14.2± 2.2	-18.8± 4.2	.001

## 2073 Board #214 May 28 9:00 AM - 10:30 AM The Effect Of Acute Vs. Chronic Sodium Citrate Ingestion On 200m Time Trial Swimming Performance.

Thomas Zochowski, Ben Sporer, Gord Sleivert. *Canadian Sport Centre Pacific, Victoria, BC, Canada.*

Email: zochowski@gmail.com

(No relationships reported)

Ingestion of sodium bicarbonate is known to improve anaerobic exercise performance, probably via increased buffering of intracellular acidity. Other buffering agents have been used with some success. Sodium citrate is one such substance and has been used without the normal gastro-intestinal discomfort usually associated with sodium bicarbonate ingestion. However, an ideal ingestion protocol (acute vs. chronic) has yet to be determined for swimming.

**PURPOSE:** To determine an ideal sodium citrate ingestion protocol for swimming.

**METHODS:** Seven elite swimmers ingested the daily dose of sodium citrate (0.3g / kg body mass) 1.5hrs before the time trial on the performance day for both acute and chronic treatments. Additionally, for the chronic treatment sodium citrate was ingested each of the 4 days prior to the time trial day. Following a standard warm-up, participants were asked to swim a 200m freestyle time trial. In addition to performance time, measures of blood lactate, heart rate and perceived exertion were recorded at baseline, post warm-up, pre-race and post-race times. Measure of pH was recorded at baseline and pre-race.

**RESULTS:** There was no significant difference in final time between treatments (Acute: 125.4 (SD 7.1) sec, Chronic: 125.8 (SD 7.2) sec, Placebo: 125.7 (SD 8.1) sec,  $p < 0.05$ ). There was a significant increase over time for all treatments in pH (baseline to pre-race), blood lactate (pre-race to post-race), heart rate (pre-race to post-race) and perceived exertion (pre-race to post-race). There was no difference between acute, chronic and placebo at the various time points for blood lactate, heart rate and perceived exertion. There was a significant difference in pH level at the pre-race time point. The chronic and acute loading protocols were both different than placebo but were not different to each other (Acute: 7.46 (SD 0.02), Chronic: 7.47 (SD 0.02), Placebo: 7.41 (SD 0.02),  $p < 0.05$ ).

**CONCLUSION:** While both sodium citrate dose protocols altered blood pH they did not have a significant effect on final swim performance.

## 2074 Board #215 May 28 9:00 AM - 10:30 AM Application Of Athlete Monitoring System To Evaluate The Physical Capacity Of The Soccer Players

Youn Tae Kim<sup>1</sup>, Kyeong Ho Byun<sup>2</sup>, Hyo Jung Kim<sup>2</sup>, Jaemin Kang<sup>2</sup>. <sup>1</sup>*Chosun University, Gwangju, Republic of Korea.* <sup>2</sup>*Seoul National University, Seoul, Republic of Korea.*

Email: petruskim@chosun.ac.kr

(No relationships reported)

We have evaluated the physical capacity of the soccer players by using athlete monitoring system composed of the flexible patch type sensor module and the monitoring station.

**PURPOSE:** To evaluate the physiological responses during the shuttle run test were monitored and reliability and validity were analyzed for the effective and scientific training.

**METHODS:** To investigate the reliability, reproducibility was verified through test-retest and to evaluate its validity, correlation between results of the test and  $VO_{2max}$ , and relation between changes of the results of the test during pre-season training period, and relation between shuttle run test and performance in actual games were examined. Heart rate was measured, and blood lactate ( $N=13$ ) was obtained before, during, and after the shuttle run test in 27 high school soccer players. And they performed two to three seasonal tests during the pre-season training period, and the results were related to changes of the maximal oxygen uptakes measured in pre and post pre-season training. Additionally, 31 male professional soccer players performed two types of shuttle run test and each result was related to physical performance in matches.

**RESULTS:** The intra-individual difference between test and retest averaged within 5% of distance covered in 1<sup>st</sup> test. During the shuttle run test, heart rate and blood lactate increased ( $p < 0.05$ ) to  $90 \pm 3\%$  of peak heart rate and  $3.4 \pm 1.3$  mmol/L, respectively, after 67<sup>th</sup> repetitions. During the pre-season training period, players ( $N=15$ ) improved ( $p < 0.05$ ) distance covered in the test and maximal oxygen uptake ( $VO_{2max}$ ) by  $4 \pm 1\%$ , equally. In addition, heart rate after 67<sup>th</sup> repetitions at the start decreased ( $p < 0.05$ ) to  $3 \pm 1\%$  of HR peak at the end.

**CONCLUSIONS:** The shuttle run test had high reproducibility and sensitivity, allowing it to be a reliable method to evaluate the physical capacity of the players participated in the intermittent sports.

The  $VO_{2max}$  also increased during the pre-season training period as well as the shuttle run test performance. Especially, since the physiological response after the 67<sup>th</sup> repetition showed similar lactate threshold, we have found that measuring the heart rate right after the 67<sup>th</sup> repetition is as effective and valid as recording the test performance at the last repetition.

## 2075 Board #216 May 28 9:00 AM - 10:30 AM Elite America's Cup Sailors Are Among The Most Powerful Upper Body Trained Athletes

Vernon Neville, Matthew Pain, Jonathan Folland. *Loughborough University, Loughborough, United Kingdom.*

Email: vernon.neville@hotmail.com

(No relationships reported)

**BACKGROUND:** Big-boat yacht racing is one of the only able bodied sporting activities where standing arm-cranking ('grinding') is the primary physical activity. However, the physiological capabilities of elite sailors for standing arm-cranking have been largely unreported.

**PURPOSE:** To assess aerobic parameters,  $VO_{2peak}$  and lactate threshold ( $LT_4$ ), and anaerobic performance, torque- and power-crank velocity relationships and therefore peak power ( $P_{max}$ ) and optimum crank-velocity ( $w_{opt}$ ), of America's Cup sailors during standing arm-cranking.

**METHODS:** Thirty-three elite professional sailors performed a step test to exhaustion, and a subset of ten *grinders* performed maximal 7 s isokinetic sprints at different crank velocities, using a standing arm-crank ergometer.

**RESULTS:**  $VO_{2peak}$  was 4.7 (0.5) L/min (range: 3.6 to 5.5 L/min) at a power output of 332 (44) W (range: 235 to 425 W).  $LT_4$  occurred at a power output of 202 (31) W (61% of  $W_{max}$ ) and  $VO_2$  of 3.3 (0.4) L/min (71% of  $VO_{2peak}$ ). The torque-crank velocity relationship was linear for all participants ( $r=0.9$  (0.1)).  $P_{max}$  was 1420 (37) W (range: 1192 to 1617 W), and  $w_{opt}$  was 125 (6) rpm.

**CONCLUSIONS:** These data are among the highest upper-body anaerobic and aerobic power values reported. The unique nature of these athletes, with their high fat-free mass and specific selection and training for standing arm cranking, likely accounts for the high values. The influence of crank velocity on peak power implies that power production during on-board 'grinding' may be optimised through the use of appropriate gear-ratios and the development of efficient gear change mechanisms.

---

**2076 Board #217 May 28 9:00 AM - 10:30 AM****Food And Body Composition Of Brazilian Male Swimmers**

Ana Paula Franzese, Desire Coelho, Patricia Oliveira, Camila Freitas, Mariana Fontana, Patricia Ferraz, Luciana Lancha, Antonio Herbet Lancha Junior. *Vita Care - Instituto Vita, São Paulo, Brazil.*

Email: ana.franzese@vita.org.br

(No relationships reported)

**PURPOSE:** The aim of the present study was to analyze body and diet composition of 19 male brazilian swimmers and compare these variables to the international dietary recommendations for macro and micronutrients.

**METHODS:** The sample was constituted by 19 swimmers (15 + 1,2y). Body composition was determined by body mass index- BMI (kg/m<sup>2</sup>), body circumferences (cm), skinfolds (mm) and body fat percentage was evaluated according to Slaughter. Food consumption (macronutrients and micronutrients) was analyzed and nutritional software Dietwin®.

**RESULTS:** Athletes present the following body composition averages: 17 + 4.1% of body fat; 175 + 6.5 cm of stature; 67 + 10.1 kg of body mass and 22 + 2 Kg/m<sup>2</sup> of BMI. Regarding food consumption, it was observed the following results of swimmers respectively, 3210.1 + 933.7 kcal; carbohydrate content 61.6 + 6.8%; protein content 29.5 + 45%; lipid content of 29.4 + 18.4%. It was also observed low calcium ingestion of 1115.6 + 295.1 mg/day. Regarding fluid replacement it was observed that 90% of the athletes uses carbohydrate supplement (maltodextrin) with 8% concentration but the daily water consumption was 70% lower than the recommendation for high performance activities.

**CONCLUSIONS:** The high consumption of lipids interferes not only in the quality of the feeding as well as in the performance of the athletes. The low ingestion of calcium emphasize the importance of the nutritional intervention in order to improve performance and prevent any future health problem.

---

**2077 Board #218 May 28 9:00 AM - 10:30 AM****Pediatric Heart Rate And Vo<sub>2</sub> Relationships Compared To The ACSM Predicted Values**

Yvette M. Gerdes, Wayne A. Mays, Sandra K. Knecht, Timothy K. Knilans. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Email: Yvette.Gerdes@cchmc.org

(No relationships reported)

**PURPOSE:** To establish a correlation between the observed percent maximal heart rate reserve (%MaxHRR), percent maximal VO<sub>2</sub> reserve (%MaxVO<sub>2</sub>R), and percent of maximal heart rate (%MaxHR) compared to the established adult values by the American College of Sports Medicine.

**METHODS:** 1087 patients (Male 548, Female 539) referred for evaluation of chest pain, syncope and exercise intolerance were evaluated by a maximal exercise test using the James cycle ergometer protocol. The patients were cleared of structural heart disease by echocardiograph and/or physical examination and history. All exercise tests were maximal efforts. Patient demographics were: Age 14.4 years old (±3.4), Height 1.62 meters (±0.14), Weight 59kg (±18.38), and Body surface area 1.61m<sup>2</sup> (±0.30).

**RESULTS:** The maximal heart rate (MHR) was 192 beats per minute (±11). The maximal oxygen uptake, indexed maximal oxygen uptake and respiratory quotient was 2122 ± 681cc/min, 37 ± 7cc/kg/min and 1.14 ± 0.08, respectively. The observed exercise values for %MaxHR were significantly higher than the ACSM predicted values at 40%, 50%, 60%, 80% and 85% Max VO<sub>2</sub> levels. Additionally, %MaxHRR and %MaxVO<sub>2</sub>R were equivalent up to the 80% MaxVO<sub>2</sub> level at which time %MaxHRR was significantly higher.

	40%Max VO <sub>2</sub>	50%Max VO <sub>2</sub>	60%Max VO <sub>2</sub>	80%Max VO <sub>2</sub>	85%Max VO <sub>2</sub>
ACSM predicted %Max HR	55	62	70	85	90
Observed %Max HR	*61 ± 7	*67 ± 7	*75 ± 7	*89 ± 6	*92 ± 5
Observed %Max HRR	30 ± 10	39 ± 11	54 ± 13	*79 ± 10	*85 ± 10
Observed %Max VO <sub>2</sub> R	30 ± 4	41 ± 4	53 ± 4	77 ± 2	82 ± 2

\*P<0.001

**CONCLUSION:** The observed values for %MaxHR are significantly higher in pediatrics compared to the predicted values by the ACSM. Additionally, %MaxHRR and %MaxVO<sub>2</sub>R were equivalent up to the 80% MaxVO<sub>2</sub> level at which time %MaxHRR was significantly higher. When developing an exercise prescription for pediatric patients, development of percent maximal values must be based on pediatric standards.

---

**2078 Board #219 May 28 9:00 AM - 10:30 AM****Effect Of Anti-Parkinson Drug Timing On Tissue Oxygen Saturation And Ventilatory Threshold During Treadmill Exercise**

Jennifer Hrdina, Jody Anderson, Shannon Haley, Shalini NFN, Cheryl Petersen, Teresa Steffen, Reid Nelson. *Concordia University Wisconsin, Mequon, WI.*

Email: jennifer.hrdina@cuw.edu

(No relationships reported)

Treadmill training is recognized as an effective therapy for individuals with Parkinson disease (PD). Treadmill training guidelines and physiological responses are not conclusive in this population especially related to the peaks and valleys of the primary PD medications [dopamine agonists (DA)].

**PURPOSE:** To determine if timing of DA affects the relationships between tissue oxygen saturation (StO<sub>2</sub>), ventilatory threshold (VT) and ratings of perceived exertion (RPE) during treadmill exercise.

**METHODS:** Nine individuals (6M, 3F; mean age 77.3 ± 5.1 years) diagnosed with PD, participating in treadmill training, were recruited. All participants completed one familiarization session along with two data collection sessions; one session at high and one session at low DA efficacy. A ramp treadmill protocol (increased 0.1 mph every 30 seconds with 0% elevation) was conducted to submaximal endpoints corresponding to participants RPE of hard to very hard exertion. Cerebral and skeletal muscle StO<sub>2</sub> measurements were obtained with frequency-domain near infrared spectroscopy (NIRS). The time of initial sustained change in StO<sub>2</sub> from baseline; and mean change in percent StO<sub>2</sub> at RPE of somewhat hard, RPE of hard, and at test end, were identified. VT was assessed using the V-slope method with ventilatory equivalents for O<sub>2</sub> and CO<sub>2</sub> used for confirmation.

**RESULTS:** There was no significant difference in time to initial change in StO<sub>2</sub> (387.89 ± 61.46 vs. 371.22 ± 69.87 seconds), mean change in StO<sub>2</sub> at RPE somewhat hard (-3% ± 1.4 vs. -1.4% ± 1.0), mean change of StO<sub>2</sub> at RPE hard (-4% ± 1.6 vs. -3.5% ± 1.3), or mean change of StO<sub>2</sub> at test end (-5.1% ± 1.9 vs. -4.2% ± 1.6), relative to DA timing at peak vs. valley respectively. Cerebral StO<sub>2</sub> remained stable throughout exercise and was not affected by DA timing. VT was attained at peak DA timing in five individuals however only two of the five attained a VT at valley DA timing. Four individuals did not attain an identifiable VT during either DA peak or valley.

**CONCLUSION:** The results of this study suggest DA timing does not significantly affect changes in StO<sub>2</sub>, either in cerebral tissue or skeletal muscle during submaximal

treadmill exercise. In addition, the use of VT to guide exercise intensity prescription may be of limited value in individuals with PD.

**2079 Board #220 May 28 9:00 AM - 10:30 AM**

**Effects Of Cessation Of An Exercise Program On Lean Mass And Physical Performance In Burns.**

Haidy Rivero, Fatemah Emdad, David N. Herdon, Marc G. Jeschke, Ronald Mlcak, Oscar E. Suman, FACS. *Shriners Hospital / University of Texas Medical Branch, Galveston, TX.*

(No relationships reported)

The posttraumatic response to severe burns leads to marked and prolonged skeletal muscle catabolism and weakness. Previous studies have shown that participation in a standard rehabilitation program supplemented with an exercise program results in significant improvements in muscle strength (MST), lean body mass (LBM) and cardiopulmonary capacity (VO2) relative to a standard of care rehabilitation program without exercise.

**PURPOSE:** To determine if in severely burned children, these benefits are maintained 9 to 15 months (18 or 24 months post-burn) after cessation of the exercise program.

**METHODS:** We assessed leg MST, LBM and VO2 in children with  $\geq 40\%$  total body surface area burns. Patients were randomized to a 12-wk hospital rehabilitation program supplemented with an exercise training program (EX; n=44) or to a standard of care home-based rehabilitation program without exercise (SOC; n=34). Leg MST was assessed using dynamometry; LBM was determined using dual-energy X-ray absorptiometry, and VO2 was assessed using indirect calorimetry. Assessments were made 4 to 6 months post-burn, which corresponded with the period immediately before the 12 weeks exercise program, and at 18-24 months post-burn. Results are expressed as means  $\pm$  SEM, and significance accepted at  $p \leq 0.05$

**RESULTS:** MST, LBM, and VO2 significantly increased in the EX group after the exercise program ( $74 \pm 16\%$ ,  $20 \pm 3\%$ , and  $29 \pm 9\%$  respectively). In contrast, in the SOC group, MST and VO2 did not significantly increase ( $26 \pm 7\%$ , and  $5 \pm 22\%$ , respectively), while LBM significantly increased by  $13 \pm 3\%$ . Although, no significant differences were found between the EX and the SOC groups, absolute values for MST, LBM and VO2 at 18-24 months were consistently higher in the EX group

**CONCLUSION:** The effectiveness of an exercise program has been previously demonstrated in burned children. However, after the cessation of the physical activity, these exercise-induced benefits are diminished. Our results suggest the need for establishing long term rehabilitation goals, and continued education in maintaining an active and healthy lifestyle by children with severe burns.

**Neck Muscle Training Effects On Balance In Patients With Cervical Spondylosis Related Chronic Neck Pain**

Yi-Jia Lin<sup>1</sup>, Cheng-Hsiu Lai<sup>1</sup>, Meng-Ju Tsai<sup>1</sup>, Yi-Liang Chen<sup>1</sup>, Chia-Hua Kuo<sup>1</sup>, Shih-Wei Chou<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan.

<sup>2</sup>Chang Gung Memorial Hospital, Taoyuan, Taiwan. (Sponsor: John L. Ivy, FACS)

Email: dawn49241@hotmail.com

(No relationships reported)

Through cervical mechanoreceptors and their connections to sensory systems, neck provides inputs which are responsible to balance. Balance disturbances were found in patients with chronic neck pain, especially in challenging tasks. Neck muscle training help improve neck function in patients with chronic neck pain.

**PURPOSE:** The current study was to evaluate effect of neck muscle training on balance in patients with cervical spondylosis related chronic neck pain.

**METHODS:** 18 patients with chronic neck pain were recruited. X-ray of their cervical spines revealed nonspecific spondylosis. Six of them (age:  $53 \pm 5$  years) had completed 12 times training sessions, including warm-up, stretching, strengthening, and neuromuscular control exercises. A SMART Balance Master was employed to acquire equilibrium scores of sensory organization test (SOT) under 6 conditions, including eyes open & fixed support (EO), eyes closed & fixed support (EC), sway-referenced vision & fixed support (SV), eyes open & sway-referenced support (SS), eyes closed & sway-referenced support (ECSS), and sway-referenced vision & support (SVSS). Visual analog scale (VAS) of neck pain, range of motion (ROM) and isometric strength were measured and compared pre- post- intervention using paired t test.

**RESULTS:** After neck muscle training, neck pain, ROM, and strength were all improved. Equilibrium scores were significantly higher in EO ( $94.3 \pm 1.1$  vs.  $95.6 \pm 1.1$ ), EOSS ( $83.4 \pm 5.8$  vs.  $87.0 \pm 5.0$ ), ECSS ( $61.3 \pm 16.7$  vs.  $70.1 \pm 9.4$ ), and SVSS ( $64.7 \pm 6.0$  vs.  $78.5 \pm 4.4$ ). Visual ratio ( $0.88 \pm 0.05$  vs.  $0.91 \pm 0.04$ ) and vestibular ratio ( $0.65 \pm 0.18$  vs.  $0.73 \pm 0.10$ ) were increased.

**CONCLUSION:** In the patients with cervical spondylosis related chronic neck pain, neck muscle training may help reduce neck pain, improve ROM and strengthen neck muscle, that is, neck function improved. As a result, balance performance was improved in SOT. Visual and vestibular sensory ratio, which reflect the ability to use respective sensory systems, were improved after neck function improved.

**2081 Board #222 May 28 9:00 AM - 10:30 AM**

**Effect Of Continuous Positive Airway Pressure Treatment On Physical Activity In Obstructive Sleep Apnea Patients**

Trent A. Hargens, Cassandra A. Ledman, Leonard A. Kaminsky, FACS. *Ball State University, Muncie, IN.*

(No relationships reported)

Obstructive Sleep Apnea (OSA) is a disorder affecting an estimated 15 million adult Americans, and contributes to an increased risk for hypertension, diabetes mellitus, cardiovascular morbidity and mortality. Excessive daytime sleepiness (EDS), which negatively impacts physical activity (PA) levels, is a cardinal symptom of OSA. Previous reports utilizing subjective measurements have suggested that untreated OSA patients engage in less PA than the average adult. Continuous positive airway pressure treatment (CPAP) has been shown to improve EDS, but its impact on PA has not been examined.

**PURPOSE:** Pilot study to evaluate whether CPAP positively impacts objectively measured PA in newly diagnosed OSA patients under usual care, through a decrease in EDS symptoms.

**METHODS:** Six men (Mean age  $\pm$  SD =  $49.3 \pm 6.6$  years, BMI  $35.1 \pm 5.7$  kg/m<sup>2</sup>) with moderate-to-severe OSA underwent anthropometric measurements and body composition analysis via dual energy x-ray absorptiometry at baseline and following 8 weeks of CPAP treatment. The Actigraph GTIM accelerometer was used to measure PA for 7 consecutive days at baseline and at follow-up.

**RESULTS:** EDS decreased significantly with CPAP treatment from baseline to follow-up, measured by Epworth Sleepiness Scale ( $12.0 \pm 5.2$  vs.  $7.2 \pm 5.0$ ). Baseline steps/day ( $6713 \pm 1549$  steps/day) were in the low active classification and were unchanged at follow-up ( $6385 \pm 1083$ ). Total activity counts also did not change ( $227636 \pm 68003$  vs.  $220169 \pm 40471$ ). Average minutes performing light and moderate intensity PA at baseline were  $121.1 \pm 37.9$  and  $15.3 \pm 5.6$  min, respectively, and did not change with treatment. No subject performed vigorous intensity PA. Body composition measures were unchanged.

**CONCLUSION:** Results suggest that 8-weeks of CPAP treatment did not elicit changes in PA levels despite a decrease in EDS symptoms. Measured objectively, OSA patients engage in low levels of PA, below the recommended amounts. Lack of change in PA may be due to seasonal influences, the relatively short CPAP evaluation period, and adherence to CPAP treatment. More targeted interventional strategies to increase PA in OSA patients may be needed to achieve recommended levels of PA for health enhancement.

Supported by a grant from ResMed Sleep Disordered Breathing Foundation, Poway, CA.

**Factors Influencing Exercise Capacity in Obstructive Sleep Apnea Syndrome Patients**

Adrian Aron<sup>1</sup>, William G. Herbert, FACSM<sup>2</sup>. <sup>1</sup>Radford University, Radford, VA. <sup>2</sup>Virginia Tech, Blacksburg, VA.  
(No relationships reported)

Overweight is a prominent comorbidity associated with obstructive sleep apnea syndrome (OSAS). Previous studies have concluded that exercise capacity is reduced in patients with OSAS; however, these findings have only been determined in the context of overweight or obesity. Therefore, there is uncertainty whether OSAS, in the absence of excess body mass, limits exercise capacity or modifies physiologic responses important to clinical applications of exercise testing.

**PURPOSE:** To evaluate the influence of body fat or OSAS presence as the main contributing factor to low exercise capacity.

**METHODS:** Subjects were sedentary healthy men assigned to groups, according to BMI and OSAS presence: normal weight-OSAS (n = 10), normal weight-noOSAS (n = 17), overweight-OSAS (n = 20) and overweight-noOSAS (n = 22). Unattended home monitoring using a portable diagnostic device was performed to evaluate for OSAS. Body composition was measured with dual-energy X-ray absorptiometry. Subjects completed a maximal ramping cycle test to determine oxygen consumption ( $\dot{V}O_2$ ), minute ventilation (VE), and respiratory exchange ratio (RER).

**RESULTS:** There were no significant VE and RER differences between groups at sub-maximal or peak exercise level ( $p > 0.05$ ). Two-way ANOVA showed that in OSAS subjects, being overweight decreases exercise capacities at peak and sub-maximal exercise levels beginning at 85W. On the other hand, OSAS presence did not influence  $\dot{V}O_2$  levels. Stepwise linear regression using peak  $\dot{V}O_2$  as the dependent variable and selected independent measures as predictors [BMI, central fat (CF), apnea-hypopnea index, resting heart rate and blood pressures] showed that CF itself predicted 45% of the variation in peak  $\dot{V}O_2$ .

**CONCLUSIONS:** Published data has demonstrated that reduced exercise capacity in OSAS patients is largely due to factors associated with the pathophysiology of the disorder. However, our findings suggest that in young, healthy adult males, fat accumulation is responsible for exercise limitations in OSAS patients. Mediating mechanism contributing to decreased  $\dot{V}O_2$  in OSAS patients have yet to be clarified, but these data strongly suggest that decrements in maximal exercise capacity, typically reported in the literature, are a function of excess body fat, rather than OSAS, per se.

**2083 Board #224 May 28 9:00 AM - 10:30 AM**  
**Intensity And Energy Expenditure Of Sports In Elite Paralympic Athletes With Locomotor Disabilities**

Marco Bernardi<sup>1</sup>, Maria Rosaria Squeo<sup>2</sup>, Fabio Faiola<sup>2</sup>, Federico Egidi<sup>2</sup>, Vincenzo Castellano<sup>3</sup>, Yagesh Bhambhani<sup>4</sup>. <sup>1</sup>Sapienza, University of Rome; Comitato Italiano Paralimpico, Rome, Italy. <sup>2</sup>Sapienza, University of Rome, Rome, Italy. <sup>3</sup>Fondazione Santa Lucia, Rome, Italy. <sup>4</sup>University of Alberta, Edmonton, AB, Canada.  
Email: marco.bernardi@uniroma1.it  
(No relationships reported)

**INTRODUCTION:** Evaluating the physiological responses of athletes in the competitive environment is important for designing appropriate training programs.

**PURPOSE:** To examine the relationships between field test (oxygen consumption -  $\dot{V}O_2$ ) and laboratory aerobic fitness performance in elite Italian Paralympic athletes participating in the following five sports: 5k wheelchair distance racing (WR, N = 5), wheelchair basketball (WB, N = 13), wheelchair tennis (WT, N = 3), wheelchair fencing (WF, N = 6) and 5k nordic sit skiing (NS, N = 5).

We hypothesized that during these field tests, athletes would attain average intensity levels close to or higher than their individual ventilatory thresholds (VT).

**METHODS:** Each athlete completed an incremental arm cranking exercise test to determine VT from respiratory gas exchange measurements and  $\dot{V}O_{2peak}$ . In a subsequent session, to assess energy expenditure (EE) in their respective sport (these intensities are usually similar to those of training), field tests were carried out measuring  $\dot{V}O_2$ , carbon dioxide production and heart rate (HR) using a telemetric system.

**RESULTS:** Athletes of the five sport groups showed no differences in functional class (disability level). There were no significant differences in  $\dot{V}O_{2peak}$  values ( $49.8 \pm 6.77$  ml kg<sup>-1</sup> min<sup>-1</sup>), EE ( $11.9 \pm 1.44$  METS) and HR ( $175 \pm 8.4$  beats min<sup>-1</sup>) between WR and NS athletes. All these values were significantly higher compared to the athletes in the other three sport groups ( $\dot{V}O_{2peak}$ :  $35.4 \pm 4.49$  ml kg<sup>-1</sup> min<sup>-1</sup>, EE  $7.3 \pm 0.86$  METS and HR:  $151 \pm 13.4$  beats min<sup>-1</sup>). Work intensities, expressed as percentages of VT and  $\dot{V}O_{2peak}$ , were also significantly higher in WR and NS athletes ( $117.9 \pm 10.94$  %VT and  $82.4 \pm 4.61$  % $\dot{V}O_{2peak}$ ) than in WB, WF and WT athletes ( $103.8 \pm 5.01$  %VT and  $72.7 \pm 5.01$  % $\dot{V}O_{2peak}$ ). The  $\dot{V}O_2$  during the field tests showed strong relationships with both VT ( $R^2 = 0.842$ ) and  $\dot{V}O_{2peak}$  ( $R^2 = 0.898$ ).

**CONCLUSIONS:** These findings suggest that: (1) enhancing the VT and peak aerobic power in these athletes with disabilities would be of considerable importance in improving competitive sport performance; (2) greater aerobic energy demands and intensity levels during both competitive sport and training seem to be effective in increasing both these aerobic fitness variables.

**Effects Of Fenugreek, Cinnamon, & Curcumin On Post Workout Inflammatory Response.**

Colin D. Wilborn<sup>1</sup>, Lem W. Taylor<sup>1</sup>, Clifffa A. Foster<sup>1</sup>, Trevor Swift<sup>1</sup>, Courtney Burken<sup>1</sup>, Maggie Florez<sup>1</sup>, Chris Poole<sup>1</sup>, Brandon Bushey<sup>1</sup>, Richard B. Kreider, FACSM<sup>2</sup>, Daryn S. Willoughby, FACSM<sup>3</sup>. <sup>1</sup>University of Mary Hardin Baylor, Belton, TX. <sup>2</sup>Texas A&M University, College Station, TX. <sup>3</sup>Baylor University, Waco, TX.  
Email: colinwilborn@yahoo.com  
(C.D. Wilborn, Indus Biotech, Contracted Research.)

It has been documented that strenuous exercise suppresses cellular immunity leading to increased susceptibility to infections and delayed recovery. As mediators of these phenomena, cytokines released into the circulation have been a recent focus of attention.

**PURPOSE:** To assess the acute effectiveness of fenugreek, cinnamon, & curcumin on blunting inflammatory markers after muscle damage.

**METHODS:** Twenty healthy non-resistance trained male and female subjects were equally divided by gender and assigned to ingested either a proprietary blend of fenugreek, cinnamon, & curcumin (N = 10,  $21 \pm 2.8$  yrs,  $174 \pm 10$  in,  $77 \pm 20$  kg) or placebo (N = 10,  $20 \pm 1.9$  yrs  $175 \pm 14$  in,  $89 \pm 20$  kg). Subjects ingested 450 mg of either active supplement (400mg fenugreek, 25mg cinnamon, 25mg curcumin) or 450 mg of placebo for 14 days prior to the damage bout. Subjects were instructed to warm-up briefly and subsequently perform 24 sets of 10 eccentric knee extensor repetitions with one leg at 30°/s on an isokinetic device. Subjects had their blood drawn at baseline, immediately post, 1hr, 3hr, and 24hr post damage. Serum samples were analyzed for IL 1b, IL1ra, IL6, TNFa and CRP levels using a multiplex bead based assay. Data were analyzed by a

two-way ANOVA with repeated measures ( $p < 0.05$ ).

**RESULTS:** Significant ( $p < 0.05$ ) main effects for time were observed for the inflammatory markers IL 1b, IL1ra, & IL6, although there were no significant ( $p > 0.05$ ) interactions. However, a significant trend for interaction was observed for IL 6 ( $p = 0.06$ ) & IL1ra ( $p = 0.09$ ). Post hoc analysis revealed a significant difference immediately post damage in IL 1ra where active group was significantly lower than the placebo group ( $p < 0.05$ ) and a significant difference at 1hr & 3hr post damage IL6 where active was significantly lower ( $p < 0.05$ ) than placebo.

**CONCLUSION:** These results indicate that the protocol used induced significant ( $p < 0.05$ ) systemic inflammation. The experimental proprietary blend showed some positive anti-inflammatory effects as illustrated by a significantly ( $p < 0.05$ ) lower inflammatory response in IL1ra and IL 6 by 3hr post damage. It is concluded that fenugreek, cinnamon, and curcumin have potential anti-inflammatory properties and that they significantly reduced the onset of inflammation in response to muscle damage.

**Fenugreek Extract Supplementation Has No Effect On The Hormonal Profile Of Resistance-trained Males**

Lem W. Taylor<sup>1</sup>, Colin D. Wilborn<sup>1</sup>, Brandon Bushey<sup>1</sup>, Chris Poole<sup>1</sup>, Cliffla A. Foster<sup>1</sup>, Bill Campbell<sup>2</sup>, Richard B. Kreider, FACSM<sup>3</sup>, Darryn S. Willoughby, FACSM<sup>4</sup>. <sup>1</sup>University of Mary Hardin-Baylor, Belton, TX. <sup>2</sup>University of South Florida, Tampa, FL. <sup>3</sup>Texas A&M University, College Station, TX. <sup>4</sup>Baylor University, Waco, TX.  
Email: ltaylor@umhb.edu  
(No relationships reported)

Fenugreek is herb that has several purported uses in animal models. Despite no substantiated claims in human research models, fenugreek has been marketed in dietary products as having anabolic potential for resistance trained athletes.

**PURPOSE:** The purpose of this study was to investigate the potential anabolic effects of fenugreek extract supplementation in conjunction with a controlled resistance training program.

**METHODS:** Forty-five resistance trained males were matched by fat free mass and randomly assigned to ingest in a double blind manner capsules containing 500mg of a placebo (PL) (N = 24, 20.1  $\pm$  2.6 yr, 85.5  $\pm$  13.4 kg, 177.00  $\pm$  6.1 cm) or fenugreek extract (FE) (N = 21, 21.4  $\pm$  2.95 yr, 89.9  $\pm$  18.8 kg, 178.00  $\pm$  6.27 cm). Subjects participated in a supervised 4-day per week periodized resistance-training program for 8 weeks in conjunction with supplementation. Venous blood samples were obtained using standard procedures at baseline (PRE), 4 weeks, and 8-weeks (POST). Serum analyses included cortisol, insulin, leptin, free testosterone, estrogen, and DHT. Statistical analyses utilized a two-way ANOVA with repeated measures for serum hormone responses ( $p < 0.05$ ).

**RESULTS:** A significant interaction ( $p < 0.05$ ) between groups for DHT was observed for PL (PRE: 1187 $\pm$ 482; POST: 1258 $\pm$ 493 pg/ml) and FE (PRE: 1263 $\pm$ 496; POST: 1144 $\pm$ 447 pg/ml) indicating that supplementation resulted in significant decrease in DHT levels. Significant differences in DHT responses from supplementation showed a -9.42% change for the FE group accompanied with a 5.98% increase in the PL group. No significant effects for groups or interactions were observed for the anabolic hormones free testosterone and estrogen ( $p < 0.05$ ). Additionally, no significant main effects for groups or time were observed for the metabolic hormones insulin, cortisol, and leptin ( $p < 0.05$ ).

**CONCLUSIONS:** Supplementation of fenugreek extract resulted in a decrease in serum DHT levels in comparison to placebo. However, other anabolic and metabolic hormone analyses were not affected by supplementation. We conclude that in conjunction with structured resistance training, supplementation of fenugreek extract does not appear to affect hormonal status in resistance trained males and shows no anabolic potential as has been purported.

**Pre-exercise Supplementing Lower Dose Of Soy Peptide Suppresses Serum Creatine Kinase Elevation In Soccer Players**

Hisataka Ambe<sup>1</sup>, Yoshiharu Fujieda<sup>1</sup>, Kensuke Sakai<sup>2</sup>, Kenichi Suijo<sup>1</sup>, Chiaki Sanbongi<sup>3</sup>. <sup>1</sup>Tokyo Gakuji University, Tokyo, Japan. <sup>2</sup>Josai International University, Tougane, Japan. <sup>3</sup>Meiji Seika Kaisha, Ltd., Tokyo, Japan.  
Email: hisataka\_no6@hotmail.co.jp  
(No relationships reported)

Amino acids supplementation is effective not only to improve sport performance but also preservation of athletes' physical conditions. Many studies which investigated effects of amino acids supplementation usually adopt high dose of amino acids, whereas effects of lower dose of amino acids intake are still unclear. Pre-exercise intake of lower amounts of peptide form of amino acids, which can be more rapidly and efficiently absorbed than amino acids itself, may have positive effects on athletes' conditioning especially during in-season.

**PURPOSE:** To investigate the effects of pre-exercise supplementation with lower dose of soy peptide on serum creatine kinase (CK) level and psychological fatigue in soccer players through in-season. **METHOD:** Sixteen Japanese collegiate soccer players volunteered to participate in this study which was carried out in double-blind manner. The subjects were divided into two groups of soy peptide (SP) group (N=8, age; 19.1  $\pm$  0.6 yrs, height; 174.3  $\pm$  4.8 cm, weight; 65.6  $\pm$  3.5 kg), and placebo (PI) group (N=8, age; 19.6  $\pm$  1.4 yrs, height; 172.3  $\pm$  6.3 cm, weight; 66.8  $\pm$  5.9 kg). SP group was instructed to take 4,000 mg/day of soy peptide supplement one hour prior to matches or training sessions for 8 weeks, while PI group was administered placebo which was mainly composed of isocaloric dextrin powders. To assess physical and psychological aspects of the players' condition, serum CK level and profile of mood states (POMS) were utilized as conditioning parameters. These parameters were measured before and during the intervention period.

**RESULTS:** Serum CK level of SP group was significantly lower than that of PI group at the 5<sup>th</sup> week (194  $\pm$  115 vs. 355  $\pm$  143 U/L,  $p < 0.05$ ), and statistically lower trends were also observed at the 1<sup>st</sup> (248  $\pm$  108 vs. 426  $\pm$  235 U/L,  $p = 0.07$ ) and 8<sup>th</sup> week (220  $\pm$  134 vs. 506  $\pm$  411 U/L,  $p = 0.08$ ). There were no significant differences in fatigue scores of POMS.

**CONCLUSION:** Pre-exercise supplementation with 4,000 mg/day of soy peptide can suppress elevations of serum CK level, but did not affect on subjective fatigue level in soccer players through 8 weeks of in-season.

**Effect Of The Hyperimmune Egg Supplement On Indices Of Mood State And Quality Of Life**

Johannes D. Aartun<sup>1</sup>, Tyler D. Martin<sup>2</sup>, Benjamin M. Carr<sup>3</sup>, Michael J. Webster, FACSM<sup>3</sup>, Timothy P. Scheett<sup>1</sup>. <sup>1</sup>College of Charleston, Charleston, SC. <sup>2</sup>Troy University, Troy, AL. <sup>3</sup>The University of Southern Mississippi, Hattiesburg, MS.  
(No relationships reported)

Hyperimmune egg (HIE) protein is a powdered, pure egg product derived from chicken hens immunized with more than 26 killed pathogens of human origin. Anecdotal evidence suggests HIE supplementation enhances mood and overall quality of life.

**PURPOSE:** The purpose of this project was to determine if supplementation with HIE for 10 days resulted in any alteration in the subscales from the POMS and HRQL.

**METHODS:** Recreationally active males (n=24) aged 23.6  $\pm$  0.8 yrs, height 176  $\pm$  2 cm, mass 69.2  $\pm$  0.6 kg and 17.1  $\pm$  1.5 % body fat were randomly assigned to either HIE (n=12) or an egg protein placebo (PLA) group. Participants abstained from their regular exercise routine for the duration of the study and were supplemented with 4.5 g $\cdot$ d<sup>-1</sup> for 2 d, 9 g $\cdot$ d<sup>-1</sup> for 2 d and 13.5 g $\cdot$ d<sup>-1</sup> for 6 d. POMS and HRQL questionnaires were administered on Days 1, 8, 10 and 12. On days 1, 8 and 10, participants performed an exercise performance test battery. ANCOVA was used to determine significant differences between or within the groups during the 10 d of supplementation with initial differences between groups serving as a covariate. Significance was set at  $\alpha = 0.05$ .

**RESULTS:** Anger/Hostility subscale significantly decreased in HIE from Day 1 to Day 10 (-28%;  $p<0.05$ ). Pain subscale significantly decreased in HIE from Day 1 to Day 12 (-83%;  $P<0.05$ ) and was also significantly lower than PLA on Day 12 (-84%).

**CONCLUSIONS:** The data suggest that oral supplementation of hyperimmune egg for 10 d resulted in positive alterations in the subscales of Pain, Positive Effect, Depression, and Anger/Hostility. These alterations are likely a result of HIE's ability to enhance muscle repair and recovery time from prior exercise.

**Effect Of Avenanthramide Supplementation On Responses To Eccentric Exercise In Young Women**

Ryan Koenig, Jonathan Dickman, Emily Church, Robert Umfress, Li Li Ji, FACSM. *University of Wisconsin-Madison, Madison, WI.*

(No relationships reported)

Avenanthramides (AVA) are a group of nitrogen-containing diphenolic phytochemicals found exclusively in oats that have exhibited antioxidant and anti-inflammatory potential in vitro and in rodents; however, the effects of chronic AVA consumption in humans have been unexplored.

**PURPOSE:** To investigate the effects of 8 weeks of AVA supplementation on the inflammatory and oxidative responses to a single bout of downhill running in college-aged women.

**METHODS:** Ten women aged 18-29 yr were randomly assigned to receive cookies fortified with either high-AVA (23.5 mg/day) oat flour (O, Ceapro Inc., Canada) or with equal content of wheat flour as a placebo (PL). They were instructed to eat one 115 g cookie per day for 8 wks, during which dietary and physical activity levels were recorded. Before and after the supplementation period, subjects ran on a treadmill at -9% grade at a speed that elicited 75% of their maximal heart rate for 4 x 15 min bouts with 3 rest intervals of 5 min each. Blood samples were collected before and immediately and 24-h post exercise.

**RESULTS:** There was no difference in pain and soreness ratings between O and PL groups post-exercise. During the post-supplementation test, O showed a higher plasma reduced to oxidized glutathione ratio ( $P<0.05$ ) at 24 h post-exercise vs. PL group. Red blood cell (RBC) glutathione peroxidase activity decreased ( $P<0.05$ ) immediately after exercise in O, but not in PL. RBC superoxide dismutase activity was higher ( $P<0.05$ ) in O vs. PL post-exercise. There were trends toward lower plasma tumor necrosis factor (TNF)-alpha levels and white blood cell reactive oxygen species production in O compared to PL immediately and 24-h after exercise.

**CONCLUSIONS:** High-AVA oat supplementation appears to attenuate downhill exercise-induced oxidative stress and blood inflammatory markers in college-aged women.

(No relationships reported)

Intense exercise can promote biochemical changes, which involve reactions in the immunological system and reactive oxygen species (ROS) generation. Maintenance of cellular redox homeostasis requires a balance between the generation rate of ROS and the capacity of the antioxidant system. Organisms have developed a sophisticated antioxidant system for protection against ROS. Several food components have antioxidant function such resveratrol, a stilbene polyphenol found in grapes and wine, a potent antioxidant through a cytoprotection action.

**PURPOSE:** The aim of the present study was to evaluate the response to resveratrol intake of total antioxidant capacity (TAC) and immunological capacity in young basketball players.

**METHODS:** The athletes ( $n=8$ ;  $17\pm1$  y) ingested resveratrol capsules (25mg) during 30d. For each athlete, a blood sample was obtained before (T0) and after (T1) resveratrol intake. TAC was measured in plasma by scavenging of 1,1-diphenyl-2-picrylhydrazyl (DPPH). Leukocytes (LEU), monocytes (MON), eosinophils (EOS) and lymphocytes (LYM) were analyzed by using an electronic hematology analyzer (Cell-Dyn/ Cobas Vega). Statistical comparison of indices was done by paired t-test. Significant levels were established at  $p<0.05$ .

**RESULTS:** Total body mass and height did not change during the study ( $75\pm10$ kg;  $189\pm9$ cm, respectively). TAC was similar in T0 ( $16.1\pm4\%$  reduction) when compared with T1 ( $17\pm3\%$  reduction). However, immunological cell counts ( $\text{cell}\cdot\mu\text{L}^{-1}$ ) were significantly higher in T0 when compared with T1 after resveratrol intake (LEU-  $6.4\pm1$  to  $5.4\pm2$ ,  $p=0.05$ ; MON-  $0.65\pm0.2$  to  $0.45\pm0.1$ ,  $p=0.007$ ; EOS-  $0.27\pm0.02$  to  $0.18\pm0.02$ ,  $p=0.003$ ; LYM-  $2.4\pm0.4$  to  $2.0\pm0.7$ ,  $p=0.008$ ).

**CONCLUSION:** Resveratrol intake beneficially affects immunological indices reducing inflammatory process, TAC did not change after supplement use, possibly by the strong anti-inflammatory resveratrol function.

Support by: FAPERJ E26/171.257/2006.

**The Effects Of Propolis Supplementation And Acute Exercise On Inflammatory Makers And Immunity**

Younshin Nam, FACSM. *Duksung Womens' University, Seoul, Republic of Korea.*

Email: younshinkr@duksung.ac.kr

(No relationships reported)

An excessive exercise brings about increase in acute inflammatory caused by chronic heart disease and decrease of function in immunity. The main components of propolis are polyphenol and flavonoid which are known to play a role of antifungal, anti-inflammatory, immune system, and anti-cancer.

**PURPOSE:** To investigate the effects of propolis supplementation and Acute exercise on acute inflammatory makers and immunity in middle aged women.

**METHODS:** Twenty four health women (mean  $\pm$  SE: age  $28.96\pm3.33$ yr, height  $166.96\pm4.06$ cm, weight  $57.42\pm5.28$ kg, body fat  $13.45\pm3.13$ kg) were randomly assigned to three different groups of eight subjects per each (2 weeks propolis supplementation, 2 weeks placebo supplementation, and control group). Blood-sampling was sampled before and 30min of constant, heavy (~70% peak  $\text{O}_2$  uptake) cycle ergometer exercise. Two-way repeated measured ANOVA was used as the statistical analysis and significance was accepted at  $p<0.05$ .

**RESULTS:** The difference of WBC from pre- and post-experiment was significantly different ( $F=113.643$ ,  $p<0.000$ ). WBC within groups was significantly different ( $F=4.420$ ,  $p<0.025$ ). The high sensitive C-reactive protein(hs-CRP) was significantly different from pre- and post-experiment ( $F=69.690$ ,  $p<0.000$ ) and there was interaction between time and groups ( $F=5.352$ ,  $p<0.013$ ). Fibrinogen was significantly different from pre- and post-experiment ( $F=35.293$ ,  $p<0.000$ ). Albumin was significantly different from pre- and post-experiment ( $F=90.284$ ,  $p<0.000$ ), and also significantly different between groups ( $F=9.207$ ,  $p<0.001$ ). Neutrophil was significantly different from pre- and post-experiment ( $F=7.401$ ,  $p<0.013$ ). Lymphocyte was significantly different from pre- and post-experiment ( $F=11.320$ ,  $p<0.003$ ). Eosinophil was significantly different from pre- and post-experiment ( $F=16.323$ ,  $p<0.001$ ).

**CONCLUSION:** Propolis supplementation with maximal exercise is found effective on acute inflammatory makers and immunity.

## Almond Intake Enhances Resistance Against Fatigue In Elite Chinese Endurance Athletes

Muqing Yi, Lili Zhou. *National Institute of Sports Medicine, China, Beijing, China.*

Email: muqingyi@163.com

(No relationships reported)

**PURPOSE:** To test the effect of almond intake on endurance performance in elite athletes.

**METHODS:** We conducted a randomized, crossover trial with elite male cycling (n=8) and triathlon (n=4) athletes (22 y; BMI: 22.7;  $\dot{V}O_{2max}$ : 69.0 mL/min/kg) by supplementing their diets isocalorically with 75 g almonds (ALM) or sugar cookies (COK) daily for 4 wk with a 2-wk washout period. ALM and COK consumption was divided into 3 portions and consumed prior to each meal. Before and after supplementation, all athletes underwent a 2-h cycling performance test at 60%  $\dot{V}O_{2max}$  and a subsequent 20-min time trial. During each visit, fasted blood was drawn at 0, 60, 125, 135, 155 min of the test and again at 3, 6, 9, and 15 h after exercise. Paired t-tests were performed to assess significance between treatments.

**RESULTS:** Neither ALM nor COK affected body composition or weight. ALM intake increased cycling distance during the 20-min time trial by 5.2% compared to COK (20.81 km,  $P \leq 0.05$ ). ALM intake resulted in a 7% increase in plasma glucose during the 20-min time trial while COK intake was associated with a 9% decrease ( $P \leq 0.05$ ). Plasma nitrogen oxide at 155 min was 78% greater in the ALM than COK group. Plasma total antioxidant capacity before and 15 h after exercise was 23 and 43% higher in the ALM than COK group, respectively ( $P \leq 0.05$ ). The degree of exercise-induced increase in xanthine oxidase activity was 59% lower in the ALM than the COK ( $P \leq 0.05$ ).

**CONCLUSION:** Our results suggest that 4-wk daily supplement of 75 g almonds enhances cycling performance and resistance against fatigue in elite endurance athletes. The potential mechanisms for this action may include improved fuel utilization, oxygen transportation, and antioxidant activity.

Supported by The Almond Board of California.

#### Effects Of Olive Extract Supplementation On Post-exercise Markers Of Muscle Recovery

Kay L. Lehman<sup>1</sup>, Anne E. Mishler<sup>1</sup>, Michael J. Saunders, FACSM<sup>1</sup>, Christopher J. Womack, FACSM<sup>1</sup>, Lori L. Stern<sup>2</sup>, M. Kent Todd, FACSM<sup>1</sup>, Tammy L. Wagner<sup>1</sup>. <sup>1</sup>James Madison University, Harrisonburg, VA. <sup>2</sup>DSM Nutritional Products, Inc., Parsippany, NJ.

Email: lehmankl@jmu.edu

(No relationships reported)

**PURPOSE:** Olive extract (OE) is derived from the aqueous fraction of olives and is rich in polyphenols, including the potent antioxidant hydroxytyrosol (HT). Previous studies have shown that olive polyphenols can confer antioxidant protection in vivo, as shown by increased plasma total antioxidant capacity and protection against LDL oxidation. Antioxidants may affect muscle recovery following strenuous exercise. The purpose of this study was to determine if OE supplementation influenced plasma creatine kinase (CK), muscle soreness, and muscle function following heavy aerobic exercise.

**METHODS:** 19 male subjects (21.2±2.9 yr, 23.9±1.7 BMI) underwent 3 treatment phases, consisting of 14-day supplementation periods with either 0 mg OE/d (placebo: PL), 400 mg OE/d (OE-400), or 800 mg OE/d (OE-800), administered in two daily doses providing a total of 8 and 16 mg HT, respectively. The exercise bout included 100 minutes of ergometer cycling at 60%  $\dot{V}O_{2peak}$ , followed by 20 minutes of treadmill running at 70%  $\dot{V}O_{2peak}$ . Plasma CK levels, muscle soreness ratings and peak isometric force (MVC) of the leg-extensors were obtained prior to the supplementation period (BL), pre-exercise, immediately post-exercise (0-PO), 2 hours post-exercise (2-PO) and 24 hours post-exercise (24-PO). A 12-day washout period separated the treatment phases, which were administered in a double-blind design.

**RESULTS:** Following supplementation, total area under the curve (AUC) for HT was significantly greater for OE-800 versus OE-400 and PL. HT AUC was also significantly greater with OE-400 versus PL. Plasma CK levels rose significantly from pre- (273.4±310.6 U/L) to post-exercise (peak at 24-PO: 429.2±381.5 U/L). Muscle soreness also increased from pre- (14.5±9.6 mm) to post-exercise (peak at 0-PO: 50.7±20.0 mm). MVC declined significantly from pre-exercise (574.3±165.3 N) to post-exercise (0-PO: 524.0±169.7 N). No treatment\*time interactions or differences in AUC were observed for muscle recovery variables.

**CONCLUSION:** OE supplementation significantly increased plasma HT concentrations, but did not affect plasma CK levels, muscle soreness or muscle function following heavy aerobic exercise. Further study is required to determine if higher doses of OE elicit positive effects on these variables.

#### The Effects Of Rhodiola Rosea On Human Immune Function And Endurance Performance

Kristen Dulacki, Kerry S. Kuehl, Diane L. Elliot, FACSM. *Oregon Health & Science University, Portland, OR.* (Sponsor: Diane Elliot, FACSM)

Email: kuehlk@ohsu.edu

(No relationships reported)

It has been well-documented that high intensity exercise alters immune function in humans and exposes them to a higher risk of bacterial and viral infections following such activity. There are a number of herbal and other supplements which claim to enhance immune function and athletic performance.

**PURPOSE:** Assess the efficacy of the botanical *Rhodiola rosea* to enhance immune function of individuals who participate in intense exercise and also determine its performance-enhancing qualities.

**METHODS:** This was a prospective, double-blind placebo-controlled study (N=15) in which immune parameters (morning cortisol, interleukin 6, and tumor necrosis factor alpha) and aerobic fitness (maximal oxygen uptake) were measured before and 28 days after taking 600 mg standardized 3% rosavin (botanical *rhodiola rosea*) or placebo. Maximal oxygen uptake was measured during a standard maximal exertion treadmill or cycle test; immune parameters were collected at the same time following the exercise test. Data was analyzed by an independent (two-way) t-test between baseline and 25-day post supplement or placebo interval.

**RESULTS:** There was no significant difference among the immune system parameters (cortisol, IL-6, TNF-alpha) between *rhodiola* supplement and placebo. There was no difference in change in maximal oxygen uptake between *rhodiola* supplementation for 28 days and placebo group.

**CONCLUSIONS:** *Rhodiola rosea* herbal supplement did not alter immune parameters and maximal oxygen uptake in elite endurance athletes after 28 days of supplementation.

#### Effects Of Olive Extract Supplementation On Markers Of Oxidative Stress Following Heavy Aerobic Exercise.

Anne E. Mishler<sup>1</sup>, Kay L. Lehman<sup>1</sup>, Michael J. Saunders, FACSM<sup>1</sup>, Christopher J. Womack, FACSM<sup>1</sup>, Lori L. Stern<sup>2</sup>, Jeffrey B. Blumberg<sup>3</sup>, M. Kent Todd, FACSM<sup>1</sup>. <sup>1</sup>James Madison University, Harrisonburg, VA. <sup>2</sup>DSM Nutritional Products, Parsippany, NJ. <sup>3</sup>Tufts University, Boston, MA.

Email: mishleae@jmu.edu

(No relationships reported)

**PURPOSE:** Polyphenol-enriched olive oil has been shown to increase serum antioxidant capacity, reduce lipid peroxidation, and reduce DNA oxidation in humans. Olive extract (OE) is derived from the polyphenol-rich aqueous phase of olives and contains hydroxytyrosol (HT), a potent antioxidant. Reactive oxygen species produced during aerobic exercise may result in oxidative damage to proteins, lipids, and DNA. Therefore, the purpose of this study was to determine if OE supplementation for 2 wk influences biomarkers of oxidative stress following heavy aerobic exercise.

**METHODS:** 19 non-endurance trained males ( $21.2 \pm 2.9$  y,  $23.9 \pm 1.7$  BMI) performed 3 aerobic exercise sessions, each consisting of cycling at 60%  $\text{VO}_{2\text{peak}}$  for 100 min on an electrically-braked ergometer followed by a treadmill run at 70%  $\text{VO}_{2\text{peak}}$  for 20 min. For 2 wk prior to each exercise session, subjects were randomized to consume a placebo (PL), 400 mg OE/d (OE-400) or 800 mg OE/d (OE-800) supplement, administered twice daily in double-blind fashion and providing a total of 8 and 16 mg HT, respectively. Blood samples were obtained prior to supplementation, pre-exercise, immediately post-exercise, and 2- and 24-h post-exercise. Samples were analyzed for plasma HT, serum total antioxidant capacity (TAC, determined by reduction of  $\text{Cu}^{++}$ ), plasma malondialdehyde (MDA) and serum C-reactive protein (CRP). Treatments were separated by a washout period of  $\geq 12$ -d before cross-over.

**RESULTS:** Total area under the curve (AUC) for HT was significantly greater ( $p < 0.05$ ) following supplementation for OE-800 versus OE-400 and PL. HT AUC was also greater with OE-400 versus PL. MDA decreased from pre-exercise ( $0.59 \pm 0.13$   $\mu\text{M}$ ) to 2-h post-exercise ( $0.54 \pm 0.13$   $\mu\text{M}$ ). CRP increased from pre-exercise ( $1.46 \pm 1.01$  mg/L) to 24-h post-exercise ( $3.71 \pm 2.40$  mg/L). TAC was not significantly affected by time. No treatment\*time interactions and no differences in the AUC by treatment were observed for MDA, CRP or TAC.

**CONCLUSIONS:** OE supplementation increased plasma concentrations of HT in a dose-related manner; however, biomarkers of oxidative stress were not altered by OE supplementation in this protocol. This could reflect that the OE dose was too low, or that the timing of measurements may not have been optimal to assess peak antioxidant activity.

**Ginger Supplementation Attenuates Muscle Pain and Dysfunction Following Eccentric Exercise**

Christopher D. Black<sup>1</sup>, Matthew P. Herring<sup>2</sup>, David J. Hurley<sup>2</sup>, Patrick J. O'Connor, FACSM<sup>3</sup>. <sup>1</sup>Georgia College and State University, Milledgeville, GA. <sup>2</sup>The University of Georgia, Athens, GA. <sup>3</sup>The University of Georgia, Athens, GA.

Email: chris.black@gcsu.edu

(No relationships reported)

Ginger supplementation has known hypoalgesic and anti-inflammatory effects in rodents, but its effect on inflammation and pain in humans is not well characterized.

**PURPOSE:** The purpose of this experiment was to determine whether 11 days of ginger supplementation would attenuate arm muscle pain, inflammation, and/or dysfunction induced by high intensity eccentric exercise.

**METHODS:** Thirty-four participants were block randomized ( $n=17$  in each condition) to consume 2 grams of either ground ginger or placebo for 11 consecutive days. On Day 8 participants performed 18 eccentric actions of the non-dominant elbow flexors at an intensity of 120% of their concentric one-repetition maximum. Immediately prior to and for 3 days after eccentric exercise, muscle pain intensity, perceived effort, arm range-of-motion (ROM), isometric strength (MVIC), arm volume and plasma prostaglandin E2 were assessed. The ginger and placebo groups were compared on the days when peak responses occurred for the primary outcome measures in the placebo group.

**RESULTS:** Peak pain ratings were 25% lower in the ginger group (9.3 VAS units, a Cohen's d effect size = -0.77 SD;  $p = 0.04$ ). Ginger also attenuated the peak decline in ROM by 35% (a 4.6° difference,  $d = 0.67$  SD;  $p = 0.04$ ). Smaller effect size changes in arm volume ( $d = -0.39$ ), plasma PGE2 ( $d = -0.42$ ), and MVIC ( $d = 0.29$ ) favored the ginger group but did not reach statistical significance.

**CONCLUSIONS:** It is concluded that ginger supplementation attenuates peak muscle pain and the decline in ROM caused by intense eccentric exercise.

**Steamed Ginger Supplementation Reduces Pain Following Eccentric Exercise-induced Injury**

Matthew P. Herring<sup>1</sup>, Christopher D. Black<sup>2</sup>, Lauren E. Magee<sup>1</sup>, Patrick J. O'Connor, FACSM<sup>1</sup>. <sup>1</sup>The University of Georgia, Athens, GA. <sup>2</sup>Georgia College and State University, Milledgeville, GA.

Email: mph8@uga.edu

(No relationships reported)

We recently found that 11 days of supplementation with 2 grams of raw, ground ginger reduced arm muscle pain and disability induced by eccentric exercise. These effects could plausibly be attributed to compounds in ginger such as gingerols and shogaols that act on vanilloid receptors.

**PURPOSE:** To learn whether 11 days of supplementation with ginger treated by steaming, a process known to increase the concentration of shogaols, also influences arm muscle pain, inflammation and/or disability induced by eccentric exercise.

**METHODS:** Raw ginger was ground and heated for 3 hours and 15 minutes at 100°C and dried. Ginger (0.33 gram) and placebo (brown sugar) was placed in hypromellose capsules, shipped in light impenetrable containers from Baltimore to Athens and stored at 5°C. 40 participants were block randomized ( $n = 20$  in each condition) to consume either 6 ginger or 6 placebo capsules daily for 11 consecutive days. On Day 8 participants performed 18 eccentric actions of the non-dominant elbow flexors at an intensity of 120% of their concentric one-repetition maximum (CON1-RM). Before and for 3 days after eccentric exercise, assessments were made of arm volume, arm range-of-motion (ROM), isometric strength (MVIC), and muscle pain intensity and perceived effort (6-20 RPE) responses to three flexions and extensions of the elbow at 50% CON1-RM.

**RESULTS:** Group x Time ANCOVAs controlling for immediate-post eccentric exercise force decline (a marker of injury magnitude; mean  $\pm$  SD decline of  $33.1 \pm 10.1\%$  and  $30.3 \pm 11.9\%$  for the control and ginger groups) showed a significant interaction for pain intensity ( $F(1.648, 60.98) = 3.701$ ) and RPE ( $F(2, 74) = 4.368$ ). Post-hoc tests showed that pain (-12.7 VAS units, -30.6%, Cohen's  $d = 0.77$  SD;  $t(38) = -2.255$ ,  $p = .03$ ) and RPE (-2.0 raw units, -30.6%, Cohen's  $d = 1.06$  SD;  $t(38) = -3.166$ ,  $p = .003$ ) were substantially lower in the ginger group 24-hours after eccentric exercise. ROM was not influenced by the intervention and small effect size differences in arm volume ( $d = 0.28$  SD, 79.4%) and MVIC ( $d = 0.28$  SD, 8.4%) 24-hours after exercise favored the ginger group but did not reach statistical significance.

**CONCLUSION:** Supplementation with steamed ginger reduces muscle pain and perceptions of effort the day after a bout of eccentric exercise.

**2097 Board #238 May 28 8:00 AM - 9:30 AM**

**Epigallocatechin-3-gallate Advances The Onset Of The Ventilatory Threshold But Does Not Affect Maximal Oxygen Uptake**

Mark C. Lonac, Jennifer C. Richards, Sarah E. Deemer, Tyler K. Johnson, Melani M. Schweder, Ryan J. Supon, Christopher Bell. Colorado State University, Fort Collins, CO.

Email: lonac@cahs.colostate.edu

(No relationships reported)

Epigallocatechin-3-gallate (EGCG), a catechin present in green tea, increases endurance performance in animals and promotes fat oxidation during prolonged cycle ergometer exercise in adult humans. Accordingly, we hypothesized that EGCG delays the onset of the ventilatory threshold ( $T_{VE}$ ) and increases maximal oxygen uptake ( $\text{VO}_{2\text{max}}$ ).

**PURPOSE:** To compare  $T_{VE}$  and  $\text{VO}_{2\text{max}}$  after consumption of EGCG and placebo.

**METHODS:** 7 EGCG capsules (135 mg/capsule) and 7 placebo capsules were administered in a randomized, double blind manner to 8 recreationally active young adults (6 males, 2 females, age:  $29 \pm 5$  yr (mean  $\pm$  SE)). One capsule was consumed every 12 hours over 48 hours, and the final capsule consumed 2-hours prior to exercise testing. On

two occasions, separated by a minimum of 14 days,  $T_{VE}$  and  $VO_{2max}$  were determined from breath-by-breath indirect calorimetry data collected during continuous incremental stationary cycle ergometer exercise (20-25 W/min), from rest until volitional fatigue.

**RESULTS:** Contrary to our hypothesis the  $VO_2$  corresponding to  $T_{VE}$  was lower ( $P = 0.04$ ) following consumption of EGCG ( $1.5 \pm 0.1$  L/min) compared with placebo ( $1.7 \pm 0.2$  L/min).  $VO_{2max}$ , maximal heart rate and maximal work rate were unaffected (Placebo:  $3.2 \pm 0.4$  L/min,  $179 \pm 7$  beats/min,  $307 \pm 25$  W vs. EGCG:  $3.3 \pm 0.4$  L/min,  $179 \pm 7$  beats/min,  $297 \pm 29$  W; all  $P > 0.05$ ).

**CONCLUSION:** The onset of the  $T_{VE}$  is advanced by EGCG. EGCG is thought to inhibit catechol-*O*-methyl transferase, an enzyme contributing to the degradation of catecholamines. Delayed degradation of catecholamines could contribute to accelerated glycolysis and decreased blood flow to lactate clearing tissues during incremental exercise. These combined actions may promote earlier lactate accumulation, decreased blood pH, and hence advanced  $T_{VE}$ .

**2098 Board #239 May 28 8:00 AM - 9:30 AM**

**Effects Of Rice Bran Arabinoxylan Compound On Intense Exercise-induced Secretory Immunoglobulin A Suppression In Rats.**

Fuminori Kimura<sup>1</sup>, Kazuhiro Shimizu<sup>1</sup>, Sachiko Ikemune<sup>1</sup>, Keisuke Nokura<sup>2</sup>, Eiko Narita<sup>3</sup>, Hisayoshi Kato<sup>3</sup>, Takao Akama<sup>2</sup>, Ichiro Kono<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Japan. <sup>2</sup>Waseda University, Tokorozawa, Japan. <sup>3</sup>Daiwa Pharmaceutical Co., Ltd., Tokyo, Japan.

( F. Kimura, Daiwa Pharmaceutical Co., Ltd., Contracted Research.)

Secretory immunoglobulin A (SIgA) plays a major role in specific immunity and provides a protection at mucosal surfaces via several mechanisms. Polymeric immunoglobulin receptor (pIgR) on the surface of the epithelial cells combines with immunoglobulin A to form SIgA. Intense exercise causes a functional decline in several components of the immune system. Rice Bran Arabinoxylan Compound (RBAC; Daiwa Pharmaceutical Co., Ltd.) is obtained by reacting rice bran hemicellulose with multiple carbohydrate hydrolyzing enzymes from *Lentinula edodes* mycelia and seems to act as a potent biological response modifier.

**PURPOSE:** To evaluate the effects of RBAC supplementation on the SIgA in rat saliva and on inhibitory effect of intense exercise-induced SIgA suppression.

**METHODS:** Male Wistar rats (8 weeks of age) were assigned to one of the following treatment groups: (1) RBAC-Ex, a RBAC ingested exercised group (n=7); (2) RBAC-Sed, a RBAC ingested sedentary group (n=6); (3) DW-Ex, a distilled water ingested exercised group (n=7); (4) DW-Sed, a distilled water ingested sedentary group (n=6). Rats received RBAC (150 mg/kg body weight) or distilled water orally for two weeks. Their saliva was collected before (0w), after 1 week (1w), 2 weeks (2w) of RBAC intake, and before (pre) and after (post) exercise; the salivary glands were removed after exercise. SIgA concentration in saliva was measured by ELISA, and pIgR mRNA expression in the salivary glands was analyzed by the 7500 Fast Real Time PCR System.

**RESULTS:** Treatment with RBAC significantly increased SIgA concentration (0w:  $6.27 \pm 0.37$  vs. 2w:  $9.82 \pm 1.79$   $\mu$ g/ml,  $p < 0.05$ ), while there was no significant change in the DW groups. SIgA in the RBAC-Ex and DW-Ex groups significantly decreased after exercise compared with before ( $p < 0.05$ ). The expression of pIgR mRNA did not show significant difference between RBAC-Ex and DW-Ex groups.

**CONCLUSION:** RBAC supplementation for two weeks enhances saliva SIgA concentration, and it may be a potent biological response modifier for exercise-induced immune suppression.

**Effects Of Rice Bran Arabinoxylan Compound On Gut Immunity In Response To Exhaustive Intense Exercise.**

Kazuhiro Shimizu<sup>1</sup>, Fuminori Kimura<sup>2</sup>, Keisuke Nokura<sup>1</sup>, Sachiko Ikemune<sup>2</sup>, Eiko Narita<sup>3</sup>, Hisayoshi Kato<sup>3</sup>, Takao Akama<sup>1</sup>, Ichiro Kono<sup>2</sup>. <sup>1</sup>Waseda University, Tokorozawa, Japan. <sup>2</sup>University of Tsukuba, Tsukuba, Japan. <sup>3</sup>Daiwa Pharmaceutical Co., Ltd., Tokyo, Japan.

Email: shimikazu@aoni.waseda.jp

(No relationships reported)

**PURPOSE:** The intestinal tract has gut-associated lymphoid tissues response for protecting the host from pathogenic invasion. T and B lymphocytes in the mucosa of the intestinal tract are presumed to promote local immunity in the host. Reportedly, intense exercise results in impairment of normal gut barrier to luminal microorganisms, and results in elevation of circulatory levels of bacterial endotoxin. Rice Bran Arabinoxylan Compound (RBAC; Daiwa Pharmaceutical Co., Ltd.), an enzymatically modified arabinoxylan extracted from rice bran, has a potential to act as a biological response modifier. However, effects of RBAC and strenuous exercise on gut immunity including T and B lymphocytes-mediated immunity have not yet been elucidated.

The purpose of this study was to assess the effects of RBAC supplementation on the gut immunity, particularly T cells and B cells, in response to exhaustive intense exercise.

**METHODS:** Twenty-six male Wistar rats (8 weeks old) were randomized to: (1) RBAC-Ex, RBAC administered (150 mg/kg body weight for two weeks) and exercised (exhaustive treadmill running) group (n=7); (2) RBAC-nEX, RBAC administered and non-exercised group (n=6); (3) DW-Ex, distilled water administered and exercised group (n=7); (4) DW-nEX, distilled water administered and non-exercised group (n=6). The mesenteric lymph nodes were removed after exercise and CD3+CD4+ (T-helper cell), CD3+CD8+ (T-cytotoxic cell), and CD45RA+ (B cell) cells were measured by Flow cytometry analysis.

**RESULTS:** The Flow cytometry indicated that percentage of intestinal CD45RA+ cells tended to higher in RBAC-nEX ( $81.8 \pm 1.2\%$ ) compared with DW-nEX ( $68.0 \pm 2.5\%$ ) ( $p = 0.08$ ). CD3+CD4+ and CD3+CD8+ cells did not show significant differences between RBAC-nEX and DW-nEX groups. CD45RA+ and CD3+CD8+ cells were significantly lower in exercised groups (RBAC-EX or DW-EX) compared with non-exercised groups (RBAC-nEX or DW-nEX) ( $p < 0.05$ ). There were not significant differences of CD3+CD4+ cells among groups.

**CONCLUSIONS:** RBAC supplementation for two weeks indicated possibility to up-regulate B-cell-mediated humoral immunity. Exhaustive intense exercise could impair gut immunity, particularly T-cell- and B-cell-mediated immunity.

**Analysis on Ten Kinds Of Elimination Exercise Fatigue Of Traditional Chinese Medicine**

Yan Shoufu. Prof., Bei Jing, China.

Email: wuhao@cipe.net.cn

(No relationships reported)

**PURPOSE:** To examine the pertinence of 10 kinds of familiar tonic traditional Chinese medicines and their elements, and provide some references to choose or farther investigate the efficacy of traditional Chinese medicines in exercise fatigue.

**METHODS:** Our research had measured elements content in the 10 kinds of tonic traditional Chinese medicines with ICP/AES, such as Ca, Mg, Na, K, Fe, Zn, Cu, Cr, Mo, Co, Ni, V, Sr, Mn and Sn; and had measured the elements content of Se and As in 10 kinds of tonic traditional Chinese medicines with the Atomic fluorescence spectrographic. And we carried SAS software to take corresponding analyze to these 10 kinds of traditional Chinese medicines and 17 kinds of elements.

**RESULTS:** The content of K,Na,Ca,Mg was most in the 10 traditional Chinese medicines, the varieties of microelements were most in hairy antler, panax and shorthorned epimedium herb. The content of K was most in medlar, Na and Ca was most in hairy antler, Mg was most in angelica. The distributing of traditional Chinese medicines and elements take on territorial characteristic.

**CONCLUSIONS:** 1.We can principium divide these elements into 4 comparative concentrative assemble parts according to the compactness of superposition in the 10 traditional Chinese medicines and the elements. 2.The function of the 10 traditional Chinese medicines and the elements showed some characteristic of coherence in their content and their relative traditional Chinese medicine attribution channel theory, and it might be one of the important birth reasons of "assemble parts". 3.The function of the elements in the traditional Chinese medicines relate to their variety,quantity and their state. The conclusion shows that we should take the all and the one into general account before choose traditional Chinese medicines., and it's very important.

**2101 Board #242 May 28 8:00 AM - 9:30 AM**  
**Effects Of An Energy Drink On Performance Of Varsity Hockey Players.**

Stephanie K. O'Neill, Jonathon R. Fowles, Rene J.L. Murphy. *Acadia University, Wolfville, NS, Canada.*  
*(No relationships reported)*

A number of varsity athletes may use commonly available stimulant supplements as a means to attempt to improve performance in their sport.

**PURPOSE:** To assess the effects of consuming 250 ml of a commercially available energy drink or a placebo on game type performance in varsity hockey players.

**METHODS:** 20 varsity hockey players (Mean±SD; 22.1±1.1 years, 181.3±4.8 cm, 88.2±7.2 kg, 11.2±3.6% body fat, and 17.2±1.2 years of playing experience) volunteered to participate in a double blind, placebo controlled study. Participants reported to the arena at 4pm and received either a placebo drink or the energy drink. At 4:30pm, they performed a Reed Repeat skating test and then participated in a ~60 min standardized hockey practice led by 3 coaches. The last 20 min was a scrimmage and their performance was rated from best to worst by 3 coaches blinded on the treatment received. Following the on-ice tests, the players removed their hockey gear and performed a 60 sec Bosco jump test. 48 hours later, after following the same diet as on the first testing day, the players performed the exact same procedures following consumption of the other treatment drink.

**RESULTS:** There were no significant ( $p<0.05$ ) changes in Reed Repeat skate test fastest time on ice, on-ice drop off, fatigue index and total time, or in ranks during practice/scrabble, or in Bosco jump test peak height, relative power and fatigue index between energy drink and placebo treatments. Because some ( $n=7$ ) were regular users of energy drinks, we also analyzed the results between users and non-users. There was a trend ( $p=0.088$ ) indicating that users performed better according to the coaches' ranks when consuming the energy drink while non-users tended to be ranked lower when consuming the drink.

**CONCLUSION:** Compared to a placebo, consumption of a commercially available energy drink 30 min prior to a hockey practice does not improve or harm performance for approximately 2 hours in varsity hockey players.

**Effects Of Rooibos Tea, Bottled Water, And A Carbohydrate Beverage On Blood And Urinary Measures Of Hydration After Acute Dehydration.**

Alan C. Utter, FACSM<sup>1</sup>, John C. Quindry C. Quindry, FACSM<sup>1</sup>, Gian Pietro Emerenziani<sup>2</sup>, J. Scott Valiente<sup>1</sup>. <sup>1</sup>*Appalachian State University, Boone, NC.* <sup>2</sup>*University of Rome, Roma, Italy.*  
 Email: utterac@appstate.edu  
 ( A.C. Utter, Reddrex Inc, Eagle, Idaho, Contracted Research.)

**PURPOSE:** Rooibos tea contains polyphenol antioxidants, including flavonoids and phenolic acids that are potent free radical scavengers and has purported benefits for accelerated rehydration. The objective was to evaluate the effects of three different drinks (rooibos tea, bottled water, and a carbohydrate beverage) on blood and urinary markers of hydration after acute dehydration in collegiate wrestlers.

**METHODS:** Twenty three athletes were recruited and followed a randomized, cross-over design with 3 different study arms comparing the effectiveness of rooibos tea, carbohydrate (6% or 60 grams l<sup>-1</sup>), or bottled water (placebo) in promoting rehydration after a 3% reduction in body mass. Urine specific gravity (U<sub>sg</sub>), urine (U<sub>osm</sub>) and plasma osmolality (P<sub>osm</sub>), and plasma volume were measured pre- and post- dehydration and at 1-h after rehydration. Statistical analyses utilized a 3 (conditions) x 3 (times) repeated measures analysis of variance to test main effects.

**RESULTS:** Significant interaction effects were found for P<sub>osm</sub> and U<sub>osm</sub> both of which remained in negative balance after 1-h rehydration in the rooibos tea and water trials. No significant interaction effects were found for either urine U<sub>sg</sub> or plasma volume shift.

**CONCLUSIONS:** The findings of this study demonstrate that a carbohydrate/electrolyte solution was more effective in promoting rehydration than either rooibos tea or plain water in collegiate wrestlers after a 3% reduction in body mass and a rehydration period of 1-h when consuming 100% of their body weight loss.

**Hyperhydration In Resting Trained Males: Effects Of Solutions With Differing Concentrations Of Sodium**

Hal W. Goforth, Jr., FACSM, Nicholas Koreerat. *Point Loma Nazarene University, San Diego, CA.*  
 Email: hgoforth@cox.net  
*(No relationships reported)*

Hyperhydration of euhydrated resting athletes using hyperosmotic saline solutions is rarely studied. Hyperosmotic saline solutions are often studied for rehydration.

**PURPOSE:** To compare the retention of 3 hyperosmotic saline solutions and ability to increase total body water of resting athletes.

**METHODS:** Nine aerobically trained, male subjects; age 21 + 1.5 yr, 177 +5.8 cm, 74 +8.2 kg, and 14 +2.9 % body fat, gave informed consent to participate in a repeated-measures, single-blinded, cross-over design study. Subjects were randomly assigned to group A,B, or C. Treatment order was; A,B,C; B,C,A, or C,A,B. Trials were 3hr conducted > 3da apart. Subjects followed behavioral/dietary guidelines 72hr before testing. Urine density (1.015-1.040) verified euhydration status. The base solution for treatments made from a 50% diluted sports drink, contained; 100mg Na, 90mg K, and 7g CHO. NaCl was added to make 3 saline solutions: S30-30 mmol/L (0.91g NaCl) (the full strength sports drink); S60-60 mmol/L (1.8g NaCl), and S90- 90 mmol/L (3.6g NaCl). Treatment volume (1.4±0.14L) was determined as 3% of subjects estimated total body water. Urine output, urine density, plasma osmolality, Hct, and Hb were measured hourly. Subjects remained seated except to empty bladders.

**RESULTS:**

VOLUME RETAINED, URINE OUTPUT and PLASMA OSMOLALITY			
Treatment Group	1hr	2hr	3hr
S30 n=9 (%) Retained	66+13	16+21	(-) 6+24
Urine Output (mL)	471+166	684+137	308+166
Plasma (mOsm)	269+6	270+5	272+4
S60 n=9 (%) Retained	80+9*	39+17*	25+178*

Urine Output (mL)	274+110*	555+139*	197+78*
Plasma (mOsm)	274+6*	287+22*	281+3*
S90 n=9 (%) Retained	80+9*	49+18*	35+21*
Urine Output (mL)	279+127*	411+158*	191+83*
Plasma (mOsm)	288+6*	282+5*	288+9*

(\*) Significantly different from S30 trials,  $p < 0.01$ .

Urine Density decreased over time but did not differ between treatments.

Hct and Hb values did not change significantly, indicating a constant red cell volume.

**CONCLUSION:** Drinking 1.4L of a 30mmol/L Na solution (equal to a sports drink with the most Na) produced a net loss of body water. Drinking 1.4L of the 60 and 90mmol/L solutions allowed subjects to retain 25% (341mL) and 35% (479mL), and may be ergogenic for some athletes.

**2104 Board #245 May 28 8:00 AM - 9:30 AM**  
**Effects Of Electrolytes In Drinks Ingested Before And During Cycling Time Trials**

Maurie J. Luetkemeier<sup>1</sup>, John R. Stofan<sup>2</sup>, Roshan Patel<sup>2</sup>. <sup>1</sup>*Alma College, Alma, MI.* <sup>2</sup>*Gatorade Sports Science Institute, Barrington, IL.*  
Email: luetkemeier@alma.edu

( M.J. LUETKEMEIER, Gatorade Sport Science Institute, Consulting Fee.)

**PURPOSE:** To determine whether the addition of electrolytes to drinks consumed before and during exercise improves cycling time trial performance.

**METHODS:** Healthy, active males (n=7; mean age=38.8±5.1 years, weight=75.1± 6.1 kg, %fat=12.7±5.3%, OBLA=215 ±38 Watts) participated in 4 randomly ordered conditions combining 1 of 2 pre-exercise drink formulations with 1 of 2 during-exercise drink formulations. Each condition consisted of a 2-h drinking phase followed immediately by a cycling time trial designed to last ~90-min. The 2 pre-exercise drinks (13-ml/kg BW) were either (W) flavored water or (E) flavored water containing 9.62 g/L of Gatorlytes electrolyte mixture (Na=2.18 g/L, K=1.10 g/L, Osm=300 mOsm/L). The during-exercise drinks (17-ml/kg BW) were either (w) a 6% carbohydrate beverage or (e) a 6% carbohydrate beverage plus electrolytes (Na=0.83 grams/L, K=0.375g/L). Thus, the 4 conditions were Ww, We, Ew, and Ee, which were tested using 1-way ANOVA for effects on primary outcomes of time-trial performance, fluid balance and change in relative plasma volume (PV).

**RESULTS:** Urine rates during the drinking phase were higher for Ww and We (9.43± 3.15 ml/min) than for Ew and Ee (5.98±ml/min) leading to a greater positive fluid balance (input - output) for Ew and Ee (+199± 280ml) vs. Ww and We (-109±365 ml). Fluid balance differences were largely attributed to disparity in urinary free water clearance between Ew and Ee (0.5±1.8 ml/min) vs. Ww and We (4.2±2.3 ml/min). Change in PV from blood samples taken before and after the drinking phase was greater for Ew and Ee (1.5±10.0 ml) than for Ww and We (-4.6±6.9 ml). This difference in PV was not assoc. with s.d's. in HR, SV, CO or BP. Cycling time was slower ( $p < 0.05$ ) for Ww (90.1± 6.0 min) compared to times for Ew (85.4±6.2 min), We (87.0±5.7 min) and Ee (87.6±6.2 min), which were not different among each other ( $p > 0.05$ ).

**CONCLUSION:** Pre-exercise administration of a drink containing a 300 mOsm/L electrolyte mixture caused a reduction in urine output leading to a higher fluid balance and PV. Cycling time trial performance lasting ~90-min was improved in conditions where electrolytes were added to the drink either before or during exercise but there was no additional improvement in performance when electrolytes were added to both the before and during-exercise drinks.

(No relationships reported)

**PURPOSE:** Athletes with spinal cord injury (SCI) often experience high heat storage due to reduced sweating capacity below the spinal injury. Spray bottles (SB) maybe used to apply mist for evaporative cooling during breaks in competitions. This study examined the efficacy of spray bottle during rest breaks.

**METHODS:** Seven participants, four female and three males, (mean ± SD age 24 ± 4.1 yr, weight 56.2 ± 7.0 kg, upper-body VO<sub>2</sub> peak 2.4 ± 0.6 L·min<sup>-1</sup>) volunteered for the study. Participants were paraplegic athletes (T3 to T12/L1) with both complete and incomplete lesions. Participants arm-cranked using a ramp protocol in an environment of 21°C ± 1.5°C and 55 ± 3 % rh once using a SB during 1-min rest between seven-minute stages of increasing intensity and once without the SB (CON).

**RESULTS:** Mean total work was similar ( $p = 0.86$ ) for the SB and CON (2495.7 ± 914.6 kJ vs. 2407.1 ± 982.3 kJ, respectively). Likewise, the mean work times were similar between trials (27 ± 6 min and 26 ± 7 min for SB and CON, respectively). Furthermore, there were no significant differences detected between trials for skin temperature, rectal temperature, esophageal temperature ( $p > 0.05$ ). There were also no significant differences detected for RPE between trials ( $p > 0.05$ ).

**CONCLUSIONS:** Application of artificial sweat via a spray bottle was ineffective in attenuating the onset of uncompensable heat strain during high intensity arm exercise under the conditions of this study. However, even in absence of physiological changes, participants commonly commented positively regarding perceived cooling from the spray bottle.

**Suitability Of The Megaduct Sweat Collector For Sweat Mineral Analysis**

Matthew R. Ely, Brett R. Ely, Troy D. Chinevere, Samuel N. Cheuvront, FACSM. *USARIEM, Natick, MA.*

Email: matthew.ely@us.army.mil

(No relationships reported)

Regional arm sweat collection for electrolyte and mineral analysis during exercise is typically made using polyethylene arm bags. The arm bag technique is able to collect a high volume of sweat in a relatively short amount of time, but encapsulation and hidromeiosis are concerning for local sweat electrolyte and mineral secretion. The Megaduct sweat collector may be a suitable alternative as its construction and small size avoids encapsulation and hidromeiosis. However, the Megaduct's small surface area covers fewer

sweat glands, thus the time taken to obtain an appropriate volume of sweat may be too slow to reflect dynamic changes in sweating rate or composition.

**PURPOSE:** To compare the time required to obtain the minimal volume of sweat (0.5 ml) needed for a broad panel mineral analysis using the arm bag and Megaduct sweat collection techniques.

**METHODS:** Eighteen heat-acclimated subjects walked 100-min (treadmill, 425 W) in a hot environment (45°C, 20% rh). Ten subjects wore the Megaduct sweat collector while eight were fitted with a polyethylene arm bag. To perform a broad panel sweat mineral analysis at least 0.5 ml of sweat must be collected. Therefore, we compared the amount of time required to collect 0.5 ml of sweat using each of the Methods Megaduct and arm bag.

**RESULTS:** The minimum sweat volume required for broad panel sweat mineral analysis requires approximately 60 min using the Megaduct but less than 5 min using the arm bag. Collection time was significantly ( $p < 0.05$ ) longer in the Megaduct.

**CONCLUSION:** Regional sweat collection from the forearm using the arm bag required less than 10% of the time needed for the Megaduct to reach the minimum volumes for a broad panel mineral analysis. Because collection durations in excess of 30-min may produce independent errors in electrolyte and mineral sweat content, we conclude that the commercial Megaduct sweat collector is an inferior alternative to the arm bag technique for broad panel sweat mineral analysis during exercise-heat stress.

## 2107 Board #248 May 28 9:00 AM - 10:30 AM Comparison Of Regional Patch Collection Vs. Whole-body Washdown For Measuring Sweat Sodium Loss During Exercise

John R. Stofan, Lindsay B. Baker, Adam A. Hamilton, Craig A. Horswill. *Gatorade Sports Science Institute, Gatorade R&D, Barrington, IL.*

Email: john.stofan@gatorade.com

( J.R. Stofan, PepsiCo, Salary.)

**BACKGROUND:** Whole-body washdown (WBW) is the criterion method to determine whole-body (WB) sweat sodium ( $\text{Na}^+$ ) loss, while regional skin surface (REG) collections overestimate  $\text{Na}^+$  loss. Validation of REG against WBW would improve the accuracy of REG, particularly for use in field studies.

**PURPOSE:** Make simultaneous WBW and REG sweat collections during exercise to generate regression equations to predict WB sweat [ $\text{Na}^+$ ] from single- and 5-site REG sweat patch collections.

**METHODS:** Athletes (10 men, 10 women;  $37 \pm 10$  yr) cycled (75% max heart rate) in a plastic isolation chamber for 90 min in the heat. Prior to exercise, the subject and bike were washed with deionized water. After the onset of sweating, sterile patches were attached to the forearm, back, chest, forehead, and thigh, and removed upon saturation with sweat. After exercise, the subject and bike were washed with 5L of ammonium sulfate solution to ensure collection of all WB  $\text{Na}^+$  loss and determine the volume of unevaporated sweat. Total sweat loss was calculated from the change in pre-to post-exercise nude body mass, corrected for fluid intake and urine and respiratory water losses. The 5-site REG sweat [ $\text{Na}^+$ ] was calculated using an equation weighted for local sweat rate and body surface area. REG and WBW [ $\text{Na}^+$ ] were measured using flame photometry. Regression analyses, standard error of estimates (SEE, mEq/L), and intraclass correlation coefficients (ICC) were used to determine the most accurate and reliable REG sites for predicting WBW sweat [ $\text{Na}^+$ ].

**RESULTS:** Sex did not influence the relation between REG and WBW. Average sweat loss and fluid intake were 1.4 and 1.1 L, respectively (-0.3% net D body mass). The 5-site REG and WBW sweat [ $\text{Na}^+$ ] were  $61 \pm 27$  mEq/L and  $38 \pm 18$  mEq/L, respectively ( $p < 0.05$ ). The regression equation for predicting WB sweat [ $\text{Na}^+$ ] from the 5-site REG method was  $y = 0.63x - 0.26$  (overestimated WBW by 59%;  $R^2 = 0.92$ , SEE = 25, ICC = 0.61). The best single REG site for predicting WB sweat [ $\text{Na}^+$ ] was the thigh (overestimated WBW by 7%;  $y = 0.69x + 9.9$ ,  $R^2 = 0.90$ , SEE = 10, ICC = 0.90), followed by the forearm (overestimated WBW by 40%;  $y = 0.53x + 9.8$ ,  $R^2 = 0.90$ , SEE = 22, ICC = 0.70).

**CONCLUSION:** Although the REG method overestimates WBW sweat [ $\text{Na}^+$ ], these correction equations can be used to accurately and reliably predict WB sweat [ $\text{Na}^+$ ] from REG sweat samples collected in the field.

---

## 2108 Board #249 May 28 9:00 AM - 10:30 AM Sweat Losses During A Soccer Match Played In Hot Conditions

Susan M. Shirreffs, FACSM<sup>1</sup>, Ronald J. Maughan, FACSM<sup>1</sup>, S. Sadi Kurdak<sup>2</sup>, Kerem T. Özgün<sup>2</sup>, Jiri Dvorak<sup>3</sup>, Gülfem Ersöz<sup>4</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>Çukurova University, Adana, Turkey. <sup>3</sup>FIFA/FMARC, Zurich, Switzerland. <sup>4</sup>Ankara University, Ankara, Turkey.

Email: s.shirreffs@lboro.ac.uk

(No relationships reported)

Soccer is a global sport played in a wide range of environmental conditions. Large inter-individual sweating responses of soccer players during training and match play have been reported, but there are no data on these losses during match play in hot conditions.

**PURPOSE:** To investigate sweat losses in soccer players, 19 adult male players were studied in one full FIFA regulation match in hot conditions: 35°C, 37%rh, heat index 36°C. By virtue of their home location, 8 players were acclimated (A) and 11 were unacclimated (UA) to the conditions. At the time of testing all players were regularly training with and playing for their University club team.

**METHODS:** In the 30min before the start of a match, absorbent patches were placed on the right forearm, thigh, chest and back of players. These remained in place for the 1st half of the match. Players were weighed nude within 30 min before and 15 min after the end of the match. All urine passed between body mass measurements was collected. Drink bottles were weighed to determine volume consumed. The sweat volume lost was estimated from body mass change, urine volume and drink volume consumed. Sweat sodium (Na) concentration was determined by flame photometry and an overall concentration determined as the mean of the four patches. Salt loss was estimated by assuming that all Na loss was sodium chloride. Comparisons between A and UA players were by unpaired t-test.

**RESULTS:** Results are summarised in the Table.

A (n=8); UA (n=11)	P value	Mean	SD	Median	Min	Max
Body mass loss (kg)	0.533	1.44; 1.60	0.63; 0.41	1.43; 1.65	0.55; 0.80	2.40; 2.30
Body mass loss (%)	0.682	2.1; 2.3	0.9; 0.7	2.3; 2.4	1.1; 1.1	3.4; 3.4
Drink consumed (ml)	0.084	930; 1280	170; 510	960; 1150	690; 660	1140; 2440
Sweat loss (ml)	0.049	2.33; 2.87	0.70; 0.40	2.48; 2.68	1.13; 2.48	3.10; 3.55
Sweat Na conc (mmol/l)	0.777	31; 32	13; 12	29; 32	18; 15	55; 54
Sweat salt loss (g)	0.363	4.4; 5.6	2.7; 2.8	4.0; 5.0	1.5; 2.3	9.2; 11.2

**CONCLUSION:** Sweat volume was greater in the UA players, but due to the drinking practices there was no difference in body mass loss between groups. Sweat sodium and salt losses were not difference between groups.

**2109 Board #250 May 28 9:00 AM - 10:30 AM**  
**Effects Of Exercise At Moderate Altitude On Sweat Composition And Sweat Rate**

Lauren J. Hasler, Amanda Carlson, Katy J. Green, Drew Johnson, Maurie J. Luetkemeier, John E. Davis. *Alma College, Alma, MI.*  
 Email: 10ljhasl@alma.edu

(No relationships reported)

**PURPOSE:** To examine the physiological effects of exercise at altitude on the ability of the sweat gland to regulate sodium, potassium, and osmolality as well as sweat rate.

**METHODS:** Six healthy, active subjects (age =  $20.3 \pm 1.1$  yrs,  $\text{VO}_2$  max =  $2.91 \pm .7$  l/min, weight =  $62.15 \pm 10.7$  kg.) were asked to complete four 30-minute cycle ergometer exercise bouts at a relative workload (60% of a  $\text{VO}_2$  max) at sea level (SL1), upon acute exposure 3400 m (ALT1), two weeks following acclimatization at 3400m (ALT2), and upon return to sea level (SL2). The subjects also performed two 30-minute cycle ergometer exercise tests at an absolute workload (60% of  $\text{VO}_2$  max of SL1) at ALT1 and ALT2. All tests were performed in a temperature controlled environment (temperature= 82°F and humidity = 41%). Sweat was collected with sweat pads applied to forehead, forearm, chest, and back bilaterally during each exercise period. The sweat was then analyzed for sodium and potassium concentration (Flame Photometer) and osmolality (Microsmometer).

**RESULTS:** Sweat rates and total sweat loss did not change significantly at ALT1 or ALT2. The average sodium potassium ratio also showed no significant variation between tests. The average osmolality, sodium, and potassium concentrations were significantly higher at ALT1 than SL1, and osmolality was still significantly higher at ALT2 than SL1, but lower than ALT1.

**CONCLUSION:** Results from this study suggest that altitude has an effect on sweat content rather than sweat rate or loss. The significant increase in osmolality indicates a possible increase in water reabsorption at the sweat gland. Altitude induced dehydration is a possible mechanism for the increased reabsorption.

**2110 Board #251 May 28 9:00 AM - 10:30 AM**  
**Gender Differences In Fluid And Electrolyte Balance During Endurance Exercise**

Thijs M.H. Eijssvogels, Dick H.J. Thijssen, Maria T.E. Hopman, FACSM. *Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

(No relationships reported)

Maintaining a proper fluid and electrolyte balance is essential during endurance exercise, as dehydration impairs aerobic exercise performance and more rapidly increases core body temperature during exercise. However, little is known about gender differences in fluid and electrolyte balance during endurance exercise.

**PURPOSE:** To compare fluid intake, body weight changes, sodium concentration ( $[\text{Na}^+]$ ) and plasma volume changes between men and women during a four day walking event.

**METHODS:** Ninety-nine volunteers (21-82 years) participated in our study and walked 30 (n=35, 63% men), 40 (n=36, 53% men), or 50 km (n=28, 57% men) per day for 4 consecutive days. Prior to the event and immediately after finishing on each day, body weight was measured and venous blood was taken to analyze sodium concentrations. Dehydration was defined as >2% body weight loss, while hyponatremia was identified as  $[\text{Na}^+] > 145$  mmol/L. Subjects reported their fluid intake using a diary.

**RESULTS:** Maximum ambient temperature was relatively stable over the walking days (17.6°C - 20.5°C). On the first day, gender differences were seen for changes in  $[\text{Na}^+]$  (M=+1.5 mmol/L; F=-0.5 mmol/L,  $p < 0.05$ ), body weight loss (M=-1.3%; F=-0.9%,  $p < 0.05$ ) and fluid intake (M=2.9; F=3.8 mL/hour/kg,  $p < 0.005$ ). A significant difference (Chi-test,  $p < 0.001$ ) in the incidence of dehydration (M=18; F=5), and hyponatremia (M=15; F=0) between men and women supported these findings. On subsequent days, no important gender differences were found (fluid intake, change in  $[\text{Na}^+]$ , body weight loss), while the incidence of dehydration (n=5, 2 and 5, respectively) and hyponatremia (n=3, 1 and 1, respectively) was markedly decreased.

**CONCLUSION:** Dehydration was observed in 23% of our participants on day 1. More importantly, our data indicate that men are more sensitive to develop dehydration than women, likely explained through gender differences in fluid ingestion. Despite comparable ambient conditions on consecutive days, prevalence of dehydration dropped markedly, while gender differences disappeared.

**2111 Board #252 May 28 9:00 AM - 10:30 AM**  
**Exercise-associated Hyponatremia In A Cold Weather Ultraendurance Race**

Kristin J. Stuenkel, FACSM. *Gettysburg College, Gettysburg, PA.*  
 Email: kstuenkel@gettysburg.edu

(No relationships reported)

Exercise-associated hyponatremia is the occurrence of hyponatremia during prolonged physical activity and is defined by a serum sodium concentration < 135 mmol/L.

**PURPOSE:** To investigate change in sodium level and its cause during the Susitna 100, a cold weather ultraendurance race.

**METHODS:** Thirty six athletes in the 2000 and 2002 Susitna 100 participated in the study. Subjects were weighed and had blood drawn for sodium concentration and hematocrit pre- and post-race. Arginine vasopressin (AVP) was measured in 2002. Race dietary analysis determined fluid intake. Subjects were split into three groups for statistical analysis: normonatremic 2000, hyponatremic 2000, and 2002. ANOVA compared the three groups and paired t tests evaluated pre- and post-race measurements.

**RESULTS:**

	Normonatremic 2000	2002	Hyponatremic 2000
Pre-race $\text{Na}^+$ (mmol/L)	$138.8 \pm 2.9$	$140.8 \pm 1.2 \dagger$	$137.0 \pm 1.7$
Post-race $\text{Na}^+$ (mmol/L)	$136.8 \pm 1.2$	$138.4 \pm 2.2 *$	$132.9 \pm 1.9 *$
Δ Body mass (kg)	$-1.9 \pm 2.4 *$	$-1.2 \pm 1.2 *$	$-0.8 \pm 1.0$
Δ Hematocrit	$-1.8 \pm 4.2$	$-2.0 \pm 2.0 *$	$-2.6 \pm 3.8$
Δ Plasma volume	$9.0 \pm 20.0$	$9.0 \pm 9.2$	$12.4 \pm 19.3$
Fluid/h (L)	$0.4 \pm 0.2$	$0.3 \pm 0.1 \dagger$	$0.5 \pm 0.2$

$\dagger p < 0.05$  2002 vs. normonatremic and hyponatremic

$*$   $p < 0.05$  pre-race vs. post-race

The normonatremic group maintained sodium levels with post-race values  $\geq 135$  mmol/L. Sodium decreased significantly in 2002, but no athletes were hyponatremic. Sodium decreased significantly with post-race values < 135 mmol/L in the hyponatremic group. All three groups exhibited signs of fluid overload, including minimal weight loss, decreased hematocrit, and increased plasma volume. Fluid overload indicators were largest in the hyponatremic group. Fluid consumption was greatest in the hyponatremic group. In 2002, AVP increased significantly pre- ( $2.6 \pm 0.7$  pg/ml) to post-race ( $6.0 \pm 4.6$  pg/ml).

**CONCLUSION:** Exercise-associated hyponatremia occurs in a cold weather ultraendurance race, and appears to be the result of fluid overload. The fluid overload may have been

caused by excessive fluid consumption and the inappropriate secretion of AVP.

---

**2112 Board #253 May 28 9:00 AM - 10:30 AM**

**Exercise-associated Hyponatremia: The Effects Of Carbohydrate And Hydration Status On IL-6, Adh, And Sodium Concentrations**

Laura R. Quigg<sup>1</sup>, Kimberly A. Hubing<sup>1</sup>, John T. Bassett<sup>1</sup>, Melody D. Phillips<sup>1</sup>, James J. Barbee<sup>2</sup>, Joel B. Mitchell, FACSM<sup>1</sup>. <sup>1</sup>TCU, Ft. Worth, TX. <sup>2</sup>JPS Sports Medicine Program, Ft. Worth, TX.

(No relationships reported)

Exercise-associated hyponatremia (serum sodium < 135 mmol/L) is a rare, but serious condition that has been identified in those engaging in prolonged, physical activity conducted in the heat.

**PURPOSE:** The purpose of this study was to evaluate the effect of hydration status and glycogen level on plasma IL-6, ADH, and sodium concentrations during and after prolonged exercise in the heat.

**METHODS:** Ten male participants completed four trials: a glycogen depleted, euhydrated condition (DE); a glycogen depleted, dehydrated condition (DD); a glycogen loaded, euhydrated condition (LE); and a glycogen loaded, dehydrated condition (LD) consisting of cycling 90 minutes at 60% VO<sub>2</sub> max in a 35°C environment followed by a 3-h rehydration (RH) period. During RH, subjects received either 150% of fluid lost (DD & LD) or an additional 50% of fluid lost (DE & LE). Exercise and RH blood samples were analyzed for glucose, IL-6, ADH, and Na<sup>+</sup>. Sweat and urine samples were analyzed for [Na<sup>+</sup>].

**RESULTS:** Post-exercise to post-rehydration [Na<sup>+</sup>] changes for LD, DD, DE and LE were -6.85, -6.7, -1.45 and 0.10 mM, respectively. Post-exercise [IL-6] for DD, LD, DE, and LE were 5.4, 4.0, 3.7, and 3.49 pg/mL, respectively. Post-exercise [ADH] for LD, DD, DE, and LE were 21.5, 12.8, 7.6, and 1.9 pg/mL, respectively. The number of hyponatremic measurements for all RH samples was 5, 5, 20, and 10 for LD, DD, DE, and LE, respectively.

**CONCLUSION:** Despite our glycogen and hydration manipulations, no regulatory effects of IL-6 and ADH on plasma sodium were observed. The timing of fluid intake did alter plasma sodium since euhydration during exercise combined with an additional 50% intake during RH, and a post-exercise RH volume of 150% of fluid lost both resulted in sodium concentrations below initial levels.

Supported by a grant from the Gatorade Sports Science Institute.

(No relationships reported)

Little is known about the combined effects of cold and altitude on the risk for cold injuries, while in most situations cold and altitude co-exist. The cold induced vasodilation (CIVD) test assesses the risk for cold injuries.

**PURPOSE:** To determine the differences in finger skin temperature between hypoxic and normoxic circumstances in a cold and a thermoneutral climate.

**METHODS:** Six healthy, well-trained male subjects (24±3 years) participated in the experiment. All subjects participated in four experimental conditions: normobaric normoxia in a cold (10°C) climate (NNC), normobaric normoxia in a neutral (22°C) climate (NNN), normobaric hypoxia (14.1% O<sub>2</sub>) in a cold climate (NHC) and normobaric hypoxia in a neutral climate (NHN). In each condition subjects performed a CIVD-test in which the right middle finger was immersed for 30 minutes in 5°C water. Skin temperature of the middle finger was determined.

**RESULTS:** Mean finger skin temperature between minute 10 and 30 (NNC: 9.7±1.8, NNN: 12.4±1.7, NHC: 8.7±1.0, NHN: 10.9±1.2 °C) was significantly lower in the cold compared to the thermoneutral conditions and significantly lower in the hypoxic compared to the normoxic conditions in the same environment.

Onset time of CIVD was not different between normoxia and hypoxia and was significantly longer in NNC.

Minimal skin temperature (NNC: 6.6±0.9, NNN: 9.0±0.9, NHC: 6.2±0.4, NHN: 8.2±1.4 °C) was significantly lower in the cold compared to the thermoneutral conditions. No differences were observed between normoxic and hypoxic conditions.

**CONCLUSION:** CIVD reaction was earlier and at higher skin temperatures in thermoneutral compared to cold conditions. Mean skin temperature was lower under hypoxic compared to normoxic conditions.

(No relationships reported)

**PURPOSE:** Normobaric Intermittent Hypoxic Exposure (NIHE) pre-acclimation to high altitude is known to reduce risk of Acute Mountain Sickness (AMS) during subsequent exposure to higher altitudes. Little is known about NIHE pre-acclimation of older adult mountaineers nor the efficacy of NIHE pre-acclimation in reducing risk of AMS. The purpose of this study is to evaluate the protective effect of pre-acclimating a 69.5-year-old male using NIHE prior to a climb of Mount Kilimanjaro.

**METHODS:** RT, a 69.5 y.o., 178 cm tall, 76.2 kg, healthy male informed volunteer, participated in this IRB approved study. RT was exposed to simulated altitudes of 2438 m to 5486 m in increments of 1000 m for periods of 3-4h/d for 15d prior to air travel to Africa to climb Mount Kilimanjaro (5895 m). Prior to and after each exposure the subject completed the Environmental Symptoms Questionnaire (ESQ), Lake Louise Consensus Score (LLS), and Profile of Mood States (POMS). Every 15 minutes of each exposure, SpO<sub>2</sub> was measured as was mood state and heart rate. On d15 of NIHE, RT was exposed to simulated altitudes equivalent to each altitude of the 8 campsites on the Western Approach (Lemosho) Route of Mount Kilimanjaro after which he remained at 5486 m for 3h. During the Kilimanjaro climb, the ESQ and LLS were completed evenings and mornings at each camp. SpO<sub>2</sub>, Heart Rate, and altitude were also recorded at each camp as well as on the summit. Two months after RT returned to sea level (SL), he was again exposed over a 3h period to the 8 Lemosho Route simulated campsite altitudes for data comparison to the d15 NIHE values.

**RESULTS:** During pre-acclimation SpO<sub>2</sub> was reduced from d1 at 2486 m to d15 at 5486 m ( $r = -0.863$ ,  $P < 0.01$ ). No change in mood state or ESQ AMS-C was noted throughout the 15d pre-acclimation period. During the climb, SpO<sub>2</sub> decreased with altitude as expected and AMS-C was higher only on d7 (summit day) of the climb. When the NIHE values at the 8 Lemoshu Route simulated campsite altitudes were compared to d15 data 2 months after RT's return to SL, increases in AMS-C (Wilcoxon signed-rank test;  $P < 0.05$ ) were noted at 3505 m to 5246 m.

**CONCLUSIONS:** Pre-acclimation with NIHE reduces risk of AMS-C in healthy older adults preparing for strenuous high altitude exertion.

**Normobaric Hypoxic Simulated Altitude Reduces Appetite but Not Smell Identification**

Michio Yasukawa<sup>1</sup>, Niha Zubair<sup>2</sup>, Reina Chamberlain<sup>2</sup>, Julie Barnes<sup>2</sup>, Kristen Kappos<sup>2</sup>, Erica Jackson<sup>2</sup>, Alastair Connell<sup>2</sup>, Ken Kambis<sup>2</sup>. <sup>1</sup>*Senshu University, Kanagawa, Japan.* <sup>2</sup>*The College of William and Mary, Williamsburg, VA.*

Email: yasukawa@isc.senshu-u.ac.jp

*(No relationships reported)*

**PURPOSE:** It has long been known that extended exposure to high altitude environments can result in significant weight loss involving both fat tissue and skeletal muscle mass. The exact mechanism of this anorectic response to altitude exposure is poorly understood. Included in the complex array of cognitive appetite stimuli is the sense of smell. There is little information concerning the effect of simulated high altitude on hunger/appetite or the ability to smell different odors. Therefore, the purpose of this study is to determine the effect of intermittent hypoxic exposure to simulated high altitude on hunger/appetite and on the ability to identify odors.

**METHODS:** 30 healthy informed volunteer male and female subjects were recruited from the William & Mary student body. In single-blind fashion, subjects in this IRB approved study were placed in either a sea level (SL Control;  $n = 15$  [Age:  $20.4 \pm 0.2$  yrs; Height  $171.9 \pm 1.9$  cm; Weight:  $70.3 \pm 3.0$  kg]) or simulated high altitude (HA Treatment;  $n = 15$  [Age:  $20.1 \pm 0.4$  yr; Height:  $174.9 \pm 2.3$  cm; Weight:  $72.7 \pm 3.5$  kg]) 4300 m group. Within 7d of familiarization and after recording resting data and food intake diary, all subjects were exposed to their respective group altitude for 4h. Prior to and after each exposure, subjects were administered the University of Pennsylvania Brief Smell Identification Test (B-SIT), the 3-Factor Eating Questionnaire (Stunkard & Messick, 1984), the Environmental Survey Questionnaire (ESQ), and the Lake Louise Consensus Score for Acute Mountain Sickness (LLS).

**RESULTS:** There was no difference in caloric consumption between each group prior to testing. Hunger increased ( $P = 0.008$ ) in the SL group while no change in hunger occurred in the HA group ( $P = 0.136$ ). After 4h exposure, ESQ (AMS-C) scores were higher in the HA group ( $P < 0.05$ ) than the SL group. SpO<sub>2</sub> remained the same in the SL group pre- ( $98.5 \pm 0.2\%$ ) and during ( $98.7 \pm 0.2\%$ ) exposure while in the HA group, SpO<sub>2</sub> decreased from  $98.7 \pm 0.2\%$  pre-exposure to  $82.7 \pm 0.2\%$  ( $P < 0.001$ ) during exposure.

**CONCLUSION:** 4300 m normobaric simulated altitude IHE for 4h decreases hunger/appetite but does not affect ability to identify odors.

**Mitochondrial Substrates Modification By Skeletal Muscles After Caloric Restriction Due To Chronic Hypoxia**

Alexandra Malgoire, Sanchez Hervé, Simler Nadine, Koulmann Nathalie, Bigard Xavier. *Center of Research for Army Medical Service, La Tronche, France.*

Email: xbigard@crssa.net

*(No relationships reported)*

Prolonged exposure to hypobaric hypoxia leads to alterations in muscle function. Mitochondrial oxidative capacities seem to be affected differently depending on muscle phenotype. However, little is known concerning the impact of chronic hypoxia on fuel sensitivity from mitochondria of slow and fast-twitch skeletal muscles.

**PURPOSE:** To determine both effects of ambient hypoxia on the pattern of substrates preferential utilization by mitochondria from glycolytic extensor digitorum longus (EDL) and oxidative soleus (SOL).

**METHODS:** Three experimental groups of rats were constituted: hypoxic (H : exposed 3 weeks to a simulated altitude of 5500 m in an hypobaric chamber), normoxic (N), and N pair fed (PF) to dissociate the respective effects of hypoxia and associated caloric restriction. PF animals received a food supply equivalent to the amount consumed by H rats. We measured in situ ADP (2 mM)-stimulated, mitochondrial respiration rates from skinned fibers in presence of increasing concentrations of palmitoyl-carnitine (Palm-C)+malate (Mal) for both muscles, pyruvate (Pyr)+Mal for SOL, and glycerol-3-phosphate (G3-P) for EDL. Because fibers oxygen uptake (V<sub>s</sub>) followed Michaelis-Menten kinetics in function of substrates level, V<sub>s</sub> and K<sub>m</sub> (mitochondrial sensitivity) were calculated for each substrate.

**RESULTS:** V<sub>G3P</sub>, K<sub>mG3P</sub> as well as V<sub>Palm-C</sub> in EDL muscle remained not altered in H and PF rats. V<sub>Palm-C</sub> in SOL of PF animals was lower when compared with both N and H rats (-16% and -24%,  $p < 0.05$ , respectively), while K<sub>mPalm-C</sub> were not affected by experimental conditioning. V<sub>Pyr</sub> was also reduced in SOL of PF animals in comparison with N and H rats (-14% and -16%,  $p < 0.05$ , respectively). K<sub>mPyr</sub> was decreased in the same way both in H and PF rats (-25% and -23%,  $p < 0.01$ , respectively), indicating a higher sensitivity for Pyr mainly due to caloric restriction. Then, both maximal capacities to oxidize Palm-C and Pyr seem to be influenced independently by anorexia and O<sub>2</sub> availability in SOL.

**CONCLUSION:** Maximal Palm-C and Pyr utilization by mitochondria was decreased by caloric restriction and increased by hypoxia alone in SOL. Moreover, the present experiment suggests for the first time that the hypoxia-induced caloric restriction also enhanced the mitochondrial sensitivity for Pyr in SOL.

**Overnight Hypoxia Attenuates Glucose Response In Glucose Tolerance Test In Relatives Of Type 2 Diabetics**

Anne S. Koponen<sup>1</sup>, Heikki O. Tikkanen<sup>1</sup>, Juha Saltevo<sup>2</sup>, Jukka Puolakkka<sup>2</sup>, Heikki K. Rusko<sup>3</sup>. <sup>1</sup>*University of Helsinki, Helsinki, Finland.* <sup>2</sup>*Central Hospital of Central Finland, Jyväskylä, Finland.* <sup>3</sup>*University of Jyväskylä, Jyväskylä, Finland.*

Email: anne.s.koponen@helsinki.fi

*(No relationships reported)*

Insulin resistance of skeletal muscle, resulting in impaired glucose transport, is a common feature in patients with Type 2 diabetes (T2D) and in their healthy first-degree relatives. In addition to insulin, muscle contraction and hypoxia are the major stimuli to glucose transport in the skeletal muscle.

**PURPOSE:** To determine the effects of acute and chronic intermittent exposure to normobaric hypoxia on the blood glucose concentration and on the insulin sensitivity in oral glucose tolerance test (OGTT).

**METHODS:** In the acute cross-over overnight hypoxia study, patients with T2D ( $n = 11$ ), relatives of T2D (REL,  $n = 14$ ) and endurance athletes (ATH,  $n = 8$ ) were randomized (single-blind) either to hypoxic (FIO<sub>2</sub> = 0.153 ~ 2500 m) or normoxic 12-h exposure for the first night, and to opposite 12-h exposure for the second night. In the morning, arterial oxygen saturation (SpO<sub>2</sub>%) was measured, and subjects moved into a normoxic room for a 30-min rest, after which an OGTT was performed. In the chronic intermittent hypoxia study, ATH ( $n = 12$ ) slept and stayed 12-h daily for two weeks in hypoxic rooms, accomplishing daily activities and regular training in ambient normoxia at sea level. Plasma glucose (PG) and serum insulin were determined in OGTT, area under the curve (AUC) for glucose concentration was calculated, and insulin sensitivity (ISI<sub>est</sub>) was estimated from demographic parameters and values obtained from OGTT.

**RESULTS:** Acute overnight hypoxia: SpO<sub>2</sub>% reduced in all groups (mean $\pm$ SD; T2D:  $97 \pm 3$  vs.  $91 \pm 3$ , REL:  $98 \pm 4$  vs.  $94 \pm 7$ , ATH:  $97 \pm 3$  vs.  $91 \pm 6$ ; all  $p < 0.001$ ). In T2D and in ATH, hypoxia did not influence fasting PG or insulin concentrations, or their responses in OGTT, but ISI<sub>est</sub> improved in ATH ( $0.18 \pm 0.14$  vs.  $0.22 \pm 0.14$ ,  $p < 0.01$ ). In REL, PG decreased both in the fasting state ( $4.60 \pm 0.24$  vs.  $4.41 \pm 0.34$ ,  $p < 0.05$ ) and at 120-min ( $5.34 \pm 0.97$  vs.  $4.83 \pm 1.03$ ,  $p < 0.05$ ), AUC decreased ( $864 \pm 107$  vs.  $813 \pm 112$ ,  $p < 0.01$ ) and ISI<sub>est</sub> improved ( $0.16 \pm 0.04$  vs.

0.19±0.07, p<0.01). Chronic two weeks hypoxia: AUC decreased (702±73 vs. 654±67, p=0.06) and ISI<sub>est</sub> improved with 20 % (0.18±0.04 vs. 0.22±0.04, p<0.01).

**CONCLUSION:** Hypoxia improves insulin sensitivity and stimulates glucose disposal in relatives of T2D and in athletes, independent of exercise, but not in patients with T2D.

**New Altitude Device Alters Markers Of Glucose Metabolism Using Cyclic Hypobaric Hypoxia**

Anne L. Friedlander<sup>1</sup>, Scott Rubinstein<sup>2</sup>, Andrew R. Hoffman<sup>2</sup>, Omer Shah<sup>2</sup>, Jill A. Fattor<sup>1</sup>. <sup>1</sup>Stanford University, Palo Alto, CA. <sup>2</sup>VA Palo Alto Health Care System, Palo Alto, CA. (Sponsor: Barry Braun, FACSM)

(No relationships reported)

In humans, chronic hypoxia increases dependence on glucose as a substrate in men and increases insulin sensitivity in men and women over time. In rats, intermittent hypoxic exposure improves oral glucose tolerance test (OGTT) response and, when combined with exercise training, increases GLUT4 protein expression more than exercise training alone. Cyclic Variations in Altitude Conditioning (CVAC) is a novel technology that provides whole-body exposure to rapidly fluctuating intermittent hypobaric hypoxia (IH).

**PURPOSE:** To test the hypothesis that markers of glucose metabolism would be changed with CVAC IH, two groups of sedentary, middle-aged men were exposed to 10 weeks (40 min/d, 3d/wk) of either IH or sham (SH) sessions.

**METHODS:** IH subjects (age:48±6, weight:86±12 kg, BMI:27.1±3, n=11) experienced cyclic pressures (approximately 200 cycles/20 min) simulating altitudes initially ranging from sea level to 10,000 ft (week 1) and progressing to 20,000 ft (by week 5). SH subjects (age:50±4, weight:89±15 kg, BMI:27.5±3, n=10) were exposed to slowly-fluctuating pressures up to 2,000 ft (all subjects blinded to elevation). Physical function and blood markers of metabolic syndrome risk factors were measured at baseline, 3, 6 and 10 wks.

**RESULTS:** Two IH subjects were dropped from analysis for failure to progress past 10,000 ft (unable to equalize ears, IH: n=9). Body weight and physical activity remained stable throughout 10 weeks for both groups. There was a group-by-time interaction in fasting glucose concentration (IH: 96±9 to 90±7 mg/dl, SH: 94±7 to 97±9 mg/dl, p<0.03). The reduction in blood glucose response to oral glucose tolerance test [area under the curve (AUC)] was greater in IH compared to SH following 10 weeks of CVAC exposure (p<0.05). There was no change in fasting insulin or in the insulin response during the OGTT for either group. Functional measures (strength, timed walk test and step test) also did not change over 10 weeks in IH or SH.

**CONCLUSION:** Ten weeks of CVAC IH exposure reduces glucose concentration in middle-aged men at risk for metabolic syndrome.

**Effects Of Hypoxia On Muscle Energy Metabolism During Exercise**

Toshiyuki Homma, Nobuhisa Ugaya, Takashi Kawahara, Hideyuki Takahashi. *Japan Institute of Sports Sciences, Tokyo, Japan.*

Email: homma.toshiyuki@jiss.naash.go.jp

(No relationships reported)

Recently, high-altitude training has been used for improving the performance of athletes participating in not only endurance events but also relatively short-distance events. However, the effects of high-altitude training on muscle energy metabolism have not been clarified.

**PURPOSE:** This study aimed to determine the characteristics of muscle energy metabolism during exercise under conditions of acute hypoxia.

**METHODS:** Six subjects (age: 27-31 years) performed dynamic knee-extension exercise while lying supine on a super-conducting magnet under conditions of normoxia (F<sub>O2</sub> = 20.9%) and hypoxia (F<sub>O2</sub> = 13.0%). The workload was increased every 2 min until exhaustion. Quadriceps femoris muscle energy metabolism and oxygen kinetics were measured using <sup>31</sup>P-phosphorus magnetic resonance spectroscopy (<sup>31</sup>P-MRS) and near-infrared spectroscopy (NIRS). The muscle oxygen consumption (VO<sub>2mus</sub>) was estimated by the decreasing rate of oxygenated hemoglobin during temporal arterial occlusion. The pulmonary oxygen uptake (VO<sub>2pul</sub>) was also measured by the Douglas bag method.

**RESULTS:** The values of muscle phosphocreatinine (PCr), muscle pH, VO<sub>2mus</sub>, and VO<sub>2pul</sub> significantly reduced at identical submaximal workloads under hypoxic conditions as compared to the corresponding values under normoxic conditions (p < 0.05). The muscle PCr at exhaustion was almost entirely depleted under both conditions, and these values did not significantly differ between the 2 conditions. However, the muscle pH, VO<sub>2mus</sub>, and VO<sub>2pul</sub> values at exhaustion were significantly lower during hypoxia than during normoxia (p < 0.05).

**CONCLUSIONS:** The data of muscle PCr and pH at exhaustion suggest that glycolytic system contributes to a greater extent under hypoxic conditions than normoxic conditions during high-intensity exhaustive exercise. The results of this study suggest that as compared to normoxic conditions, hypoxic conditions cause a reduction in the muscle aerobic energy supply and an increment in the anaerobic energy supply during exercise at identical workloads.

**2120 Board #8 May 28 2:00 PM - 3:30 PM**

**The Effects Of Exercise And Atmospheric Oxygen Concentration In Normobaric Environment On The Free Radical Generation And Antioxidant Potential In Mice**

Joo Young Park, Hee Seok Seo, Hyun Sook Park, Tae Jin Kim. *Yonsei University Wonju Coll of Medicine, Wonju, Gangwondo, Republic of Korea.*

Email: joopark@yonsei.ac.kr

(No relationships reported)

Oxidative stress induced by both reactive oxygen species (ROS) has been shown to be associated with chronic pathological events.

**PURPOSE:** The present study investigates the nature in which the exercise and the atmospheric oxygen concentration in normobaric condition have influence over the lactate, the free radical generation and antioxidant potential in blood, both of which are important oxidative stress.

**METHODS:** The experimental subjects were male Balb/c mice within 12 hours of birth. They were randomly divided into four groups: normoxia control group (NC, 21% O<sub>2</sub>), hypoxia control group (HC, 13% O<sub>2</sub>), normoxia exercise group (NE, 21% O<sub>2</sub>), and hypoxia exercise group (HE, 13% O<sub>2</sub>). Each of the exercise groups was subjected to travel 16 to 20 meters per minute for the duration of 30 to 45 minutes per day, 3 days per week, for 10 to 20 weeks, beginning on the 10<sup>th</sup> week of experimental conditions. Lactate concentration was measured before and immediately after exercise from tail vein blood with Lactate Pro. Free radicals generation was determined using dROM method and antioxidant potential was determined by BAP test.

**RESULTS:** Basal blood lactate levels were similar in the all groups and were increased by exercise. However, the increase was lower in the exercise group. The increase was much smaller in the HE group. Higher concentrations of free radicals were found in the NC group and the HE group than in the HC group and the NE group and further the NC group generated more free radicals than the HC group. Furthermore, the NE group had more antioxidant potential than the other three groups. Additionally, among both normoxia and hypoxia groups, the exercise groups had more antioxidant potential than their respective control groups. Free radical generation was more prominent in the HE group. Interestingly, there was only a small increase in the blood lactate levels and a marked increase in antioxidants in the HE group after exercise. However, the free radical concentration was very high in the same group.

**CONCLUSION:** Exercise and hypoxia influenced oxidative stress positively. However, exercise in the low oxygen concentration environment increased free radical generation. To understand more about the actual mechanisms of how each factor influences the oxidative stress, more research should be conducted.

---

## Trained Women Demonstrate Greater Preservation Of Peak Exercise Capacity During Acute Hypoxia Than Trained Men

Kevin A. Jacobs<sup>1</sup>, Mark Stoutenberg<sup>1</sup>, Jochen Kressler<sup>1</sup>, Bernard Roos<sup>2</sup>, Anne L. Friedlander<sup>3</sup>. <sup>1</sup>University of Miami, Coral Gables, FL. <sup>2</sup>University of Miami, Miller School of Medicine, Miami, FL. <sup>3</sup>Stanford University, Palo Alto, CA.

Email: k.jacobs@miami.edu

(No relationships reported)

The lower hemoglobin concentration and consequent lower arterial oxygen content in women compared to men may result in gender differences in the physiological response to acute hypoxia. However, very few reports of direct gender comparisons in the physiological response to acute hypoxia are available to date and indirect comparisons between studies exclusively of men or women are largely equivocal.

**PURPOSE:** To determine the effects of acute normobaric hypoxia on cardiovascular hemodynamics at rest and during maximal exercise in endurance trained men and women.

**METHODS:** Peak exercise capacity ( $W_{peak}$ ) at sea level (SL) and normobaric hypoxia (NH, 12.8%  $F_{iO_2}$ , ~3900 m) was determined for 20 male ( $26 \pm 1$  yr,  $56.6 \pm 1.2$  ml/kg/min  $VO_{2peak}$ , mean  $\pm$  SE) and 15 female ( $25 \pm 1$  yr,  $45.3 \pm 1.2$  ml/kg/min  $VO_{2peak}$ ) trained cyclists and triathletes at least 48 h apart. At rest and during exercise, heart rate (HR), stroke volume (SV), and cardiac output (Q) were measured continuously by noninvasive impedance cardiography while arterial oxygen saturation ( $SaO_2$ ) was measured by pulse oximetry.

**RESULTS:** HR, SV, and Q at rest did not change from SL to NH in men or women and both genders demonstrated similar reductions in  $SaO_2$  at rest ( $96 \pm 1$  to  $85 \pm 1\%$ ,  $p < 0.05$ ).  $W_{peak}$  was significantly reduced from SL to NH in both men ( $325 \pm 8$  to  $250 \pm 6$  W,  $p < 0.05$ ) and women ( $245 \pm 7$  to  $201 \pm 6$  W,  $p < 0.05$ ), but the relative decrease in  $W_{peak}$  from SL to NH was significantly greater in men than women ( $-22.7 \pm 0.9$  vs.  $-17.5 \pm 1.5\%$ ,  $p < 0.05$ ). Peak Q was similarly reduced in both genders from SL to NH ( $-9.5 \pm 3.6\%$ ,  $p < 0.05$ ), while peak SV did not change and peak HR was reduced in men more than women ( $-7.3 \pm 0.7\%$  vs.  $-4.9 \pm 0.8\%$ ,  $p < 0.05$ ).  $SaO_2$  at peak was similarly reduced in men ( $94 \pm 1$  to  $71 \pm 2\%$ ,  $p < 0.05$ ) and women ( $94 \pm 1$  to  $72 \pm 2\%$ ,  $p < 0.05$ ) from SL to NH.

**CONCLUSION:** Endurance trained women appear to be more capable of preserving peak exercise capacity during acute NH than endurance trained men despite similar decrements in Q and  $SaO_2$ .

Supported by the World Anti-Doping Agency

### 2122 Board #10 May 28 2:00 PM - 3:30 PM Erythrocytes And Stress Responses During Repeated Intermittent Normobaric Hypoxia

Jin Uchimaru, Hidekazu Takemura, Hidenori Yamano, Kazuyuki Yokokawa, Syozo Suzuki, Tasuku Sato. Sendai University, Miyagi, Japan.

Email: jn-uchimaru@scn.ac.jp

(No relationships reported)

Altitude training (chronic hypoxia; CH) and/or intermittent normobaric hypoxia (IH or live high train low; LHTL) are considered to be effective strategy to improve endurance capacity of athletes. It is well known that exposure to hypoxia induces erythrocyte with relate to exercise performance. However, stress reactions during these altitude training may also seriously compromise physical conditions of athletes.

**PURPOSE:** To examine the changes in erythrocyte and stress responses in endurance athletes during repeated live high-train low in a normobaric hypoxic room.

**METHODS:** Twelve-male college long distance runners and triathletes participated in this study approved by the Human Ethics Committee of Sendai University in accordance with the Declaration of Helsinki. They were divided into a normoxic (N, n=6) or a hypoxic group [two 7-night blocks of hypoxia, interspersed with 7 nights of normoxia (H, n=6)]. H group subjects stayed in a normobaric hypoxic room (15.4%  $O_2$ ; 2500m) in a for 10-12h a day at night. Subjects were undergone the hematological tests for erythrocyte (RBC, Hb Hct, reticulocyte, EPO) and stress responses (WBC, subset count and stress hormone) before, during and after the experimental period. Also, resting erythrocyte parameters, white blood cell subsets and stress hormones were measured before (pre) and 1st, 3rd and 7th day at each series.

**RESULTS:** Erythropoietin (EPO) and Reticulocyte (Ret) as erythrocyte was stimulated by hypoxia. RBC, Hb and Hct of H group at the end of experiment (RBC;  $536 \pm 27$   $10^4/\mu$ l, Hb;  $16.5 \pm 0.4$  g/dl, Hct;  $48 \pm 1.4\%$ ) tendency to increase from pre values (RBC;  $521 \pm 19$   $10^4/\mu$ l, Hb;  $15.8 \pm 0.4$  g/dl, Hct;  $46.9 \pm 1.3\%$ ). WBC subsets and epinephrine and norepinephrine as stress hormone were increased by hypoxia.

**CONCLUSIONS:** It was concluded that repeated intermittent normobaric hypoxia was stimulate the erythrocyte. Also, Stress responses as WBC subsets and/or stress hormone may be relate the improvement of exercise performance in athletes.

---

### 2123 Board #11 May 28 2:00 PM - 3:30 PM Effect Of Sodium Bicarbonate Ingestion During Altitude Acclimatization On High-altitude, Short-duration, Cycling Performance

(No relationships reported)

**PURPOSE:** Acute altitude exposure induces hyperventilation which, in turn, results in respiratory alkalosis. In an attempt to restore blood pH, the kidneys enhance the rate of bicarbonate excretion which may reduce the buffering capacity of the blood and, thus, the performance in exercises that generate large amounts of lactic acid. Consequently, bicarbonate supplementation during altitude acclimatization may restore the buffering capacity of the blood and enhance exercise performance more so than supplementation at sea level. The purpose of this study, therefore, was to evaluate the effect of sodium bicarbonate ingestion during an 8-hour altitude acclimatization period on subsequent short-duration, high-intensity cycling performance at an altitude of 10,000 ft.

**METHODS:** Following 3 to 5 accommodation trials, four time-trials (TT) were conducted on ten trained males under the following conditions: normobaric/placebo (NPO); normobaric/sodium bicarbonate (NSB); hypobaric/placebo (HPO); and hypobaric/sodium bicarbonate (HSB). All trials were performed in a hypobaric altitude simulator. The TT included completing 360 revolutions as fast as possible on a cycle ergometer at a resistance equal to  $\approx 5.5\%$  body weight.

**RESULTS:** The rate of urinary bicarbonate excretion was significantly ( $p = .005$ ) higher during the hypobaric ( $1.264 \pm 1.05$  mg $\cdot$ min $^{-1}$ ) versus the normobaric ( $.324 \pm .37$  mg $\cdot$ min $^{-1}$ ) acclimatization period. Pre- to post-exercise increment in serum lactate concentration was larger ( $p = .03$ ) by  $4.08 \pm 2.6$  mmol $\cdot$ L $^{-1}$  in HSB TT compared to HPO TT but the difference between the Normobaric TTs ( $2.58 \pm 1.5$  mmol $\cdot$ L $^{-1}$ ) was not significant. No significant differences between placebo and SB ingestion trials under both hypobaric and normobaric conditions were found for pre- to post-exercise drop in serum bicarbonate concentration. Additionally, no significant difference was observed between placebo and SB ingestion trials for performance time under normobaric conditions (NPO:  $305.0 \pm 47.7$  sec; NSB:  $304.9 \pm 44.8$  sec) but a significant difference resulted under hypobaric conditions (HPO:  $352.5 \pm 55.1$  sec; HSB:  $341.2 \pm 58.1$  sec;  $p = .02$ ).

**CONCLUSIONS:** SB ingestion improved cycling performance under hypobaric conditions but not under normobaric conditions.

---

### 2124 Board #12 May 28 2:00 PM - 3:30 PM Effect Of Normobaric Different Oxygen Concentration On Anaerobic Energy Release During Supramaximal Exercise In Cyclists

Norio Saga, Tomoki Nagata, Shizuo Katamoto, Hisashi Naito, Mitsutoshi Kurosaka, Ikumi Kobayashi, Ryo Kakigi, Noriko Ichinoseki-Sekine.

*Juntendo University, Chiba, Japan.*

*(No relationships reported)*

**PURPOSE:** The purpose of this study was to clarify the critical level of inspired oxygen concentration for increased anaerobic energy release during supramaximal cycling exercise under normobaric condition.

**METHODS:** Eight collegiate cyclists volunteered to participate in this study. They underwent three exercise tests. First, they performed a maximal incremental cycling exercise test to determine their maximal oxygen uptake ( $\text{VO}_2$  peak). Second, 12 submaximal cycling tests were performed to establish the  $\text{VO}_2$ - workload  $\times$  cadence relationship for determining the oxygen demand of supramaximal cycling. Finally, the subjects performed six 40-second Wingate anaerobic tests (WAnT) to determine the anaerobic energy release under different inspired oxygen conditions (20.94(sea level), 16.4, 15.4, 14.5, 13.6, and 12.7%  $\text{O}_2$ ) using a Douglas bag. Anaerobic energy release was evaluated by oxygen deficit accumulated over 40-second.

**RESULTS:** The mechanical power output during WAnT was almost the same between sea level and hypoxic conditions. However,  $\text{VO}_2$  during WAnT was significantly lower in 14.5, 13.6 and 12.7%  $\text{O}_2$  compared with sea level. The absolute values and percentages of anaerobic energy release were significantly higher in 13.6%  $\text{O}_2$ , and in 13.6 and 12.7%  $\text{O}_2$  compared with sea level, respectively ( $P < 0.05$ ).

**CONCLUSIONS:** The results suggest that anaerobic energy release in 40-second supramaximal cycling could be increased when the subjects exercise under hypoxic condition of oxygen concentrations below 14.5%  $\text{O}_2$ , which correspond to the altitude of 3000m.

Whyte, FACSM<sup>3</sup>. <sup>1</sup>English Institute of Sport, Twickenham, United Kingdom. <sup>2</sup>Brunel University, Uxbridge, United Kingdom. <sup>3</sup>Liverpool John Moores University, Liverpool, United Kingdom.

Email: charles.pedlar@eis2win.co.uk

*(No relationships reported)*

**PURPOSE:** To examine the chronic effects (8 nights) of sleeping in a normobaric hypoxic tent (10 hours.night<sup>-1</sup>) in Great Britain International athletes from a range of sports (Rowing, Running, Kayaking; n = 12; age: 26.2  $\pm$  3.7 years; stature: 184.4  $\pm$  7.3 cm; body mass: 74.4  $\pm$  6.9 kg).

**METHODS:** the Leeds Sleep Evaluation Questionnaire (LSEQ) combined with Wristwatch Actigraphy (WA) was used to examine subjective and objective markers of sleep quality and compare these to baseline sleep.

**RESULTS:** Data were considered on a case by case basis revealing a heterogeneous response, with some individuals experiencing negative effects. As a group, there were no significant differences in sleep quality between baseline and night 1 sleep for any measurement. Sleep latency was significantly shorter on night 8 in the tent compared to night 1 ( $P < 0.05$ ). Other WA data revealed that behavioural aspects of sleep such as sleep fragmentation continued to be negatively affected in some individuals despite chronic exposure to NH.

**CONCLUSIONS:** Sleep quality in a hypoxic tent, is altered in some individuals, and is not universally improved following 8 nights. This may have significant consequences for recovery from training in some individuals.

**2126 Board #14 May 28 2:00 PM - 3:30 PM**

**Muscle Deoxygenation And Electromyographic Activity During Isolated Muscle Exercise In Hypoxia**

Keisho Katayama<sup>1</sup>, Yutaka Takeuchi<sup>1</sup>, Yasuhide Yoshitake<sup>2</sup>, Osamu Fujita<sup>1</sup>, Kohei Watanabe<sup>1</sup>, Hiroshi Akima<sup>1</sup>, Koji Ishida<sup>1</sup>. <sup>1</sup>Nagoya University, Nagoya, Japan. <sup>2</sup>National Institute of Fitness and Sports, Kanoya, Japan. (Sponsor: Jerome A. Dempsey, FACSM)

Email: katayama@htc.nagoya-u.ac.jp

*(No relationships reported)*

It is well known that acute hypoxia significantly increased the rates of development of exercise-induced muscle fatigue. It is hypothesized that muscle deoxygenation is accelerated during exercise in hypoxia, and that this would be related to the rate of increase in electromyographic (EMG) activity as an index of motor unit recruitment.

**PURPOSE:** The aim of the present study was to elucidate the changes in muscle deoxygenation and EMG activity during isolated muscle exercise in hypoxia and the relationship between the changes in deoxygenation and EMG activity.

**METHODS:** Seven healthy male subjects performed intermittent, unilateral, isometric, submaximal quadriceps muscle contractions [60% maximal voluntary contraction (MVC), 5 sec of contraction/5 sec of rest] while breathing normoxic ( $\text{FIO}_2=0.21$ ) or hypoxia ( $\text{FIO}_2=0.11-0.12$ ) gas mixture. MVC was obtained before and at the end of each minute of submaximal exercise until exhaustion, defined as the inability to exert or maintain 60% of rested MVC. The change in muscle deoxygenation was measured by near-infrared spectroscopy. Surface EMG and muscle deoxygenation were simultaneously recorded from the vastus lateralis muscle.

**RESULTS:** The deoxygenation index (deoxygenated Hb/Mb - oxygenated Hb/Mb) during exercise in hypoxia was larger ( $P < 0.05$ ) than that in normoxia. The rate of increase in iEMG during exercise in hypoxia was greater ( $P < 0.05$ ) than in normoxia. The rate of percent reduction of MVC in hypoxia was larger ( $P < 0.05$ ) than normoxia. To clarify the relationship between parameters during exercise in hypoxia and normoxia, the magnitude of the changes in deoxygenation index and iEMG at end of first three minutes during submaximal exercise were calculated individually as the difference between those obtained in hypoxia and normoxia (delta = hypoxia - normoxia). A significant positive correlation was observed between delta deoxygenation index and delta iEMG at the second ( $r=0.71$ ,  $P < 0.05$ ) and third ( $r=0.75$ ,  $P < 0.05$ ) minutes during exercise.

**CONCLUSIONS:** These results suggest that the rates of rise of muscle activity and development of fatigue during submaximal isolated muscle exercise in acute hypoxia are linked to the magnitude of muscle deoxygenation.

**Oxygen Transport In Kenyan Runners**

Nicole Prommer<sup>1</sup>, Stefanie Thoma<sup>2</sup>, Lennart Quecke<sup>1</sup>, Thomas Gutekunst<sup>1</sup>, Christian Voelzke<sup>1</sup>, Nadine Wachsmuth<sup>1</sup>, Andreas Michael Niess<sup>2</sup>, Walter Schmidt<sup>1</sup>. <sup>1</sup>University of Bayreuth, Bayreuth, Germany. <sup>2</sup>University of Tübingen, Tübingen, Germany. (Sponsor: Juergen Steinacker, FACSM)

Email: nicole.prommer@uni-bayreuth.de

*(No relationships reported)*

It is assumed that the excellent performance of Kenyan runners is mainly due to a high running economy in connection with high  $\text{VO}_{2\text{max}}$ . To explain underlying physiological reasons research mainly focused on muscular oxygen consumption.

**PURPOSE:** To investigate basic factors of oxygen transport, i.e. total hemoglobin mass (tHb-mass), blood volume (BV) and heart size in elite Kenyan runners and adaptation processes of these parameters during a sojourn at lowland.

**METHODS:** Ten Kenyan runners (group K; competing between 1.500m and marathon) living and training at moderate altitude (~2100m) performed a 6-weeks lasting training camp at 350m in Germany. Training (volume ~210km/week) was similar to that normally performed in Kenya. tHb-mass and BV were determined using the optimized  $\text{CO}$ -rebreathing method on the first day after arrival to Germany and weekly during their whole stay. In addition BV and haemoglobin concentration [Hb] were also examined before departure at altitude.  $\text{VO}_{2\text{max}}$  was determined in three field tests and running economy in a laboratory test on a treadmill. 11 German elite runners served as a control group (group G).

**RESULTS:** The Kenyan runners had a significantly lower body mass (K 57.2  $\pm$  7.0kg; G 66.5  $\pm$  6.3kg) and BMI (K 18.5  $\pm$  0.9; G 20.4  $\pm$  0.9). Relative  $\text{VO}_{2\text{max}}$  did not differ between the

groups (K 71.5 ± 5.0 ml/kg/min; G 70.7 ± 3.7 ml/kg/min) and absolute VO<sub>2</sub>max did not change during the 6 weeks at low altitude. Relative tHb-mass (K 14.2 ± 1.0g/kg; G 14.0 ± 0.7g/kg) and BV (K 101.9 ± 4.5ml/kg; G 99.6 ± 5.8ml/kg) were similar in both groups but continuously decreased in K during the stay at lowland (absolute tHb-mass from 813 ± 90g to 767 ± 90g, p < 0.001; BV from 5828 ± 703ml to 5513 ± 708ml, p < 0.01). [Hb] tended to decrease (-0.7 ± 0.7g/dl) when commuting altitude but did not differ at sea level between the groups (K 15.4 ± 1.0g/dl, G 15.5 ± 1.2g/dl). The relative heart volume was slightly lower in the Kenyans (K 14.0 ± 1.5ml/kg; G 15.2 ± 2.0ml/kg). Running economy was higher (p < 0.05) in K at speeds of 18km/h and above and can partly be attributed to the smaller calve circumference (p < 0.001) and lower BMI (p < 0.001).

**CONCLUSIONS:** The excellent running performance of Kenyans is not due to an improved oxygen transport system but due to a lower demand of oxygen at higher speeds compared to German runners.

**Interaction Of 4% Hypohydration And 3,048 M Altitude On Aerobic Exercise Performance**

John W. Castellani, FACSM, Samuel N. Cheuvront, FACSM, Stephen R. Muza, FACSM, Charles S. Fulco, Robert W. Kenefick, FACSM, Beth A. Beidleman, Michael N. Sawka, FACSM. *USARIEM, Natick, MA.*

Email: john.castellani@us.army.mil

(No relationships reported)

Body water deficits (3-4% of body weight) degrade aerobic exercise performance in temperate and hot environments. Hypoxia will induce body water deficits (hypohydration, HYP), however, the effects of HYP on aerobic exercise performance at high altitude has not been reported.

**PURPOSE:** Determine effects of HYP (~4% body weight loss) on aerobic exercise performance at sea-level (SL) and high-altitude (ALT, 3,048 m). We hypothesized that HYP and ALT would each degrade exercise performance relative to SL-euhydrated (EUH) conditions and combining HYP and ALT would further degrade performance more than one stressor alone.

**METHODS:** Seven men (25 ± 7 yr; 82 ± 11 kg; mean ± SD) completed 4 separate experimental trials. Trials were: a) SL-EUH; b) SL-HYP; c) ALT-EUH; and d) ALT-HYP. The day before each trial, subjects walked for ~2.5 h in the heat (50°C) either with (EUH) or without (HYP) fluid replacement. In HYP, exercise continued until 4% of body weight was lost. Subjects maintained hydration status overnight and the following morning entered a hypobaric chamber where they completed submaximal exercise (cycle ergometry) at 45% VO<sub>2</sub>max (20 min) and 60% VO<sub>2</sub>max (10 min) immediately followed by a 30-min performance time-trial (TT) at an ambient temperature of 27°C. Performance was assessed by the total amount of work (kJ) completed during the TT.

**RESULTS:** Total TT work (kJ, mean ± SD) for each trial was: SL-EUH (334 ± 64), SL-HYP (278 ± 87, p < 0.05 vs. SL-EUH), ALT-EUH (293 ± 33, p = 0.06 vs. SL-EUH), and ALT-HYP (227 ± 95, p < 0.05 compared to the other 3 trials). The change in performance, relative to the SL-EUH, trial was -18.6 ± 12.2% for SL-HYP, -11.0 ± 10.4% for ALT-EUH, and -33.7 ± 22.3% for ALT-HYP. Individual performance changes, relative to SL-EUH, demonstrated that 6/7 volunteers did worse during ALT-EUH, while 7/7 subjects did worse during SL-HYP and ALT-HYP. The total work during ALT-HYP was significantly lower (P < 0.05) vs. the other trials.

**CONCLUSION:** These data support the hypothesis that moderate body water deficits and high-altitude degrade aerobic performance, and that when these two stressors are combined, aerobic performance is degraded in an additive manner. These findings demonstrate the importance of maintaining euhydration on sustaining aerobic exercise performance at high-altitude.

**Green Tea Supplementation Improves Cycling Time-trial Performance At Simulated Altitude**

Michael D. Pugh<sup>1</sup>, Robert D. Sawyer<sup>2</sup>, Dustin C. Loftis<sup>2</sup>, Charles A. Gremillion<sup>2</sup>, James S. Williams, FACSM<sup>2</sup>. <sup>1</sup>The University of Texas Southwestern Medical Center at Dallas, Dallas, TX. <sup>2</sup>Texas Tech University, Lubbock, TX.

Email: michael.pugh@utsouthwestern.edu

(No relationships reported)

Reactive oxygen species (ROS) or free radicals are unstable molecules that have been implicated in the processes of muscle damage and fatigue. Previous studies have shown that both exercise and hypoxia associated with altitude exposure result in increased production of ROS. Catechins in green tea extract (GTE) are powerful antioxidants capable of scavenging ROS and possibly preventing muscle damage and fatigue.

**PURPOSE:** To determine the effects of GTE supplementation on endurance performance and ROS production during exercise at simulated altitude.

**METHODS:** Ten recreationally-active (VO<sub>2</sub>max = 51.4 ± 1.2 ml/kg/min; 23.1 ± 1.5 yrs) male subjects first completed a maximal graded exercise test (GXT) on a cycle ergometer followed by three time-trial (TT) performances. The first TT served as a practice session and was followed by two experimental TT performances at simulated altitude (2500 m). The experimental TT performances were randomized and all TT performances were separated by 48 hrs. Based on the maximal power output achieved on the GXT, each subject was assigned a specific amount of work (joules) to be completed as fast as possible during the experimental TT performances. Subjects ingested GTE or placebo capsules 1 hr prior to the experimental TT performances and a blood sample was obtained before the GTE or placebo ingestion and 60 min after the TT performance for the determination of ROS (malondialdehyde-MDA).

**RESULTS:** Cycling TT performance was significantly faster (p < 0.01) at simulated altitude with GTE supplementation compared to placebo (28.9 ± 22.2 sec). Nine of the ten subjects demonstrated an improvement in time. Mean power output for the subjects was also significantly higher at simulated altitude (p < 0.01) with GTE supplementation compared to placebo (6.97 ± 3.93 W). No significant differences (p > 0.05) were found in plasma MDA levels between conditions or time.

**CONCLUSION:** Supplementation with GTE improves cycling TT performance at simulated altitude however; the improvement in TT performance does not appear to be related to MDA levels.

**Normobaric Hypoxia Exposure During Sleep Produces Sleep-Specific Ventilatory Acclimatization At High Altitude**

Stephen R. Muza, FACSM, Charles S. Fulco, Beth A. Beidleman, Juli E. Jones, Rob N. Demes, Janet E. Staab, Paul B. Rock, Allen Cymerman. *USARIEM, Natick, MA.*

Email: stephen.muza@us.army.mil

(No relationships reported)

Sea-level (SL) residents have used repeated exposures to normobaric hypoxia (NH) during sleep to induce ventilatory acclimatization prior to rapid ascent to high altitude (HA). However, few reports have verified whether ventilatory acclimatization resulting from sleeping in NH is retained during subsequent HA exposure.

**PURPOSE:** To determine if ventilatory acclimatization induced during NH is present during HA exposure.

**METHODS:** Two groups of SL residents having similar resting end-tidal partial pressure of CO<sub>2</sub> (PetCO<sub>2</sub>), peak oxygen uptake (~47 ml/kg/min), and age (~24 yr) slept for ~6.5 hrs/night for 7 consecutive nights in portable rooms under blinded NH (n=14) or sham (n=8) conditions. Ambient % O<sub>2</sub> for the NH group was progressively reduced by ~0.30% O<sub>2</sub> each night from ~16.2% O<sub>2</sub> (2200 m equivalent) on the 1<sup>st</sup> night to ~14.4% O<sub>2</sub> (3050 m) on the 7<sup>th</sup> night. The sham group remained at ≥20.5% O<sub>2</sub> (150 m). Within 25 hrs of treatment end, all were exposed to HA (Pikes Peak, CO; 4300 m). At SL before and within 1 hr after treatment end, and in the first 24 hrs of HA, resting arterial oxygen saturation (SaO<sub>2</sub>) and PetCO<sub>2</sub>, and

steady-state exercise and sleep SaO<sub>2</sub> were measured.

**RESULTS:** (Mean±SE) Over 7 nights during sleep, NH SaO<sub>2</sub> decreased ( $p<0.05$ ) from  $92\pm1$  to  $88\pm1\%$ , but sham SaO<sub>2</sub> remained at  $96\pm1\%$ . From before to after treatment, SL resting PetCO<sub>2</sub> decreased ( $p<0.001$ ) for the NH group ( $39.1\pm0.8$  to  $34.9\pm0.7$  mmHg) but not for the sham group ( $39.1\pm0.7$  vs  $38.3\pm1.0$  mmHg). Within the first 5 hrs of HA, there were no between-group differences (NH vs sham) in resting PetCO<sub>2</sub> ( $33.5\pm0.7$  vs  $33.1\pm1.0$  mmHg), SaO<sub>2</sub> ( $83\pm2$  vs  $83\pm1\%$ ) or exercise SaO<sub>2</sub> ( $74\pm1$  vs  $73\pm2\%$ ). First night sleep SaO<sub>2</sub> in HA was higher ( $p=0.031$ ) for NH than for sham ( $78\pm1.3$  vs  $73\pm1.5\%$ ).

**CONCLUSION:** These results indicate that ventilatory acclimatization induced by sleeping in NH is present at HA during sleep but not during the awake state. Thus, sleeping in NH at SL may not induce functionally useful ventilatory acclimatization for subsequent rapid ascent to high altitude. Funding: US Army MRMCA ATO IV.MD.2006.01. Authors' views; not official U.S. Army or DoD policy.

#### **Muscle Activation Of The Contralateral Leg During An Acute Achilles Tendon Rupture**

Gretchen D. Oliver<sup>1</sup>, Christopher P. Dougherty<sup>2</sup>. <sup>1</sup>University of Arkansas, Fayetteville, AR. <sup>2</sup>The Agility Center Orthopedics, Bentonville, AR. (Sponsor: Charles Riggs, FACSM)

Email: goliver@uark.edu

(No relationships reported)

**PURPOSE:** To describe muscle activation of the contralateral (non-injured) leg during an acute Achilles tendon rupture.

**METHODS:** Electromyographic (EMG) data were collected on the following muscles: medial hamstring (semimembranosus and semitendinosus), biceps femoris, gluteus medius, gluteus maximus, and the gastrocnemius when the subject was performing a round-off dismount type of maneuver in which she sustained an Achilles tendon rupture.

**RESULTS:** EMG data analysis suggested that the subject fell into a knee valgus flexed hip position on the contralateral leg immediately following the injury. VMO activity indicated a position of knee valgus, while the shutdown of the gluteus medius and gluteus maximus indicated the patient's hip was falling into hip collapse. The lateral hamstring activity indicated an attempt to catch the falling pelvis and that the medial hamstrings were most likely caught in the reflex arc of the gluteals.

**CONCLUSIONS:** A compensatory theory was postulated by the researchers. "Lazy Leg Syndrome", where the injury occurred subsequent to the muscle activation that we described. The decreased EMG activity in the contralateral limb (lazy leg) predisposed the Achilles injury by requiring the tendon to rapidly absorb the extra force that would have been distributed throughout the kinetic chain because the proximal muscles of the lazy leg did not generate force sufficient to maintain control. If the decreased EMG activity in the contralateral limb occurred subsequently to the rupture, the resultant kinetic chain activity displays the way the body adapts due to a traumatic injury of the lower extremity. Reproduction of the muscular pattern of activity in landing maneuvers and subsequent training intervention may reveal targeting muscle groups that have been shown to fail early. Targeting the muscle groups through training interventions may have an impact on injury reduction patterns.

#### **Surgical Versus Conservative Treatment Of Acute Glenohumeral Dislocations For Preventing Recurrent Dislocations: A Systematic Review**

Jihong Park<sup>1</sup>, Nicole L. Cosby<sup>2</sup>, Jay Hertel, FACSM<sup>2</sup>. <sup>1</sup>Brigham Young University, Provo, UT. <sup>2</sup>University of Virginia, Charlottesville, VA.

Email: fchongs@gmail.com

(No relationships reported)

**PURPOSE:** To perform a systematic review to determine the numbers needed to treat (NNT) and relative risk reduction (RRR) associated with arthroscopic surgical repair versus conservative therapy in reducing recurrence rates among patients with acute traumatic shoulder dislocations.

**METHODS:** We searched MEDLINE, SPORT Discus, and CINAHL from inception to September 2008 using combinations of the terms *shoulder, glenohumeral, instability, dislocation, acute, traumatic, rehabilitation, strengthening, surgery, surgical, repair, reconstruction, arthroscopic, and arthroscopy*. Selected articles were from peer-reviewed journals written in English. All articles were studies that compared arthroscopic surgical repair versus conservative therapy for reducing recurrence rates among patients recovering from acute traumatic glenohumeral dislocations. Nine studies met the inclusion criteria and were independently rated by 2 reviewers using the Physiotherapy Evidence Database (PEDro) scale. PEDro scores ranged from 4 to 8 out of 10. The total number of subjects and the number of recurrent dislocations within each group were used to calculate NNT and RRR for each study. The results were also pooled across studies. The average follow-up time for the studies included in the pooled results was 25.4 months.

**RESULTS:** All 9 studies clearly demonstrated that the arthroscopic surgical procedure was more effective than conservative treatment in reducing the risk of recurrence among acute traumatic glenohumeral dislocators. The pooled NNT to benefit was 1.8 (95% CI = 1.6 to 2.1), indicating that 2 individuals would need to be treated surgically, rather than conservatively, in order to prevent one recurrent glenohumeral dislocation. The pooled RRR for prevention of recurrent dislocation was 84.1% (95% CI = 75.0% to 89.8%) in favor of those who received surgical treatment versus conservative treatment.

**CONCLUSIONS:** The use of arthroscopic surgical repair over conservative treatment in patients with acute traumatic glenohumeral dislocations is supported with a Strength of Recommendation Taxonomy level of evidence of 1 and a grade A recommendation.

### **2133 Board #21 May 28 3:30 PM - 5:00 PM**

#### **The Biomechanical Impact Of Hyaluronic Acid In Knee Osteoarthritis Patients: A Randomized, Double-blind, Placebo-controlled Study.**

Joseph E. DeCaria, Robert J. Petrella, FACSM, Manuel Montero-Odasso, Dalton Wolfe, Bert Chesworth. *The University of Western Ontario, London, ON, Canada.*

Email: jdecaria@uwo.ca

(No relationships reported)

**PURPOSE:** To determine how Hyaluronic acid (HA) impacts clinical outcomes and gait function in knee osteoarthritis (OA) patients.

**METHODS:** Nineteen mild-moderate knee OA patients were randomized to receive 3 consecutive weekly knee injections of 2ml Suplasyn (20mg HA) or 1.2 ml placebo (P) (0.01mg HA). Clinical outcomes were assessed using the WOMAC OA Index and gait characteristics were determined with GAITRite software.

**RESULTS:** Means and standard deviations are presented thus, Mx (SD). The patient population was 72.21 (6.61) years old, 167.47(9.26) cm tall and weighed 81.54 (12.68) kg. Eight patients received HA and 11 patients received P. Treatment effects were determined by comparing week 1(W1) to week 4(W4) outcomes, using 1-tail Wilcoxon signed-ranks tests for within group, and 1-tail Mann-Whitney tests, for between groups comparison. At W1 the HA groups normal walking velocity (NWV) = 112.17 (19.42) cm/s and

fast walking velocity (FWV) = 152.58 (28.48) cm/s. By W4 their NWV = 120.24 (22.14) cm/s ( $p=.025$ ) and FWV = 157.58 (30.39) cm/s ( $p=.164$ ). At W1 the P groups NWV = 108.81 (24.55) cm/s and FWV = 141.54 (31.86) cm/s. By W4 their NWV = 117.76 (22.77) cm/s ( $p=.03$ ) and a FWV = 143.40 (32.05) cm/s ( $p=.297$ ). No significant difference existed at either W1 or W4 between the two groups regarding both NWV and FWV ( $p>.05$ ). At W1 WOMAC pain, stiffness, and function scores for the HA group were 11.25 (4.17), 5.75 (1.39), and 42.63 (13.64), respectively, and by W4 were 8.50 (2.98) ( $p=.008$ ), 4.50 (1.07) ( $p=.021$ ), and 32.50 (13.18) ( $p=.014$ ), respectively. For the P group, W1 WOMAC scores for pain, stiffness and function were 11.55 (2.21), 5.73 (1.42), and 45.36 (6.19), respectively, and by W4 were 11.00 (3.13) ( $p=.297$ ), 5.27 (1.49) ( $p=.130$ ), and 39.73 (9.32) ( $p=.038$ ), respectively. The HA group showed greater improvement in WOMAC scores, but they were not significantly different from P scores at W4 for pain ( $p=.152$ ), stiffness ( $p=.272$ ), and function ( $p=.129$ ).

**CONCLUSIONS:** At one week post-treatment modest improvement in clinical symptoms and gait function may be experienced in knee OA patients treated with 3 consecutive HA injections. These improvements may indicate the progressive nature of the onset of HA treatment in knee OA patients, and provide preliminary evidence for greater improvements expected at 3 and 6 months follow up.

**Relationship Between Functional And Mechanical Ankle Instability In Physically Active Individuals**

Derek K. Hirai, Carrie L. Docherty, John Schrader. *Indiana University, Bloomington, IN.* (Sponsor: Dr. Anthony Luke, FACSM)  
(No relationships reported)

Individuals suffering lateral ankle sprains can develop functional ankle instability (FAI) and/or mechanical ankle instability (MAI). While some consider these to be two separate entities under the umbrella of chronic ankle instability, the relationship between FAI and MAI remains unclear.

**PURPOSE:** The purpose of this investigation was to evaluate the relationship between functional and mechanical ankle instability in physically active individuals.

**METHODS:** Eighty college aged physically active individuals (male=50, female=30,  $19.81 \pm 1.42$  yrs,  $176.5 \pm 9.9$  cm,  $74.77 \pm 15.31$  kg) from a large Division 1 institution were recruited for this study. All subjects had unilateral FAI. FAI was defined as a history of at least two ankle sprains and a score of less than or equal to 27 on the Cumberland Ankle Instability Tool (CAIT). The contralateral limb had no history of ankle injury. Anterior displacement (mm) and talar tilt ( $^{\circ}$ ) testing was performed using a joint arthrometer to measure MAI. Individuals were tested bilaterally and the maximum value attained during talar tilt and anterior displacement was used for statistical analysis. Dependent t-tests were used to compare the anterior displacement and talar tilt between the FAI and uninjured ankle. Two Pearson product moment correlations were used to examine the relationship between FAI and MAI, one for anterior displacement and one for talar tilt.

**RESULTS:** We found no significant difference between the FAI and uninjured ankle for anterior displacement ( $t_{1,79} = 1.66, p = .10$ ) or talar tilt ( $t_{1,79} = -.07, p = .95$ ). Additionally, no significant correlations were identified between the CAIT score for the FAI limb and anterior displacement ( $r = .18, p = .12$ ) or talar tilt ( $r = .09, p = .42$ ).

**CONCLUSION:** Functional and mechanical ankle instability appears to be two discreet entities. This study suggests FAI can occur independently from MAI. In addition, individuals with a greater degree of FAI do not possess more MAI.

**2135 Board #23 May 28 3:30 PM - 5:00 PM**  
**The Effect Of Time On Navicular Height With Low-Dye Arch Taping**

Nicole C. Dabbs, Nicole A. Hurst, Robert D. Kersey, Karen L. Perell, Michele L. Barr, Lee E. Brown, FACSM. *California State University, Fullerton, Fullerton, CA.*  
Email: ncdabbs@hotmail.com  
(No relationships reported)

Low-Dye arch taping is primarily used as a short term intervention for athletes who present with low navicular height. This technique is designed to help support the medial longitudinal arch in the foot and maintain a proper height.

**PURPOSE:** Therefore, the purpose of this study was to determine the efficiency of a modified low-Dye arch taping across a 30 second time period.

**METHODS:** Twenty-one healthy physically active men and women (age  $23.52 \pm 4.75$  years, height  $152.07 \pm 45.02$  cm, body mass  $72.90 \pm 25.17$  kg) with a navicular drop of 10mm or greater volunteered to participate. A certified athletic trainer applied the modified low-Dye arch taping directly to a clean, dry foot surface. A second certified athletic trainer measured navicular height three times within 30 seconds while standing on one foot.

**RESULTS:** Data were analyzed using a 1x3 repeated measures ANOVA for time. There was a significant ( $p<0.05$ ) decrease in navicular height between time 1 ( $29.63 \pm 6.22$ ) and time 3 ( $29.01 \pm 6.01$ ). The results of this study indicate that navicular height decreased within 30 seconds of having the medial longitudinal arch taped.

**CONCLUSION:** Therefore, modified low-Dye arch taping may lose efficiency quickly following only weight bearing activities. Future research should investigate longer times, greater activity levels and different taping techniques.

**Gleno Humeral Internal Rotation Deficiency In The Over Arm Throwing Athlete.**

Helmut R. Perez, Daniel J. Migliaccio. *Adelphi Univ., Garden City, NY.*  
(No relationships reported)

Glenohumeral Internal Rotation Deficiency (GIRD) is considered pathologic when the loss of shoulder internal rotation (IR) is not compensated by an increase in external rotation (ER). There is a greater presence of GIRD in baseball players vs. controls (C) but the measurement of GIRD remains indistinct. In this study, GIRD was defined by 2 variables: a loss of IR in the dominant (D) arm compared with the non dominant (ND) arm, and a loss of IR as compared to normative data ( $60^{\circ}$  IR,  $90^{\circ}$  ER).

**PURPOSE:** To measure the occurrence of GIRD among Division II collegiate baseball players (BB) and the possible clinical implications this may define.

**METHODS:** Supine goniometric measurements (ER, IR) were performed on BB ( $n=10$ , Age:  $20.1 \pm 1.1$ , Ht:  $1.83 \pm 0.09$  m, Wt:  $83.2 \pm 13.7$  kg, Body Fat (BF):  $13.2 \pm 5.7$ , Yrs BB Experience:  $15 \pm 3.4$ , %) and compared to C ( $n=5$ , Age:  $22.8 \pm 3.5$ , Ht:  $1.72 \pm 0.04$  m, Wt:  $84 \pm 7.4$  kg, Yrs BB Experience:  $4.8 \pm 3.3$ , % BF:  $18.6 \pm 3.9$ ). In this study GIRD was determined using the formula:  $[(60^{\circ}/90^{\circ}) - (IR/ER \text{ ratio})] = \text{positive value}$ . BB vs. C and D vs. ND comparisons were made using paired T-tests.

**RESULTS:** Difference was found in both IR and ER D vs. ND only in BB ( $p=0.01$  and  $p=0.01$  respectively). This finding leads to the conclusion that GIRD, as a %, was evident in the D shoulder of BB ( $+2.3 \pm 19.1$ ). Difference was found in the % GIRD D vs. ND shoulders of the BB ( $2.3 \pm 19.1$  vs.  $-30.1 \pm 33.2$ ,  $p=0.009$ ).

**CONCLUSION:** The occurrence of GIRD among BB may be clinically revealed as anterior rotator cuff instability that may lead to superior labral anterior posterior lesions (SLAP). The measure of GIRD proposed, may expedite the evaluation of the over-arm throwing athlete in terms of exercising corrective measures to avoid potential SLAP lesions.

**Effects Of Intraarticular Injection And Therapeutic Exercise In Patients With Idiopathic Adhesive Capsulitis**

Eun Young Park<sup>1</sup>, Nicole L. Rogers<sup>1</sup>, Michael E. Rogers, FACSM<sup>1</sup>, Jong-Ha Lee<sup>2</sup>. <sup>1</sup>Wichita State University, Wichita, KS. <sup>2</sup>Kyung Hee University Medical Center, Seoul, Republic of Korea.

Email: joyoung93@daum.net

(No relationships reported)

Idiopathic adhesive capsulitis or frozen shoulder is a painful condition that progressively restricts all planes of movement in the shoulder. It is the leading cause of shoulder pain and dysfunction in middle-aged and older adults.

**PURPOSE:** To compare the impact of therapeutic interventions consisting of only intraarticular corticosteroid injection to intraarticular injection combined with therapeutic exercise in patients with idiopathic adhesive capsulitis.

**METHODS:** Subjects (n=19) with idiopathic adhesive capsulitis were randomly assigned to one of two therapeutic interventions: Group 1 (n=9, age=52.3±6.5yrs) received intraarticular injections and therapeutic exercise and Group 2 (n=10, age=59.3±10.5yrs) received only intraarticular injections. Both groups were injected with intraarticular corticosteroids (20mg Triamcinolone; 10cc of saline and 10cc of 1% Lidocaine) every other week for 8 wk (4 total). Group 1 also participated in daily therapeutic exercise 2 times a day for 8 wk. Shoulder Range of Motion (S-ROM; flexion, extension, abduction, internal rotation and external rotation), Visual Analogue Scale (VAS), and Modified Shoulder Pain and Disability Index (M-SPADI) were measured before and after the 8-wk protocol. Paired samples t-tests were used to determine improvement in each group.

**RESULTS:** For Group 1, improvements ( $p<.05$ ) in S-ROM (flexion 28.6%; abduction 46.8%; internal rotation 116.5%; external rotation 67.1%), VAS (62.5%), and M-SPADI (72.4%) were observed after treatment. For Group 2, S-ROM (flexion 12.3%; abduction 23.7%; internal rotation 10.0%), VAS (34.9%), and M-SPADI (55.7%) improved ( $p<.05$ ) after treatment. However, no differences were found between Group 1 and Group 2 for the therapeutic interventions.

**CONCLUSIONS:** These results suggest that these therapeutic interventions can be successful and clinically significant in improving the function of the shoulder and for relieving pain. The small sample size may have contributed to the lack of statistical significance between groups. Future studies should examine if a therapeutic exercise program could effectively restore shoulder range of motion and improve shoulder strength to allow individuals to return their normal daily activities compared to untreated or injection groups.

**2138 Board #26 May 28 3:30 PM - 5:00 PM**

**Hamstring Training On Stabilizing Knee Joints With Anterior Drawer Instability**

Cheng-Hsiu Lai<sup>1</sup>, Kuan-Chou Chen<sup>2</sup>, Shu-Chun Huang<sup>3</sup>, Ching-Ya Huang<sup>1</sup>, Chia-Hua Kuo<sup>1</sup>, Shih-Wei Chou<sup>3</sup>. <sup>1</sup>Taipei Physical Education College, Taipei City, Taiwan. <sup>2</sup>University of Florida, Gainesville, FL. <sup>3</sup>Chang Gung Memorial Hospital, Taipei City, Taiwan. (Sponsor: Dr. John L. Ivy, FACSM)

Email: annlai@tpcc.edu.tw

(No relationships reported)

**PURPOSE:** In order to find out an effective training mode, we compare the effects of three different hamstring muscle training modes on muscle strength and knee joint stability.

**METHODS:** To investigate how different modes of thigh muscles strengthening exercises emphasizing the knee internal rotators can be as effective as possible in improving static and dynamic stability of the knee, twenty young men with knees of anterior drawer laxity compared to his contralateral side were randomly assigned to three experimental groups: plate-loaded squat press (SP), plate-loaded kneeling leg curl with internal rotation (KLCIR), and kneeling leg curl (KLC). Static stability, agility, and isokinetic strength were measured before and after six-week training. The control group with stable knees received no training.

**RESULTS:** The results demonstrate that the knee with anterior drawer laxity is less agile than its sound side and this vulnerability appeared to be improved after six-week SP and KLCIR training. The isokinetic strength of the knee internal rotator increased in SP and KLCIR group. We found that the KLCIR, emphasizing the knee internal rotators, improves significantly in both static and dynamic stability as the SP group. The improvement of agility in KLCIR is very likely due to the increased strength of internal rotators. As far as an ACL rehabilitation program is concerned, KLCIR can surely be either an advanced or an alternative mode to SP.

**CONCLUSION:** This current study revealed that the static anterior drawer laxity of knee can be compensated by hamstring strengthening exercise in all three training modes. We also found that the knee with anterior drawer laxity features poorer agility than its sound side, and such a vulnerability is very likely to be amended in either SP or KLCIR training mode. KLCIR and SP, both emphasizing knee internal rotators, revealed significant improvements in both static stability and agility, but KLCIR was more effective in internal rotator strengthening. As far as an ACL rehabilitation program is concerned, KLCIR can surely be either an advanced or alternative mode to SP.

**2139 Board #27 May 28 3:30 PM - 5:00 PM**

**Quantitative Assessment Of The Effect Of Prolotherapy On Patients With Cervicogenic Cephalic Syndrome**

Yin-Chou Lin, MD.. Chang Gung Memorial Hospital, Taoyuan, Taiwan. (Sponsor: John L. Ivy, FACSM)

Email: siriuslin@yahoo.com.tw

(No relationships reported)

Cervicogenic headache has the greatest potential of losing physical function when compared with the other groups of headache disorders. Dizziness and/or unsteadiness are also common symptoms associated with neck pain in patients with cervical pathology. In addition to headache, dizziness and/or dysequilibrium, cervical lesions may also result in ophthalmic, olfactory and/or throat complaints. Collectively, we introduce the term "cervicogenic cephalic syndrome" (CCS). We also conduct a quantitative assessment to evaluate the treatment effect of prolotherapy on patients with CCS.

**PURPOSE:** To access the effect of prolotherapy on the neck function of patients with CCS.

**METHODS:** forty-five subjects, 23 males and 22 females, with chronic neck pain were recruited. An electronic instrument of combined goniometer and muscle test will be used to measure flexibility and isometric strength of neck. The sensory organization test (SOT) will conducted to assess the balance control of subjects. During the SOT, subjects will be exposed to 6 combinations of visual and support surface conditions as follows: (1) eyes open and fixed support (EO), (2) eyes closed and fixed support (EC), (3) sway-referenced vision and fixed support (SV), (4) eyes open and sway-referenced support (SS), (5) eyes closed and sway-referenced support (ECSS), and (6) sway-referenced vision and support (SVSS).

**RESULTS:** The average age were 38.0±14.8, and 39.6±12.1 years old, in male and female respectively. The average duration of symptoms in male patients are 9.3±9.9 and female patients 3.7±4.1 years. The ROM of cervical spine are increased in left and right lateral flexion after treatment ( $p<0.05$ ). The isometric strength increased in left lateral flexion and rotation after treatment ( $p<0.05$ ). After treatment, the subjects showed increased postural stability in the EC and SS conditions of SOT. The visual and somatosensory ratios are also increased after treatment. The ankle strategy improved in the SV and ECSS conditions of SOT.

**CONCLUSION:** prolotherapy is effective in treating patients with CCS. SOT could be a quantitative assessment tool of neck function.

**The Effect Of Seat Height On VMO/VL Ratio During Cycling**

Yi-Chun Chen, Li-Lan Fu. National Taiwan Sport University(Taoyuan), Taoyuan County, Taiwan.

(No relationships reported)

Patellofemoral pain syndrome is one of the most frequently seen knee problems. Different cycling protocol could provide various VMO selective training effect.

**PURPOSE:** The purpose of this study was to compare the effect of 90, 95 and 100% seat height on VMO and VL activation during cycling.

**METHODS:** Subjects were 6 healthy male without any musculoskeletal or neurological diseases. The intervention included cycling with three different seat height. The seat

height was adjusted to 90, 95 and 100% of the leg length of each subject. The leg length was measured from the greater trochanter to the floor with the subject standing straight-legged on barefoot. The seat height is the distance from the top of seat to pedal at the lowest level. Before testing, all subjects performed stretching of 5 muscle groups, including quadriceps, hamstrings, calf muscles, hip flexor and gluteus maximus. Amplified surface electrodes were placed over VMO and VL of the right leg during maximum voluntary isometric contraction (MVIC) and also different cycling conditions. EMG data was collected by Biopac systems, MP150. The VMO and VL EMG of 90, 95 and 100% seat height was calculated as %MVIC. The warm-up was cycling at 1 kp/85 rpm for 5 minutes on a stationary ergometer. The three tests were done on the same stationary ergometer at 1.5 kp/85 rpm for 5 minutes. The order of the three interventions was randomly decided, and there was a two-day-interval between each. The data was determined statistically using one-way analysis of variance. The level of significance was set at 0.05.

**RESULTS:** Six healthy male subjects (age  $23.5 \pm 1.6$  years, height  $172.9 \pm 5.1$  cm, weight  $65.4 \pm 7.4$  kg) completed all trial. There were no significant ( $p > 0.05$ ) difference among 90, 95 and 100% seat height for VMO, VL %MVIC and VMO/VL ratio. The VMO (%MVIC) for three cycling conditions (90, 95 and 100% seat height) were  $38.6 \pm 31.2$ ,  $43.1 \pm 24.7$  and  $34.8 \pm 18.7\%$  ( $p = 0.85$ ). The VL (%MVIC) for three cycling conditions were  $29.7 \pm 4.4$ ,  $39.4 \pm 9.8$  and  $38.1 \pm 15.5\%$  ( $p = 0.28$ ). And the VMO/VL ratio for three cycling conditions were  $134.8 \pm 113.7$ ,  $114.8 \pm 76.1$  and  $90.0 \pm 19.2\%$  ( $p = 0.63$ ).

**CONCLUSIONS:** The results do not demonstrated that decreases in seat height during cycling can change the VMO and VL ratio effectively. Adjustment of seat height is not an appropriate way of VMO selective training during cycling.

**2141 Board #29 May 28 3:30 PM - 5:00 PM**

**Ankle Joint Laxity Is Decreased In Patients With Moderate Knee Osteoarthritis**

Tricia J. Hubbard<sup>1</sup>, Charlie A. Hicks-Little<sup>2</sup>, Richard D. Peindl<sup>3</sup>, Mitchell L. Cordova, FACSM<sup>1</sup>. <sup>1</sup>University of North Carolina @ Charlotte, Charlotte, NC. <sup>2</sup>The University of Utah, Salt Lake City, UT. <sup>3</sup>Carolinas Medical Center, Charlotte, NC.

Email: thubbar1@uncc.edu

(No relationships reported)

Changes in knee joint alignment associated with progressive knee osteoarthritis (OA) results in altered joint mechanics during walking gait, as well as deficits in other measures of functional activity. It is believed that changes in ankle joint motion may also contribute to the gait and functional activity deficits observed.

**PURPOSE:** To evaluate the ankle joint mechanical stability in patients with knee OA.

**METHODS:** Fifteen subjects with knee OA (5 males and 10 females, age= $60.3 \pm 10.2$ yr., mass= $93.9 \pm 18.3$ kg, ht= $167.23 \pm 9.5$ cm) were matched by gender, age, and weight to 15 healthy controls (5 males and 10 females, age= $59.6 \pm 12.6$ yr., mass= $83.5 \pm 19.2$ kg, ht= $169.7 \pm 12.6$ cm). Standardized radiographs of all knees for each subject were performed to determine study eligibility as well as to quantify knee OA severity using a standardized scoring system. Mechanical ankle joint stability was assessed in all subjects with an instrumented arthrometer. The arthrometer measured ankle-subtalar joint motion for anterior/posterior displacement (mm) during loading at 125 N and inversion/eversion rotation (degrees of ROM) during loading at 4000 N-mm. Separate 2 x 2 (group x side) mixed model ANOVAs were performed for all dependent measures.

**RESULTS:** There were significant group x side interactions for: anterior and posterior displacement ( $P < .05$ ). The subjects with knee OA had significantly less anterior ( $7.4 + .51$ mm) and posterior ( $2.2 + .31$ mm) ankle displacement compared to values observed in the healthy group (anterior  $10.5 + .51$ mm, posterior  $4.2 + .31$ mm), as well as compared to their unaffected extremity (anterior  $9.5 + .48$ mm, posterior  $2.6 + .25$ mm). There were significant main effects for group on inversion rotation and eversion rotation ( $P < .05$ ). The knee OA group had significantly less inversion ( $25.4^\circ + 1.6$ ) and eversion ( $13.1^\circ + 1.1$ ) rotation compared to the healthy group ( $31.1^\circ + 1.6$ ,  $20.2^\circ + 1.3$ ).

**CONCLUSION:** Knee OA subjects demonstrated significant decreases in anterior and posterior displacement as well as inversion and eversion rotation compared to healthy controls. These impairments may be the result of alterations in ankle joint alignment secondary to structural changes at the knee. Deviations in ankle joint mechanics must also be considered when addressing functional deficits in patients with knee OA.

**2142 Board #30 May 28 3:30 PM - 5:00 PM**

**The Relationships Between Range Of Motion, Performance, And Club Head Speed In Older Female Golfers**

Michael C. Rabel, Lorraine A. Lacoppola, Katherine E. James, Erin E. Ruest. University of Maryland Eastern Shore, Princess Anne, MD.

Email: mcrabel@umes.edu

(No relationships reported)

Research on range of motion (ROM) of the trunk, shoulder and hip in older amateur female golfers is limited. It is unknown if club head speed (CHS) is related to these physical characteristics or golf performance.

**PURPOSE:** The aims of this study were to: 1) determine the relationships between ROM, performance, and CHS in older amateur female golfers; and 2) evaluate the relationship between ROM and CHS in two age groups of older golfers, middle and senior.

**METHODS:** Twenty-eight healthy, amateur female golfers [mean age  $\pm$  SD (range),  $63.7 \pm 7.8$ , (49-86 years)] who swung right-handed were measured for trunk, hip, and shoulder rotation passive ROM with inclinometers. Trunk rotation was measured in sidelying using dual inclinometers and pelvic stabilization. Hip rotation was measured prone with the contralateral hip in  $30^\circ$  of abduction and pelvic motion prevented. Shoulder rotation was measured supine with the shoulder placed in  $90^\circ$  of abduction and scapula motion prevented. CHS was recorded with a ground level radar device. Each golfer used her driver of choice and swung from a standardized golf mat and tee. A self-report questionnaire was given to record performance data for both 9-hole and 18-hole games and driving distance. ICC values were calculated for repeated passive ROM measures. Relationships between ROM, performance, and CHS were examined with a Pearson product moment correlation coefficient analysis using SPSS v. 16.0.

**RESULTS:** The ICC values for intratester measures were 0.82, 0.88 (trunk: right, left), 0.81, 0.83 (shoulder: internal, external), and 0.95, 0.92 (hip: internal, external). A significant relationship ( $r = 0.85$ ,  $p < 0.01$ ) between CHS and driving distance was found. There were also inverse correlations ( $r = -0.49$  to  $-0.80$ ,  $p < 0.01$ ) between age, 9-hole score, 18-hole score and CHS. In the middle age group ( $\leq 60$  years of age), left hip external rotation was inversely correlated with CHS ( $r = -0.70$ ,  $p < 0.05$ ). No significant correlations were identified between ROM and CHS in the senior group ( $> 60$  years of age).

**CONCLUSIONS:** The ability to produce a greater club head speed was associated with better golf performance and increased driving distance. Club speed was shown to decline with age. Assessment of hip flexibility should be considered for rehabilitation and training programs in older female golfers.

**2143 Board #31 May 28 3:30 PM - 5:00 PM**

**The Use Of Transcranial Magnetic Stimulation In The Assessment Of Quadriceps Activation: A Pilot Study**

Brian G. Pietrosimone<sup>1</sup>, Christopher E. Gibbons<sup>2</sup>, Robert A. Huggins<sup>3</sup>, Susan A. Saliba<sup>1</sup>, Joseph M. Hart<sup>1</sup>, Christopher D. Ingersoll, FACSM<sup>1</sup>.

<sup>1</sup>University of Virginia, Charlottesville, VA. <sup>2</sup>University of Wisconsin, Madison, WI. <sup>3</sup>Sacred Heart University, Fairfield, CT.

Email: bgp7a@virginia.edu

(No relationships reported)

Percutaneous electrical stimulation has commonly been used to assess quadriceps activation, yet the discomfort associated with electrical stimulation may limit the populations that can be studied. Transcranial magnetic stimulation (TMS) has been reported as a non-painful, effective intervention for increasing quadriceps activation by stimulating descending cortical tracts, yet no research has determined if TMS can be used to assess muscle activation.

**PURPOSE:** To determine the relationship of quadriceps central activation ratio (CAR) derived from the TMS (CAR<sub>TMS</sub>) and the quadriceps CAR derived using percutaneous electrical stimulation with the superimposed burst method (CAR<sub>SB</sub>) in participants with partial meniscectomies.

**METHODS:** Ten participants (6 M, 4 F;  $36.8 \pm 16.4$  yrs;  $177.4 \pm 11.9$  cm;  $92.32 \pm 28.9$  kg;  $35.29 \pm 36.5$  weeks post partial meniscectomy) participated in this study. TMS stimulation did not produce an increase in knee extension force in 3 participants, who were excluded from analysis. Participants first performed 3 CAR<sub>SIB</sub> trials followed by 3 CAR<sub>TMS</sub> trials at 70° of knee flexion. The 3 CAR<sub>SIB</sub> and 3 CAR<sub>TMS</sub> trials were averaged for data analysis. A Spearman's rank correlation was performed to determine the relationship between CAR<sub>SIB</sub> and CAR<sub>TMS</sub> scores. Wilcoxon signed ranks tests were used to analyze differences between means and a Bland-Altman plot was used to determine the limits of agreement (LOA) between the measures.

**RESULTS:** The data were not normally distributed. The median CAR<sub>SIB</sub> (71%; Range 51.6 - 84.1) was significantly lower than the CAR<sub>TMS</sub> (92.%; 82.1 - 95.1;  $Z = -2.34$ ,  $P = .018$ ). The relationship between the CAR<sub>SIB</sub> and the CAR<sub>TMS</sub> was not statistically significant ( $p = .714$ ,  $P = .071$ ). The mean between measure difference score was  $21.7 \pm 11.01$ , with the LOA between -32 and 43.72. All point estimates were contained within the LOA and above 0.

**CONCLUSIONS:** CAR<sub>TMS</sub> was found to estimate significantly higher volitional activation values compared to CAR<sub>SIB</sub>. The LOA would be considered large for these measurements, which may indicate that CAR<sub>SIB</sub> and CAR<sub>TMS</sub> are not measuring the same characteristics of muscle activation. A CAR<sub>TMS</sub> measurement could not be elicited in 30% of this population, which could be a limitation of this technique.

---

**2144 Board #32 May 28 3:30 PM - 5:00 PM**  
**Grip Norms And Reliability Of The Hand Grip ForceMap System**

MARK DeBeliso<sup>1</sup>, Dallas Fichtner<sup>2</sup>, Louis Murdock<sup>3</sup>, Kent J. Adams, FACSM<sup>1</sup>. <sup>1</sup>California State University Monterey Bay, Seaside, CA. <sup>2</sup>Nebraska Wesleyan University, Lincoln, NE. <sup>3</sup>Intermountain Orthopedics, Boise, ID.  
(No relationships reported)

Strength testing of the injured hand and forearm is of considerable interest to patients, treating physicians, therapists, and insurance companies. While, over the past many years, traditional parallel-bar dynamometers have made a significant and positive contribution to medical grip strength evaluation, these devices are now less than optimal for the comprehensive analysis of overall grip and finger function. The ForceMap grip force mapping system utilizes tactile array technology to assess the complex grip capability/capacity of a human hand.

**PURPOSE:** This study's aim was to evaluate the reliability of the hand grip ForceMap system and to establish max grip force (MGF) and force distribution norms (D1-thumb; D2-index; D3-middle; D4-ring; D5-little finger; N/cm<sup>2</sup>) for healthy adults.

**METHODS:** Adults (Female n=28;  $38.9 \pm 11.0$  yrs;  $165.3 \pm 6.7$  cm;  $69.8 \pm 13.0$  kg; Male n=28;  $34.2 \pm 13.0$  yrs;  $181.3 \pm 8.0$  cm;  $86.4 \pm 15.1$  kg) completed trials of maximal grip on the ForceMap system with the elbow at 90 degrees flexion. The ForceMap system is comprised of a high resolution tactile array sensor mounted to a 5 x 15 cm solid Delrin cylinder (grip map transducer) that is interfaced to an amplifier/processor and laptop computer. The ForceMap system provides visual and numerical assessment of grip force including the palm and individual digits both statically and dynamically (100 hz). The reliability of the ForceMap was determined using a Pearson Correlation Coefficient (r), Intra-class Correlation Coefficient (ICC) and a Bland-Altman Plot (BAP) of repeated trials of the male dominant hand MGF.

**RESULTS:** Female norms dominant hand: MGF=  $471.2 \pm 119.6$  (N); D1=  $29.0 \pm 9.4$ ; D2=  $23.6 \pm 8.3$ ; D3=  $25.0 \pm 5.6$ ; D4=  $20.8 \pm 6.3$ ; D5=  $14.9 \pm 6.6$  (N/cm<sup>2</sup>). Male norms dominant hand: MGF=  $820.9 \pm 210.5$  (N); D1=  $34.5 \pm 9.1$ ; D2=  $29.5 \pm 8.3$ ; D3=  $34.3 \pm 8.8$ ; D4=  $26.9 \pm 9.0$ ; D5=  $23.2 \pm 9.2$  (N/cm<sup>2</sup>). Male dominant hand MGF:  $r = 0.92$  and ICC=0.92. The BAP plot revealed that 100% of the differences between trials were within  $\pm 2$  standard deviations of the mean difference.

**CONCLUSION:** Given the ability of the ForceMap system to reliably assess grip force along with the establishment of grip force and force distribution norms, it appears the ForceMap system is a viable means for detailed grip assessment.

**Influence Of Bicycle Seat Design On Perceived Comfort And Stability During Non-stationary Bicycling**

Eadric Bressel<sup>1</sup>, Shantelle Bliss<sup>2</sup>, John Cronin<sup>2</sup>. <sup>1</sup>Utah State University, Logan, UT. <sup>2</sup>Auckland University of Technology, Auckland, New Zealand.  
(Sponsor: Gerald Smith, FACSM)  
Email: eadric.bressel@usu.edu  
(No relationships reported)

It has been reported that bicycle seat discomfort influences over half of all bicyclists following short and long distance rides. Although researchers have provided insightful information regarding factors that influence seat pressure it is well documented that pressure and comfort may not always be related. A study that assesses how seat design influences perceived comfort and stability in male and female cyclists may help seat manufacturers and clinicians who aim to reduce cycling discomfort without compromising stability.

**PURPOSE:** To examine the interaction between three different seat designs and perceived comfort and stability in male, female, experienced and novice cyclists.

**METHODS:** Fifty-seven volunteers, comprising male experienced (13), male novice (19), female experienced (12) and female novice (13) cyclists rode three times over a 350 m flat course pedaling at 80 rpm at 118 W. Three different seat designs (standard, partial, and complete cut-out) were randomly interchanged. The comfort level of the crotch, sit bones, overall seat and handlebar areas, as well as stability were assessed with continuous visual analogue scales.

**RESULTS:** Subjects reported 29.2% and 37.1% greater levels of crotch comfort on the complete cut-out seat than the standard and partial cut-out designs, but reduced stability compared to the other two seats. Males reported greater comfort for the standard seat than females for crotch, sit bone, overall seat and hand comfort. Males reported greater comfort for the partial cut-out seat compared to females for crotch and hand comfort. Experienced cyclists perceived the crotch (male 23.8% and female 44.4%) and the overall seat (male 12.8% and female 36.1%) areas to have greater comfort than novice subjects for the partial cut-out seat.

**CONCLUSIONS:** It is recommended that experienced and novice male cyclists use either the standard or partial cut-out seat, experienced female cyclists use the partial cut-out seat and novice female cyclists use either the standard or partial cut-out seat. The major drawback of the complete cut-out seat was the perception of decreased stability.

---

**2146 Board #34 May 28 3:30 PM - 5:00 PM**  
**On Tackling And Tackling-related Injuries In International Soccer; A Gender Comparison**

Donald Kirkendall, FACSM, Colin Fuller, Philippe Tscholl, Jiri Dvorak. FIFA Medical Assessment and Research Centre, Zurich, Switzerland.  
Email: donald\_kirkendall@yahoo.com  
(No relationships reported)

Tackling is the most dangerous aspect of soccer and the cause of the majority of traumatic injuries. Rates of injury can be reported as per 1000 hr or per 1000 events that often show dissimilar results.

**PURPOSE:** to compare 2 methods of reporting rates for international male and female soccer players.

**METHODS:** We compared the injury rates in international men's and women's soccer tournaments to compare tackling and tackling-related injuries. We reanalyzed our tackling data from AJSM (2004) and BJSM (2007) to obtain rates (and 95% CI) per 1000 hr and per 1000 events for a direct gender comparison. All tackles during 123 of 128 matches of the 1998 World Cup, 1999 U-17 World Cup and the 2000 Olympics (men-total = 8572 tackles) and 24 matches from the 1999 and 2003 Women's World Cup, 2000 and 2004 Olympics, and the 2002 and 2004 U-19 Women's World Championship (total = 3531 tackles) were categorized according to established parameters. 200 injuries were recorded for both men and women. Rates (and 95% CI) were determined per 1000ph and per 1000 tackling events.

**RESULTS:** While the ranking of tackling preference was similar for men and women, men left their feet to make a tackle more often than women (44% vs. 35%,  $p < 0.05$ ). The overall injury rates per 1000 ph between genders were not different (49.3 and 42.7 for men and women respectively), yet the injury rate per 1000 events was significantly higher

for the men (23.3 vs 9.6,  $p < .05$ ). There were few gender differences in injury rates per 1000 player-hours. However, when compared per 1000 events, numerous gender-related differences were seen with the male rate exceeding the female rate in most cases. For both genders, leaving the feet to make a tackle resulted in a higher injury rate.

**CONCLUSIONS:** The two different methods of reporting rates show significant differences when comparing males and females. Similar incidences of injuries per time were found, but higher frequencies of injuries per tackle were found in men. These data illustrate a fundamental difference in the men's and women's game. Men leave their feet more to tackle than women and that may contribute to the higher rate of injury per tackle in men.

**2147 Board #35 Abstract Withdrawn**

**2148 Board #36 May 28 3:30 PM - 5:00 PM**

**The Physical Demands And Challenges Of Participating In Marching Band**

Gary Granata<sup>1</sup>, Dan Benardot, FACSM<sup>2</sup>. <sup>1</sup>*PerformWell, LLC, New Orleans, LA.* <sup>2</sup>*Georgia State University, Atlanta, GA.*

Email: gary@performwell.net

(No relationships reported)

Marching band is a physical activity that has been largely overlooked in sports medicine research and practice. The visual design of today's marching band shows, which is mainly influenced by competitive drum and bugle corps, places high physical demands on the individual performer. Repetitive use injuries, normally associated with traditional athletics, appear to be on the rise in both marching band and drum corps participants.

**PURPOSE:** To document the physical demands, challenges and injury prevalence that results from marching band participation.

**METHODS:** 172 (74 female, 98 male, age 15.5 + 1 yrs) members of the Avon High School Marching Band (Avon, IN) completed an anonymous questionnaire that addressed the physical demands and injuries resulting from regular participation in a marching band. The Avon Marching Band competes in Bands of America's highest division and has won numerous national and state titles.

**RESULTS:** Responders indicated that, as a result of either rehearsal or performance, 17.4% (N=30) indicated they were always tired, 43.6% (N=75) were frequently tired and 38.4% (N=66) were occasionally tired. They also reported that 24.4% (N=42) had experienced episodes of faintness or nausea after marching band participation, and 51.7% (N=89) experienced heat-related illness. Nearly all responders (95.3%; N=164) experienced sore or stiff muscles following marching band rehearsal or performance; 38.9% (N=67) reported an injury that was a direct result of marching band participation; 24.6% (N=44) had a previous injury that was worsened by marching band participation; and 27.6% (N=39) reported seeing a physician to diagnose a marching injury or injury worsened by participation. Marching band related injuries were the cause of missing rehearsal or performance in 7.5% (N=13) of responders.

**CONCLUSIONS:** This initial survey of health and injury issues associated with marching band participation suggests an activity-related injury rate that is similar to competitive sport. As a result, more attention should be given to the development of preventative strategies that could successfully reduce fatigue and injury in marching band participants.

**2149 Board #37 May 28 3:30 PM - 5:00 PM**

**The Bioknotless Suture Anchor For The Treatment Of Shoulder Instability: Clinical Results**

Jeremy Statton, Troy Diehl, Paul Favorito. *Wellington Orthopedics and Sports Medicine, Cincinnati, OH.*

(No relationships reported)

**PURPOSE:** Arthroscopic treatment of symptomatic shoulder instability has become a well accepted procedure. Knotless suture anchors are one type of implant utilized for capsulolabral repair and have several advantages compared to other available devices. The use of these anchors, however, has been associated with unfavorable outcomes. The purpose of this study is to report our results of arthroscopically treated shoulder instability with a knotless, bioabsorbable suture anchor.

**METHODS:** We identified and contacted patients who underwent arthroscopic capsulolabral repair of the shoulder with the BioKnotless anchor (DePuy Mitek, Raynham, Massachusetts). All patients had a minimum follow up of 2 years. Patient evaluation included a subjective questionnaire, physical exam, radiographs, and an MRI if indicated. All patients completed validated shoulder and health measurement outcome tools including the Simple Shoulder Test, the Short Form 12 Health Survey (SF-12), and the Western Ontario Shoulder Instability Index (WOSI).

**RESULTS:** Eight patients were evaluated. The mean age was 28.9 years. There were 6 males and 2 females. The mean time to follow up was 33.6 months. No patients had any episodes of recurrent instability. When compared to the contralateral shoulder, patients lost an average of 2.5° of forward flexion, 6.3° of external rotation, and 11.3° of internal rotation. No patients had instability on physical exam as determined by apprehension, relocation or load and shift testing. Radiographic examination revealed no evidence of osteolysis, chondrolysis or degenerative changes. The mean WOSI score was 65.2% (out of 100%). The mean Simple Shoulder Test score was 10.4 (out of 12). The mean physical component to the SF-12 was 51.0 (population mean 52.5) and the mental component was 55.5 (population mean 53.1).

**CONCLUSIONS:** Patients did report some level of disability of the shoulder determined by the WOSI, Simple Shoulder Test, and SF-12 scores. There was no radiographic evidence of osteolysis or glenohumeral arthritis. None of the patients reported any recurrence of instability. When properly utilized, the Bioknotless anchor remains a viable and safe option for successful treating symptomatic shoulder instability.

**2150 Board #38 May 28 3:30 PM - 5:00 PM**

**Assessing Person-environment Interaction Using The Movement And Activity In Physical Space (maps) Score In Orthopedic Knee Patients**

Brian G. Ragan<sup>1</sup>, Stephen Herrmann<sup>2</sup>, CaraLynn Scott<sup>3</sup>, Minsoo Kang<sup>4</sup>. <sup>1</sup>*Case Western Reserve University, Cleveland, OH.* <sup>2</sup>*Arizona State University, Mesa, AZ.* <sup>3</sup>*University of Northern Iowa, Cedar Falls, IA.* <sup>4</sup>*Middle Tennessee State University, Murfreesboro, TN.* (Sponsor: Barbara Ainsworth, FACSM)

Email: brian.ragan@case.edu

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the validity and reliability of the Movement and Activity in Physical Space (MAPS) score. MAPS is a quantifiable functional outcome measure that incorporates physical activity data from accelerometers and environmental factors evaluated through GPS to assess person-environment interaction.

**METHODS:** Sixteen participants (age = 28.9±12.0 years) were matched into two groups; post-surgical knee ( $n=8$ ; <7 days after surgery = 4.1±2.8 days) and non-surgical control ( $n=8$ ). Step count (volume - MAPS<sub>v</sub>) and activity count (intensity - MAPS<sub>i</sub>) were obtained using accelerometry. Travel and activity locations were recorded using GPS. Participants wore Atigraph accelerometers and LandAirSea GPS receivers on their waist for three days, one week and two months following knee surgery. Step counts and GPS data were combined to produce a MAPS<sub>v</sub> score. Activity count and GPS data were combined to produce a MAPS<sub>i</sub> score. MAPS scores were compared with the five subscales of the Knee Injury and Osteoarthritis Outcome Score (KOOS), a self-report functional knee scale.

**RESULTS:** The reliability for MAPS scores over three days was acceptable (ICC[1, 1] = .84 - .89). MAPS<sub>v</sub> was correlated with all KOOS subscales. MAPS<sub>i</sub> was correlated with all of the KOOS subscales except pain ( $r = .48$ ;  $p = 0.06$ ). There were significant group differences for MAPS<sub>v</sub> ( $t_{9,9} = -3.60$ ;  $p = .007$ ; post-surgical = 14.2 ± 9.7, control = 57.3 ± 32.5) and MAPS<sub>i</sub> ( $t_{10,8} = -3.22$ ;  $p = .013$ ; post-surgical = 480 ± 344, control = 2143 ± 1419) immediately following surgery. At two months, there was a significant time-group interaction for MAPS<sub>v</sub>,  $F(1, 12) = 4.60$ ,  $p = .05$ , but not for MAPS<sub>i</sub>,  $F(1, 12) = 3.42$ ,  $p = .09$ .

### 2151 Board #39 May 28 2:00 PM - 3:30 PM **Physiological Demands Of A Taekwondo Combat**

Adriana del Pilar Urbina-Bonilla<sup>1</sup>, Dario Mendoza Romero<sup>2</sup>, Yolman Sanchez Patiño<sup>2</sup>. <sup>1</sup>Universidad del Rosario, Bogota, Colombia. <sup>2</sup>Universidad UDCA, Bogota, Colombia.  
Email: adriana.urbina38@urosario.edu.co  
(No relationships reported)

Although taekwondo (TKD) is the most popular martial art in the world, it has not been researched extensively. Some studies report the physiological profile of TKD athletes, but the functional demands of a TKD combat are unknown.

**PURPOSE:** To determinate the physiological demands of a TKD combat.

**METHODS:** Five women from the Colombian TKD team (21 ± 2.92 years; 55.8 ± 5.45 kg; 1.64 ± 2.68 m) in their precompetitive season gave their informed consent for the study. They performed a simulated combat: three 2-minutes rounds with 1-minute rest intervals. In the first and second rounds, they did intermittently movements of defense/attack (10/15s round 1 and 10/10s round 2); and in the third round, they did their higher effort to attack during the whole round. Oxygen consumption (VO<sub>2</sub>) and respiratory quotient (R) were measured during combat using a portable gas analyzer system (Metamax II). Blood lactate levels (LAC) were measured in capillary blood using Accutrend. Maximal VO<sub>2</sub> (VO<sub>2</sub> max) were measured following endurance Bangsbo test protocol and using gas analysis. Comparisons between rounds and rest periods were made with one way ANOVA for repeated measures and Holm-Sidak method for pairwise comparisons.

**RESULTS:** VO<sub>2</sub> max were 46.99 ± 2.68 ml.kg<sup>-1</sup>.min<sup>-1</sup>. Combat VO<sub>2</sub> expressed as VO<sub>2</sub> max percentage were above than 85% during the 3 rounds (85.1 ± 8.5; 85.9 ± 8.5 and 85.3 ± 4.8%, respectively, p=0.916), and were above the anaerobic threshold of each athlete (p<0.05). In contrast, during rest periods VO<sub>2</sub> significantly decreased (57.1 ± 8.3 and 55.8 ± 12 %, for the first and second rests respectively) (p<0.01). R values during rounds and rests were between 1.09 and 1.12. LAC were 2.3±0.4 mmol/l in rest and significantly increased (p<0.013) during combat to reach 6.3±2.4; 8.8±2.8 and 9.8±3.1 mmol/l for the 3 rounds respectively.

**CONCLUSIONS:** VO<sub>2</sub> max of female TKD athletes were similar to the reported in other studies (43.6 ± 6.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>)(1). TKD combat may be considered as a lactic anaerobic (high intensity) intermittent work because the VO<sub>2</sub> were higher than 85% and above anaerobic threshold; R were always above 1.09; and LAC were higher than 6.3 mmol/l. TKD athletes should have high aerobic capacities that permit a better recovery during rest periods.

1.Cetim C, Karatosum H, Baydar ML, Kosarcian K. Saudi Med J 2005; 26: 848-850.

### 2152 Board #40 May 28 2:00 PM - 3:30 PM **Effect Of Knee-protected Tai Chi Aerobic For Community-dwelling Middle-aged Adults**

Li-Lan Fu, Yu-Tzu Liu. National Taiwan Sport University, Taoyuan, Taiwan.  
Email: lfust@mail.ncpes.edu.tw  
(No relationships reported)

Knee-Protected Tai Chi Aerobic (KPTCA) was modified from Tai Chi Aerobic with reduction in the balance challenge, and lower extremity impact. Lots of studies proved the benefit of Tai Chi in middle-aged or elderly people, but the effects of the KPTCA in middle-aged were unclear.

**PURPOSE:** To detect how the KPTCA training influence the functional performance of the community dwelling middle-aged.

**METHODS:** Volunteers were recruited from community in Taoyuan. One-hour group KPTCA was held three times weekly for 8 weeks. Three functional evaluations were executed before/after whole training course. Assessment of functional dynamic balance used Four Square Step Test, which asked subject to step as fast as possible in a special sequence. Time (seconds) taken to complete the test was recorded. Maximal isometric strengths of bilateral knee extensors/flexors were measured by hand-held dynamometer. Subjects were asked to perform an isometric contraction (lb) for 3 seconds. Aerobic capacity was measured by six-minute walk test (6-MWT) which asked subjects to walk at a regular pace, covering as great a distance as possible in the allotted time. The total distance covered in meters was measured and recorded. All data were analyzed using paired t tests (p < 0.05).

**RESULTS:** Twelve middle aged adults finished all training and assessments. The demographic data of all subjects were age: 50.1 ± 5.2 y; BMI: 24.8 ± 2.6 kg/m<sup>2</sup>. Compared with baseline, subjects showed statistically significant improvement in body mass (61.2 ± 4.7 vs. 59.9 ± 4.6 kg), dynamic balance test (6.9 ± 1.0 vs. 6.4 ± 0.9 s), flexors strength (right knee 34.4 ± 10.4 vs. 41.3 ± 8.5 lb and left knee 34.4 ± 11.7 vs. 40.9 ± 7.0 lb) and 6-MWT (561.7 ± 41.5 vs. 582.2 ± 45.0 m)(all p < 0.05) after training. But no statistically significant improvement was found in the knee extensors (right knee 50.9 ± 12.6 vs. 52.3 ± 8.0 lb and left knee 50.3 ± 12.1 vs. 54.4 ± 7.1 lb) and the HR<sub>rest</sub> (78.5 ± 11.5 vs. 79.0 ± 10.1 bpm)(all p > 0.05) after training.

**CONCLUSIONS:** These results indicated that the KPTCA is effective in improving dynamic balance, lower extremity flexor strength, and aerobic capacity in community-dwelling middle-aged adults. These improvements may increase the ability of the middle-aged to face the physical challenge in the everyday life.

Supported by NSC 95-2413-H-179-009.

### 2153 Board #41 May 28 2:00 PM - 3:30 PM **The Effects Of Sodium Bicarbonate Ingestion On Boxing Performance**

Lars R. Mc Naughton, FACSM, Kristian, Hirscher, Jason Siegler. University of Hull, Hull, United Kingdom.  
Email: l.mcnaughton@hull.ac.uk  
(No relationships reported)

**PURPOSE:** Boxing is a sport that consists of multiple high intensity bouts separated by minimal recovery time and may benefit from a pre-exercise alkalotic state. To observe the ergogenic potential of sodium bicarbonate (NaHCO<sub>3</sub>) ingestion on boxing performance.

**METHODS:** Ten amateur boxers volunteered to participate in two competitive sparing bouts (repeated-measures design separated by one week). The boxers were pre- matched for weight and boxing ability and consumed either 0.3g.kg<sup>-1</sup>BW of NaHCO<sub>3</sub> (BICARB) or 0.045g.kg<sup>-1</sup>BW of NaCl placebo (PLAC) mixed in diluted low-calorie flavoured cordial. The sparing bouts consisted of four 3-minute rounds, each separated by 1-minute seated recovery. Blood acid-base (pH, bicarbonate (HCO<sub>3</sub><sup>-</sup>), base excess (BE)) and performance (RPE, HR (HR<sub>ave</sub> & HR<sub>max</sub>), total punches landed successfully) profiles were analyzed pre (where applicable) and post-sparing.

**RESULTS:** There was a significant condition x time interaction effect for HCO<sub>3</sub><sup>-</sup> (F = 23.7; p ≤ 0.001; Figure 1) and BE (F = 27.0; p < 0.001), but not for pH (F = 0.54; p = 0.48). Post hoc analysis revealed higher pre-sparing HCO<sub>3</sub><sup>-</sup> and BE for the BICARB condition, but no differences between the BICARB and PLAC conditions post-sparing. There was no

significant condition x time interaction effects for HR<sub>ave</sub> (F = 2.0; p = 0.15), HR<sub>max</sub> (F = 1.2; p = 0.32), RPE (F = 1.1; p = 0.38) or punches landed (F = 0.58; p = 0.64).

**CONCLUSION:** Although NaHCO<sub>3</sub> elevated pre-sparring blood buffering capacity, it had no effect on four round sparring performance.

**2154 Board #42 May 28 2:00 PM - 3:30 PM**

**A Comparison Of Two Pre-season Measures Of Body Weight, Percent Body Fat, Peak Torque, And Percent Decline In College Wrestlers**

Doug Smith<sup>1</sup>, Aric Warren<sup>1</sup>, Matt O'Brien<sup>1</sup>, Steve Rossi<sup>2</sup>, Thomas Buford<sup>3</sup>, Matt Herrill<sup>1</sup>, Joanna Fedick<sup>1</sup>, Crishel Kline<sup>1</sup>, Ali Boolani<sup>1</sup>. <sup>1</sup>Oklahoma State University, Stillwater, OK. <sup>2</sup>Georgia Southern University, Statesboro, GA. <sup>3</sup>Baylor University, Waco, TX. (Sponsor: Bert H. Jacobson, FACSM)  
Email: doug.smith@okstate.edu

(No relationships reported)

**PURPOSE:** The purpose of this study is to determine if there is a difference between two pre-season measures of body weight (BW), percent body fat (BF), peak torque (PT) and percent decline (PD) in college wrestlers.

**METHODS:** Eight Division I collegiate wrestlers volunteered for participation in this study. The wrestlers BW was recorded along with PT and PD of the quadriceps femoris at 180 °/sec using a Biodex II isokinetic machine. The subjects completed fifty maximal leg extensions at 180 °/sec. Peak torque was recorded as the greatest amount of torque produced during any one repetition and PD was determined by taking the initial PT minus the final PT divided by the initial PT. T-tests were used to determine if significant (p<0.05) changes occurred in these measures between one year of pre-season measures and the following year of pre-season measures. Both recording times were scheduled during the second week in November.

**RESULTS:** The results of the study indicated that there was a significant (p>0.05) increase in PT from the first pre-season measure compared to the following pre-season measure. There was no significant (p>0.05) change in BW, BF, or PD between the two years.

**CONCLUSIONS:** The results suggest that the off season training programs are significantly increasing strength in the lower extremity without compromising the wrestler's body weight and percent body fat. The lack of significant change in PD indicates that even though PT was increasing the final PT during the 50 rep test had also increased. This is important information for the coach and the strength training staff showing that the training programs are having a positive impact on strength.

**Near Infrared Spectroscopy (nirs) Describes Physiologic Payback Associated With Excess Post-exercise Oxygen Consumption (epoc).**

Michael J. Danduran, Rohit P. Rao. *Children's Hospital of Wisconsin, Milwaukee, WI.*

(No relationships reported)

The human response to exercise is well described. Increased demands associated with exercise creates a physiologic burden resulting in the individual meeting demands or succumbing to exhaustion. Recovery from such efforts are crucial to adaptation. Excess Post-Exercise Oxygen Consumption (EPOC) refers to the body's increased metabolic need following physical work.

**PURPOSE:** To determine the role of NIRS (a non-invasive method of measuring regional tissue oxygenation) in the description of exercise recovery in healthy children and adolescents.

**METHODS:** Healthy adolescents were recruited. Exercise testing was performed to exhaustion. Physiologic parameters measured included: HR, BP, and breath-by-breath gas analysis. Four site NIRS (brain, kidney, deltoid, and vastus lateralis) were measured during exercise and into recovery to establish trends.

**RESULTS:** 29 individuals (14 M, 15 F) age 15.6 yrs (7-20 yrs) underwent testing. Exercise (Ex) results as follows: ExTime: 13.1 ± 2.52 mins, PeakHR: 193 ± 11.4 bpm, PeakVO<sub>2</sub>: 42.5 ± 4.09 ml/kg/min, RQ: 1.12 ± 0.07. EPOC was observed in all 29 patients. NIRS values are presented at 4 distinct intervals below. A significantly higher rate of re-perfusion was seen in the vastus lateralis with super-compensation well above baseline at 2 and 5 minutes post exercise. (\*=P<0.01)

Site	Rest	Peak Exercise	Change	2 Min Post Ex	Change	5 Min Post Ex	Change
Kidney	75.4%	51.5%	-31%	75.5%	0%	77.6%	-3%
Brain	70.4%	60.8%	-13%	68.5%	-2%	74.9%	6%
Deltoid	78.1%	53.5%	-31%	74.3%	-5%	77.7%	-1%
Leg	63.9%	51.5%	-19%	78.5%	23%*	80.7%	26%*

**CONCLUSIONS:** The identified trends support an immediate compensation of organ systems to re-establish homeostasis through enhanced perfusion. Moreover, non-invasive NIRS monitoring helps delineate patterns of redistribution associated with EPOC in healthy adolescents, emphasized by the super-compensation in the exercising leg. The sensitivity of such measurements in assessment of exercise pathology is intriguing.

**2156 Board #44 May 28 3:30 PM - 5:00 PM**

**Comparison Of Stress-induced Myocardial Ischemia And Cardiac Autonomic Control**

Adi Shachar<sup>1</sup>, Mickey Scheinowitz<sup>1</sup>, Tali Sharir<sup>2</sup>, Itzik Pinhas<sup>3</sup>, Solange Akselrod<sup>1</sup>, Linda R. Davrath<sup>3</sup>. <sup>1</sup>Tel Aviv University, Tel Aviv, Israel. <sup>2</sup>Maccabi Healthcare Services, Procardia, Tel Aviv, Israel. <sup>3</sup>Biological Signal Processing Inc., Tel Aviv, Israel.

Email: adie@radvision.com

(No relationships reported)

In a prospective study, we previously described autonomic function in a small group of patients with abnormal heart rate recovery (HRR) defined as a reduction in HR of ≤ 18 bpm during the 1st min of recovery immediately after a maximal exercise treadmill test (ETT).

**PURPOSE:** The goal of this retrospective analysis was to investigate autonomic contributions to HRR in a large patient cohort referred for evaluation of coronary artery

disease, and examine the association with stress induced ischemia.

**METHODS:** Exercise myocardial perfusion SPECT imaging (MPI) was performed in 894 consecutive pts and used as gold standard for ischemia. High resolution ECG was acquired throughout the ETT using the HyperQ™ System (BSP, Israel). Time-dependent spectral analysis was computed on HR from ETT to provide dynamic measures of low (LF) and high-frequency (HF) peaks associated with autonomic activity.

**RESULTS:** Moderate to severe MPI ischemia was found in 36 pts. Patients were classified based on HRR:  $HRR \leq 12$  (P12, n=53);  $HRR \leq 18$  (P18, n=80); normal HRR (NHRR, n=753). NHRR patients were selected for comparison (n=98) by random sampling. Presence of coronary artery disease (MPI ischemia, history of MI, CAD, PCI or CABG) was not different between groups. HF fluctuations, representative of vagal activity were significantly depressed in P12 vs. PN during the first min of recovery, indicating delayed vagal reactivation after exercise. Additionally, LF fluctuations recovered immediately upon cessation of exercise in PN, but were similarly depressed in P12 and P18, indicating prolonged sympathetic stimulation in P12 and P18.

**CONCLUSIONS:** Abnormal HRR is associated with impaired autonomic function, and is not related to stress induced myocardial ischemia.

	NHRR	P18	P12	P-Value*
Rest HR (b/min)	78±11.4	87.5±14.8	85.8±16.1	0.000
Hypertension	35.7%	57.5%	50.9%	0.012
Diabetes	17.3%	13.8%	34.0%	0.012
METS	11.5±2.6	10.6±2.6	9.9±2.4	0.001
Exercise Induced Ischemia	0.9±3.2	0.9±3.4	0.9±2.7	0.855

## 2157 Board #45 May 28 3:30 PM - 5:00 PM A Scoring System To Aid In The Interpretation Of Cardiopulmonary Test Results

H. Singh, K. Kumasaka, S. Stevens, C. Snell, J. M. VanNess. *University of the Pacific, Stockton, CA.*

Email: hsingh24@gmail.com

(No relationships reported)

Cardiopulmonary analysis during graded exercise testing (CPX) is commonly used to diagnose illness and determine physical working capacity. Given the number of variables generated during CPX it can be difficult to provide concise and meaningful interpretations for health personnel not familiar with its use. We proposed to develop a scoring system yielding a composite score that describes physiological function and working capacity using the results from a two day test-retest CPX. The purpose is to provide a single score that accurately describes performance in order to compare one day's performance with the next.

**METHODS:** CPX results from a group of women with chronic fatigue syndrome (n=15) and age-, gender- and weight-matched sedentary controls (n=15) were employed to develop the scoring system. Peak values for oxygen consumption, heart rate and ventilation were compared with age- and gender-predicted values. If an individual achieved at least 85% of predicted values this corresponded to value of 5 points. One point was subtracted for each 10% decrement below the 85% predicted value, and 1 point was added for each 10% increment above 100% of predicted. Scoring for anaerobic threshold (AT) was given a full 5 point value for achieving 40% of predicted peak oxygen consumption and one point deducted for 10% increments below 40% and above 60% of predicted peak oxygen consumption. Reaching 85% of predicted values for every variable resulted in a composite score of 25 points.

**RESULTS:** To be included, each subject reached ACSM criteria for maximal effort on both test days the control subjects achieved an average score of 27.9±4.0 on test 1 and 29.1±5.6 on test 2. The CFS subjects scored 26.0±5.3 on test 1 and 24.7±5.3 on test 2. For the control subjects eleven out of 15 achieved at least 85% of their predicted max and scores of 25 or above for test one. For test two, ten out of 15 achieved values of 25 or above. In the CFS group 10 out of 15 achieved 25 points on test one and 7 out of 15 for test 2.

**CONCLUSIONS:** The scoring system as employed can be used to describe performance compared with age- and gender-predicted values and may be helpful in describing the reduction in physical performance in a test-retest situation. This scoring system better describes the differences in physical capabilities than a previously employed method.

## 2158 Board #46 May 28 3:30 PM - 5:00 PM Gender Affects On Pediatric Heart Rate And Vo2 Relationships Compared To The ACSM Predicted Values

Wayne A. Mays, Yvette M. Gerdes, Sandra K. Knecht, Timothy K. Knilians. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Email: wayne.mays@cchmc.org

(No relationships reported)

**PURPOSE:** To evaluate the gender affect on the percent of maximal heart rate (%Max HR) and oxygen consumption relationship in pediatric patients compared to the established adult values by the American College of Sports Medicine.

**METHODS:** 1087 patients (Male 548, Female 539) referred for evaluation of chest pain, syncope and exercise intolerance were evaluated by a maximal exercise test using the James cycle ergometer protocol. The patients were cleared of structural heart disease by echocardiograph and/or physical examination and history. All exercise tests were maximal efforts. Patient demographics for the males and females were: Age 14.1±3.1 vs 14.8±3.3 years, Height 1.64±0.17 vs 1.60±0.11 meters and Weight 61.2±21.3 vs 56.7±14.5 kg, respectively.

**RESULTS:** The observed exercise values for %MaxHR for both male and female were significantly higher than the ACSM predicted values at 40%, 50%, 60%, 80% and 85% Max VO<sub>2</sub> levels. Additionally, the %MaxHR was significantly higher in females compared to males. Heart rate for females was significantly higher than males at all stages except 80%MaxVO<sub>2</sub>.

	40%Max VO2	50%Max VO2	60%Max VO2	80%Max VO2	85%Max VO2
ACSM predicted %Max HR	55	62	70	85	90
Male Observed %Max HR	60 ± 7	66 ± 7	73 ± 7	88 ± 6	91 ± 6
Female Observed %Max HR	**63 ± 7	**69 ± 7	**76 ± 7	**90 ± 6	**93 ± 4
Male Heart Rate	116 ± 15	127 ± 15	142 ± 16	169 ± 14	174 ± 17
Female Heart Rate	*120 ± 14	*132 ± 16	*146 ± 17	171 ± 16	*179 ± 13

\*P<0.05, \*\*P<0.01

**CONCLUSION:** The observed values for %MaxHR are significantly higher in pediatrics compared to the predicted values by the ACSM. Additionally, %MaxHR and HR was significantly higher in females. When developing an exercise prescription for pediatric patients, values must be based on pediatric standards divided into gender strata.

**Utilization Of Exercise Sestamibi In The Evaluation Of Cardiac Ischemia In Pediatric Patients**

Sandra K. Knecht<sup>1</sup>, Wayne A. Mays<sup>2</sup>, Yvette M. Gerdes<sup>3</sup>, Timothy K. Knillans<sup>3</sup>. <sup>1</sup>Cincinnati Children's Hospital, Moores Hill, IN. <sup>2</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH. <sup>3</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Email: sandy.knecht@cchmc.org

(No relationships reported)

**PURPOSE:** We evaluated the utility of exercise sestamibi (SM) in the diagnosis of exercise cardiac ischemia in pediatric patients with heart disease or referred for evaluation of chest pain or syncope.

**METHODS:** We evaluated 40 pediatric patients (19 female, mean age 13.6 years) presenting with possible exercise induced cardiac ischemia with a standard cycle ergometer (31 patients) or treadmill protocol (9 patients). The group consisted of: 13 Kawasaki, 5 TGV, 3 HLHS, 3 CM, 2 Heart Transplant, 3 Coronary Artery Abnormality, 2 PS, 9 with cardiac symptoms. SM was injected 1 minute before termination of the exercise test with a follow-up perfusion scan post exercise. The exercise test and the nuclear medicine report were interpreted by separate physicians blinded to the results of the coexisting test. A positive exercise test was based on ST depression in any lead greater than or equal to 1.5mm.

**RESULTS:** All exercise tests were maximal with a mean respiratory quotient of 1.14 and a maximal heart rate of 187 BPM. There were 10 positive exercise tests for ischemia with 2 showing normal SM perfusion. Both patients had abnormal apical myocardial thinning delineated by the perfusion report. There were 11 positive SM tests for perfusion defects, 3 of these showed normal exercise tests (no ST segment depression). In patients with a cardiac diagnosis, 9 of 31 showed perfusion defects. In patients referred for symptoms, 2 of 9 showed perfusion defects.

	(+) Sesta Mibi	(-) Sesta Mibi
(+) Graded Exercise Test	8	2
(-) Graded Exercise Test	3	27

**CONCLUSION:** These results demonstrate good agreement between a positive exercise test and the presence of SM perfusion defects. However, there was not a 100% agreement between the 2 methods. This could be a lack of sensitivity of one or both methods or as a need to utilize both methods in the evaluation of cardiac ischemia.

**2160 Board #48 May 28 3:30 PM - 5:00 PM**  
**Comparison Of Oxygen Pulse In Healthy Smokers And Nonsmokers During Cycle Ergometry Exercise**

George L. Hoyt, III. Mississippi State University, Mississippi State, MS.

Email: glh39@colled.msstate.edu

(No relationships reported)

Oxygen pulse ( $O_2$  pulse), the ratio of oxygen consumption ( $VO_2$ ) and heart rate (HR), estimates the product of stroke volume and arteriovenous oxygen difference and thus has been used as an indicator of oxygen transport in the circulatory system. Blunted HR responses to exercise have been observed in smokers (S) as have lower peak heart rates. Because HR is a component of  $O_2$  pulse, differences in  $O_2$  pulse during exercise may be seen between S and nonsmokers (NS).

**PURPOSE:** To compare the maximal and submaximal  $O_2$  pulse in healthy S and NS during stationary cycle exercise.

**METHODS:** Eight untrained male S (M±SD: 25.8±5.3 years) and eleven untrained male NS (25.6±3.4 years) participated in the study. Peak measurements for  $VO_2$ , HR and  $O_2$  pulse were assessed using a standardized cycle protocol. Submaximal measurements for  $VO_2$ , HR, and  $O_2$  pulse were recorded during a 60 minute session of cycle exercise at 50% of  $VO_{2PEAK}$ .

**RESULTS:** MANOVA procedure yielded a significant overall multivariate effect for the peak measurements ( $F_{3,15}=5.75$ ,  $p<.01$ ). Follow-up univariate tests revealed a significantly lower peak HR ( $159\pm12$  vs.  $175\pm11$  beats  $min^{-1}$ ,  $p<.01$ ) and a significantly higher peak  $O_2$  pulse ( $17.4\pm2.8$  vs.  $14.7\pm2.2$  ml  $beat^{-1}$ ,  $p<.05$ ) for S. No significant differences between groups were noted for the submaximal measurements for  $VO_2$ , HR, and  $O_2$  pulse. Strong positive correlations were seen between  $VO_{2PEAK}$  and peak  $O_2$  pulse for both S ( $r=.953$ ,  $p<.001$ ) and NS ( $r=.928$ ,  $p<.001$ ). No significant correlations between  $O_2$  pulse and HR were noted for either group.

**CONCLUSION:** Compared to NS, healthy S demonstrated a higher peak  $O_2$  pulse due to a significantly attenuated peak HR response, although peak  $O_2$  pulse was more strongly related to  $VO_{2PEAK}$  than to peak HR.

**2161 Board #49 May 28 3:30 PM - 5:00 PM**  
**Echocardiography with Tissue Doppler Imaging And Cardiopulmonary Exercise Testing Correlates In Patients With Diastolic Heart Failure**

Ross Arena, FACSM<sup>1</sup>, Jonathan Myers<sup>2</sup>, Mary Ann Peberdy<sup>1</sup>, Daniel Bensimhon<sup>3</sup>, Paul Chase<sup>3</sup>, Sherry Pinkstaff<sup>4</sup>, Marco Guazzi<sup>4</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, VA. <sup>2</sup>VA Palo Alto Health Care System, Palo Alto, CA. <sup>3</sup>LeBauer Cardiovascular Research Foundation, Greensboro, NC. <sup>4</sup>University of Milano, San Paolo Hospital, Milano, Italy.

Email: raarena@vcu.edu

(No relationships reported)

Previous investigations have reported a relationship between variables obtained from echocardiography with tissue Doppler imaging (TDI) and cardiopulmonary exercise testing (CPX) in patients diagnosed with systolic heart failure (HF).

**PURPOSE:** We are unaware of any prior study performing such an analysis in patients with diastolic HF, which is the purpose of the present investigation.

**METHODS:** Thirty-two patients with diastolic HF [69% male, age:  $62.8\pm9.7$  years, left ventricular ejection fraction (LVEF):  $55.5\pm4.5\%$ ] underwent echocardiography with TDI and CPX to determine the following variables: 1. the ratio between mitral early (E) to mitral annular (E') velocity, 2. LVEF, LV mass, 3. LV end systolic volume (LVESV), 4. peak oxygen consumption ( $VO_2$ ), 5. ventilatory efficiency ( $VE/VCO_2$  slope), 6. the partial pressure of end-tidal carbon dioxide ( $P_{ET}CO_2$ ) at rest and peak exercise and 7. heart rate recovery at one minute (HRR<sub>1</sub>).

**RESULTS:** Pearson correlation results are listed in Table 1. LV mass and LVESV were not correlated with any CPX variable. LVEF was correlated with HRR<sub>1</sub> and approached statistical significance with peak  $VO_2$ . E/E' demonstrated significant correlations with all CPX variables. A HRR<sub>1</sub> threshold of  $\leq 17$  beats per minute (higher

value positive) identified subjects with an E/E'  $\leq 10$  (lower value positive) with a 77% sensitivity and 88% specificity.

Table 1

	LVEF (%)	E/E'	LV mass (grams)	LVESV (mL)
Peak VO <sub>2</sub> (mLO <sub>2</sub> •kg <sup>-1</sup> •min <sup>-1</sup> )	-0.35 p=0.05	-0.49* p=0.005	-0.18 p=0.32	0.12 p=0.50
VE/VCO <sub>2</sub> slope	0.14 p=0.45	0.57* p=0.001	0.18 p=0.33	-0.07 p=0.69
PETCO <sub>2</sub> at rest (mmHg)	-0.23 p=0.21	-0.36* p=0.04	-0.25 p=0.17	-0.11 p=0.54
PETCO <sub>2</sub> at peak exercise (mmHg)	-0.26 p=0.15	-0.49* p=0.005	-0.23 p=0.21	-0.19 p=0.52
HRR1 (beats per minute)	-0.55* p=0.001	-0.63* p<0.001	-0.05 p=0.79	0.14 p=0.45

**CONCLUSION:** E/E' provides an accurate reflection of LV relaxation, uninfluenced by changes in filling pressure. An association between E/E' and peak VO<sub>2</sub> has previously been reported in patients with systolic HF. The present study demonstrates a significant correlation between E/E' and clinically important CPX variables in patients with diastolic HF.

**Indices Of Autonomic Dysfunction During Exercise Testing: Relationship To Reduced Levels Of Cardiorespiratory Fitness**

Emily E. Balagna, Angela K. Fern, Judith Boura, Barry A. Franklin, FACSM, Adam T. deJong. *William Beaumont Hospital, Royal Oak, MI.*  
Email: ebalagna@beaumont.edu  
(No relationships reported)

Reduced levels of cardiorespiratory fitness are associated with an increased risk of coronary artery disease. Moreover, indices of autonomic dysfunction, including chronotropic impairment (CI) and/or abnormal heart rate recovery (HRR), have been linked to an increased incidence of cardiac events.

**PURPOSE:** To identify differences in levels of cardiorespiratory fitness, expressed as metabolic equivalents (METs), in patients referred for diagnostic exercise testing who demonstrate CI, abnormal HRR, or both.

**METHODS:** Diagnostic exercise tests (n=1035) in the Beaumont database utilizing a modified, stage half or conventional Bruce treadmill protocol were reviewed. Subjects on beta-blocker therapy were excluded. Subjects whose exercise tests were terminated for reasons other than fatigue were excluded from comparisons involving CI. CI was identified in those patients who were unable to achieve  $\geq 80\%$  of heart rate reserve. Abnormal HRR was signified by a reduction in heart rate of  $< 12$  beats per minute within the first minute post exercise. Fitness was estimated from the treadmill time, speed, and grade.

**RESULTS:** Subjects who met the criteria for study inclusion (n=632) were divided into two groups: those with CI (n=145) and those without CI (n=487). Subjects with CI were more likely to have a lower fitness level (8.3 + 2.2 METs) as compared to those without CI (10.0 + 2.2 METs; p < 0.001). In a second analysis, 761 subjects were divided into two groups: normal HRR (n=699) and abnormal HRR (n=62). Those with abnormal HRR tended to be older and have lower fitness levels (7.0 + 2.3 METs) than those with normal HRR (9.5 + 2.3 METs; p < 0.001). Finally, 639 subjects were divided into two groups: those with CI and abnormal HRR (n=20) and those with neither or only one marker of autonomic dysfunction (n=619). Subjects with both CI and abnormal HRR tended to be older and have lower fitness levels (6.6 + 2.8 METs) than those with neither or only one abnormal index (9.7 + 2.2 METs; p < 0.001).

**CONCLUSIONS:** Subjects with abnormal HRR, with and without CI, tend to be older and have significantly reduced levels of cardiorespiratory fitness than individuals without these markers of autonomic dysfunction. Improving aerobic fitness may serve to normalize these prognostic indicators in patients with and without known cardiovascular disease.

**2163 Board #51 May 28 3:30 PM - 5:00 PM**

**Early Repolarization And Ectopy During Stress Testing**

Christopher C. Dunbar, FACSM<sup>1</sup>, Lisa Chaves-Toth<sup>1</sup>, Christopher M. Hearon, FACSM<sup>2</sup>, Barry I. Saul<sup>3</sup>. <sup>1</sup>Brooklyn College, C.U.N.Y., Brooklyn, NY. <sup>2</sup>Texas A&M University - Kingsville, Kingsville, TX. <sup>3</sup>The New York Methodist Hospital, Brooklyn, NY.  
( C.C. Dunbar, Pfizer, Consulting Fee.)

**PURPOSE:** To examine the interaction between resting early repolarization and the occurrence of ectopy during clinical exercise testing.

**METHODS:** Pre-stress 12-lead resting ECGs of patients presenting for the following types of stress testing were examined for evidence of early repolarization (ER): exercise ECG, nuclear exercise ECG, exercise echocardiography, dipyridamole nuclear, dobutamine nuclear and dobutamine echocardiography. Each case of ER (n=26) identified was matched with two randomly selected control patients without ER (n=52). Stress tests were performed using standard hospital protocols. The ECGs recorded before, during and after stress were examined for supraventricular (PAC) and ventricular ectopy (PVC). Ectopy was further categorized by type (uniform versus multiform PVC, isolated ectopic beats versus runs of ectopy, etc.). A chi-square test for two independent samples (2 x 2 contingency table) was used to determine if a significant interaction was present between the occurrence of resting ER and the presence of each of the following before, during and/or after stress: PAC and/or PVC, PAC only, PVC only, multiform PVC, and PVC runs.

**RESULTS:** The proportions of the sample exhibiting and not exhibiting ectopy before, during and/or after stress did not differ significantly between patients with and without evidence of ER on resting ECG. That is, there were no significant (p>0.05) interactions between the occurrence of ER and the presence of ectopy.

**CONCLUSIONS:** The presence of ER on the resting ECG does not appear to be indicative of ectopy during clinical stress testing.

**Exercise Recovery Hemodynamics In Overweight Vs. Obese Patients Diagnosed With Coronary Disease.**

John S. Green, FACSM<sup>1</sup>, Robert Berent<sup>2</sup>, Serge P. von Duvillard, FACSM<sup>3</sup>, Peter B. Schmid<sup>4</sup>, Stephen F. Crouse, FACSM<sup>1</sup>. <sup>1</sup>Texas A&M University, College Station, TX. <sup>2</sup>Center for Cardiac Rehabilitation, Bad Schallerbach, Austria. <sup>3</sup>University of Salzburg, Salzburg, Austria. <sup>4</sup>Institute for Diagnosis and Treatment for Atherosclerosis and Lipid Disorders, Vienna, Austria.

(No relationships reported)

**PURPOSE:** To determine if blood pressures assessed during exercise recovery differ in overweight vs. obese patients diagnosed with coronary artery disease (CAD).

**METHODS:** A group of 225 patients with CAD (N=183 males, mean age=63.5, mean BMI=30.2; N=42 females, mean age=64.0, mean BMI=30.2) underwent cycle exercise testing. Height and weight were assessed using calibrated equipment and BMI was calculated as weight (kg) / height (m) squared. All 225 test subjects were classified as either "overweight" (OW)(N=126) or "obese" (OB)(N=99) according to the National Institutes of Health guidelines. Resting systolic (SBP) and diastolic (DBP) blood pressures were taken following a 3 minute rest period. Mean arterial pressure (MAP) was estimated as  $[(3(SBP-DBP))+DBP]$ . Pressures were also assessed at 1, 3, and 5 minutes after the test. An analysis of covariance (ANCOVA) with resting pressure and body weight as covariates was used to determine if differences in recovery SBP, DBP, and estimated MAP were present at the three post-exercise recovery times (RT).

**RESULTS:** After ANCOVA adjustment, all three recovery pressures were higher in the obese group at every RT with statistical significance found at the 1 minute time point for DBP and MAP.

**CONCLUSION:** Obese subjects with CAD demonstrate higher recovery SBP's, DBP's, and estimated MAP's than overweight subjects.

Table: unadjusted means + SD, * = sig. different from OW, p<0.05			
RT	1:00	3:00	5:00
	SBP	SBP	SBP
OB	179.7+30.7	159.0+23.11	140.9+18.8
OW	167.9+28.2	152.5+25.1	135.3+23.6
	DBP	DBP	DBP
OB	85.0+11.53*	82.5+10.5	81.0+10.1

#### Estimating Cardiorespiratory Fitness In Morbidly Obese Patients: Validity Of The Duke Activity Status Index

Kristy Kazmierczak, Tom Spring, Judy Bora, Adam deJong, Barry Franklin, FACSM. *William Beaumont Hospital, Royal Oak, MI.*

Email: KKazmierczak@beaumont-hospitals.com

(No relationships reported)

**PURPOSE:** To assess the accuracy of the Duke Activity Status Index (DASI) questionnaire in morbidly obese patients (MOP) undergoing pre-surgical graded exercise testing (GXT).

**BACKGROUND:** Although the DASI has been previously established as a valid and reliable predictor of cardiorespiratory fitness in healthy individuals, its applicability in the morbidly obese remains unclear.

**METHOD:** As part of a pre-bariatric surgery evaluation, the DASI questionnaire was administered to MOP scheduled to undergo a GXT with concomitant measures of cardiorespiratory fitness ( $VO_{2max}$ ). Questions about the survey were not clarified by the test administrator to minimize bias. Upon completion of the DASI, each patient completed their GXT using a treadmill or combined arm-leg ergometer protocol.

**RESULTS:** The DASI and subsequent GXT with  $VO_{2max}$  were completed on 122 patients [101 women (mean age + SD = 43.7 + 12.2) and 21 men (mean age + SD = 43.6 + 14.3)]. Mean + SD body mass index of the MOP was 49.9 + 7.9 kg/m<sup>2</sup>. Utilizing the DASI, our study population achieved a predicted  $VO_{2max}$  of 27.4 + 5.9 ml/kg/min. Measured  $VO_{2max}$  in this population was 18.3 + 4.2 ml/kg/min, resulting in a significant overestimation of the predicted versus measured level of cardiorespiratory fitness ( $p<0.0001$ ). Mean + SD respiratory exchange ratio achieved during exercise testing was 1.15 + 0.13.

**CONCLUSION:** The DASI questionnaire significantly overestimates predicted aerobic capacity in MOP prior to gastric bypass surgery. Measured  $VO_{2max}$ , expressed as ml/kg/min, can be predicted from the following regression equation: measured  $VO_{2max}$  = 10.23 + 0.29(predicted  $VO_{2max}$ ).

---

2166 Board #54 May 28 3:30 PM - 5:00 PM

#### Body Weight As A Determinant Of Exercise Capacity In Overweight Adolescents

Josh Woolstenhulme<sup>1</sup>, Bart E. Drinkard<sup>1</sup>, Michelle Kennedy<sup>1</sup>, Randall E. Keyser, FACSM<sup>2</sup>, Jack A. Yanovski<sup>1</sup>. <sup>1</sup>NIH, Bethesda, MD. <sup>2</sup>NIH and George Mason University, Bethesda, MD.

(No relationships reported)

Excess bodyweight may increase the metabolic cost of work and diminish physical activity tolerance.

**PURPOSE:** To determine the influence of excess bodyweight on exercise capacity in adolescents who were overweight.

**METHODS:** Subjects were 30 (16 females and 14 males) normal weight (NW), (height: 1.6±0.1 m, weight: 55.5±12.1 kg) and 63 (45 females and 18 males) overweight (OW) (height: 1.7±0.1 m, weight: 107.5±20.3 kg) adolescents. The NW and OW groups were 14.5±1.7 years and 14.8±1.4 years of age respectively. Oxygen uptake ( $VO_2$ ) was first measured during unloaded cycling (UL $VO_2$ ). Subjects then completed a maximum cycle ergometer test to exhaustion. Maximum  $VO_2$ , and power output ( $W_{max}$ ) were measured. The change in  $VO_2$  from unloaded cycling to maximum exercise (Net $VO_2$ ) was calculated as the difference between  $VO_{2max}$  and UL $VO_2$ . Group differences in the dependent variables were determined by Student's t tests. A Pearson product moment coefficient of determination ( $r^2$ ) was used to characterize the relationship between UL $VO_2$  and body weight (BW) and  $W_{max}$  and Net $VO_2$ .

**RESULTS:**  $VO_{2max}$  was similar for NW (2067±571 mlO<sub>2</sub>/min) and OW (2041±481 mlO<sub>2</sub>/min). UL $VO_2$  in OW (693±169 mlO<sub>2</sub>/min) was significantly ( $p<0.001$ ) higher than in NW (406±125 mlO<sub>2</sub>/min) and significantly related to BW ( $r^2=0.63$ ,  $p<0.0001$ ).  $W_{max}$  (185±44 in NW vs 153±34 watts in OW;  $p<0.001$ ) and Net $VO_2$  (1661±495 in NW vs 1348±427 mlO<sub>2</sub>/min in OW;  $p<0.004$ ) were significantly lower in OW than in NW.  $W_{max}$  and Net $VO_2$  were determinately related ( $r^2=0.85$ ,  $p<0.001$ ).  $W_{max}$  and Net $VO_2$  were 17.3% and 18.8 % lower in OW than in NW.

**CONCLUSION:** The gender make-up of the NW and OW groups was disproportional. Nonetheless, the very high coefficient of determination, combined with the close proportionality between the reduction in Net $VO_2$  and  $W_{max}$ , suggested that the increased metabolic cost of work was likely the cause of the reduced exercise capacity in these adolescents who were overweight.

---

**2167 Board #55 May 28 3:30 PM - 5:00 PM****Age-predicted Heart Rate Equations: Comparisons Of Equations In College-aged Subjects**

Michelle A. Cleary, Ronald K. Hetzler, FACSM, Jennifer J. Wages, Melissa A. Lentz, Christopher D. Stickley, Iris F. Kimura. *University of Hawaii, Honolulu, HI.*

Email: mcleary@hawaii.edu

(No relationships reported)

Although the maximum heart rate ( $HR_{max}$ )-prediction model of 220-age (Fox et al.) is well established and widely used in clinical and fitness settings, its validity is uncertain in the college-aged population.

**PURPOSE:** To compare several age-predicted  $HR_{max}$  equations to recorded maximum heart rate (RMHR) from sprint tests in college-aged subjects.

**METHODS:** Informed consent was obtained for 96 (52 males and 44 females, age=22.0±2.8 yr, height=163.9±9.5 cm, 70.6±14.7 kg, resting HR=68.9±11.2 bpm) healthy volunteers. RMHR was obtained during three sprint tests (Wingate cycle test and two-200 m sprints on a standard track) and maximal effort was confirmed via plasma lactate ≥6 mmol/L and rating of perceived exertion ≥16 points. The highest RMHR from the sprint test was compared to 7 age-predicted  $HR_{max}$  equations: Fox, 3 equations from Gellish et al., Tanaka et al, and gender-specific equations from Fairbairn et al. and Hossack et al. Descriptive statistics and standard errors of estimate (SEE) were calculated. One-way ANOVA was used to assess differences between RMHR and age-predicted  $HR_{max}$ .

**RESULTS:** Predicted  $HR_{max}$  from Fox, Gellish<sub>2</sub>, Tanaka and Hossack were all significantly higher ( $p \leq .05$ ) than RMHR. In 88.5% (n=85) of the cases, the most commonly used equation (Fox) over-predicted  $HR_{max}$ . Compared to RMHR (189.2±8.1 bpm), the Fox equation predicted a  $HR_{max}$  of 104.6% of RMHR (198.0±2.8 bpm, SEE=12.2), Gellish<sub>1</sub> = 99.4% (188.1±1.0 bpm, SEE=10.1), Gellish<sub>2</sub> = 101.6% (192.1±1.9, SEE=5.9), Gellish<sub>3</sub> = 99.7% (188.6±1.0 bpm, SEE=8.1), Tanaka = 101.8% (192.6±2.0 bpm, SEE=5.5), Fairbairn = 99.9% (males and females=188.9±2.7, SEE=8.3), and Hossack = 105.0% (males and females=198.7±6.0, SEE=13.3).

**CONCLUSIONS:** The most accurate equation was Gellish<sub>3</sub> ( $HR_{max}=192-0.007 \times \text{age}^2$ ) with one of the closest estimates of the RMHR without exceeding it and one of the lowest SEE. Although it is not the simplest equation to use, in a healthy, college-aged population, the Gellish<sub>3</sub> equation is the safest and most accurate estimate of  $HR_{max}$  and should be used when prescribing exercise intensity.

---

**2168 Board #56 May 28 3:30 PM - 5:00 PM****Reference Equation for the Incremental Shuttle Walk Test in Healthy Adults**

Incremental shuttle walk test (ISWT), in which the speed of walking is imposed by pre-recorded signals, was developed in an attempt to standardize and improve reproducibility of field walk tests. Nowadays, ISWT is an established measure of exercise capacity in patients with cardiopulmonary disease. Despite its widespread use, there is no reference equation for prediction of the distance walked in the ISWT in healthy subjects.

**PURPOSE:** To evaluate the ISWT for healthy subjects aged 38-84 years and to establish a reference equation for its prediction.
